Impulsivity, suicide risk and cannabis consumption

E. Smaoui^{1*}, D. Mnif¹, R. Ouali¹, R. Sellami¹, I. Feki¹, I. Baati¹ and J. Masmoudi¹

¹Psychiatry, CHU hédi chaker, Sfax, Tunisia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.725

Introduction: Cannabis is the most widely consumed illegal drug in the world and one of the easiest to access. This drug provides a feeling of well-being and euphoria. However, frequent consumption is associated with several complications including increased impulsivity and an increased risk of suicidal behaviour.

Objectives: Our objective was to study the link between cannabis consumption, impulsivity and suicide intentionality.

Methods: We conducted a cross-sectional study, during the period from September 2020 to October 2021, among cannabis users consulting the Sfax Detoxification Center in Tunisia. Impulsivity was studied using the Barrat Impulsivity Scale (BIS 15) and suicide intentionality was assessed using the Suicide intent scale Beck; Pierce (SIS) in subjects with history of a suicide attempt.

Results: We included 38 consumers. The average age is 26 years old and the sex ratio was 8.5 with an over-representation of men. The average BIS15 score was 38.2 ranging between 19 and 45. We have demonstrated that the higher the level of cannabis dependence, the higher the level of impulsivity. A high level of impulsivity was found in younger subjects ($p=0.04$) and with a low socio-economic level and unemployment ($p=0.021$). Suicidal intentionality, assessed in 10 patients with a history of suicide attempt, was low and intermediate in 40% and 60% of users respectively, which means a low to intermediate risk of subsequent completed suicide.

Conclusions: Impulsivity is associated with aggressive behaviour, various accidents including motor vehicle accidents, more self-mutilation and a much greater risk of dying by suicide than the general population. Frequent cannabis use is also associated with increased risk of developing all types of suicidal behaviours independently of the existence of depressive symptomatology. Overall, it is important to take into account the issues of impulsivity and substance abuse in daily clinical work as they influence the level of dangerousness.

EPP0622

Maternal substance used during labor and neonatal outcome

J. Na Bangxang^{1*}, D. Sudjai², V. Arthayukti¹, S. Cheepo¹ and K. Pipatjarussakul¹

¹Psychiatry and ²Obstetrics and gynecology, Rajavithi Hospital, Bangkok, Thailand

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.726

Introduction: Substance use during pregnancy has become challenging clinical issue. Substance affects the brain, causing an addictive lifestyle. In pregnant women could lead more harm to neonatal life.

Objectives: This study investigates the neonatal outcome of substance use and associated factors.

Methods: A cross-sectional study was designed. Data were collected from pregnant women who used substance during labor and refer to rehabilitative consultation between 2017-2020. Neonate data were collected from perinatal care. Chi-square test and Fisher exact test were performed to analyze associated factors. A p-value less than 0.05 is considered significantly.

Results: 162 participants were included in this study. Mean age was 27.37 ± 6.46 years. Mean age at first substance used was 21.93 ± 6.52 years. No antenatal care was found 45.7%. Methamphetamine was the most used during the first use (67.9%) and latest used (72.2%). Average birth weight was $2,734.97 \pm 617.51$ gram. Gestational age at birth was 36.75 ± 2.83 week. Average head circumference was 32.81 ± 1.39 centimeters. Average femur length was 47.77 ± 2.17 centimeters. Apgar score ≥ 7 at 1 minute and 5 minute was found 94.4% and 97.2%. Neonatal complications were preterm labor (34.6%), low birth weight (25.3%), small for gestational age (19.8%), premature rupture of membranes (4.9%), and stillbirth (3.7%). No antenatal care ($p=0.048$), no antenatal care and birth before admission ($p=0.023$), a cesarean delivery ($p=0.024$), and gestational age more than 37 weeks ($p<0.001$) were associated with neonatal outcome in maternal with substance used during labor. Using amphetamine as the first substance related to neonatal complication ($p=0.028$).

Conclusions: Preterm labor, low birth weight and small gestational age are the most found as neonatal complications in maternal substance used during labor. No antenatal care was related with neonatal complications in this group.

Therefore, an integrated system for the assessment of substances used in a pregnant woman and the system to reach out women who used substance and pregnant access to antenatal care should be established. Evaluation and rehabilitation are the interventions that should be done as soon as possible as primary, secondary intervention.

Functional Neurologic Disorders: The Role of Limbic System

M. Lima Magalhães^{1*}, M. Andrade¹, A. Lourenço² and G. Soares²
¹Clínica 6 and ²Clínica 3, Centro Hospitalar Psiquiátrico de Lisboa, Lisboa, Portugal

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.727

Introduction: Functional Neurological Disorders (FND), also called hysteria or conversion disorder, have represented a challenge over the centuries in terms of comprehension of the mechanisms responsible for symptoms which mimic neurological diseases without organic damage. Charcot considered hysteria primarily a hereditary disorder, but also considered that environmental factors including physical and emotional stress served as provoking

factors. The prevailing etiologic theories of FND are psychosocial and still strongly dominated by the Freudian concept of conversion – a psychological symptom is converted into a somatic symptom as a way of dealing with the distress of the symptom. However, physiologic studies with fMRI are necessary to understand the neurological mechanisms involved in FND symptoms. Convergent neuroimaging findings have implicated abnormal limbic-motor interactions in response to emotional stimuli in FND patients, demonstrated a possible role of the limbic system (LS) in FND neurophysiology.

Objectives: Understand the role of LS in the neurophysiologic mechanisms involve in FND.

Methods: Systematic review of the literature published in PubMed, using the terms “Functional Neurological Disorders”, “Limbic System”, “Emotions”.

Results: Physiologic studies of functional weakness and sensory loss reveal normal functioning of primary motor and sensory cortex, but abnormalities of premotor cortex and association cortices. This suggests a top-down influence creating the dysfunction during the action control. Indeed, fMRI studies with FND motor patients show a hypoactivation of cortical and subcortical motor pathways, and a hyperactivity in limbic areas related with an abnormal limbic regulation with increased amygdala activity. In fact, studies have found a dysfunction in the medial prefrontal areas in FND patients suggesting that they might have an abnormal affective representation (AR) of self-relevant information encoded in this region, which can later induce specific behavioral patterns of thought interaction with sensorimotor circuits. The abnormal AR could be influenced by a dysfunction in LS regulation. Indeed, emotions are one of the major factors influencing movement choice. Moreover, limbic structures, such as the amygdala, can be influenced by genetic factors and/or early life stress. Thus, abnormal functioning of LS could lead to functional disorders by deranged top-down control.

Conclusions: In conclusion, FND patients may have an abnormal AR and/or emotion regulation mechanisms possibly due to prior experience or partly genetically determined which interact with lower-order functions leading to the production of the functional symptoms, where LS have an important role. However, much further empiric research is needed to better understand this fascinating and debilitating condition, as well as to derive new perspectives for more efficient therapeutic interventions in these patients.

Relationship between the practice of chemsex and taking PrEP

O. De Juan Viladegut^{1*}, H. Andreu Gracia¹, L. Bueno Sanya¹, L. Olivier Mayorga¹, E. Cesari¹, J. I. Mena¹, I. Ochandiano¹, S. Salmeron¹ and L. Miquel¹

¹Psychiatry and Psychology Department, Hospital Clínic de Barcelona, Institut Clínic de Neurociències, Barcelona, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.728

Introduction: Chemsex refers to the use of drugs, typically stimulants and/or psychoactive substances, in a sexual context, often in

the context of casual or group sex encounters. Currently, the practice of chemsex focuses on men who have sex with men (MSM). On the other hand, Pre-exposure prophylaxis (PrEP) is a biomedical method that has proven effective in preventing HIV transmission, particularly among individuals at a heightened risk, including those who engage in chemsex. MSM account for two thirds of new HIV cases in the US. It is estimated that in 70% of cases seroconversion occurs through “condomless anal sex” (CAS). According to the CDC, one in six MSM will be infected with HIV during their lifetime. The consumption of methamphetamine (MA) has been identified as the main driver of the practice of CAS, alteration of rectal immunological function and faster seroconversion. One in three new HIV infections have been associated with MA consumption. (Groß C *et al.* JAIDS 2020; 85 272-279).

Objectives: The primary goal of this study is to describe the prevalence of chemsex engagement among PrEP users, delineate user characteristics and requirements, gain deeper insights into this phenomenon within the Barcelona region, and formulate customized strategies accordingly.

Methods: This study conducts a literature review to explore the current correlation between engaging in chemsex and the utilization of PrEP. We identified research articles published between January 2020 and December 2022, that discussed the utilization of chemsex drugs prior to or during sexual activities. The findings were synthesised using a narrative approach and conceptualised using a behavioural analysis framework.

Results: According to a recent cross-sectional study performed at Hospital Clínic de Barcelona, SUD among patients who are being followed-up in the outpatient clinic of PrEP was higher (89%) compared with other European regions such as England (38.5%) or Amsterdam (41%). Moreover, according to data collected in the EMIS 2017 survey, Barcelona is the city with the highest prevalence of chemsex in Spain. (De La Mora L *et al.* AIDS Beh. 2022; 26: 4055-4062).

Conclusions: The frequency of chemsex practice among individuals using PrEP in Barcelona surpasses what has been observed in other groups. Nearly 25% of the participants express worries and a requirement for assistance regarding the management of drug use, matters associated with their sexuality, and sexually transmitted infections (STIs). MSM who suffers from substance use disorder may experience difficulty achieving effective daily oral PrEP adherence prevention levels that may serve as early indicators of increased risk of disengagement from PrEP care and discontinuation the PrEP. These results highlight the importance of adopting an interdisciplinary approach that incorporates education about substances and the implementation of risk mitigation strategies within the context of riskier sexual behaviors.

Reasons for Individuals not Enrolling for Yoga trial in Addiction

S. Sarkar^{1*}, A. Dhawan¹, R. Quraishi¹, P. S. Negi¹ and A. Kumar¹

¹National Drug Dependence Treatment Centre, All India Institute of Medical Sciences, New Delhi, India

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.729

Introduction: Yoga has been demonstrated to have a range of beneficial effects on individuals with substance use disorders, including opioid use disorders. We initiated a randomized clinical trial to find out the efficacy of add-on yoga among patients with opioid dependence stabilized on treatment to find out whether it led to improvement in sleep and quality of life. However, the rate of enrolment into the study was quite low.

Objectives: In this interim analysis, we present the preliminary data on the reasons for non-enrolment in the yoga trial.

Methods: The single-centre trial involved 1:1 randomization of patients with opioid dependence stabilized on medications (naltrexone or buprenorphine) for a period of at least 4 weeks into two groups (add-on yoga or wait-list control). The yoga included *asanas* and *panchakosha* meditation, taught for a period of 7 days and to be practiced by the participants for a period of 12 weeks. We recorded the reasons for non-participation among those who did not participate and asked them questions about their views on yoga.

Results: Of the 310 patients recruited between August 2022 and July 2023 (99.7% male, mean age 34 years, 56.5% married), 255 (82.3%) could not be enrolled in the trial. The most common reasons for non-enrolment were not having time for training (n = 206, 80.8%), not having time for doing yoga (n = 180, 70.6%), not having a smartphone for continued training or contact (n = 31, 12.2%), distance from the center (n = 17, 5.5%) do not feel the need for yoga (n = 16, 5.2%), injury or disability (n = 9, 3.5%), old age or medical condition (n = 7, 2.7%), already doing gym exercises (n = 7, 2.7%), nature of job (n = 5, 2.0%), do not have knowledge of yoga (n = 5, 2.0%), and do not think yoga would be useful (n = 4, 1.6%). Among those who could not be enrolled, 35.1% reported doing yoga sometime in the past, and 21.6% reported that at least one of the family members did yoga. When asked whether they would be interested if yoga was available online, 16 (5.2%) responded 'yes' and 45 (14.5%) responded 'maybe'.

Conclusions: Expressed time constraints may be an important factor deterring patients with opioid dependence from engaging in yoga as an add-on yoga. There are other reasons as well that may deter patients from such an intervention. The findings should be seen in the light of the limitation of a single medically oriented center, and patients already stabilized on treatment.

Anxiety disorders and intravenous drug use in chemsex context

J. Curto Ramos^{1,2*}, A. Rodríguez Laguna², P. Barrio², L. Ibaguchi², A. García², I. Azqueta² and H. Dolengevich Segal³

¹Department of Psychiatry, Clinical Psychology and Mental Health, La Paz University Hospital; ²Apoyo Positivo and ³Dual Disorders Program. Department of Psychiatry, Henares University Hospital, Madrid, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.730

Introduction: Several studies have called attention to the mental health disorders associated with chemsex -the intentional use of drugs before or during sexual intercourse GBMSM (gay, bisexual and men who have sex with men) population-. Sexualized intravenous drug use is also known as slam or slamsex. There are few

studies that analyze the mental health differences between intravenous drug users compared to non-intravenous drug users in chemsex context.

Objectives: We aim to describe the mental health outcomes including current and past anxiety disorders diagnosis in a sample of users with sexualized drug use (chemsex) attended by the non-governmental organization Apoyo Positivo in the program "Sex, Drugs and You" and to compare the differences of current and previous diagnosis of anxiety disorders between intravenous drug users compared to non-intravenous drug users.

Methods: A cross-sectional descriptive analysis of a sample of users attended by the non-governmental organization Apoyo Positivo in the program "Sex, Drugs and You" between 2016-2019 was performed.

Results: We included 217 participants. Current or past diagnosis of anxiety disorders was found in 142 participants. Anxiety disorders were significantly higher in the intravenous drug use group compared to the non-intravenous drug use group (p<0.05).

Conclusions: Previous studies have reported that MSM who practiced chemsex were more likely to experience from anxiety. In our study, anxiety disorders were higher in participants who engaged in intravenous drug use. A multidisciplinary team is necessary to address chemsex and provide care and treatment for mental health problems such as anxiety, depression, suicidal behaviour or drug-induced psychosis.

Evaluation of anxiety and depression in patients with knee osteoarthritis

A. Feki^{1,2}, I. Sellami^{2,3*}, I. Mnif¹, Z. Gassara¹, S. Ben Djemaa¹, A. Abbes³, M. Ezzeddine¹, M. H. Kallel¹, H. Fourati¹, R. Akrou¹ and S. Baklouti¹

¹Rheumatology, Hédi Chaker Hospital; ²Medicine university and ³Occupational medicine, Hédi Chaker Hospital, Sfax, Tunisia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.731

Introduction: Knee osteoarthritis is one of the most common causes of functional impairment, significantly impacting patients' quality of life and leading to severe mood disorders. Our objective is to assess the prevalence of depression and anxiety in knee osteoarthritis patients.

Objectives: Evaluate the prevalence of depression and anxiety in patients with knee osteoarthritis.

Methods: This was a cross-sectional study conducted over a three-month period from February to April 2022, including consecutive patients who consulted in a Rheumatology department. We assessed each patient using a validated version of the HAD (Hospital Anxiety and Depression) scale, which includes 14 items, each rated from 0 to 3, measuring two components: depression and anxiety.

Results: We enrolled 82 patients (67 women and 15 men) with an average age of 60.4 years [44-89 years]. The average disease duration was 10 years [2-30]. Knee osteoarthritis was bilateral in 79% of cases. Knee deformities were observed in 74.4% of cases (40.2% had

genu valgum, and 29.3% had genu varum). Radiological assessment showed that most of our patients were at Kellgren-Lawrence (KL) stage 3 (50%). All patients received analgesics, with 92.7% receiving NSAIDs, 67.1% local corticosteroid infiltrations, and 18.3% hyaluronic acid injections. The mean visual analog scale (VAS) score was 6.9 out of 10 [1-10]. The mean anxiety score was 7.5 [4-16], with 25.4% of patients exhibiting no anxiety symptoms (score ≤ 7), 40.3% displaying doubtful anxiety symptomatology (score between 8 and 10), and 34.3% having certain anxiety symptomatology (score ≥ 11). The mean depression score was 9.6 ± 4 [0-19]. 40% of patients had no depressive symptoms (score ≤ 7), 53.3% had doubtful depressive symptoms (score between 8 and 10), and 6.7% had certain depressive symptoms (score ≥ 11). The statistical analysis revealed a significant association between anxiety scores and KL stage, but no association with age, sex, mobility limitation, or VAS. Regarding depression, there was no significant association with epidemiological, clinical, or radiological parameters of knee osteoarthritis.

Conclusions: Although knee osteoarthritis may appear to be a benign pathology, its impact can be severe, including depression and anxiety. These mood disorders are primarily influenced by the disease stage. Therefore, psychological care is sometimes necessary in the management of these chronic degenerative diseases.

Obsessive-compulsive symptoms in professional tennis players

R. Gurrieri^{1*}, A. Arone², E. Parra², S. Palermo², D. Marazziti^{2,3} and A. Gemignani¹

¹Department of Surgical- Medical and Molecular Pathology and Critical Care Medicine; ²Department of Clinical and Experimental Medicine, University of Pisa, Pisa and ³Saint Camillus International University of Health and Medical Sciences, Unicamillus, Roma, Italy
*Corresponding author.

doi: 10.1192/j.eurpsy.2024.732

Introduction: Engaging in moderate physical activity holds a vital role in our daily lives, serving as both a means of social recreation and a fundamental contributor to physical and mental wellbeing. It is also worth noting that such activity can potentially produce mood-enhancing effects by promoting neurogenesis and neuronal adaptability. Intriguingly, certain individual psychological traits such as rituals, compulsions, obsessional thinking, and superstitious beliefs, as well as inflexibility in daily routines, appear to serve a purpose in competitive athletic endeavors.

Objectives: The aim of our study was to investigate the possible presence of obsessive-compulsive symptoms or disorders, as well as of superstitions or magical thinking, in a group of professional tennis players, by means of standardized assessment scales, as compared with healthy subjects who did not professionally perform any kind of sport activity.

Methods: Twenty-five current or former professional tennis were recruited within the Italian Tennis Federation during an

international competition and during a master meeting of coaches. All of them underwent a psychiatric interview with a structured scale and a psychopathological assessment carried out with the Mini-International Neuropsychiatric Interview (MINI) and the Yale-Brown Obsessive-Compulsive Scale (Y-BOCS). Data were analyzed and compared. analysis was performed by means of contingency tables, χ^2 tests, group statistics, paired, independent and Mann Whitney's tests.

Results: The Y-BOCS total score was significantly higher in both current and retired athletes than control subjects (5.96 ± 5.76 versus 1.24 ± 2.65 , $p = 0.001$, $t = 3.72$). Current athletes showed more frequently current aggressive obsessions ($\chi^2 = 0.041$, $r = 5.24$) and current miscellaneous compulsions ($\chi^2 = 0.030$, $r = 5.94$) than past athletes. The Y-BOCS ($t = 3.4$, $p = 0.002$) obsessions ($t = 3.48$, $p = 0.002$), and compulsions subscale ($t = 3.11$, $p = 0.005$) scores were higher in current players than in the other group.

Conclusions: Our results support the hypothesis that high-level competitive sports activities, which suppose compliance with strict daily routines and extensive training, could constitute a risk factor for the onset of full-blown obsessive-compulsive disorder in more vulnerable subjects. Similarly, there is a growing demand for sport psychological support experts in order to prevent high stress in training and competitions.

Does duration of untreated illness impact long-term outcome in obsessive-compulsive disorder?

S. Cipolla^{1*}, P. Catapano¹, S. Pascolo¹, M. Luciano¹, G. Sampogna¹, F. Perris¹, V. Giallonardo¹, V. Del Vecchio¹, M. Fabrazzo¹, A. Fiorillo¹ and F. Catapano¹

¹Psychiatry, University of Campania "L. Vanvitelli", Naples, Italy

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.733

Introduction: The time period between the onset of a mental disorder and its first adequate treatment (duration of untreated illness - DUI) influence long-term prognosis and outcome in patients with severe mental disorders. The relationship between DUI and outcome was originally found in people affected by schizophrenia spectrum disorders, however in patients with Obsessive-Compulsive Disorder (OCD) DUI is significantly longer compared with that of patients with other severe mental disorders, such as schizophrenia and bipolar disorder.

Objectives: Aims of the present study is to assess the impact of DUI on long-term outcomes in OCD patients across published studies.

Methods: A systematic review was carried out by selecting relevant articles on the topic present in three common on-line databases, such as PubMed, APA PsycInfo, and Scopus, up to June 2023.

Results: Among included studies, DUI ranged from 7.0 ± 8.5 to 20.9 ± 11.2 years. Patients reporting a longer DUI have a poor long-term outcome, in terms of greater symptom severity and lower level of treatment response, whether pharmacological treatment or psychotherapy or a combination of these two. This is particularly true

when the onset of the disease is insidious and subthreshold. However, there are severe early-onset forms of OCD in which the request for help is anticipated due to the severity of the symptoms, the DUI is shorter, but the prognosis is still negative.

Conclusions: The present review confirms that longer DUI has a negative impact on the long-term outcome of patients with OCD. Furthermore, it is reasonable to hypothesize that cultural factors, such as the perception of the disease and the ability to access treatment, may result in a prolongation of the DUI. All these elements cannot be evaluated in our review due to the paucity of studies on the topic. Future studies could be useful to better understand the causes of a longer DUI, to guide and to promote the dissemination of early interventions with a specific focus on OCD symptoms.

EPP0632

Habit Learning in OCD: Preliminary Data from a Spanish Sample

M. Prime Tous^{1*}, C. Lopez Solà², L. Hermida² and M. A. Fullana²

¹Child and Adolescent Psychiatry and Psychology Department, Institute of Neurosciences and ²Adult Psychiatry and Psychology Department, Institute of Neurosciences, Hospital Clínic, Barcelona, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.734

Introduction: Instrumental learning involves goal-directed and habitual systems. The Slips-of-Action Task (SOAT) is extensively used to measure habit tendencies and the likelihood of making erroneous responses for devalued outcomes. The SOAT provides a Devaluation Sensitivity Index (DSI), a measure of the balance between relative goal-directed and habitual learning. Individuals with Obsessive-Compulsive Disorder (OCD) often engage in repetitive actions, suggesting a potential deficit in goal-directed control and an increased reliance on habitual learning. Previous literature has shown that medicated OCD adults performed worse on the SOAT task than healthy controls.

Objectives: To compare habit learning performance in an unmedicated sample:

- **Goal 1:** Between OCD and Healthy Controls (HC)
- **Goal 2:** Across four groups: adult OCD, adult HC, children OCD, and children HC

Methods: Participants: Eighty-three participants (44 OCD patients and 38 healthy controls) completed the study with usable task data. The 44 OCD patients comprised 17 adults (mean age: 26.76 years, SD: 8.61 years) and 27 children/adolescents (mean age: 12.84 years, SD: 2.59 years). The 38 healthy controls included 17 adults (mean age: 30 years, SD: 7.49 years) and 21 children/adolescents (mean age: 14.1 years, SD: 2.19 years). All participants were unmedicated. **Measures:** Participants completed an adapted version of the "Fabulous Fruit Game", which included an instrumental training phase to learn Stimulus-Response-Outcomes (S-R-O) associations and a SOAT

to assess the strength of learned S-R-O associations. DSI was calculated by subtracting the percentage of responses made toward devalued outcomes from the percentage of responses made toward still valuable outcomes. **Behavioral Analyses:** Student's t-test comparing individuals with OCD to HC and a ONEWAY ANOVA to examine group differences across multiple categories.

Results: Goal 1: DSI comparison between individuals with OCD and HC revealed a significant difference, with HC demonstrating superior performance ($t(60.9) = 2.60, p = .012$, Cohen's $d = .546$).

Goal 2: The overall DSI comparison across adult OCD, adult HC, children OCD, and children HC showed a non-significant difference ($F(3) = 3.407, p = 0.22$). However, post hoc analysis revealed significant differences between Adult HC and Youth OCD (I-J Scheffe = 28.82, $p = .033$), indicating superior performance in adult HC.

Conclusions: This study highlights altered Habit Learning in unmedicated OCD individuals, supported by significant DSI differences compared to HC. Age-related distinctions were observed, emphasizing the need for age-sensitive interventions in understanding and addressing habit-related challenges in OCD.

EPP0633

Acute obsessive symptoms: case report of a PANDAS-like syndrome in an adult patient.

Á. de Vicente Blanco^{1*}, B. Orgaz Álvarez¹, P. Ibáñez Mendoza¹ and M. Velasco Santos¹

¹Hospital Universitario La Paz, Madrid, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.735

Introduction: Neuropsychiatric disorders can develop following a group A β -hemolytic streptococcal infection, through autoimmune inflammation of the nervous system. Sydenham's chorea and PANDAS (Pediatric Autoimmune Neuropsychiatric Disorders Associated with Streptococcal Infection) are the two most well-known syndromes, primarily affecting children but rarely observed in adults.

Objectives: Our aims are to contribute to the scientific understanding of adult PANDAS-like syndrome and provide a comprehensive literature review on the subject.

Methods: Case report using clinical records and a non-systematic literature review.

Results: A 24-year-old female presented to the emergency department with profound emotional distress triggered by intrusive thoughts of existential dread, accompanied by compulsive praying. She reported that these symptoms had commenced five days earlier. Two days prior to the onset of her obsessions, she had experienced a high fever, odynophagia, cough, and chills and received an empirical diagnosis of tonsillitis following a physical examination. She was prescribed antibiotics with good response. She revealed that she had experienced two prior episodes of similar anxiety and obsessions when she was approximately seven years old.

She developed acute obsessive thoughts, including doubts about the meaning of her life, and engaged in compulsive prayer and seeking reassurance from relatives. Notably, there were no signs of affective, dissociative, or psychotic disorders during her admission to the ED or in the preceding months. She reported suffering from anxiety, insomnia, and loss of appetite in the past five days but did not express any suicidal ideation.

Physical examination indicated mild laryngeal erythema, and laboratory tests showed non-specific signs of infection with no further significant findings. Symptoms were alleviated within a week, aided by treatment with benzodiazepines (lorazepam 1 mg/8h), and she did not require further psychiatric counselling.

Conclusions: It is worth noting that adult patients can experience a PANDAS-like reaction after a streptococcal infection and may also undergo symptom relapse following new immunological challenges upon reinfection. The existence of a PANDAS spectrum has been postulated, encompassing various manifestations. Thus, when presented with acute obsessive symptoms, healthcare providers should consider this diagnosis, inquire about previous episodes, and conduct a comprehensive medical history and etiological assessment.

Avoidance of Negative Emotional Contrasts as a Diagnostic Feature of OCD: A Receiver-Operator Characteristic Curve Analysis of the Contrast Avoidance Questionnaires

V. Swisher^{1*} and M. G. Newman¹

¹Psychology, The Pennsylvania State University, State College, United States

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.736

Introduction: The Contrast Avoidance Model (CAM) was developed to explain pathological worry in generalized anxiety disorder (GAD). The CAM posits that those with GAD are sensitive to sharp increases in emotions, and use worry to maintain heightened states of negative arousal to avoid these emotional shifts. Research has widely supported the CAM in the conceptualization of GAD, and has extended these findings to other disorders, including major depressive disorder (MDD) and social anxiety disorder (SAD). Despite the utility of the CAM model in informing the etiology of these conditions, research has yet to expand these findings beyond GAD, MDD, and SAD. Specifically, obsessive-compulsive disorder (OCD), which co-occurs with GAD, MDD, and SAD in adults at a rate of 15.0%, 40.7%, and 14.7%, respectively, and shares many of their etiological features, has yet to be examined in the context of the CAM. Thus, examining CA as a relevant mechanism and therapeutic target for OCD is an unstudied conceptual framework that may offer meaningful clinical utility.

Objectives: The present study used receiver operator curve (ROC) analyses to examine the predictive utility of the CAQ-W and CAQ-

GE in detecting probable OCD in a large undergraduate sample. We hypothesized that the CAQ-W and CAQ-GE would be higher in participants with probable OCD and would offer sufficient sensitivity and specificity in predicting probable OCD.

Methods: 1259 undergraduates were recruited for a mass University screening. Participants were included in the OCD group (N = 291) if they met diagnostic criteria for OCD (DOCS total score > 20). Participants were included in the nondisordered group (n = 249) if they did not meet diagnostic criteria for any of the screened disorders (SAD, MDD, GAD, OCD, panic disorder, post-traumatic stress disorder, OCD, borderline personality disorder), denied suicidality, and denied receiving mental health treatment in the last 12 months. ROC analyses were used to examine the accuracy of the CAQ-W and the CAQ-GE in detecting probable OCD.

Results: Results of ROC analyses are reported in Table 1. AUC values for the CAQ-W and CAQ-GE were significantly different from the null hypothesis (AUC = .50, $p < .001$), and demonstrated excellent (.89) to outstanding (.91) accuracy in predicting probable OCD (Figure 1), respectively. Optimal sensitivity and specificity to detect probable OCD (Table 2) was achieved at a cut off score of 67.5 for the CAQ-W (Sensitivity = 81.4%; Specificity = 82.3%) and a cutoff score of 43.5 for the CAQ-GE (Sensitivity = 84.9%; Specificity = 85.5%).

Image:

Table 1
ROC analyses of the CAQ-W and CAQ-GE in detecting probable OCD

	AUC (SE)	AUC [95% CI]	Optimal cut-off score	Sensitivity %	Specificity %
CAQ-W	.89 (.01)	[.87, .92]	67.5	81.44%	82.33%
CAQ-GE	.91 (.01)	[.89, .94]	43.5	84.88%	85.54%

Note. CAQ-W = Contrast Avoidance Questionnaire – Worry;
CAQ-GE = Contrast Avoidance Questionnaire – General Emotion;
AUC = Area Under the Curve

Image 2:

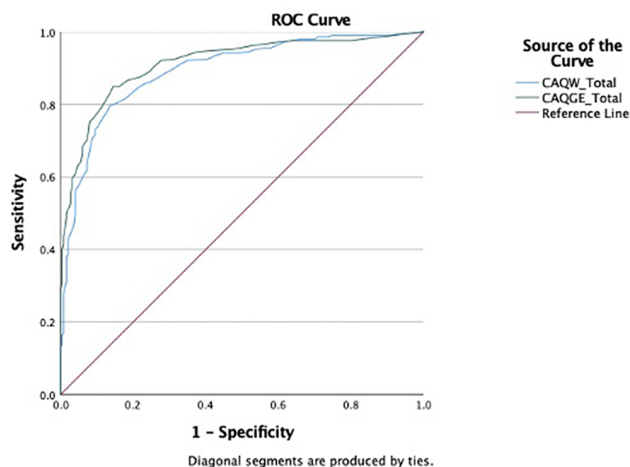

Table 2
Sensitivity, Specificity, and Cutoff Scores of the CAQ-W and CAQ-GE

	Cutoff Score	Sensitivity %	Specificity %
CAQ-W	63.5	85.57	77.11
	64.5	84.54	78.71
	65.5	83.85	79.52
	66.5	82.13	81.53
	67.5	81.44	82.33
	68.5	81.10	83.13
CAQ-GE	69.5	80.07	85.14
	39.5	89.00	75.50
	40.5	87.63	77.91
	41.5	86.60	81.53
	42.5	84.88	83.94
	43.5	84.88	85.54
	44.5	83.16	86.35
	45.5	80.41	87.95

Note. CAQ-W = Contrast Avoidance Questionnaire – Worry;
CAQ-GE = Contrast Avoidance Questionnaire – General Emotion

Image 3:

Figure 1
ROC curves for CAQ-W and CAQ-GE to detect probable OCD

Note. CAQ-W = Contrast Avoidance Questionnaire – Worry;
CAQ-GE = Contrast Avoidance Questionnaire – General Emotion

Conclusions: Results suggest that OCD can be accurately characterized by CA. Findings also highlight the utility of examining CA as a relevant maintenance factor for OCD symptoms. Future research should examine the impact of CA on OCD symptoms in-laboratory and ecological settings.

Through the Parent's Eyes: Exploring the Relationship Between Parental Perceptions of Difficulties and SDQ Scale Results in Children and Adolescents

A. S. Gonçalves^{1*}, R. Rodrigues¹, F. Monteleone¹, B. Couto¹, R. Ortiga¹ and V. Rocha²

¹Service of Psychiatry and ²Service of Child and Adolescent Psychiatry, Hospital da Senhora da Oliveira Guimarães, Guimarães, Portugal

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.737

Introduction: The Strengths and Difficulties Questionnaire (SDQ) is a widely used assessment tool for measuring the psychological well-being of children and adolescents. It consists of 25 items that assess emotional symptoms, conduct problems, hyperactivity/inattention, peer relationship difficulties, and prosocial behavior.

Objectives: The present study aimed to investigate the relationship between parental perceptions of difficulties and the results obtained from the SDQ.

Methods: Participants were recruited from the initial consultation of Child and Adolescent Psychiatry (N=132). Parents completed a questionnaire assessing their subjective perceptions of their child's

difficulties in various domains (home, school, learning activities, relations with friends) on a 4-point scale ranging from "no notion of difficulties" to "very severe difficulties". They also completed the SDQ scale. Data were analyzed using SPSS software.

Results: In this study, 74% of participants had scores on the SDQ indicating potential psychological difficulties. Additionally, 17.4% of participants had scores on the borderline between normal and abnormal results. 47% of patients scored above the cut-line for problems on the hyperactivity/inattention subscale, indicating higher levels of difficulties in this area. Conversely, only 3% of participants scored problematic scores on the peer relationship difficulties subscale. There was no statistical difference between sexes in terms of SDQ scores. A correlation analysis revealed a significant positive correlation ($p < 0.01$) between parental perceptions of difficulties and higher SDQ scores and the mean score on the SDQ scale was found to be significantly higher in patients who were rescheduled for another consultation following the evaluation by doctors, compared to those patients who received clinical discharge from the initial consultation (p -value 0,040).

Conclusions: This study provides valuable insights into the concordance between parental perceptions and objective assessments of difficulties in children and adolescents. Parents who perceived their child to have more difficulties also reported higher levels of psychological difficulties on the SDQ. This study highlights the importance of using tools like the SDQ to assess psychological well-being in children and adolescents. It also emphasizes the practical utility of the SDQ as a time-efficient assessment tool for use during initial consultations in child and adolescent psychiatry.

Maternal awareness and practices in managing screen-time for children

H. Atturu¹ and S. C. Gujju^{2*}

¹Dept of Psychiatry, Care Hospital Hitech, Hyderabad, India and ²Year 13 A-Level, The English College, Dubai, United Arab Emirates

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.738

Introduction: The issue of screen time usage among children has become a contentious topic for parents in contemporary society. While electronic devices offer undeniable benefits, their inappropriate use can lead to substantial mental and physical health challenges for children. Parents are tasked with the responsibility of equipping themselves and their children with the knowledge and skills necessary for mindful electronic device use.

Objectives: This study aims to assess the awareness levels of mothers regarding their children's screen time usage and to promote mindful screen usage. It also aims to understand the reasons behind parents' decisions to allow their children access to electronic devices.

Methods: An adapted short online screen-time questionnaire (Vizcaino et al 2019), was distributed through online Google forms, primarily to mothers residing in India. The questionnaire comprised of ten questions encompassing topics related to the child's background, mothers' awareness and patterns of screen-time usage.

Results: 213 mothers with children aged one year to 17 years responded. 157 mothers (73.7%) were in employment (104 were working in an office, 32 were working from home and 18 were freelancing). 121 mothers had >one child. Majority of the mothers ($n=170$, 79.81%), believed that children should have <one hour screen-time. However, they also admitted that majority of their children spent >one hour per day screen-time. The usage was more during weekends (>one hour= 161 , 75.58%) than weekdays (>one hour = 145 , 68%)($p=0.021$). Weekend screen-time was more in children whose mothers were employed ($p=0.006$). There is a significant increase in weekday ($p=0.044$) and weekend ($p=0.006$) screen-time usage as the child's age increased. Children predominantly watched television, followed by mobile phones and tablets. Except for 29 children, the rest enjoyed interacting with other people (54 with everyone, 73 with only family members and 57 only for some time). The primary context in which children engaged with electronic devices was while they were being fed/ meals-time ($n = 114$, 54%) or when the mothers were busy with household chores ($n = 85$, 40%).

Conclusions: Despite maternal awareness about healthy screen-time, majority of the children were allowed to use higher screen-time. Efficient strategies should be imparted to parents to change the current practices of using digital-media as pacifier or distractor to mindful screen-time including usage for educational purposes.

EPP0638

The relationship between children's rumination and parental rumination, worry and depressive symptoms

J. Szőke^{1,2*}, M. Klein^{1,2}, Á. Örkényi¹ and G. Kökönyei^{1,3}

¹Institute of Psychology, ELTE Eötvös Loránd University; ²Doctoral School of Psychology, ELTE Eötvös Loránd University and ³NAP3.0-SE Neuropsychopharmacology Research Group, Hungarian Brain Research Program, Semmelweis University, Budapest, Hungary

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.739

Introduction: Rumination is a transdiagnostic phenomenon that is linked to psychological and physical symptoms not only in adulthood but also in childhood. Several distal and proximal factors are believed to underlie the development of ruminative tendencies, with parental characteristics and modelling being among those with a potential association with the increased levels of children's rumination.

Objectives: The primary aim of the study was to investigate the link between rumination in children and parental functioning, including rumination, worry and depressive symptoms. Additionally, we aimed to test the association between rumination and psychological and somatic health in a sample of healthy children and early adolescents.

Methods: 153 children (87 girls, mean age = 10.74; SD = 0.91 years) and their parents (130 females, mean age = 42.65; SD = 4.08 years) participated in the study. For children, Kid Rumination Interview (KRI; Baiocco et al., 2017) was used, alongside the assessment of nine subjective health complaints. KRI employs 4 images to

measure the frequency of rumination. Self-reported questionnaires were also completed by parents to report on worry, rumination, and depressive symptoms.

Results: Contrary to our expectations, there was no significant association between children's rumination and parental rumination ($r = .06$, $p = .506$), worry ($r = -.02$, $p = .850$) and depressive symptoms ($r = -.01$, $p = .979$). Psychosomatic complaints in children exhibited a positive albeit weak association with parental depressive symptoms ($r = .17$, $p = .046$). Regression analysis revealed that the frequency of rumination occurring in the four situations associated significantly with psychosomatic symptoms ($\beta = .266$; $t = 3.321$; $p = .001$) after controlling for sex and age.

Conclusions: Our findings are in line with previous studies demonstrating the relationship between rumination and psychosomatic symptoms in older adolescent samples. However, parental perseverative cognitions and depression were unrelated to ruminative tendencies in children. Nevertheless, the modest sample size and the employment of a different assessment approach compared to self-report questionnaires may have influenced our findings.

Long-term prognosis of chronic depression in adolescence

V. Kaleda^{1*} and V. Migalina¹

¹Mental Health Research Centre, Moscow, Russian Federation

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.740

Introduction: juvenile chronic depression is characterized by high prevalence, difficulties in diagnosis, nosological qualification and prognostic assessment. According to epidemiological data, the frequency of these conditions ranges from 1.5% to 3% in the general population (Gutiérrez-Rojas et al. Braz. J. Psychiatr 2020; 42 657-672), and among all depressions in adolescence, a chronic course develops in about 20% of cases (Blanco C., 2010 et al. The J clinical psychiatry 2010; 71(12) 6501). Due to the polymorphism of the clinical picture and the peculiarities of juvenile ontogenesis, difficulties arise in nosological and prognostic assessment.

Objectives: to study the long-term prognosis of chronic depression, depending on the variant of its course.

Methods: Catamnestic examination was performed on 64 patients of adolescent age (16-25 years), for chronic depressive state lasting more than two years (F31.3, F31.4, F32 (except F32.3), F33 (except F33.3), F34, F34.1, F21, F20 according to ICD-10). The duration of the catamnesis is more than 10 years. The PSP scale was used for psychometric assessment.

Results: when analyzing the ten-year course of juvenile chronic depression, three variants were identified: regredient (23.4%), monotonous (35.9%) and progredient (40.6%). The regredient course was characterized by a marked reduction or disappearance of psychopathological disorders with the formation of further remission with a high level of functioning in all spheres of life and complete social and labor adaptation (81-100 points on the PSP scale). The monotonous course was characterized by low variability

and insignificant dynamics of individual manifestations throughout the disease with the preservation or some decrease in the level of educational and labor adaptation with the restoration of previous social contacts and a fairly high quality of life (scores 61-80 on the PSP scale). The progressive course was characterized by the gradual addition of new psychopathological disorders, or the aggravation of existing ones, patients had a distinct decrease in educational, labor and social adaptation (scores 50-31 on the PSP scale) or complete maladaptation of all spheres of life (scores <40 on the PSP scale).

Conclusions: The high incidence of progressive and monotonous course in juvenile chronic depression, contributing to a decrease in the level of functioning of patients, indicates the importance of timely detection of these conditions and the need for careful selection of therapy.

²Psychology, La Fe Research Institute and ³Psychology, Hospital Universitario y Politécnico La Fe de Valencia, Valencia, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.741

Introduction: Emotional dysregulation are considered early manifestations of neuropsychiatric disorders. Recent research has shown that a threatened preterm labour (TPL) represents an adverse prenatal event that involves temperament disturbances, even in absence of prematurity. Thus, full-term TPL infants at 6 months of age are characterized by lower positive affect, higher negative affect, and worse emotional regulation relative to a full-term non-TPL control group.

Objectives: The aim of this study is to explore the predictors of change of emotional infant competences.

Methods: This prospective cohort study recruited mothers who suffered from a TPL. Infants' temperament assessment was performed at 6 and 30 months of age using the Rothbart Behaviour Questionnaires, examining positive affectivity/surgency, negative emotionality, and orienting and emotional regulatory capacity. A regression model was carried out, including gestational age at birth, maternal anxiety trait, maternal history of psychological traumas, prenatal and postnatal maternal depression, anxiety, and cortisol as well as parenting stress as predictors.

Results: Increased positive affectivity was related with lower paternal stress ($p = .044$). Maternal history of trauma and parenting stress was associated with increased negative emotionality ($p = .037$ and $p = .045$, respectively). Increased emotional regulation disturbance was linked to low gestational age at birth ($p < .001$), higher postnatal depression ($p = .002$), higher prenatal anxiety at TPL diagnosis ($p = .039$) and higher postnatal anxiety ($p = .008$).

Conclusions: Therefore, maternal previous traumas, maternal psychopathology from pregnancy to postpartum as well as parenting

stress should be considered in psychological treatment to improve infant's emotional competences and prevent subsequent neuro-psychiatric disorders.

EPP0642

The Friendship Gap: Investigating gender differences in adolescent friendships and mental health

T. Manchanda^{1*}, A. Stein¹ and M. Fazel¹

¹Psychiatry, University of Oxford, Oxford, United Kingdom

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.742

Introduction: Friendships are vital relationships throughout the lifespan, but become especially meaningful during adolescence. Adolescents between the ages of 10 and 18 name a friend as one of the most important people in their lives (Kiesner et al., 2004). Authentic social groups, defined as mutual social relationships that adolescents voluntarily engage in, are sources of support and companionship for adolescents, more than parents (Furman & Buhrmester, 1992). Past research shows adolescents turn to their friends most for mental health support in a crisis, yet less than half report finding the support helpful (Geulayov et al., 2022). Thus, it's crucial to understand friendship dynamics of adolescents in order to address an appropriate intervention. Past literature has demonstrated gender differences in how adolescents approach friendships and social relationships (Lempers & Clark- Lempers, 1993).

Objectives: I aim to investigate whether girls, boys, and gender non-binary individuals differ in their perceptions of friendship quality and friendship dynamics (i.e. social support seeking) and whether these differences have implications for their mental health outcomes. By studying gender differences in friendship quality and mental health, I hope to shed light on potential avenues for promoting inclusivity and positive mental health outcomes for both gender binary and gender non-binary adolescents.

Methods: A cross-sectional survey (OxWell) was administered online to students across secondary schools and further education colleges in England to assess their self-reported friendship quality. The RCADS and WEMWBS scales were used to assess depression and anxiety symptomology, and well-being, respectively. The results from the survey were analysed in R.

Results: Gender-binary and gender non-binary adolescents differed in friendship quality, friendship dynamics, mental health scores, and help-seeking behaviours. Gender non-binary adolescents had the worst mental health scores and reported lowest friendship quality compared to girls and boys. Boys had the best mental health when compared to girls and gender non-binary adolescents, and were more likely to perceive support provided by their friends as helpful. Surprisingly, gender non-binary adolescents reached out to their friends the most (when compared to girls and boys) for mental health support, despite having proportionally lower quality friendships, and were the least likely to find support received from friends helpful.

Conclusions: This data presents evidence for the difference in social relationships across adolescents of all genders. It highlights the need for specialized and inclusive mental health support being made available for gender non-binary youth in England—a

minoritized group in need of intervention. This data hopes to inform school-based friendship interventions targeted to improve friendships and mental health of gender non-binary youth.

The quality of life of Hungarian adolescents in the light of their emotions

N. Rábavölgyi¹, Z. Mayer^{1*}, B. Szabó² and M. Miklósi^{1,3,4}

¹Department of Developmental and Clinical Child Psychology, Eötvös Loránd University Institute of Psychology; ²Eötvös Loránd University Doctoral School of Psychology; ³Department of Clinical Psychology, Semmelweis University and ⁴Mentalhygienic Centre, Heim Pál National Pediatric Institute, Budapest, Hungary

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.743

Introduction: Mental health professionals pay particular attention to adolescents, as many psychiatric disorders begin at this age, and the mental state of adolescents has been deteriorating worldwide in the last decade. Based on previous international research, the ability to regulate negative emotions and mentalizing - that is, the ability to identify the thoughts and emotions behind one's own and others' behaviour - mediate the negative effects of attachment difficulties experienced in close relationships on the quality of life. This relationship has not yet been investigated among Hungarian adolescents. Adolescent events can have a long-term effect on a person's mental health, so it is very important to examine the factors that influence the quality of life.

Objectives: This research aimed to examine the relationship between attachment, mentalizing, emotion regulation and quality of life among adolescents between 14 and 18 years of age.

Methods: In our non-clinical cross-sectional research, 141 adolescents filled out the Experiences in Close Relationships questionnaire, the Difficulties in Emotion Regulation Scale, the Reflective Functioning Questionnaire and the Quality of Life Scale after informed consent. We tested two mediator models, in which emotion regulation and mentalizing were the mediating variables in the relationship between attachment difficulty and quality of life.

Results: In our analyses, attachment difficulties ($c' = -1.87, p < .001, \beta = -0.41$) and emotion regulation problems ($b = -0.08, p < .001, \beta = -0.39$) also predicted a reduced quality of life. Attachment problems also reduce the quality of life of young people through emotional regulation difficulties ($\sum ab = -0.81 [-1.21 - -0.45], \beta = -0.17$). However, mentalizing was not significantly related to the adolescents' quality of life ($b = -0.05, p = .10, \beta = -0.11$). Mentalizing also did not mediate the relationship between attachment and quality of life ($\sum ab = -0.09 [-0.27 - -0.02], \beta = -0.02$).

Conclusions: Our results suggest that adolescents' emotion regulation has a prominent role in their quality of life in addition to attachment styles. To improve the quality of life among adolescents, we recommend using techniques that develop emotion regulation.

Alexithymia in population with depressive disorders and suicidal ideation: results of an observational study

P. Martínez, A. R. Campos*, T. Jiménez Aparicio, M. Fernández Lozano and M. Merizalde Torres

HCUV, Valladolid, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.744

Introduction: In clinical practice, significant delays in requesting help are observed in patients with depressive symptoms and suicidal ideation.

Objectives: The objective of this study was to determine factors associated with the time of untreated illness in a population with depressive disorder attending mental health for the first time in the area of Hospital Clínico Universitario de Valladolid (HCUV).

Methods: Methods: This is an observational study including adult patients of both sexes, referred to their first mental health consultation from their Primary Care Physician, with a picture of depressive symptomatology associated with an identifiable stressor. Informed consent was obtained from the patients and authorized by the Ethics Committee of the HCUV. R Studio ® statistical analysis.

The degree of emotional confusion was quantified with item 1 ("I am often confused about the emotions I feel") of the Toronto Alexithymia Scale (TAS). This item is scored (1-5) from most severe (1) to least (5). On the other hand, the time in weeks between symptom onset to referral, age and symptom severity according to the Montgomery Scale (MADRS) were recorded.

Results: Results: We present data collected in an initial sample of 278 treated patients, with a female predominance (68%), a MADRS severity score (18.05 ± 5.01) and a calculated time without treatment of 59.66 ± 62.26 weeks (Tables 1,2,3).

A subsample of 72 patients with death ideation was studied, with a female predominance (75%) compared to the overall sample ($X^2 = 1.99, p = 0.1585$) (Table 4).

It was also observed that death ideation was higher in younger patients ($t = 3.18, p = 0.001907$) and with a severe MADRS depression score ($t = -7.92, p < 0.0001$), however they took a similar length of time to receive mental health treatment (T student $t = -1.6605, p = 0.099$); (Table 5).

There is no previous published evidence that considers the timing of untreated symptoms. According to test statistics, there are differences in untreated symptom time considering gender and TAS score (Table 6).

Conclusions: Death ideation is a current health problem that deserves attention. In multivariate analysis models, an association with clinical and demographic factors has been found; however, there is up to 20% of the variation in prevalence that is not explained by the aforementioned factors. The factors that determine the time delay in seeking help (treatment delays) have not been studied so far.

In this study we observe how a single variable doesn't explain the delay in the first visit. The interaction between age, gender, alexithymia and hypoprosexia explains the delay in seeking help, although symptom severity doesn't seem to be related. These data suggest that unexplained causality in multivariate studies may be related to the interaction between clinical and neuropsychological factors.

Psychiatry on fire: Climate change and the role of mental healthcare

F. Poukhovski-Sheremetyev

Psychiatry, McGill University, Montréal, Canada

doi: 10.1192/j.eurpsy.2024.745

Introduction: What is the psychiatrist's role on a burning planet? As our world faces the existential ramifications of irreversible climate change, clinicians are contending with what purpose a normalizing institution like psychiatry can have in increasingly abnormal times.

Objectives: This presentation investigates the role of the modern mental health clinician by examining psychiatry's current impotence in the face of climate crisis. It will be shown that current approaches are often complicit in psychiatry's historical depoliticization of mental health and subsequent individualization of social concerns. It will be argued that the only way psychiatry can maintain its ethical obligations to its patients is by taking a courageous sociopolitical stance.

Methods: Emerging from a multidisciplinary literature review on the relationship between psychiatry and social crises, this work examines our field's response to climate change in particular. A focus is made on literature that explores psychiatry's political obligations, current trends in climate psychiatry, and proposed social psychiatric approaches to the climate crisis.

Results: It is shown that while ecological collapse tangibly affects our patients, psychiatry often fails to engage socio-politically with the crisis' root causes. Framing intense reactions to climate change as trauma responses and developing neo-diagnoses such as "ecoanxiety" both risk individualizing inherently social experiences. However, Psychiatrists are also uniquely positioned to speak with authority about social crises and to articulate what a more comprehensive medical response to climate change might look like.

Conclusions: Given climate change's disproportionate effects on disenfranchised populations, it is increasingly clear that health is inextricable from social circumstances. As a result, political inaction is incompatible with our ethical duty to serve patients' health, both in the clinic and beyond it.

Functional connectivity subtypes of MDD and their associations with gene expression profile, neurotransmitter, and cognition

Q. Li^{1*}, Y. Wang¹, F. Long¹, Y. Chen¹, Y. Wang¹, Q. Gong¹ and F. Li¹

¹Department of Radiology and Huaxi MR Research Center (HMRR), Functional and Molecular Imaging Key Laboratory of Sichuan Province, West China Hospital, Sichuan University, Chengdu, China

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.746

Introduction: There's large heterogeneity present in major depressive disorder (MDD) and controversial evidence on alterations of brain functional connectivity (FC), making it hard to elucidate the neurobiological basis of MDD. Subtyping is one promising solution to characterize this heterogeneity.

Objectives: To identify neurophysiological subtypes of MDD based on FC derived from resting-state functional magnetic resonance imaging using large multisite data and investigate the differences in genetic mechanisms and neurotransmitter basis of FC alterations, and the differences of FC-related cognition between each subtype.

Methods: Consensus clustering of FC patterns was applied to a population of 829 MDD patients from REST-Meta-MDD database after data cleaning and image quality control. Gene transcriptomic data derived from Allen Human Brain Atlas and neurotransmitter receptor/transporter density data acquired by using neuromap toolbox were used to characterize the molecular mechanism underlying each FC-based subtype by identifying the gene set and neurotransmitters/transporters showing high spatial similarity with the profiles of FC alterations between each subtype and 770 healthy controls. The FC-related cognition in each subtype was also selected by lasso regression.

Results: Two stable neurophysiological MDD subtypes were found and labeled as hypoconnectivity (n=527) and hyperconnectivity (n=299) characterized by the FC differences in each subtype relative to controls, respectively. The two subtypes did not differ in age, sex, and scores of Hamilton Depression/Anxiety Scale.

The genes related to FC alterations were enriched in ion transmembrane transport, synaptic transmission/organization, axon development, and regulation of neurotransmitter level for both subtypes, but specifically enriched in glial cell differentiation for hypoconnectivity subtype, while enriched in regulation of presynaptic membrane and regulation of neuron differentiation for hyperconnectivity subtype.

FC alterations were associated with the density of 5-HT_{2a} receptor in both subtypes. For hyperconnectivity subtype, FC alterations were also correlated with the density of norepinephrine transporter, glutamate receptor, GABA receptor, 5-HT_{1b} receptor, and cannabinoid receptor.

Both subtypes showed correlations between FC and categorization, motor inhibition, and localization. The FC in hypoconnectivity subtype correlated with response inhibition, selective attention, face recognition, sleep, empathy, expertise, uncertainty, and anticipation, while that was related to inference, speech perception, and reward anticipation in hyperconnectivity subtype.

Conclusions: Our findings suggested the presence of two neuroimaging subtypes of MDD characterized by hypo or hyperconnectivity. The two subtypes had both shared and distinct genetic mechanisms, neurotransmitter receptor/transporter profiles, and cognition types.

doi: 10.1192/j.eurpsy.2024.747

Introduction: Major depressive disorder (MDD) is a common multifactorial disorder, but the exact pathophysiology is still unknown. *in vivo* and post-mortem studies document volumetric and cellular changes in the hippocampus of depressed patients. Chemical synapses are key functional units of the central nervous system and earlier studies found reduced number of synapses in the prefrontal cortex of depressed patients (Kang HJ *et al.* Nature Medicine 2012;18(9):1413-1417). Mitochondria are intracellular powerhouses generating chemical energy for cellular biochemical reactions. Recent findings suggest that individuals with impaired mitochondrial function may be vulnerable to develop psychopathologies.

Objectives: We investigated synapses and mitochondria in post-mortem hippocampal samples from psychiatric patients.

Methods: The three study groups were: 1) MDD patients (n=11); 2) patients with alcohol dependence (n=8) and 3) controls (n=10). Controls were individuals who accidentally deceased and had no neuropsychiatric disorders. Three sub-regions of the hippocampus (dentate gyrus, CA3 and CA1 areas) were investigated. Ultrathin sections were examined, and photomicrographs were taken for further analysis using a JEOL JEM 1400 FLASH transmission electron microscope. Systematic quantitative analysis was conducted with the Neurolucida system using unbiased counting principles.

Results: We could not detect any differences in synapse and mitochondria densities between the patients and controls subjects.

Conclusions: Our preliminary data suggest that despite our expectations hippocampal synapse and mitochondrial densities are rather constant parameters which are not easily affected by psychopathology or alcohol consumption. Potential methodical limitations may also explain this negative finding.

The association between depressive symptoms and medication adherence among polypharmacy older adults

G. Alhashem¹, R. Alyasery^{1*} and S. Al-Hassan¹

¹Pharmacy, AlSafwa University College, Karbala, Iraq

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.748

Introduction: Among many polypharmacy term definitions, the most common definition refers to the concurrent use of five or

more medications. Multiple medication administration is highly prevalent in older populations with multimorbidity. Apart from polypharmacy impacts on physical health, it might be detrimental to mental health.

Objectives: The present study aims to evaluate the association between depression and poor adherence in multimorbidity Iraqi older population using five or more medications.

Methods: This cross-sectional study was conducted in Iraq during July and August 2023, involving a sample of 196 older adults recruited from private clinics and hospital clinical medicine wards, all of whom had polypharmacy regimens. The questionnaire includes age, gender, medication regimen adherence and Patient Health Questionnaire-8 (PHQ-8) using a cutoff score of 10. Chi-square and binary logistic regression were performed to determine the association between poor adherence and the presence of depressive symptoms.

Results: A total of 196 respondents, mean age = (61±11.4), 49 (25%) male and 147 (75%) female, 178 (90.8%) good adherence and 18 (9.2%) poor compliance, 81 (41.3%) participants have PHQ-8 score was equal or less than ten while 115 (58.7%) have PHQ-8 score was more than 10. Depressive symptoms and patient adherence showed a significant association ($p = 0.02$). Moreover, poor adherence polypharmacy participants were more likely to have depression odd ratio (OR) = 3.9, 95% confidence interval (CI = 1.09 – 13.9; $p = 0.036$).

Conclusions: Our findings suggest that depressive symptoms are associated with poor adherence polypharmacy older adults and, highlighting the importance of addressing medication management and mental health in this population.

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.749

Introduction: In ESCAPE-TRD esketamine nasal spray (ESK-NS) significantly increased the probability of achieving remission at Week (Wk) 8 and being relapse-free through Wk32 after remission at Wk8 versus (vs) quetiapine extended release (Q-XR) in patients (pts) with treatment resistant depression (TRD) (Reif *et al.* DGPPN 2022; P-01-04). We report ESK-NS vs Q-XR effects on pt-reported health-related quality of life (HRQoL) over 32 wks.

Objectives: Evaluate pt-reported HRQoL using the generic 36-item Short-Form Health Survey version 2 (SF-36v2, 4-wk recall, 2009 US population norms) in ESCAPE-TRD.

Methods: ESCAPE-TRD (NCT04338321) was a randomised phase IIb trial comparing the efficacy of ESK-NS vs Q-XR, both alongside an ongoing selective serotonin/serotonin-norepinephrine reuptake inhibitor, in pts with TRD. SF-36v2 was assessed every 4 wks (on-treatment and retrieved dropout visits). Domain scores and change from baseline (CfB) were analysed using a mixed model for repeated measures (MMRM; observed cases) adjusted for age, prior treatment failures, baseline score. Higher scores indicate better HRQoL. P values were not adjusted for multiple testing.

Results: 336 and 340 pts were randomised to ESK-NS and Q-XR. Baseline domain scores were below general population norms and lowest in Role Emotional, Mental Health and Social Functioning (Figure 1A). All scores improved to Wk32 in both arms (Figure 1B). At Wk4, CfB was significantly higher (better HRQoL) with ESK-NS vs Q-XR across domains (all $p < 0.01$). At Wk8, CfB was significantly higher with ESK-NS vs Q-XR across all domains ($p < 0.05$) except Bodily Pain and Role Physical. At Wk32, CfB was significantly higher with ESK-NS vs Q-XR for Mental Health ($p = 0.014$), Role Emotional ($p = 0.001$), Role Physical ($p = 0.046$) and Social Functioning ($p = 0.006$); a trend of numerical advantage was seen for all other domains (Figure 2).

Image:

Figure 1. Mean baseline SF-36v2 domain scores

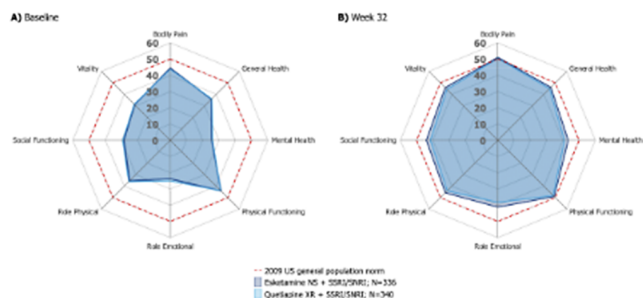

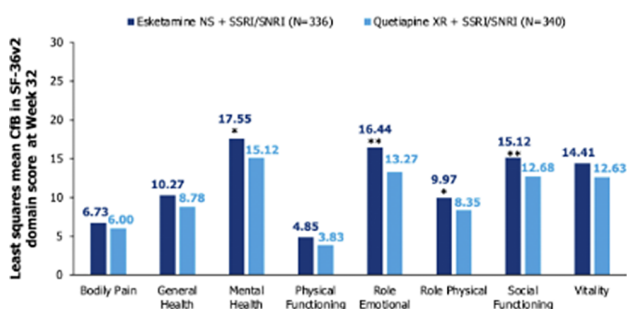

Image 2:

Figure 2. Least squares mean change from baseline in SF-36 score at Week 32 by treatment group (MMRM)

Full analysis set. Tested at a two-sided 0.05 significance level without adjustment for multiple testing. * $p < 0.05$; ** $p < 0.01$.

Conclusions: In addition to the superior clinical benefits provided by ESK-NS vs Q-XR in ESCAPE-TRD, pts receiving ESK-NS experienced significantly greater improvements in HRQoL vs Q-XR over 32 wks.

Comorbidity/Dual Pathologies

EPP0654

Dual diagnosis of bipolar disorder and substance use disorder – type of substance used and its impact on treatment adherence and maintenance of abstinence

I. A. Silva^{1*}, C. Silva², I. Faria² and V. S. Melo³

¹Unidade Local de Saúde do Norte Alentejano, Portalegre; ²Centro Hospitalar e Universitário de Coimbra, Coimbra and ³Centro Hospitalar do Médio Tejo, Tomar, Portugal

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.750

Introduction: Substance use disorder is a common comorbidity with bipolar disorder, delaying its diagnosis and making treatment of both disorders more complex and challenging.

Objectives: We aim to analyze the types of substances used by patients with bipolar disorder and to find if there's a relationship between the substance used both with treatment adherence and maintenance of abstinence.

Methods: We collected, retrospectively, data from the hospital platform and analyzed it on SPSS Statistics 26, along with a literature review. Our study looks over 3 years, and all patients analyzed have a dual diagnosis of both bipolar disorder and substance use disorder and were hospitalized in the psychiatric ward of a tertiary university hospital.

Results: There were 2384 hospitalizations in the Coimbra's University Hospital psychiatric ward, and 88 hospitalizations were coded with a dual diagnosis of bipolar disorder and substance use disorder. Tobacco was the substance more consumed by the patients (53.4%), followed by alcohol (46.6%) and cannabinoids (30.7%). In 18.2% of the patients was identified consumption of cocaine and in 6.8% there was an abuse of opioids. It is important to highlight that 20.5% of the patients used 2 or more substances at the same time.

Regarding adherence to treatment for both their bipolar disorder and substance use disorder, in 25% of the patients, there wasn't a satisfactory compliance with the treatment prescribed.

In the group of patients with polydrug use, half of them didn't comply with the treatment. In the patients consuming only one substance, we found out that 30% of patients who use alcohol didn't adhere to the treatment, while around 13% of the patients using cannabinoids didn't comply with the suggested treatment.

The relationship between the type of substance used and treatment adherence was statistically significant with a $p=0.004$ (considering $p<0.05$).

Regarding abstinence from consumption, around 42% of the patients keep using at least one substance. In the group with polydrug use, around 65% of the patients were not abstinent in the last appointments, while in the cannabinoids users' group around 50% of them were still using the drug. In the group with patients using alcohol, around 43% of them are not abstinent.

The relationship between the type of substance used and maintenance of abstinence was found to be statistically significant with a $p=0.037$ (considering $p<0.05$).

Conclusions: Substance use disorder can have a huge impact on adherence to treatment, worsening the prognosis of the comorbid bipolar disorder. On the other hand, this dual diagnosis can impact the maintenance of abstinence.

Early detection of both diagnosis and simultaneous treatment from an early phase are essential to improve the prognosis of both diseases.

EFFICIENCY OF VORTIOXETINE IN DEPRESSIVE SYMPTOMS IN PARKINSON'S DISEASE.

M. Z. Cvitanovic^{1*}, D. Vukorepa¹, M. Mustapić¹, G. Džamonja², M. Čičmir-Vestić² and D. Petrić³

¹Department of Psychiatry; ²Department of Neurology, University Hospital Split, Split and ³Department of Child and Adolescent Psychiatry, Clinical Hospital Centre Rijeka, Rijeka, Croatia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.751

Introduction: Parkinson's disease (PD) is the most common serious movement disorder in the world, affecting about 1% of adults older than 60 years. The disease is attributed to selective loss of neurons in the substantia nigra, and its cause is enigmatic in most individuals. Patients with PD display both motor and non-motor symptoms. For some patients, the non-motor symptoms are more bothersome than the motor symptoms. One of the most common non-motor symptoms of PD is depression.

Objectives: Treatment of depression with antidepressant drugs is well established. In the last 20 years use of antidepressant has risen mainly due to the introduction of the selective serotonin reuptake inhibitors (SSRIs). Our primary aim was to demonstrate an improvement in depressive symptoms in patients who started treatment with vortioxetine. A secondary aim was to show those who was successfully treated with vortioxetine but was unresponsive to paroxetine and escitalopram without worsening the extrapyramidal symptoms of PD.

Methods: In collaboration with the Department of Neurology, we included patients who are being treated for Parkinson's disease and who meet the criteria for depressive disorder after a psychiatric examination. We divided the patients into two groups: those who had not previously taken any antidepressant drugs and those who were already on therapy with paroxetine and escitalopram but without the expected therapeutic response. All patients were prescribed vortioxetine in their treatment, and the Hamilton Depression Rating Scale (HDRS) was determined during their first meeting with the psychiatrist, and then again after 6 weeks of taking the medication. Also, we used Mini mental state examination (MMSE) to measure cognitive impairment. Our primary outcome measure was the number of patients in each treatment group who responded to treatment. Response was defined as the proportion of patients who had a reduction of at least 50% from the baseline score on the Hamilton Depression Rating Scale (HDRS)

Results: Our primary outcome measure was the number of patients in each treatment group who responded to treatment. Response was defined as the proportion of patients who had a reduction of at least 50% from the baseline score on the Hamilton Depression Rating Scale (HDRS)

Conclusions: In our research, vortioxetine has proven to be effective in treating depressive symptoms without worsening Parkinson's disease, unlike paroxetine and escitalopram, which resulted in partial effects.

Emotional disorders in the structure of psychoorganic pathology in tumors of the diencephalon

Y. Sidneva^{1,2*}, L. Astafyeva³, O. Zaitsev¹, P. Kalinin⁴, M. Kutin⁴, A. Shkarubo⁴, D. Fomichev⁴, I. Voronina⁴, D. Andreev⁴, O. Sharipov⁴, I. Chernov⁴, I. Klochkova³, I. Badmaeva³ and A. Donskoy⁴

¹Neuropsychiatric research, N.N.Burdenko National Medical Research Center of Neurosurgery; ²Rehabilitation, Clinical and Research Institute of Emergency Pediatric Surgery and Trauma; ³Neuroendocrinology and ⁴Neurosurgery, N.N.Burdenko National Medical Research Center of Neurosurgery, Moscow, Russian Federation

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.752

Introduction: The tumors of the diencephalon region (thalamic-hypothalamic-pituitary system) include a large group: pituitary adenomas, craniopharyngiomas, gliomas, and others. Tumors differ in the histological structure, and manifestations of the clinical symptoms; by hormonal data; by approaches and methods in treatment.

Psychic symptoms are revealed in disease in addition to cerebral, neuroendocrine symptoms, neurological disorders. Psychoorganic syndrome is represented by emotional, motivational, personal, cognitive impairments, inversion of the sleep-wake cycle, seizures. Disorders of mental activity are detected in all tumors of this localization in varying degrees, according to the different authors from 20 to 100%; affective pathology varies from 2 to 80% by the literature.

Objectives: To study the emotional disorders in the structure of psychoorganic pathology in tumors of diencephalon region

Methods: 290 patients (18-78 years old, mean age 38±2): pituitary adenomas (PA), as the most common – 170 (58,6%), craniopharyngiomas (CG), as with the most varied manifestation of mental symptoms – 120 (41,4%). Methods: psychopathological, data from endocrinological, neurological, neuroimaging methods.

Results: Emotional disorders were detected in patients from 30 to 68% of cases, depending on the histology of the tumours: PA with excessive secretion of growth hormone - emotional disorders are in 60%; PA with excessive secretion of adrenocorticotrophic hormone - in 50%; PA with excessive secretion of prolactin - in 30%; with excessive secretion of thyroid-stimulating hormone - in 40%; non-functioning PA - in 16%; CG - in 68%.

Emotional disorders were more often represented by changeable mood, depression, apathy, sleep disturbance, and visceral symptoms. Symptoms differed depending on the histology of the tumor (type and level of hormones), the volume of the lesion and direction of growth, and concomitant hypertensive-hydrocephalic symptoms. Emotional disturbances often include memory impairment, personality and behavior changes.

Conclusions: Emotional disorders are detected in patients in 30-68% of cases in the structure of psychoorganic pathology with damage to the diencephalon region (in particular, with pituitary adenomas and craniopharyngiomas); are determined by the topography of the tumor and histology with the involvement of the corresponding structures and nuclei in the pathological process.

Rapid cycling bipolar disorder and atypical anorexia nervosa: changes in drug metabolism

J. Teišerskytė^{1*} and K. Norvainytė²

¹Lithuanian University of Health Sciences and ²Department of Psychiatry, Kaunas Hospital of the Lithuanian University of Health Sciences, Kaunas, Lithuania

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.753

Introduction: Bipolar disorder (BD) is a complex mental illness described by recurrent episodes of mania and depression. One subtype of the illness is rapid cycling BD, characterized by experiencing four or more extreme mood swings within a year. Diagnosing and treating BD can be complicated by comorbid conditions, such as atypical anorexia nervosa (AAN), marked by disordered eating and disturbing weight-related thoughts.

Objectives: To discuss the diagnosis and treatment plan of a patient with rapid cycling BD, who experienced adverse effects from prescribed medication and later was diagnosed with comorbid AAN.

Methods: We present a case of a 21 year-old man initially presenting with anxiety, low mood, and obsessive weight-related thoughts, ultimately diagnosed with major depression and mixed anxiety disorder.

Results: 21 year-old man was diagnosed with major depression and mixed anxiety disorder, initially treated with mirtazapine and fluoxetine (limited success), later attempting escitalopram and bupropion combination (partial remission). After 2 years the

patient discontinued the treatment due to feeling “euphoric”, subsequently experiencing depression and manic episodes – the initial diagnosis was rapid cycling BD. The treatment was changed to sodium valproate (up to 1500 mg/day) and aripiprazole (up to 10 mg/day), however extremely rare adverse medication effects (nosebleeds, diarrhea with blood admixture, “high-frequency sounds”) were reported. Throughout valproate treatment, the patient experienced persistent diarrhea. During hospitalization for treatment adjustment lithium carbonate was introduced at a starting dose of 900 mg/day, maintaining blood lithium levels between 0.4 mmol/l and 0.49 mmol/l. Later the dose was adjusted and a therapeutic lithium blood level was reached with 1575 mg/day of lithium carbonate. Additionally, risperidone was prescribed, however, the patient experienced an uncommon adverse reaction – nasal congestion. Subsequently, amisulpride was introduced, which provoked severe anxiety and fear, resulting in medication discontinuation. During the latest outpatient visit, fluoxetine was added to the treatment due to observed depressive symptoms. Throughout the treatment, the patient episodically intermittently starved, had persistent distressing thoughts about weight and was diagnosed with AAN. While planning further treatment it was hypothesized that comorbid AAN might affect drug metabolism and the patient was referred to a specialized inpatient facility for eating disorder management.

Conclusions: This case report highlights the complexity of psychiatric disorders and the importance of monitoring and adjusting treatment based on patient response and side effects. Additionally, it emphasizes comorbid conditions significance in influencing the primary disorder's dynamics as well as the metabolism and effectiveness of psychiatric medications.

EPP0659

Cancer Survivors in Delaware: Impact of Comorbidity

S. Gupta

Delaware State University, Dover, United States
doi: 10.1192/j.eurpsy.2024.754

Introduction: Delaware's recent longevity and aging trends predict a continual increase in the number of cancer survivors. As the cancer survivors live longer and age, the prevalence of comorbid chronic conditions tends to increase. Dual burden of cancer and comorbid chronic conditions can have significant and wide-ranging ramifications for cancer survivors. Comorbidity potentially affects the development, stage at diagnosis, treatment options, recurrence and long-term survival of people with cancer. Detailed delineation of Delaware adult cancer survivors including an exploration of comorbidity is critical.

Objectives: The primary objective was to characterize selected chronic conditions among Delaware adults with cancer in order to present: (i) disparities amongst cancer survivors by select socio-demographic and survivorship characteristics, and (ii) compare the prevalence of chronic conditions among cancer survivors and adult Delawareans without a cancer diagnosis.

Methods: Combined data (2018, 2020 and 2021) for Delaware were obtained from the Behavioral Risk Factor Surveillance System. The final data set included 927 Delawareans with at least one type of

cancer (excluding skin cancers other than melanoma) and 11,917 participants without a cancer diagnosis. Descriptive statistics examined sociodemographic characteristics and chronic conditions in Delawareans with and without a cancer diagnosis.

Results: Amongst adult Delawareans, 5.1% (CI: 4.6–5.5) were cancer survivors. Across the state, the majority of cancer survivors (76.8%) reported having only one cancer diagnosis. In this sample of Delaware cancer survivors, 83.5% identified as White. Majority were female (57.4%), aged 65 or older (58.9%), had some college or more education (63.7%), and with an income of \$50,000 or more (51.1%). Arthritis (46.3%), diabetes (21.5%), depression (18.7%), asthma (14.1%), chronic obstructive pulmonary disease (13.7%) angina (11.9%) and heart attack (11.6%) were the most prevalent comorbid conditions. Prevalence of certain chronic conditions was 2-3 times higher among cancer survivors. Nearly 23% reported not receiving instructions regarding cancer follow-up-care.

Conclusions: Cancer survivors have unique concerns. Results aim to facilitate targeted interventions aimed at coordinated managed care among cancer survivors in Delaware. This study bolsters the ongoing public health effort towards the Healthy People 2030 goal of increasing the proportion of cancer survivors.

Alexithymia, emotion regulation and autistic traits in Familial adenomatous polyposis

A. Vieira*, F. Martins and A. S. Machado

Psychiatry, Centro Hospitalar Universitário de São João, Porto, Portugal

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.755

Introduction: Familial adenomatous polyposis (FAP) is a condition characterised by multiple polyps inside the colon or rectum, leading to colorectal cancer in all patients who do not perform prophylactic colectomy and a higher risk of cancer in other organs. Nevertheless, it has been reported that 14-48% of patients do not comply with regular endoscopic surveillance, which seems to be related to the lower levels of emotional distress observed in these patients. Also, APC gene polymorphisms have been described as being related to neurodevelopmental disorders, such as autism.

Objectives: To study the prevalence of alexithymia, autistic traits and emotion regulation strategies in patients with FAP.

Methods: We conducted a cross-sectional study of patients with a genetic or clinical FAP diagnosis and assessed for alexithymia, autistic traits and emotion regulation using psychometric tests - Toronto Alexithymia Scale - 20 items (TAS-20), Autism-Spectrum Quotient Test (AQ) and Emotion Regulation Questionnaire (ERQ), respectively. The control group were patients with Lynch Syndrome. Statistical analysis was performed using SPSS vs.26.

Results: We recruited a total of 20 patients (10 with FAP vs 10 with Lynch Syndrome). Nine patients were male (45%) versus 11 female (55%). The mean age was 53,35 years (SD 18,4). Half the sample presented a low educational level (equal or inferior to 4th grade).

The overall prevalence of alexithymia was 65%, with an 80% prevalence in FAP patients and 50% in Lynch Syndrome. TAS-20 total score was higher in FAP patients (69,0 vs 60,7; $p=0,68$). Externally-oriented thinking subscale score was statistically higher in FAP patients ($p=0,024$).

The overall prevalence of autistic traits was 25%, and the mean AQ score was higher in FAP (23,4; SD 4.97) compared to Lynch Syndrome patients (20,2; SD 5.57), but there were no statistically significant differences between the diagnoses ($p=0,192$).

A moderate positive correlation exists between Total AQ and Total TAS ($r=0.51$; $p=0.020$).

Concerning the scores obtained on the ERQ scale, most participants (14; 70%) use Expressive Suppression as a regulation strategy. Patients with Lynch Syndrome had higher scores than those with FAP, both in the Cognitive Reappraisal (4.22; SD 1.58 vs 4.28; SD 0.90) and Expressive Suppression (4.58; SD 1.08 vs 5.15; SD 1.03) domains.

The average AQ score for patients who mostly use expressive suppression is significantly higher than for those who use cognitive reappraisal (23.86 (3.63) vs 17.00 (6.6); $p=0.039$).

Conclusions: The preliminary results of this study point to high levels of alexithymia and autistic traits in this population, and a higher tendency to regulate emotions by expressive suppression.

The main limitation of the study was the small sample size, which reduced the power of the study to find statistically significant differences. Also, in future studies, a different control group should be considered.

doi: 10.1192/j.eurpsy.2024.756

Introduction: Motor Conversion Disorders (also called Functional Movement Disorders, FMD) are a group of neuropsychiatric conditions characterized by neurological symptoms of altered voluntary motor function that cannot be explained by typical neurological diseases or other medical conditions. In the last decade, several hypotheses have been formulated with respect to their pathophysiology, and a major line of research, trying to integrate psychological, cognitive, and neurobiological factors, focused on the subjective experience that patients feel of their own bodies. However, no study has, so far, directly investigated their Body Schema (the implicit sensorimotor representation of one's own body) and its plasticity.

Objectives: To investigate the Body Schema in patients with FMD through a paradigm specifically designed to assess their perceived body metrics, through a spatial estimation of body parts length, and to compare their results with the ones obtained on a group of healthy control subjects (HC)

Methods: 10 patients with FMD and 11 HC underwent the Forearm Bisection Task, aimed at assessing perceived body metrics, which consists in asking the subject, blindfolded, to repeatedly point at the perceived middle point of their dominant forearm with the index finger of their contralateral hand, and a psychometric assessment for anxiety, depression, alexithymia, and tendency to dissociation.

Results: FMD patients bisected their forearm more proximally (with an increased shift towards their elbow equal to 7.5%) with respect to HC; average bisection point was positively associated with anxiety levels in the whole sample, and with the tendency to dissociation in the FMD group.

Conclusions: FMD patients seem to perceive their forearm as shorter than HC do, which might suggest an alteration of their Body Schema. The Body Schema can go through short- and long-term plastic changes in the life course, mainly related to the use of each body segment; we speculate that, despite FMD being a disorder of functional nature, characterized by variability and fluctuations in symptomatology, the lack of sense of agency over a body part might be interpreted by the nervous system as disuse and hence influence the Body Schema, as deficits of organic aetiology do.

Socio-demographic characteristics and pharmacological treatment options in patients with delirium

F. J. Cruz Aviña^{1*}, A. Salazar Rodriguez¹, D. N. M. Sanchez¹, E. A. C. Martinez¹, L. C. Rocha Reza², S. V. Nuñez Pichardo¹, H. A. Barranco Rogel¹, M. G. Ochoa Madrigal¹ and O. Meneses Luna¹

¹Psychiatry, psychology and neuro psychology, Centro Médico Nacional 20 de noviembre and ²Psychiatry, Hospital Psiquiátrico Fray Bernardino Alvarez, Mexico City, Mexico

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.757

Introduction: Delirium is common in hospital settings, with approximately 3% to 45% of older patients in hospitals developing delirium during their stay. Among the elderly and those with severe or advanced medical conditions, the reported percentage of patients with delirium is over 56%. The three motor subtypes of delirium are hyperactive, hypoactive, and mixed. Another way to characterize delirium is based on whether it is reversible, irreversible, or terminal.

Objectives: Identifying appropriate pharmacological treatment options among antipsychotics and their correlation with various precipitating and predisposing factors in the in-hospital context

Methods: This was a retrospective, cross-sectional, observational study that utilized a database created by the psychiatry department at the National Medical Center 20 de Noviembre, with data collected from April 2021 to April 2022. The database contains anonymized administrative and clinical data of patients who were

seen in the psychiatry department for the diagnosis of any type of delirium, using the CAM scale for classification. The database includes records and data of hospitalized patients, encompassing all specialties at this medical center

Results: A total of 139 patients were included in the study, of which 39% were female and 61% were male, with a mean age of 67 and a median age of 68 years. It was observed that the average duration of delirium symptoms, from receiving the consultation to remission, was approximately 6 days ($p < 0.005$) (OR 5.12-6.62), and the average length of hospital stay was approximately 20 days (OR 17.3-22.09). Among the patients, 50.39% were overweight, 63% had hypertension (HTA), 29% had chronic kidney injury, 24% had a history of delirium, and 73% had recent surgical interventions. Patients with diabetes mellitus had a 3.1 times higher risk, those with HTA had a 2.8 times higher risk, and those with kidney injury had a 3.8 times higher risk of having a positive CAM result. It was observed that haloperidol, used in 84% of the patients, showed the highest percentage reduction in CAM scores

Image:

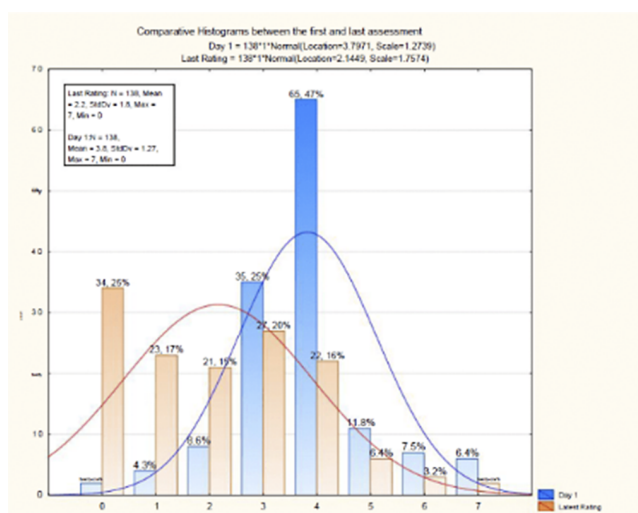

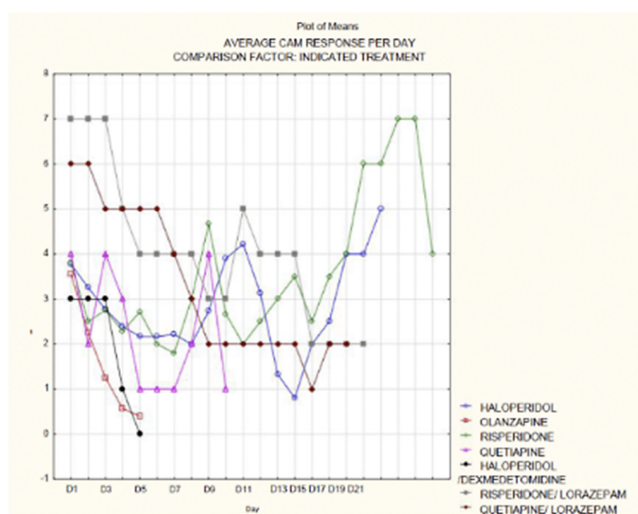

Image 2:

Conclusions: The results of this study emphasize the importance of identifying risk factors associated with delirium and implementing effective treatment for this condition. It was observed that the average duration of delirium symptoms was approximately 6 days, which is relevant for understanding the course and management of this illness. Furthermore, it was found that the average hospital stay was 20 days, underscoring the burden that delirium can place on healthcare systems.

In conclusion, this study highlights the importance of identifying risk factors and providing appropriate treatment, such as the use of haloperidol, to improve outcomes in patients with delirium.

Characteristics and Management of Patients with Substance Use Disorders Referred to a Consultation-Liaison Psychiatry Service in Lebanon

S. El Hayek^{1*}, G. Kassir², H. Zalzali³, K. Al Hasanieh², M. Cherro², N. Ibrahim² and M. Bizri²

¹Erada Center for Treatment and Rehabilitation in Dubai, Dubai, United Arab Emirates; ²American University of Beirut, Beirut, Lebanon and ³King's College London, London, United Kingdom

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.758

Introduction: Substance use disorders (SUDs) are a growing public health concern in the Arab world. To our knowledge, no previous study in Lebanon assessed the characteristics, management, and outcomes of patients with SUDs seen and managed by a consultation-liaison psychiatry (CLP) service.

Objectives: This study explores the characteristics and management of individuals with SUDs who were referred to the CLP service in a tertiary care center in Lebanon.

Methods: As part of the Consultation-Liaison at the American University of Beirut (CLAUB) analysis, we conducted a retrospective record review of patients referred to our CLP service between February 2019 and May 2020. We assessed differences between SUD and non-SUD consults using Chi-square analysis, Fisher's exact test, or Mann-Whitney U test, as appropriate.

Results: Of 1475 patients, 278 (18.8%) received a diagnosis of SUD. They were mostly males (73.7%) with an average age of 38.8 years. The most used substances were alcohol (60%) and cannabis (28.4%). Compared to non-SUD consults, patients with SUDs were more likely to be males (odds ratio OR=3.18, $p < 0.001$) and to get intubated during admission (OR=1.81, $p = 0.048$). Predictors of intensive care unit admission in patients with alcohol use disorder included pulmonary or endocrinological disease, benzodiazepine use disorder, and days until CLP referral.

Conclusions: The results of this study highlight the high prevalence of alcohol use among individuals with SUD referred to the CLP service. Additionally, they underscore the limited treatment avenues available in this part of the world. The institution of a comprehensive CLP service is crucial to address the unmet needs of patients with SUDs who present to a general hospital setting.

A systematic review of the prevalence of psychosis in people with tuberculosisS. M. Gunawardena^{1,2*}, E. McMahon^{1,2} and A. M. Doherty^{1,2}¹Department of Psychiatry, University College Dublin, 63 Eccles Street and ²Department of Liaison Psychiatry, The Mater Misericordiae University, Dublin 7, Ireland

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.759

Introduction: Tuberculosis is a bacterial infectious disease caused by *Mycobacterium tuberculosis*. This disease predominately affects the lungs but also affects other parts of the body, including the central nervous system. According to the the World Health Organization (2023), tuberculosis has an incidence of 6.4 million people in 2022, with 1.5 million deaths attributed to this disease. Psychosis describes a group of disorders that affects a person's thought process and perception. It is a serious disorder that can have a profound impact on a person's mental and physical health. As a result, psychosis symptoms and its treatment can complicate the management of tuberculosis.

Objectives: The aim of this systematic review is to explore the association between tuberculosis and psychosis. It has been shown that up to 70% of patients with tuberculosis also have comorbid mental illness, this is likely to include psychosis. There are also shared risk factors between tuberculosis and psychosis, including poverty and homelessness, substance abuse, HIV positive serology and isolation. Tuberculosis medication, including isoniazid and rifampicin have been shown to have adverse psychiatric effects and we will examine if this includes psychosis.

Methods: A systematic review was pre-registered with PROSPRO and performed using Preferred Reporting Items for Systematic Reviews and Meta-Analyses guidelines. MEDLINE, OVID and PsychINFO databases were searched from beginning of records to September 2023. This included hand-search of relevant reference lists. Observational and epidemiological studies were included along with population based registries.

Results: Over one thousand (1,154) articles were identified and screened. There was significant heterogeneity in results and over half of studies were from Asia and Africa. Many studies reported cases of drug-induced psychosis from anti-tubercular agents. Studies also discussed the increased risk of TB incidence among patients with psychosis and other psychiatric disorders.

Conclusions: This study identifies the importance of training healthcare workers in rapid detection of co-morbid psychosis in patients with tuberculosis, along with neuropsychiatric side effects of antitubercular agents. Integration of psychiatric and medical care of these patients would be of benefit to improve outcomes in this patient population. More research is needed on co-morbidity of tuberculosis and psychosis.

Fibronectin as a Marker of Myocardial Remodeling in Patients with Depression and Chronic Heart FailureA. K. Sikora^{1*} and S. Fedorov²¹Psychiatry, Narcology and Medical Psychology and ²Ivano-Frankliskenderun National Medical University, Ivano-Frankivsk, Ukraine

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.760

Introduction: Depression is a significant issue in chronic heart failure (HF), with a prevalence of about 20–40%, which is 4–5% higher than in the general population (Mbakwem A., et al., 2016).

Objectives: The purpose of this study was to evaluate plasma fibronectin levels in patients with depression and chronic heart failure.

Methods: A total of 80 patients with HF II-III NYHA classes due to chronic coronary artery diseases (CAD) were observed. All patients were divided into two groups: Group 1 - 20 individuals without signs of depression, and Group 2 - 60 individuals with depression. The diagnosis of HF was confirmed based on ESC guidelines (2021). Depression was diagnosed using several questionnaires (Zung Self-Rating Depression Scale, Beck Depression Inventory, Hamilton's Depression Scale). Standard laboratory and instrumental tests were conducted. The plasma levels of fibronectin and interleukin-1 β (IL-1 β) were identified using ELISA methods. Statistical analyses were performed using Statistica system software, version 12.0.

Results: The average plasma fibronectin concentration in patients with depression and HF was 1.24 times higher than a similar indicator in HF patients without depression: (259.63 \pm 5.71) μ g/ml versus (203.41 \pm 9.51) μ g/ml (p <0.05). The conducted correlation analysis indicated a moderate positive correlation between the level of fibronectin and the number of neutrophils in peripheral blood (r =0.35; p <0.05), the level of fibronectin and the magnitude of endogenous intoxication according to the erythrocyte absorption ability test (r =0.44; p <0.01), the level of fibronectin and IL-1 β concentration (r =0.39; p <0.05), and an inverse correlation with left ventricle ejection fraction (r =0.32; p <0.05).

Conclusions: Thus, the plasma fibronectin content in patients with depression and ischemic HF serves as a marker of the progression of myocardial remodeling processes and the intensity of the inflammatory process.

EPP0666

Psychosomatic relationships between the state of mental health and the level of vital threat of dermatological diseaseM. Markova^{1*}, T. Abdriakhimova², H. Skrebtsova² and M. Chemerys³¹Kharkiv National Medical University, Kharkiv; ²Bogomolets National Medical University, Kyiv and ³Danylo Halytsky Lviv National Medical University, Lviv, Ukraine

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.761

Introduction: According to the literature, 25-60% of dermatological patients have mental disorders. In the case of oncodermatological disease, the patient is under the influence of two stressogenic factors – existential experiences and social discomfort from the manifestations of the disease, which imprints on the patient's mental health and promotes the development of mental maladaptation (MM).

Objectives: To study the features of mental state in patients with dermatological diseases with different levels of vital threat.

Methods: The examination included the use of clinical-psychological, psychodiagnostic and psychometric research methods.

Results: 120 dermatological patients were examined: 60 patients with non-vital dermatological diseases (L82, A63.0, D18.0, L80), and 60 patients with dermatological diseases posing a vital threat (C43, C44, D04).

The identification of clinical signs of MM proved their presence in 70 (58.4%) people in the total sample. Among patients with non-vital diseases, the signs of MM were established in 33 (55.0%), among the patients with vital diseases – in 37 (61.7%). So, among patients with dermatological diseases, there are both psychologically adapted and maladapted individuals, regardless of the vitality/non-vitality of the pathological process.

In dermatological patients with signs of MM, the clinical picture is dominated by anxious (mainly in patients with non-vital diseases) and depressive (mainly in patients with vital diseases) radicals. Auxiliary psychopathological constructs are represented by manifestations of somatization, obsessive-compulsive symptoms, interpersonal sensitivity, and phobic anxiety. Affective symptoms are most pronounced in patients with MM and vital diseases, it is less pronounced in patients with non-vital pathology.

The presence and intensity of maladaptive pathopsychological-affective reactions in patients with dermatological pathology are not clearly associated with the vitality of the dermatological process, but are based on mechanisms of the mutual influence of biological predisposition and psychological and psychosocial factors, the mosaic combination of which determines the individual's resource capabilities for constructive acceptance the fact of the presence of a dermatological disease and the development of an adequate strategy for its mastery, regardless of the severity of the disease.

Conclusions: These patterns should be considered when developing treatment measures and rehabilitation for patients with dermatological pathology.

Lithium Intoxication with Therapeutic Doses Following Laparoscopic Sleeve Gastrectomy: A Case Report and Review of the Literature

S. Kukurt^{1*}, Z. Dönmez¹, O. Kilic¹, G. Dokuz¹, F. Coşkun¹, E. Yardımcı¹ and I. Kırpınar¹

¹Bezmialem Vakıf University, İstanbul, Türkiye

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.762

Introduction: Lithium is a mood stabilizer often used as a first-line treatment for bipolar disorder. Its narrow therapeutic window and changes in the absorption, distribution, and elimination of the drug following bariatric surgery have important implications regarding patient safety.

Objectives: We present a 51-year-old female patient with bipolar disorder and a medical history of morbid obesity, type 2 diabetes mellitus, hypothyroidism, hyperlipidemia, and essential hypertension. She was mentally stable on lithium 1200 mg/day, valproate 500 mg/day, and quetiapine 400 mg/day. She had undergone laparoscopic sleeve gastrectomy. After a month, she showed up to the emergency room (ER) with nausea, vomiting, diarrhea, and fatigue. Gastroenteritis was suspected until the patient started showing neurological symptoms such as delirium, dysarthria, ataxia, chorea, and athetosis.

Methods: The patient was monitored and received aggressive intravenous hydration (3000 cc of 0.9% serum isotonic) in the intensive care unit (ICU). She was prescribed intramuscular biperiden injection of 5 mg/ml/day, pheniramine 45.5 mg/2 ml/day, and lorazepam 1 mg/day. Her lithium levels were checked every six hours. She was agitated and disoriented for the first five days despite lithium levels being in the therapeutic range. On day six, her blood lithium levels dropped to 0.399 mmol/L. Her psychiatric examination revealed that she resumed cooperation and orientation, her dysarthria subsided. However, her thought content and attitude were grandiose, and she had a labile affect. We prescribed 5 mg/day of olanzapine routinely and 1 mg/day of lorazepam on a needed basis. The next day, her labile affect became calmer, and her sleep improved so she was discharged from the ICU and admitted to general surgery inpatient service, and olanzapine was titrated to 10 mg per day since she had elevated mood symptoms.

Results: After 7 days of intravenous hydration and supportive treatment, her neurological symptoms completely subsided except for a fine tremor, which lasted for another 3 days and then ceased. She was clinically stabilized without further need for intervention. Her lithium level was 0.206 mmol/L before her discharge.

Conclusions: We believe it is of utmost importance to build a consensus in guidelines and inform physicians about lithium toxicity and its symptoms after bariatric surgeries. We recommend a careful follow-up of the patient pre-and postoperatively. Preoperative psychiatric intervention includes decreasing the lithium dose gradually and discontinuing it. After the operation, lithium can be started with a much lower dose and may be increased by checking lithium levels every week for at least 6 weeks after the operation until the patient can digest solid food again, and then every 2 weeks for 6 months, and thereafter every month for one year.

Comparison of inpatient psychiatric care for SARS-CoV-2 positive and negative adults in Vienna

A. Erfurth

1st Department of Psychiatry and Psychotherapeutic Medicine, Klinik Hietzing, Vienna, Austria

doi: 10.1192/j.eurpsy.2024.763

Introduction: The structure of psychiatric care has undergone many changes in recent decades. In addition, the SARS-CoV-2 pandemic has posed specific challenges for inpatient psychiatric

care. In Vienna, the admission of SARS-CoV-2 positive psychiatric patients has been centralised in one department, the 1st Department of Psychiatry and Psychotherapeutic Medicine, Klinik Hietzing.

Objectives: It will be investigated to what extent the admissions of SARS-CoV-2 positive and negative patients differ with regard to age, gender, diagnosis, need for involuntary admission, medication, duration of treatment, country of birth and the question of where the patients come from and where they are discharged to.

Methods: Between 15 March 2020 and 21 May 2022 (start and end of cohorting of all Vienna SARS-CoV-2 positive inpatient psychiatric patients in one department), 338 SARS-CoV-2 positive and 1312 SARS-CoV-2 negative patients were treated as inpatients at the 1st Department of Psychiatry and Psychotherapeutic Medicine of the Klinik Hietzing.

Results: The results of the study will be shown.

Conclusions: The SARS-CoV-2 pandemic has presented an outstanding challenge to inpatient psychiatry. An accurate portrayal of differences in the treatment of positive and negative patients is of importance for assessing the impact of the pandemic.

Touch hunger: trajectory and predictors of longing for physical contact during the COVID-19 pandemic in people with and without psychiatric disorders

S. E. Mann^{1*}, A. L. Kok², N. Rius Ottenheim¹, E. J. Giltay^{1,3} and B. W. Penninx²

¹Psychiatry, Leiden University Medical Center, Leiden; ²Psychiatry, Amsterdam University Medical Center, Amsterdam and ³Health Campus, Leiden University, Den Haag, Netherlands

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.764

Introduction: Little is known about touch hunger (longing for physical contact) during the COVID-19 pandemic, particularly for people with pre-existing mental health disorders.

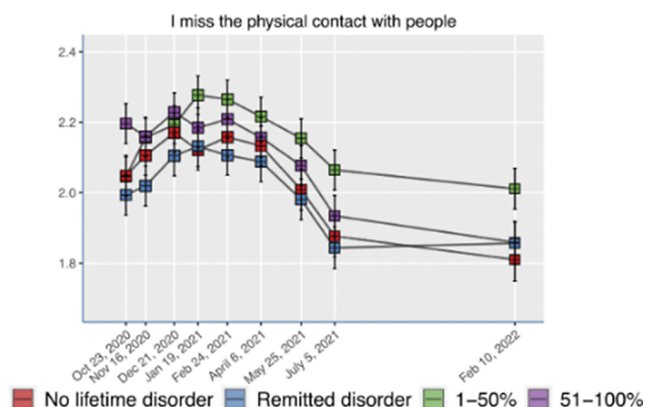

Objectives: We aim to investigate the dynamics of touch hunger in people with and without depressive, anxiety, or obsessive-compulsive disorders during the COVID-19 pandemic, and the potential predictors for touch hunger during lockdown.

Methods: Data were aggregated from three Dutch ongoing prospective cohorts with similar methodology for data collection. We included participants with pre-pandemic data gathered during 2006–2016, and who completed up to 9 online questionnaires between October 2020 and February 2022. We compared trajectories between subgroups with different pre-pandemic chronicity of disorders and healthy controls using linear mixed models. Socio-demographic, clinical (number and type of mental health disorders, personality traits) and COVID-19-related variables were analysed as predictors of touch hunger using multivariate linear regression analyses.

Results: We included 1061 participants with ($n = 811$) and without ($n = 250$) mental health disorders. In all groups, touch hunger increased during lockdown (Fig. 1). Extraversion ($\beta = 0.256$, $P < 0.001$), social distancing due to COVID-19 anxiety ($\beta = 0.122$, $P = 0.001$) and death of a close contact from COVID-19 ($\beta = 0.073$,

$P = 0.02$) predicted higher touch hunger, while living with a partner ($\beta = -0.109$, $P = 0.004$) or with a partner and children ($\beta = -0.147$, $P < 0.001$) were protective factors for touch hunger. Remarkably, pre-pandemic mental disorders did not predict touch hunger during lockdown.

Image:

Conclusions: Social distancing measures have important psychological and emotional implications, as our study showed an increase in touch hunger during lockdown, which did not differ between people with and without mental health disorders. Extroverted individuals may benefit most from interventions aimed at addressing their need for physical contact during times of crisis.

EPP0673

Pain, fatigability and cognitive impairment in long-COVID: a cohort study

B. Nadia^{1*}, T. Mariem¹, B. A. Houda², E. Sahar¹, A. Wissal¹, M. Sameh³, K. Samy³, H. Najla¹ and A. Jihen¹

¹Psychiatry "B"; ²Preventive medicine and hospital hygiene and ³Pneumology, Hedi Chaker university hospital, Sfax, Tunisia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.765

Introduction: Survivors of the pandemic of COVID-19 suffered from multiple sequelae long time after recovery, such as tiredness and memory dysfunction, affecting daily life activities.

Objectives: To assess fatigability, cognitive impairment and the severity of pain in long-COVID.

Methods: We conducted a prospective cohort study including 121 Tunisian COVID-19 inpatients who had been discharged alive from hospital. Each enrolled patient was asked about the period before the hospital stay, and the 6-9 month-period after hospital discharge, using the visual analog scale (VAS), self-completed uni-dimensional scale and yes/ no question about fatigability and cognitive impairments.

Results: The median age of participants was 59 years, with extreme values ranging from 18 to 80. Among them, 51.2% were females.

Our findings showed a significant increase in VAS score after COVID infection (3.82 vs 1.69; $p < 0.001$). Sixty-eight (56.2%) participants reported spontaneously fatigability after the infection and 52 (43%) reported spontaneously a deterioration in memory capacity either with or without previous memory dysfunction. Fatigability was statistically associated to cognitive impairment (55.9% vs 26.4%; $P = 0.02$). In addition, fatigability and cognitive impairment were statistically associated with pain ($P = 0.001$ and $P = 0.022$ respectively).

There was no significative association of fatigability nor cognitive impairment with the gender of the survivors.

Conclusions: The clinician should keep in mind to screen for possible somatic or psychological distress, in particular pain, fatigability and cognitive impairment even after resolution of the COVID infection, in order to guarantee a better quality of life.

Impact of the COVID-19 pandemic on the mental health of hospital employees: single center experience

M. Kristić¹, V. Kuresić¹, I. Miskulin^{1*}, J. Dumic², L. Dumic¹ and M. Miskulin¹

¹Department of Public Health, Faculty of Medicine Osijek and

²Department of Dental Medicine, Faculty of Dental Medicine and Health Osijek, Osijek, Croatia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.766

Introduction: Hospital employees are at high risk of developing mental health issues during the coronavirus (COVID-19) pandemic. Indeed, several studies have shown increased rates of anxiety, depression, stress, and other mental health issues but existing studies show inconsistencies, and each country has some local specificities.

Objectives: This study aimed to investigate the influence of the COVID-19 pandemic on various aspects of the mental health of hospital employees (health workers and non-health workers) from Croatia.

Methods: This cross-sectional questionnaire study was conducted from February to April 2023 period. A validated, anonymous questionnaire that contained questions regarding demographic data, as well as the Pittsburgh Sleep Quality Index (PSQI), the Zung Self-Rating Anxiety Scale, and the Zung Self-Rating Depression Scale was self-administered to a convenient sample of hospital employees from one general hospital in northwestern Croatia.

Results: The study sample included 360 subjects with a median age of 42 years (interquartile range 35-50), 24.7% males, and 75.3% females. According to the PSQI, 21.1% of subjects presented sleep disturbances. According to the Zung Self-Rating Anxiety Scale, there were 39.4% of subjects with anxiety while according to the Zung Self-Rating Depression Scale, there were 6.4% of subjects with depression. Sleep disturbances were more frequent among subjects who considered their socioeconomic status as under average ($p = 0.040$), and among health workers in comparison to non-health workers employed in hospital ($p = 0.040$). Anxiety was more frequent among females ($p = 0.010$), and subjects with lower levels of education (only elementary school) ($p = 0.040$). Depression was more frequent among females ($p = 0.030$).

Conclusions: The COVID-19 pandemic has a significant negative influence on the mental health of hospital employees where health workers in comparison to non-health workers, females, subjects with lower levels of education, and subjects who considered their socioeconomic status as under average are more prone to the development of investigated mental health issues. The development of appropriate supportive programs that enhance the mental health of all hospital employees during pandemics is needed to address mental health issues in this vulnerable population.

Post-Traumatic Stress Disorder

EPP0678

Understanding the Traumatic Impact of Serious Chronic Illness

M. Theodoratou^{1*} and H. Diamanti¹

¹Social Sciences, Hellenic Open University, Patras, Greece

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.767

Introduction: The diagnosis of a severe chronic illness represents a deeply impactful traumatic event, frequently giving rise to initial adverse consequences that can manifest as post-traumatic stress. The duration and characteristics of these effects exhibit considerable variation among individuals.

Objectives: This study aims to explore the levels of post-traumatic stress, post-traumatic growth, and psychosocial adaptation among individuals coping with chronic diseases.

Methods: This cross-sectional study involved 92 participants with chronic illnesses, recruited through convenience and snowball sampling. Data collection utilized an online questionnaire that included both demographic questions to provide a comprehensive understanding of participants' experiences, as well as psychometric scales for measuring post-traumatic stress, post-traumatic growth, and psychosocial adaptation.

Instruments used :

1. PTSD Checklist for DSM-5 (PCL-5)

2. Posttraumatic Growth Inventory (PTGI) and Tedeschi and Calhoun Posttraumatic Growth Inventory (TCGI).

3. Psychosocial Adjustment to Illness Scale (PAIS).

Analysis included descriptive statistics and inductive analysis using SPSS ($p < 0.05$). Ethical considerations were observed, with informed consent and data confidentiality.

Results: The study revealed the presence of low to moderate levels of post-traumatic stress ($M = 2.45$), moderate levels of post-traumatic growth ($M = 2.90$), and moderate levels of psychosocial adaptation in various aspects of participants' lives, including work ($M = 2.36$), sexuality ($M = 2.11$), sociability ($M = 2.28$), relationships with partners and family members ($M = 1.92$), and perception of their health ($M = 1.94$). Furthermore, the overall psychosocial situation of the participants was found to range from low to moderate ($M = 2.48$). Notably, individuals with fewer chronic illnesses tended to experience lower levels of post-traumatic stress and exhibited less adaptation in their work. Additionally, higher levels of post-traumatic growth were observed in women and patients with higher educational backgrounds. The analysis revealed a positive and statistically

significant correlation ($\text{sig} < 0.05$) between post-traumatic stress, post-traumatic growth, and various dimensions of psychosocial adjustment among the participants.

Conclusions: A chronic illness diagnosis can be deeply traumatic, potentially causing post-traumatic stress. However, it's crucial to understand that this doesn't diminish the possibility of post-traumatic growth and effective psychosocial adaptation. To foster this positive path, individuals must receive holistic psychological and emotional support, along with essential social assistance as they navigate life with chronic diseases.

Traumatic Childbirth and Post Traumatic Stress Disorder: prevalence in a Brazilian cohort

F. D. L. Osório^{1*}, M. L. Baldisserotto², M. M. Theme Filha² and S. Ayers³

¹São Paulo University, Ribeirão Preto; ²Escola Nacional de Saúde Pública Sérgio Arouca (ENSP/ Fiocruz), Rio de Janeiro, Brazil and

³City - University of London, London, United Kingdom

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.768

Introduction: Although birth is experienced, in most cultures, as a positive event, for a significant percentage of women, it is considered a traumatic event, which can be associated with the development of psychopathologies, with negative impacts for the mother and the baby.

Objectives: As part of a larger, multicenter study called Intersect, we aim to assess the prevalence of women who considered childbirth traumatic, in a cohort of women in southeastern Brazil, and the association with the outcome of post-traumatic stress disorder (PTSD).

Methods: A total of 427 women who gave birth in two hospitals in southeastern Brazil in the period from May to October 2022 were included in the study, who answered self-assessment instruments, through on a telephone interview, in the period from 6 to 12 post-partum weeks. For the purposes of this study, the City Birth Trauma Scale stands out.

Results: The participants had a mean age of 28.4 (± 6.4) years, 39.2% were primiparous and 76.1% had a partner. The results showed that 51.3% of them considered the birth moderately or extremely traumatic (N=218). Of these, 50.9% met criterion A for PTSD according to the DSM-5 (N=111) and among these, 20.7% had a PTSD profile (N=23; City-Birth >28 points). These mothers represent 5.4% of the total sample.

Conclusions: there is a high prevalence of traumatic experiences during childbirth, with high rates of PTSD associated with this condition, which requires attention from the medical community in order to track and treat PTSD associated with birth and, from the public authorities, in the institution of preventive measures, through public policies aimed at this population.

Diagnosing Trauma-related Dissociative Disorders in Hungary: The Development of the Hungarian Version of MID (MID-HU)

Z. Boytha^{1*}, Á. Münnich¹ and J. Molnár¹

¹Institute of Behavioural Sciences, University of Debrecen, Debrecen, Hungary

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.769

Introduction: The recognition, diagnostics and treatment of dissociative disorders (DD) in Hungary is currently in its infancy. According to international researches the prevalence of dissociative disorders is similar to that of the major psychiatric disorders (bipolar disorder, schizophrenia, etc.). Due to the lack of valid diagnostic tools no data is available regarding the prevalence of dissociative disorders in Hungary so far.

Objectives: To fill this gap within our profession; to provide a complex diagnostic tool; developing the Hungarian version of the Multidimensional Dissociation Questionnaire (MID-HU)

Methods: 341 people participated in our study classified into four groups: (1) healthy controls (n=88), (2) patients from private practice diagnosed with DD and all those participants who have DD according to their MID results (n=103), (3) hospitalized psychiatric (mixed sample, n=60) and (4) SUD patients (n=89). The questionnaire package contained the Hungarian version of the Multidimensional Inventory of Dissociation (MID-HU), the Dissociative Experience Scale (DES), the Traumatic Antecedents Questionnaire (TAQ), the Self-Report Version of the Dissociative Disorders Interview Schedule (DDIS-SR) and additional questions. Now we present the first results regarding the adaptation process of the Hungarian MID (MID-HU).

Results: The mean age of the participants was 36 years, 61,6% were female and 38,4% male.

The MID-HU has strong internal consistency: the alpha coefficients for the 14 facet scales were 0.88 or higher. The alpha coefficients for the 23 dissociation diagnostic scales ranged from 0,74-0,95; 9 were excellent (0,90 or above), 10 were good (0,80 or above), and 4 were fair (0,70 or above). The test-retest correlation of the Mean MID-HU scores is good (0,87). Factor analysis of the MID-HU extracted one main factor: dissociation. The mean MID-HU scores correlated with mean DES scores (0,87), indicating a good convergent validity. We found significant differences between the healthy control group and the dissociative group in the mean DES (control: 9,5, dissociative: 27,6, Sig: <0,001), mean MID (control: 2,5, dissociative: 27, Sig: <0,001), the 23 dissociative diagnostics scales of the MID, 14 facet scales of the MID, and all diagnostics scales of the DDIS (using Mann-Whitney).

Conclusions: The MID-HU seems to be a valid instrument, that can differentiate between DD patients and healthy people.

Psychopathological characterization of nomophobia in a sample of patients with severe mental illnessG. Longo^{1*}, R. Volgare¹, L. Orsolini¹ and U. Volpe¹¹Dipartimento di Neuroscienze Cliniche/DIMSC, Università Politecnica delle Marche, Ancona, Italy

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.770

Introduction: Nomophobia, a neologism derived from the combination of “no mobile,” “phone” and “phobia,” represents one of the syndromes of today’s digital and virtual society. By this term, we refer to the discomfort, anxiety, nervousness, and distress generated by the individual’s loss of connection to his or her cell phone or other technological medium that allows connection to the Internet. No study has attempted to evaluate the impact of disconnection syndrome on a clinical sample of patients with Severe Mental Illness (SMI).

Objectives: Our study has the objective of characterizing subject affected by SMI with nomophobia.

Methods: Our study is conducted on inpatients (>16 years) referred to our Psychiatric ward in Ancona (Università Politecnica delle Marche, Italy). The following rating scales were administered to these subjects: Nomophobia Questionnaire (NMP-Q), Smartphone Addiction Scale - Short Version (SAS-SV), Multidimensional State Boredom Scale (MSBS), Intolerance of Uncertainty Scale (IUS), Temperament Evaluation in Memphis, Pisa and San Diego (TEMPS-M), Coping Orientation to the Problems Experiences-new Italian version (COPE-NVI).

Results: Most of the subjects included in the study tested positive for nomophobia (99%; n=97). The mean score scored on the NMPQ is 69.2 ± 27.9 , while the mean score obtained at SAS-SV is 25.1 ± 12.7 . Gender has no influence on the scores obtained at the NMPQ ($p=0.823$), as well as the type of SMI ($p=0.376$). Those not in a relationship scored a higher mean score than who has a relationship ($p=0.02$). Patients who suffer from insomnia scored higher mean score on the NMPQ ($p=0.21$). A linear univariate regression between SAS-SV and NMPQ was observed ($R^2=0.575$, $F=129.731$, $p<0.001$). A multivariate linear regression was observed between the NMPQ ($R=0.556$, $R^2=0.2830$, $F=12.057$, $p<0.001$) and the IUS ($B=1.343$, $p<0.001$), the irritable temperament subscale of the TEMPS ($B=1.293$, $p=0.003$) and the inattention subscale of the MSBS ($B=-1.029$, $p=0.033$). In the men-only sample, a multivariate linear regression was observed between the NMPQ ($R^2=0.437$, $F=9.847$, $p<0.001$) and the IUS ($B=1.361$, $p<0.001$), the anxious temperament subscale of the TEMPS ($B=1.687$, $p=0.005$) and the inattention subscale of the MSBS ($B=-1.465$, $p=0.002$).

Conclusions: Patients with higher intolerance to uncertainty, irritable temperament and lower inattention have higher risk to develop nomophobia. In men with SMI, nomophobia is associated with higher intolerance to uncertainty, anxious temperament, and lower inattention. Further study have to be conducted to expand data and results.

Sexuality of pregnant, postpartum and breast-feeding womenS. Bader^{1*}, M. aloulou¹, Z. Zran¹, A. Abdelmoula², A. Bouaziz¹ and W. Abbes¹¹psychiatry and ²obstetric gynecology, University Hospital of Gabes, Gabes, Tunisia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.771

Introduction: Pregnancy and breast-feeding represents a period of psychological maturation for the woman who becomes a mother, a period of significant changes in women’s lives that affects their sexuality and intimacy.

Objectives: To investigate the quality of sexual function in pregnant, postpartum and breastfeeding women.

Methods: It was a cross-sectional study established over a period of 3 months from the June 1st, 2023 to August 31, 2023. This study focused on a population of pregnant, postpartum and breastfeeding women recruited from outpatient consultations and inpatient of the obstetric gynecology department at the university hospital of Gabes. We used a pre-established sheet exploring socio-demographic data, medical and gynecological history and informations concerning the marital relationship and the woman’s sexual activity. We administered the validated Arabic version of the Arizona Sexual Experiences Scale (ASEX) to assess sexual functioning.

Results: Fifty-eight women were included. The average age was 35.6 ± 5.5 years, they had a university level in 40%, secondary in 37.5%, and they were unemployed in 74.2%. From an urban origin in 75%. They were pregnant in the first, second and third trimester in (15.6%, 15.6% and 25% respectively). They were in postpartum in 43.8% of cases with a cesarean delivery in 73.3% and breast-feeding in 56%. All women reported being on good terms with their spouses and satisfied with their sexuality. The usual frequency of sexual relations (SR) was (1/day: 22.6%, 1/week: 74.2%, 1/month: 3.2%) and 25% reported wanting to reduce the frequency. Only 3.44% masturbated and 5.17% had sexual fantasies. The mean ASEX score was 13 ± 4.3 and 47% of the sample had sexual dysfunction. We found a significant association between the sexual dysfunction and the trimester of pregnancy ($p=0.045$). Highest score of sexual dysfunction during the first and third trimester compared to the second one (68.9%, 77.6% and 22.4% respectively). The areas of sexual dysfunction were difficulty reaching orgasm (81%), impaired sexual desire (65.5%), insufficient lubrication (60.3%), arousal (55.1%) and pain on penetration (50%).

Conclusions: We found that sexual function is problematic among women during pregnancy especially in the first and third trimester also in postpartum and breastfeeding period. So what factors are associated with this sexual dysfunction?

Disclosure of Interest: None Declared

Body satisfaction and sexuality in pregnant and postpartum women

S. Bader^{1*}, M. aloulou¹, Z. zran¹, A. Abdelmoula², A. Bouaziz¹ and W. abbes¹

¹Psychiatry and ²obstetric gynecology, University Hospital of Gabes, Gabes, Tunisia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.772

Introduction: Pregnancy and postpartum is an important life event associated with profound physiognomic and psychosocial changes affecting the female body in all its physiological, psychic and affective reality. It might influence the sexual function in expectant mothers.

Objectives: To investigate the relationship between the body satisfaction and perception and the sexual function among pregnant and postpartum women.

Methods: It was a cross-sectional study established over a period of 3 months from the June 1st, 2023 to August 31, 2023. This study focused on a population of pregnant and postpartum women recruited from outpatient consultations and inpatient of the obstetric gynecology department at the university hospital of Gabes. We used a pre-established sheet exploring socio-demographic data, medical and gynecologic history, the body mass index (BMI) and informations concerning the marital relationship and the woman's sexual activity. We administered the validated Arabic version of the Arizona Sexual Experiences Scale (ASEX) to assess sexual functioning and we used the body satisfaction and global self-perception questionnaire (QSCPGS) to explore the body satisfaction and perception.

Results: Fifty-eight women were included. The average age was 35.6±5.5 years; they were from an urban origin in 75%. They were pregnant in the first, second and third trimester in (15.6%, 15.6% and 25% respectively). They were in postpartum in 43.8% of cases with a cesarean delivery in 73.3% and breastfeeding in 56%. All women reported being on good terms with their spouses and satisfied with their sexuality. The usual frequency of sexual relations was (1/day: 22.6%, 1/week: 74.2%, 1/month: 3.2%) and 25% reported wanting to reduce the frequency. The mean ASEX score was 13 ± 4.3 and 47% of the sample had sexual dysfunction. For the total score of the QSCPGS, we observe a mean value of 33 ± 28.3, which means that our sample has a good level of positive body satisfaction and self-perception. The mean value of the "body satisfaction" factor is higher (23.7 ± 10.4) than the mean value of the "self-perception" factor (11.4 ± 14.3). The mean value of BMI was 28.74 ± 4.4 which means an overweight. We found a significant association between the "body satisfaction" factor and the sexual dysfunction (p=0.03), insufficient lubrication (p=0.01) and difficulty reaching orgasm (p=0.001).

Conclusions: We found that body and physical changes among pregnant and postpartum women can negatively affect their body perception and it might deteriorate its global sexual function. Further researches are recommended to study other potential factors affecting sexual function during this period.

Development of a novel screening questionnaire for brain fog

Y. Jheng^{1*}, W.-C. Hsieh² and Y.-H. Chou^{1,2,3}

¹Center for Quality Management; ²Department of Psychiatry, Taipei Veterans General Hospital and ³Department of Psychiatry, School of Medicine, National Yang-Ming Chiao-Tung University, Taipei, Taiwan

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.773

Introduction: Amidst the widespread proliferation of the COVID-19 virus, brain fog has become one of the most critical issues of public health. Brain fog may lead to sub-health conditions, such as forgetfulness, difficulty thinking, and other related symptoms. Although they are not immediately life-threatening, these sub-health conditions could gradually erode the quality of life. Currently, there is no relevant screening tool for brain fog.

Objectives: The aim of this study was to develop a reliable screening tool.

Methods: A web-based brain fog screening questionnaire was developed in the study. It was based on previous studies, which summarized five parts of the most common clinical symptoms after COVID-19: forgetfulness, difficulty thinking, difficulty concentrating, feeling confused, and difficulty finding words or phrases to speak. Unfortunately, these items were used only in a way of yes or no answers in previous studies. Each of these items was expanded to five anchors to evaluate their severity in the study. Cronbach's alpha coefficient was used to assess internal consistency. K-means clustering was used as a second method to validate the cutoff points. Furthermore, the receiver operating characteristic (ROC) curve was applied to validate the appropriateness of the cutoff point.

Results: There were 534 participants who completely finished the questionnaire. It includes 183 males and 351 females, and all of them aged between 19 and 81 years. The Cronbach's Alpha value was 0.821. The cutoff point was at a total score of 6 in terms of K-means. Based on the result, the ROC curve revealed that an area under the curve (AUC) was 0.816 with a confidence interval of 0.784 to 0.849.

Conclusions: The study demonstrated the feasibility and reliability of the web-based screening test for brain fog.

Efficacy of Digital Interventions for Anxiety Disorders: A Systematic Review and Meta-Analysis

H.-G. Ji^{1*}, S. Kang¹, H. Bae¹, G. Kim¹ and J.-W. Hur¹

¹Department of Psychology, Korea University, Seoul, Korea, Republic Of

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.774

Introduction: Anxiety disorders are one of the most common mental disorders, yet only less than 20% of people with anxiety disorders receive adequate treatment. Digital interventions for anxiety disorders can potentially increase access to evidence-based treatment. However, there is no comprehensive meta-analysis study that covers all modalities of digital interventions and all anxiety disorders.

Objectives: A preliminary meta-analysis was conducted to examine the treatment efficacy of digital interventions [e.g., virtual reality (VR)-, mobile application-, internet-based interventions] for anxiety disorders and to identify potential moderators that may lead to better treatment outcomes.

Methods: We searched Embase, PubMed, PsycINFO, Web of Science, and the Cochrane Library for randomized controlled trials examining the therapeutic efficacy of digital interventions for individuals with anxiety disorders from database inception to April 18, 2023. Search keywords were developed by combining the PICOS framework and MeSH terms. Data screening and extraction adhered to PRISMA guidelines. We used a random-effects model with effect sizes expressed as Hedge's *g*. The quality of the studies was assessed using the Revised Cochrane risk-of-bias tool for randomized trials (RoB 2). The study protocol was registered in PROSPERO on April 22, 2023 (CRD42023412139).

Results: A systematic literature search identified 19 studies with randomized controlled trials (21 comparisons; 1936 participants) with high overall heterogeneity ($Q = 104.49$; $P < .001$; $I^2 = 80.9\%$). Digital interventions reduced anxiety symptoms with medium to large effect sizes ($g = 0.78$; 95% CI: 0.55-1.02; $P < .001$), with interventions for specific phobia showing the largest effect size ($n = 6$; $g = 1.22$; 95% CI: 0.51-1.93; $P < .001$). VR-based interventions had a larger effect size ($n = 6$; $g = 0.98$; 95% CI: 0.39-1.57; $P < .001$) than mobile- or internet-based interventions, which had medium effect sizes. Meta-regression results exhibited that effect sizes of digital interventions were associated with the mean age of participants ($\beta = 0.04$; 95% CI: 0.02-0.06; $P < .001$).

Conclusions: The results of this study provide evidence for the efficacy of digital interventions for anxiety disorders. However, this also suggests that the degrees of effectiveness in reducing anxiety symptoms can be moderated by the specific diagnosis, the modalities of digital technologies, and mean age, implying that the application of digital interventions for anxiety disorders should be accompanied by personalized guidance.

Risk assessment and treatment - Evaluation of a group therapy for people with pedophilia

P. Heindl*, S. Schobel, K. Fischer, T. Nenov-Matt, A. Chrobok, M. Wertz and K. Schiltz

Forensic Department, LMU Klinikum, Munich, Germany

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.775

Introduction: Deviant sexual interest for children (pedophilia, hebephilia) is associated with a higher risk of sexual offending against children (CSA) and consuming child sexual abuse images

(CSAI). There is a general shortage of therapeutic programs for individuals who feel sexually attracted to juvenile bodies and are concerned about their sexual behaviour. Efforts to establish regional centres throughout Germany offering preventive support led to the prevention network "Don't become an offender" ("Kein Täter werden").

Objectives: To identify dynamic risk factors (DRFs) and evaluate a treatment programme aiming to reduce CSA and CSAI among potential or existing pedosexual offenders (who have not been legally charged). In addition, changes in the course of therapy are examined to provide information about the accessibility and motivation of the target group and its therapeutic responsiveness.

Methods: Participants undergo standardized diagnostic and treatment procedures. Therapy comprises an outpatient psychotherapy program (group therapy) over the course of approx. 48 weekly sessions, optional individual and partner/relative including sessions, as well as additional pharmaceutical treatment. Assessments are carried out through self- and other-reported psychometric test batteries pre-, during and post-treatment up to a 3.5 year follow-up. The test battery includes clinical questionnaires (WHO-5, CTQ-SF), personality questionnaires (ISK-K, NEO-FFI), sexuality questionnaires (EKK-R, KV-M, MSI, HBI-19) and risk assessment procedures (VRAG-R, STATIC-99, VRS:SO). Main outcome measures are self- and externally-reported DRF changes well as offending behaviour characteristics.

Results: By September 20, 2023, N=12 individuals were enrolled in the treatment program. All individuals had a deviant sexual preference (exclusive/non-exclusive pedo-/hebephilia). Nine individuals reported past and/or current use of CSAI. Of these, two individuals reported at least one CSA in the past. Three had no previous use of CSAI or CSA history.

In the first treatment group (N=6), preliminary results show reduction in dynamic risk factors (e.g., Cognitive Bias, Sexual Compulsivity, Impulsivity) after the first 12 weeks of treatment. The evaluation of additional clinical data is pending.

Conclusions: To date, therapy for individuals with pedophilia or hebephilia has been insufficient – particularly when not offending. Ongoing evaluation of the therapy program should provide further insight into responsiveness and therapeutic motivation of this target group. In particular, the impact of therapy on changing dynamic risk factors for CSA and CSAI remains to be examined.

Psychological Background of Sexual Dysfunctions – a Comparative Study on Hungarian and Spanish Samples

Z. G. Pintér-Eszenyei^{1*}, S. Kató¹, Á. Hőgye-Nagy¹, A. K. Csinády¹, M. A. Rando Hurtado² and A. Szemán-Nagy¹

¹Faculty of Humanities, Institute of Psychology, University of Debrecen, Debrecen, Hungary and ²Faculty of Psychology and Speech Therapy, University of Málaga, Málaga, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.776

Introduction: Sexual dysfunctions are prevalent issues affecting individuals' sexual well-being and relationships. These conditions encompass a range of difficulties in sexual functioning, from desire

and arousal to orgasm and pain. Psychological factors, such as dysfunctional beliefs about sexuality, play a significant role in the development and perpetuation of sexual dysfunctions (Nobre, Pinto-Gouveia, 2006; Nobre, Pinto-Gouveia, 2008). Additionally, personality traits, particularly those associated with the Dark Triad (Machiavellianism, narcissism, and psychopathy), have been suggested as potential protective factors to sexual problems, probably in interaction with sexual assertiveness and a wider experience in sexual behavior (Pilch, Smolorz, 2019).

Objectives: This study investigates the interplay between sexual dysfunctions, sexual dysfunctional beliefs, and Dark Triad personality traits, and compares the differences and similarities in the two different cultural (Hungarian and Spanish) samples.

Methods: Both samples were collected online by sharing the questionnaires on various platforms. Apart from the demographic and sexuality related background questions (age, sex, gender, sexual orientation, sexual lifestyle, etc.) our set of questionnaires included the Arizona Sexual Experience Scale (ASEX), Sexual Dysfunctional Beliefs Questionnaire (SDBQ, Male and Female Version) and The Short Dark Triad Questionnaire (SD3).

Results: The Hungarian sample consists of 465 participants, the Spanish of 215. However, the processing of the data is still under way, our preliminary results show, that there is a connection between the number of dysfunctional beliefs and occurrence of sexual dysfunctions. Just like Dark Triad traits seem to have negative correlation with dysfunctions.

Conclusions: Our research gives an opportunity to a better understanding of the psychological background of sexual dysfunctions. By taking in consideration the relationship between dysfunctional beliefs and said disorders, professionals can optimize sexual education to aid the prevention of them. Nevertheless, our findings can help the practice of psychotherapy in finding more advanced treatments, thus improving individuals' overall sexual, and general well-being.

Tunisian parents' expectations and approaches regarding sex education of their children according to their age: a cross-sectional study

S. Rouached¹, M. Rouached², M. Lagha¹, S. Boudriga^{1*}, A. Boumnijel¹, A. Dakhli¹, K. Zakhama¹, I. Ben Romdhane¹, W. Homri¹ and R. Labbane¹

¹department C and ²department A, Razi psychiatric hospital, manouba, Tunisia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.777

Introduction: Adolescents often lack vital information for making wise sexual and reproductive decisions, leading to risks like abuse, unwanted pregnancies, and infections. Comprehensive, early, and age-appropriate sex education is crucial. While parents should play a significant role, many underestimate their responsibility. The perception of sex education is changing, with younger parents being more open to participating in their children's education.

Objectives: This study compares the approaches of Tunisian parents with adolescent and pre-adolescent children towards sex education.

Methods: This study used a cross-sectional design to collect data from Tunisian parents of children between the ages of 1 to 18 using an online survey. Two groups were recruited based on the age of their children, one group had parents of children younger than 10 years old, and the other had parents of adolescents. The survey included questions about the participants' demographics, approach to sex education, reasons for their approach, and opinions on sex-related education in public schools. The survey was anonymous and confidential, and data were collected from January to March 2023 through various social media platforms.

Results: This study surveyed 232 Tunisian parents with children between the ages of 1 and 18, divided into two groups based on the age of their children. The majority of participants were female (62.1%) and married (81.9%). The majority of participants in both groups agreed that sex education is important and indispensable, but only 54.7% of parents in the older children group responded positively to teaching sexual education as an independent subject. There was a significant difference between the two groups regarding their opinions about the appropriate age of sexual education for their children, and who they think should discuss sexual and reproductive health with young people. Most participants indicated that the human body and its development, sexual and reproductive health, prevention of sexually transmitted diseases and infections, contraception as well as puberty are the most important subjects to be addressed. Sexuality and sexual behaviors, the concepts of violence and safety, interpersonal relationships, consent, insults, harassment, and sexist cyberbullying were less frequently mentioned.

Conclusions: In conclusion, this study highlights the importance of sex education in Tunisia. Parents in both groups support it but differ on timing and integration. Barriers like communication challenges and religious beliefs exist. These insights can guide tailored sex education programs for Tunisian parents, promoting youth sexual and reproductive health.

Electroencephalogram monitoring during ketamine antidepressant treatment: a pilot study

M. S. Fabus^{1*}, D. Casey², K. Warnaby¹, M. Woolrich³ and R. McShane^{2,3}

¹Nuffield Department of Clinical Neurosciences, University of Oxford;

²Interventional Psychiatry, Oxford Health NHS Foundation Trust and

³Department of Psychiatry, University of Oxford, Oxford, United Kingdom

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.778

Introduction: Depression is a major cause of disability world-wide. Up to a third of patients have a treatment-resistant form (TRD), presenting a major challenge. Ketamine has been introduced as a novel rapid-acting antidepressant effective in this population. However, at present, ketamine treatment is not routinely informed by any objective neural markers. Basic research has shown promising electroencephalogram (EEG) changes including a decrease in alpha power. However, clinical translation is lacking.

Objectives: Assess the feasibility of identifying EEG correlates of ketamine infusions in a routine outpatient setting with a low-cost, easily usable system.

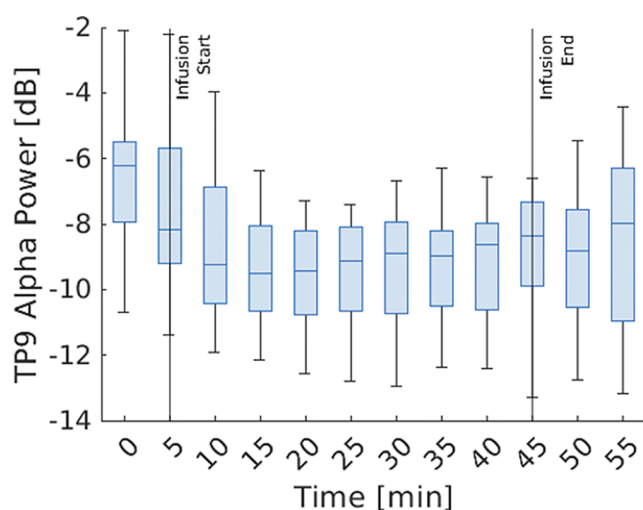

Methods: The study was carried out at the Oxford Health Foundation Trust Ketamine Clinic (ethics reference 22/EM/0226). N=18 EEG recordings from N=12 patients were collected (5 women, mean age 44, range 33-62, IV dose 0.5-1mg/kg over 40min). 4-channel EEG was collected with a Muse-S headband at 256Hz, from 5min before to 55min after infusion start. 5s epochs were rejected if gyroscope data indicated head movement above 10 deg/s or if amplitude was above 200µV. A spectrogram (4s window, 3s overlap) as well as band-limited power (theta: 4-8Hz, alpha: 8-13Hz, beta: 13-25Hz) were computed. Significance of changes was found with a repeated measures analysis of variance (RM-ANOVA) on power in 5min segments together with post-hoc Tukey's P-values.

Results: Across the ketamine infusion recordings, there was a significant effect of time ($F=3.65$, $P=0.0105$) and Channel*Time interaction ($F=3.80$, $P<0.001$) on the EEG spectrum. Effects were largest on temporal electrodes, particularly TP9 in the alpha and theta bands (Figure 1, Table 1).

Table 1: Effect sizes (Cohen's d) and FDR-corrected ANOVA P-values for ketamine effects on each EEG channel and frequency band. $P<0.05$ was considered significant (bold). n.s. = not significant ($P>0.2$).

Channel / Band	TP9	AF7	AF8	TP10
Theta	1.16 ($P=0.019$)	0.11 (n.s.)	0.11 (n.s.)	0.42 ($P=0.113$)
Alpha	1.41 ($P<0.001$)	0.12 (n.s.)	0.17 (n.s.)	0.605 ($P=0.113$)
Beta	1.19 ($P=0.112$)	0.03 (n.s.)	0.08 (n.s.)	0.21 (n.s.)

Image:

Conclusions: In a routine outpatient setting, sub-anaesthetic ketamine infusions in TRD patients were associated with decreased fronto-temporal EEG alpha and theta power. Future work should

assess the potential of low-cost routine EEG, and alpha desaturation specifically, to inform individualised ketamine treatment.

The primary motor cortex of schizophrenia patients show neuronal and subcellular impairments in the right hemisphere – postmortem study

P. Szocsics^{1,2,*}, P. Papp³, L. Havas^{4,5}, J. Löke⁵ and Z. Maglóczy¹

¹Human Brain Research Laboratory, HUN-REN, Institute of Experimental Medicine; ²János Szentágotthai Doctoral School of Neuroscience, Semmelweis University; ³Cerebral Cortex Research Group, HUN-REN, Institute of Experimental Medicine, Budapest; ⁴Department of Pathology and ⁵Department of Psychiatry, St. Borbála Hospital, Tatabánya, Hungary

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.779

Introduction: In mental disorders, very little is known about the cellular and subcellular mechanisms underlying the development of symptoms. Postmortem studies can contribute to understanding these. Our research group collects and studies cortical samples with short postmortem intervals from schizophrenia patients.

Objectives: We investigated primary motor cortical brain samples, to understand the background of motor symptoms in schizophrenia.

Methods: Both hemispheres of primary motor cortices of eight control- and eight subjects with schizophrenia were analysed by immunohistochemistry. We labelled pyramidal cells with SMI32 antibody, which binds to neurofilaments, and parvalbumin (PV) antibody, which labels one type of inhibitory input on these cells, axo-axonic and axo-somatic interneurons, and a proportion of giant pyramidal neurons (Betz cells). We were interested in the size and density of layer 3 and 5 pyramidal cells and Betz cells, the distribution of PV-labelled terminals and the PV expression of Betz cells. Results of the subjects were compared both as a whole and separately per hemisphere.

Results: Most changes were present in the primary motor cortices in the right hemisphere (presumably subdominant). Here, the density of Betz cells and their inhibitory inputs were also reduced. PV-expression of Betz cells was not dependent on the group studied, but we observed that it is decreasing with age. The other investigated characteristics show no significant differences.

Conclusions: Our results suggest that the primary motor cortex may be involved in schizophrenia. Neurodevelopmental, pharmacological and neurodegenerative causes could be involved in this process. Network dysconnectivity is likely to underlie the stronger involvement of the subdominant side, and literature data point also in this direction. We believe that our research method is suitable for the study of the background of other symptoms and may lead to a better understanding of schizophrenia, especially if we could combine our results with clinical research.

Short-term memory depends on the level of emotional burnout

S. Tukaiev^{1,2,*}, I. Zyma¹ and M. Makarchuk¹¹Institute of Biology and Medicine, Taras Shevchenko National University of Kyiv, Kyiv, Ukraine and ²Faculty of Communication, Culture, and Society, Institute of Public Health, Università della Svizzera italiana, Lugano, Switzerland

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.780

Introduction: Emotional burnout refers to a syndrome caused by chronic stress. The formation of emotional burnout may lead to persistent changes in cognitive activity and particularly in memory and attention.

Objectives: As the power of human EEG-spectrum components varies significantly under cognitive testing, the aim of our study was to investigate the dynamics of changes of EEG parameters under a memory task depending on the severity of burnout.

Methods: 42 healthy volunteers (students aged 18 to 24 years) participated in this study. EEG was registered over a period of 3 minutes during the rest state and 10 minutes during a verbal memory task. The spectral power density (SPD) of all frequencies from 0.2 to 35 Hz was estimated. The Mann-Witney criterion was carried out for the comparison of the independent data samples. The correlations were estimated using the Spearman's coefficient correlation. In order to determine the stages of burnout we used the test "Syndrome of emotional burnout" (by Boyko), adapted for students.

Results: We observed variations in parameters of EEG during memorizing and retention phases depending on the intensity of the burnout. The intensity of the Exhaustion stage varied inversely with SPD in alpha3 (parietal and temporal regions), beta1 (parietal regions) and beta2 (parietal, right occipital and temporal regions) during the memorizing phase. The formation of the Exhaustion stage of burnout was accompanied by a decrease in alpha3 (parietal, left occipital and right temporal regions), beta1 (parietal, occipital and left temporal regions) and beta2 (parietal regions) during the retention phase.

Conclusions: Our data indicate that short-term memory depends on the emotional state of subjects.

doi: 10.1192/j.eurpsy.2024.781

Introduction: Alzheimer's disease is characterized by the presence of β -amyloid deposits in senile plaques and brain vessels. β -amyloid stimulates the glial release of proinflammatory cytokines, reactive oxygen species (ROS), or nitric oxide (NO), which are potentially toxic to neurons. One potential therapy for Alzheimer's disease is the use of agents that inhibit the aggregation and formation of insoluble β -amyloid deposits in the brain, or break down the aggregates that have already formed, thus preventing their toxicity.

Objectives: This study aimed to evaluate the effect of ovocystatin on the formation and destabilization of β -amyloid aggregation.

Methods: The effect of ovocystatin on β -amyloid aggregation was determined by Thioflavin T (ThT) Assay and Transmission Electron Microscopy (TEM). The impact on PC12 cell viability was determined by MTT assay.

Results: Ovocystatin can interact directly with A β ₄₂, inhibiting its aggregation and reducing the toxicity induced by aggregated forms of β -amyloid. All effects are dose-dependent. Additionally, a significant increase in the PC12 cell viability treated simultaneously with A β ₄₂ and ovocystatin was observed.

Conclusions: Ovocystatin may be an important factor in the prevention and treatment of Alzheimer's disease by regulating the conversion of monomeric β -amyloid into larger and potentially more toxic particles. However, the mechanisms of inhibition of amyloid fibrillar protein formation and/or destabilization by ovocystatin are still unclear and require further investigation.

Temperamental and Neurocognitive predictors in Korean basketball league draft selection

B. W. Nam^{1*}, D. H. Han², S. M. Kim², J. Hong², H. Hwang² and K. J. Min²¹Dr. Nam's Psychiatric Clinic, Choongju and ²Chung Ang University Hospital, Seoul, Korea, Republic Of

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.782

Introduction: The Korean Basketball League(KBL) holds an annual draft to allow teams to select new players, mostly graduates from the elite college basketball teams even though some are from high school teams. In sports games, many factors might influence the success of an athlete. In addition to possessing excellent physical and technical factors, success in a sports game is also influenced by remarkable psychological factors. Several studies reported that elite sports players can control their anxiety during competition, which may lead to better performance. In particular, the temperament and characteristics of players have been regarded as crucial determinants of the player's performance and goal. In this regard, numerous studies suggest that personality is considered to be an important predictor of long-term success in professional sports

Objectives: Based on previous reports and studies, we hypothesized that physical status, temperament and characteristics, and neuro-cognitive functions of basketball players could predict the result of KBL draft selection. Especially, temperament and characteristics

were associated with the result of KBL selection. The basketball performances including average scores and average rebound were associated with emotional perception and mental rotation.

Methods: We recruited the number of 44 college elite basketball players(KBL selection, n=17; Non-KBL selection, n=27), and the number of 35 age-matched healthy comparison subjects who major in sports education in college. All participants were assessed with the Temperament and Character Inventory(TCI), Sports Anxiety Scales(SAS), Beck Depression Inventory(BDI), Perceived Stress Scale (PSS-10), Trail Making Test(TMT), and Computerized Neuro-cognitive Test(CNT) for Emotional Perception and Mental Rotation.

Results: Current results showed that physical status, temperament and characteristics, and Neurocognitive functions of college basketball players could predict the KBL draft selection. Among temperament and characteristics, novelty seeking and reward dependence were associated with KBL draft selection. The basketball performances including average scores and average rebound were associated with emotional perception and mental rotation.

Conclusions: In order to be a good basketball player for a long time, it was confirmed that temperamental factors and Neurocognitive factors were very closely related. Furthermore, it is also judged that these results can be used as basic data to predict potential professional basketball players.

The impact of Extremely Low Frequency Electro-Magnetic Fields on Depression Anxiety and Stress

I. Kacem^{1*}, I. Jammeli¹, A. Ghenim¹, A. Aloui¹, A. Chouchane¹, M. Bouhoula¹, A. Brahem¹, H. Kalboussi¹, O. El Maalel¹, S. Chatti¹, A. Keken², K. Bouzabia², M. Maoua¹ and N. Mrizak¹

¹Occupational Medicine Department, Farhat Hached Academic hospital and ²Medical Department, Electricity and Gas Company, Sousse, Tunisia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.783

Introduction: According to World Health Organisation (WHO), Extremely Low Frequency Electro-Magnetic Fields (ELF-EMF) include frequencies ranging from 0 to 300 Hz. They are widespread in our daily life and in the workplace. These fields have an impact on physical and mental health including depression and anxiety.

Objectives: To assess the impact of chronic occupational exposure to ELF-EMF on Depression, Anxiety and Stress among workers in the Tunisian Electricity and Gas Company of Sousse, Tunisia.

Methods: In this cross-sectional study, participants were enrolled into two groups: an “exposed group” including workers in a power plant and an “unexposed group” including administrative workers belonging to the same company. The Exposure to ELF EMFs was assessed by spot measurements using a portable magnetometer. Depression, Anxiety and Stress were assessed by the the Depression, Anxiety and Stress Scale(DASS-21).

Results: This study included 77 exposed subjects and 88 unexposed subjects. The median age was 37 years for the exposed group and

43,5 years for the unexposed ones. Almost half of the exposed group were technicians and had a work experience of 9 years. The median value of EMF was 5,86 uT in the power plant[Min 0,1 Max 40,34 ut]. The interpretation of DASS-21 showed that 24.7% of the exposed group and 3.4% of the unexposed group had depression ($p<10^{-3}$). Anxiety was reported by, 23.4% of the exposed group and by none of the unexposed group. Stress was observed among 46.8% of the exposed group and by none of the unexposed group. After multivariate analysis, ELF-EMF exposure was significantly associated only with depression ($p<10^{-3}$; OR=1,45 [1,17-1,81])).

Conclusions: Chronic occupational exposure to ELF-EMF increases the risk of Depression, anxiety and Stress. Underlying mechanisms are not established yet suggesting the need of further studies.

Who moderate the relationship between executive functions and quality of life among adults with and without adhd: structural equation model

N. Grinblat^{1*} and S. Rosenblum¹

¹Department of Occupational Therapy, Faculty of Social Welfare & Health Sciences, University of Haifa, Haifa, Israel

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.784

Introduction: Literature evidences indicates that adults with attention-deficit/hyperactivity disorder (ADHD) are struggling with executive functions deficiencies, organization in time deficits, low sleep quality, and poor quality of life (QoL). However, it is not clear how those factors associate and interact with each other.

Objectives: This study aims to compare those factors as well as the relationships between them, among adults with and without ADHD using structural equations modeling (SEM).

Methods: Sixty-nine adults with ADHD and 52 matched controls (ages 20-46) completed the Behavior Rating Inventory of Executive Function-adult version (for executive functions), Time Organisation and Participation Scale (for organization-in-time), Mini Sleep Questionnaire (for sleep quality), and Adult ADHD Quality of Life questionnaire (for QoL).

Results: Compared to adults without ADHD, adults with ADHD showed significantly poorer executive functions, organization-in-time, sleep quality and QoL. The SEM indicated that sleep quality and organization-in-time domains mediated the relationship between executive functions abilities and QoL. This SEM explained 79% of the QoL variance for adults with and without ADHD.

Conclusions: Understanding the role of organization-in-time and sleep quality as mediators between executive functions and quality of life emphasize the unique challenges of adults with ADHD, which deals with deficiencies at those factors. Those findings call for including these factors in evaluation and intervention processes to improve QoL and this population's global health.

EPP0704

Attention deficit hyperactivity disorder in adults : prevalence and association with addictive disordersS. Bader^{1*}, A. Karkni¹ and W. abbes¹¹psychiatry, University Hospital of Gabes, Gabes, Tunisia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.785

Introduction: Attention deficit hyperactivity disorder (ADHD) is a neurobehavioral disorder witch assumed to be a disorder of childhood but recently has been shown to persist into adulthood. As in children, core features of adult ADHD include inattention, impulsivity, and/or hyperactivity.Despite growing interest in adult ADHD, little is known about its prevalence or correlates.

Objectives: We aimed to estimate the prevalence of ADHD in adult outpatient psychiatric care at the university hospital of Gabes (southern Tunisia) and to explore its association with addictive disorders.

Methods: We conducted a cross-sectional, descriptive, and analytical observation study,in the outpatient psychiatry department of the Gabes university hospital, during the period ranging from 1/1/2023 to 30/06/2023. We used an anonymous pre-established information sheet exploring the socio-demographic, clinical, therapeutic data of the patients, lifestyle habits and substance use, the DSM-5 to classify diagnoses, CGI-S to rate the severity of overall mental illness, Fagerström test to assess the nicotine dependence, Adult ADHD Self-Report Scale (ASRS) in its validated Arabic version to screen ADHD and the Diagnostic Interview for ADHD in Adults (DIVA) to confirm the ADHD diagnosis. Data entry and analysis were performed using Statistical Package for Social Sciences (SPSS) version 21.0.

Results: The response rate in our study was around 64.5%, 205 patients were included.The mean age of the patients was 48years \pm 14.9, the male/female ratio was 1.The estimated prevalence of adult ADHD according to the DIVA was 5.9% (male/female ratio=1/2). At the uni-variate study, significant associations were found between ADHD and the age category ($p=0$), the marital status ($OR=0.14$; $CI [0.03- 0.55]$, $p=0.003$), theFagestrom score ($p=0.01$), cannabis consumption ($OR=19$; $CI [1.8-201]$, $p=0.018$), psychotropic drugs consumption ($OR=39$; $CI[3-196]$, $p=0.02$), self-harm behavior ($OR=6.9$, $CI[1.9-26]$, $p=0.01$), excessive use of internet and screens ($OR=38$, $CI[7-179]$, $p=0$). At the multivariate study, two determining factors were found: cannabis consumption($OR=8 [1- 58]$; $p=0.031$), and the excessive use of internet and screens ($OR=25 [4-144]$; $p=0$).

Conclusions: Regarding our findings and the important prevalence of the adult ADHD,more efforts are needed to increase the detection and treatment of this disorder, in order to set up an early intervention before major impairments and complications become irreversible.

EPP0706

Concurrent mood pathology in patients with autism spectrum disorder (ASD). A case report.C. Díaz Mayoral^{1*}, M. Martín de Argila Lorente², E. Arroyo Sánchez¹ and P. Setién Preciados¹¹Psiquiatría, Hospital Universitario Príncipe de Asturias and²Psiquiatría, Hospital Doctor Rodríguez Lafora, Madrid, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.786

Introduction: Mood disorders in patients with ASD (Autism Spectrum Disorder) have a significant impact on their well-being. Major depression and bipolar disorder are among the most common co-occurring psychiatric diagnoses in autism. Prevalence estimates range from 10-50% for depression and approximately 5% for bipolar disorder. These figures are markedly higher than those reported in the general population.

The diagnosis of these disorders in patients with autism poses several challenges: mood problems may be “overshadowed” by the diagnosis itself, symptoms vary between individuals and may present “atypically” (psychomotor agitation, regression, reduced self-care, and severe irritability). The use of assessment tools based largely on criteria developed and validated in the general population is common.

Objectives: A case of a patient diagnosed with ASD and co-occurring mood disorder is presented followed by a theoretical review on the topic.

Methods: A case is presented with a bibliographic review.

Results: A 20-year-old patient with a diagnosis of severe autism spectrum disorder was referred to the emergency department for behavioral disturbances based on episodes of heteroaggressiveness and self-aggressiveness, with a daily frequency, in the last 2 months. His parents attribute this decompensation to the introduction of Sertraline and changes in his routine, which has implied less stimulation. Having ruled out underlying organic pathology, given that her father refers to frequent episodes of crying and abandonment of leisure activities of his liking, we suspect a mood disorder. In hospitalization, Sertraline was withdrawn and Valproic Acid was introduced. Likewise, Risperidone dose was increased, already prescribed in outpatient care. Progressively, a notable improvement was observed.

Conclusions: Current clinical recommendations on the use of selective serotonin reuptake inhibitors (SSRIs) for mood problems are largely based on evidence from typically developing groups. However, it has been shown that some individuals with autism show different neural responses to pharmacological challenge compared to neurotypical individuals. In addition, the use of SSRIs in ASD may result in increased adverse side effects, such as agitation, impulsivity, hyperactivity, stereotypy, and insomnia, and it has been suggested that they should therefore only be considered on a “case-by-case” basis. A systematic review reported that mood stabilizers (Lithium, Valproic Acid) are preferable to atypical antipsychotics, which are associated with a large number of side effects. Because of the lack of strong evidence on the efficacy of pharmacologic interventions and issues regarding safety and side effects, risperidone and aripiprazole are among the few medications approved by the FDA for the treatment of irritability in people with autism. More research aimed at effective medications to treat mood problems in ASD needs to be advocated.

New approaches in the neuropsychological evaluation of aADHD

L. I. Birtalan^{1*}, S. Bálint¹, T. Kilencz¹ and J. M. Réthelyi¹¹Department of Psychiatry and Psychotherapy, Semmelweis University, Budapest, Hungary

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.787

Introduction: In Hungary, the understanding and diagnosis of adult attention-deficit/hyperactivity disorder (aADHD) are influenced by a blend of international epidemiological data and the standardized criteria established in DSM-5. The diagnostic protocols at our aADHD Outpatient Clinic at Semmelweis University have been carefully adjusted and validated to align with the practical application of empirical evidence and the extensive clinical expertise of professionals. The current diagnostic protocol encompasses the use of diagnostic interviews (symptoms identification based on DSM criteria; SCID-5-PD; M.I.N.I.-PLUS-5.0), the Conners' Adult ADHD Rating Scales-Self Report questionnaire (CAARS), heteroanamnesis with parents, a comprehensive neuropsychological instruments battery (including the Rey Auditory Verbal Learning Test, Stroop Test, Conners-CPT3, Trail Making Test) and WAIS-IV Intelligence Scale.

Objectives: A valid and appropriate diagnosis plays a crucial social role by legitimizing individuals' attention/health issues, confirming their concerns, and addressing cultural and moral expectations. The primary objective of this work is to refine the diagnostic methodology by extensive review of the international literature and the analysis of our own data.

Methods: With the aim of aggregating and analyzing the collected data based on examinations of the Hungarian adult population, our assessment methods are employed to acquire detailed information regarding ADHD prevalence, symptoms, and the related neuropsychological profiles.

Results: While various diagnostic approaches generally demonstrated good alignment, in some cases, significant discrepancies between neuropsychological assessment and the rest of our tools were observed, indicating a number of instances of false positives or false negatives. Especially the relevance of Rey Auditory Verbal Learning Test and Trail Making Test are questionable.

Conclusions: The results highlight the necessity for more refined diagnostic criteria and a meticulous selection of neuropsychological techniques to enhance consistency between various approaches, ultimately enabling a more robust diagnostic accuracy.

Self-stigma, career development and employment in young adults with ASD in Chile.

M. S. Burrone^{1*}, C. A. Barrientos¹, D. Saa-Ulloa¹, J. Madrid Lira¹, C. Alarcón², C. Cortés Rojas¹, L. D. Colantonio³ and M. T. Solís-Soto¹¹Instituto de Ciencias de la Salud, Universidad de O'Higgins, Rancagua, Chile; ²University of Sydney, Sydney, Australia and ³University of Alabama at Birmingham, Birmingham, United States

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.788

Introduction: Stigma describes prejudicial attitudes, negative stereotypes, and discrimination targeting a subgroup. Various forms of stigma have been identified in the literature, including self-stigma. Self-stigma or internalized stigma occurs when stigmatized individuals become aware of the negative stereotypes and apply these to themselves. Self-stigma may be a barrier to career development and employment in individuals with Autism Spectrum Disorder (ASD). However, there are few data available on the presence of self-stigma among young adults with ASD in Chile to inform local interventions and policies.

Objectives: To analyze self-stigma and its relation with career development and employment in young adults with ASD in Chile.

Methods: A mixed-method observational study was conducted to analyze self-stigma and its association with career development and employment among young adults with ASD in two regions of Chile. For the quantitative analysis, self-stigma was assessed using the Internalized Stigma of Mental Illness (ISMI) scale, and employment information was collected. For the qualitative analysis, in-depth interviews were conducted. Data from the interviews were digitalized and transcribed, and the analysis was conducted using ATLAS.ti following the principles of Glaser and Strauss's Grounded Theory. All participants provided written informed consent, and the study was approved by the local Institutional Review Board.

Results: Overall, 356 participants were included in the quantitative analysis (mean age: 27.8 [SD 6.2] years, 44.7% women, 14.8% with regular employment). The mean ISMI for the total sample was 2.34 (SD = 0.62). By triangulating this information with the qualitative analysis (n=27), it was observed that young adults with ASD frequently experience self-stigma attitudes. Through the in-depth interviews, we identified barriers and facilitators for the development of self-stigma. Also, we identified that negative self-perceptions among young adults with ASD may be a barrier to seeking career development opportunities and employment in this population.

Conclusions: The current study shows self-stigma is present in young adults with ASD in Chile, and this may impact negatively their career development and employment.

The Detached Mindfulness approach to anxiety disorders in an Italian mental health service

F. Raffone^{1*}, E. Pessina², A. Martini², P. Giunelli¹, A. Massa¹, E. Carbone¹, M. Russo¹ and V. Martiadis¹¹Department of Mental Health, Asl Napoli 1 Centro, Napoli and²Department of Mental Health, Asl Cuneo 2, Bra, Italy

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.789

Introduction: Anxiety disorders are one of the most common mental illnesses, and a consistent increase was observed after the COVID-19 pandemic. Mindfulness refers to a process that leads to a mental state characterized by nonjudgmental awareness of the present experience. Mindfulness can be considered both a skill and a practice. The stronger is the ability to adopt a mindful state, the less suffering one will experience. While Mindfulness-based

Psychotherapies have shown efficacy in their treatment, they have not yet been thoroughly studied in Italian public mental health services. In Detached Mindfulness, negative thoughts are acknowledged and avoided by turning them into actions using a standardized, time-limited, metacognitive intervention.

Objectives: The purpose of this study is to examine the efficacy and cost-effectiveness of Detachment Mindfulness for twelve patients with Generalized Anxiety Disorder (GAD) not being treated pharmacologically.

Methods: We enrolled 12 patients diagnosed with GAD according to DSM-V in an 8-session program of Detached Mindfulness Psychotherapy (once a week). The Generalized Anxiety Disorder - 7 Scale (GAD-7) and the Kellner Symptom Questionnaire (SQ) were used to assess anxiety symptoms at baseline (T0), after 4 sessions (T1), and at the end of treatment (T2). The Client Satisfaction Questionnaire (CSQ-8) was used to assess treatment satisfaction.

Results: The GAD-7 score showed consistent reductions in generalized anxiety symptoms after Detached Mindfulness treatment (mean decrease of -42% at the end of the program). As measured by SQ, patients also reported improvement in physical well-being, relaxation, and somatic symptoms significantly respect to baseline. As for treatment satisfaction, ten out of twelve patients rated their treatment as satisfactory. As reported by patients, mindfulness can become a powerful and effective means to relate to one's own internal experiences such as anxiety or fear, learning to recognize them, staying with them and avoiding their consequences.

Conclusions: These results showed that detached mindfulness was an effective and cost-effective intervention for GAD, given the short amount of time it requires and the ease with which it can be implemented. For its extensive use in the public mental health system to be further supported, studies on larger populations are needed.

Attention-deficit/hyperactivity symptoms and personal strengths in adults

M. Miklósi^{1,2,3*}, K. Vajsz^{1,2}, S. Oláh¹, V. Nagy² and B. Szabó^{1,2}

¹Department of Clinical Psychology, Semmelweis University;

²Department of Developmental and Clinical Child Psychology, Eötvös Loránd University and ³Centre of Mental Health, Heim Pál National Pediatric Institute, Budapest, Hungary

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.790

Introduction: Attention-deficit/hyperactivity disorder (ADHD) is one of the most prevalent chronic neuropsychiatric disorders in children and adolescents; however, it continues into adulthood in 4-77% of the cases. Due to executive dysfunction, adults with ADHD may have deficits in personal strengths, as well as difficulties utilizing existing strengths in challenging situations, which may add to the functional impairments associated with ADHD in adults.

Objectives: Therefore, we aimed to explore the association between personal strengths and ADHD symptoms in a community sample of adults.

Methods: Five hundred and twenty-eight adults (mean age = 21.41 years, *SD* = 2.29, range: 18- 28, female: *N* = 488, 92.4%) filled

out an online questionnaire after giving their informed consent. Personal strengths were assessed using Bernstein's Strengths Scale (BSS) which measures sixteen positive attributes grouped into four higher-order factors: self-directedness (Identity, Self-reflection, Self-confidence, Self-assertion, Imagination/Creativity), self-regulation (Emotional balance, Resilience, Self-control, Self-care, Reality testing), connection (Empathy, Compassion, Humour, Responsibility), and transcendence (Gratitude and Wisdom). ADHD symptoms were measured by the screening version (Part A) of the Adult ADHD Self-Report Scale (ASRS).

Results: Participants who were screened positive in ASRS (*N* = 247, 46.7%) scored lower in all but four BSS subscales than participants who were screened negative (*N* = 280, 53.3%). Effect sizes reached the medium level (Cohen's *d* > .5) for Self-confidence, Self-care, Responsibility and Wisdom, and were small (Cohen's *d* > .2) for Identity, Self-assertion, Imagination, Resilience, Reality-testing, Emotional balance, and Gratitude. However, no group differences were found in the Self-reflection, Empathy, Compassion, and Humour subscales of the BSS.

Conclusions: Our results suggest that ADHD symptoms in adults may be associated with deficits in personal strengths; that is, adults with ADHD may have difficulties, especially in trusting in their abilities, qualities, and judgements, in taking care of their own emotional and physical well-being, in taking responsibilities and in being open to learning from their experiences. Addressing personal strengths in psychosocial interventions for adult ADHD may improve patients' functioning.

This research has been supported by the National Research, Development, and Innovation Office, OTKA-PD-134849 and ÚNKP-22-2-I-ELTE-854 grants.

A Cohort Based Case Series: Learnings from an Iterative Group Therapy Model to Support Psilocybin-Assisted Therapy for Patients with a Terminal Diagnosis

V. Tsang

UBC, Vancouver, Canada

doi: 10.1192/j.eurpsy.2024.791

Introduction: While much is known about psilocybin-assisted therapy for individuals, little is known about the experience of participants in a group psilocybin therapy model.

Objectives: In an attempt to bridge this gap in the literature, a program development and quality improvement effort was launched.

Methods: Thirty-one psychedelic-assisted therapy (PaT) sessions were provided for 25 participants within four iterative cohorts over the span of one year. This article reports participant feedback in an effort to inform the benefits and challenges of group-administered-PaT.

Results: Six to eight once-weekly group resilience-based community of practice (CoP) sessions were combined with one psilocybin-assisted therapy session for patients experiencing distress related to a terminal health condition. The virtual hybrid group therapy model is research informed, with a curriculum that provides knowledge-based content, combined with the relational elements

necessary to successfully deliver group-administered psilocybin-assisted therapy.

Twenty one of the twenty five participants (84%) completed the program. Based on participant feedback, the following themes emerged: 1) Improvement of pre-treatment preparation sessions; 2) PaT Benefits: Gaining perspective, peace, non-attachment, authenticity, honesty, relational capacity; 3) The community of practice (CoP) as the primary conduit for connection and regulation 4) Population specific curriculum with a greater focus on how to navigate death, pain and loss; 5) PaT session Challenges; 6) The interpersonal and support capacity of the team as critical for the overall experience.

Conclusions: While more research is needed, results suggest that psilocybin can be delivered safely in a group setting, and that a virtual CoP is effective across the spectrum of set, setting and integration. Our findings also suggest that there is much to learn - and improve upon - in this novel area of service delivery.

Revisiting the approaches of psychotherapy in Ayurveda with Research Domain Criteria (RDoC) framework: a review

W. Upadhyaya^{1*} and A. Iyer²

¹Centre Ahimsa, Verrières-le-Buisson, France and ²Independent and unaffiliated researcher, London, United Kingdom

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.792

Introduction: Recently there have been increased acceptance of complementary and alternative medicine (including traditional medicines) not only among laypersons but also various medical specialities. Ayurveda is one such, that originated at least in 3000 BC in the Indian subcontinent. Ayurveda aims at not only treating diseases but also maintaining optimum health. Psychiatry branch of Ayurveda recommends the use of both medicines and psychotherapy. Past papers on Ayurvedic psychotherapy have limitations in terms of semantics, conveying relevance and practical implementation. To tide over such limitations, we review concepts of psychotherapy in the Ayurveda texts Charaka Samhita (CS), Sushruta Samhita (SS), Ashtanga Hridaya (AH) and their commentaries from the original Sanskrit texts, in light of RDoC framework. The approaches derived can be used not just for therapy but also as mental health promotion.

Objectives:

1. To delineate approaches to psychotherapy from Ayurveda classics and their commentaries, which are useful for both mental health promotion and therapy.
2. To view the components of Ayurvedic psychotherapy approaches in terms of RDoC constructs/subconstructs.

Methods: Relevant chapters were scanned in the texts CS, SS, AH and their commentaries for descriptions of psychotherapy. Consequently, its components were compared with the definitions of constructs and subconstructs of RDoC to identify similarities.

Results: Only CS and AH had descriptions on psychotherapy, among which, one out of the four described in CS and the only

one in AH was suitable for our purpose. The components of these models with relevant counterparts (single or combined) are tabulated in Table 1.

Table 1

CS psychotherapy model		RDoC construct/ subconstruct
1)	Spiritual awareness (Jnana)	Declarative memory (semantic)
2)	Specialised knowledge (Vijnana)	Declarative memory (semantic)
3)	Self-control & equanimity (Dhairya)	Cognitive control
4)	Memory (Smriti)	Declarative memory (episodic)
5)	Meditative focus (Samadhi)	Attention, working memory
AH psychotherapy model		RDoC construct/ subconstruct
1)	Intellect (Dhi)	Declarative memory.
2)	Self-control (Dhairya)	Cognitive control
3)	Knowledge of self and surrounding (Atmadi jnana)	Perception and understanding of self

Conclusions: Thus, CS and AH provide a 5-dimensional and a 3-dimensional approach to psychotherapy respectively (with its components having correlates with few RDoC constructs or subconstructs) which can be explored clinically and evaluated, for therapy and mental health promotion purposes.

What do patients find most helpful in group treatment? Importance of group therapeutic factors in standardized psychological group treatments

A. Rodríguez-Rey^{1*}, F. Piazza¹, X. Segú¹, A. Ruiz², C. Sorroche², G. Virgili², X. Torres¹ and I. Morilla²

¹Clinical Health Psychology Section, Psychiatry and Clinical Psychology Service and ²Collaboration Program with Primary Care, Psychiatry and Clinical Psychology Service, Hospital Clínic to Barcelona, Barcelona, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.793

Introduction: There are numerous structured group psychological treatments (GPT), especially in the cognitive behavioral paradigm, which have proven effective. In these TPG, strategies, guidelines, knowledge, etc. are worked and, in many cases, homework is prescribed as an integral part of the treatment. A group context is also generated where people relate, generally with a similar culture, ages, mental health states and life problems

Objectives: Elucidate which group therapeutic factors (GTF) are valued as most important by patients in their psychological improvement process. Know what our patients consider has helped them most in their GPT, whether the GTF or the content of the

therapy (CT), conceptualized as the set of guidelines, knowledge, strategies, exercises and learning carried out with the therapists intrasession and with the material provided intersessions

Methods: A total of 36 patients (mean age=51.04 (9.21)); 69.44% women (n=25); with main diagnoses (77.77%, n=28) of adaptive disorder, 6 patients of major depression (16.66%) and 2 unspecified anxiety disorders (5.55%) are included in GPT based on acceptance and commitment therapy (ACT) of Hayes's (2012) for primary care patients, and on a treatment protocol developed in our clinical health psychology section (Segú et al. PaP 2023; 25 6-18) in long covid patients

Patients are recruited and cared for in the collaboration program with the primary care centers (CPPC), n=22(61.11%), and 12 patients (38.89%) diagnosed with long covid in the specialized post-covid unit of internal medicine, and treated in the clinical health psychology section on the Hospital Clínic of Barcelona (HCB)

Post-treatment evaluation is carried out using the GTF questionnaire, based on Yalom's Q-short(1985), validated with 11 items, adapted to Spanish (Ribé et al. RAEN 2018; 38(134) 473-89). Patients rate from 1 to 10 how much they consider each FTG has helped them in their improvement process

Results: The relevance of the GTF are: Altruism(8.16), catharsis (7.61), cohesiveness(7.94), corrective recapitulation(6.15); socialization techniques (6.41); self-awareness of reality(6.65); imitative behavior(6.43); participated information(6.69), instill hope(6.39); interpersonal learning (7.07), universality(8.27).

Regarding the other objective, 44.44%(n=16) consider the GTF more important than the content of the therapy in their improvement; 36.11%(n=13) equal importance; 13.88%(n=5) plus the CT and 2 consider that none of it has helped them (5.55%). Total importance CT(7.18/10) and GTF(7.44/10). The perceived help in their improvement process in the GPT(CT + GTF)=7.61/10.

Conclusions: In two structured group treatments, based on ACT, a greater percentage of patients value that the GTFs have helped them more in their improvement process than the CT. The GTFs considered most relevant were universality, altruism, cohesiveness and catharsis.

EPP0715

Sex as predictor of employment at 5 years follow-up in First Episode Psychosis

A. Toll^{1*}, E. Pechuan¹, T. Legido¹, D. Berge¹, A. Manzano¹, K. El Abidi¹, V. Perez-Sola¹ and A. Mane¹

¹Institut de Salut Mental, Hospital del Mar, Barcelona, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.794

Introduction: Despite considerable growth in the last years in treatments and research in first episode psychosis (FEP), little attention has been given to the priorities of these young people, in particular, gaining employment. For most people, work is a normal part of everyday life and can be considered one of the most important factors in promoting recovery and social inclusion. Nevertheless, these patients show low employment rates (varying from 23% to 65%) since the beginning of the psychotic symptoms

and even after their contact with mental health services. But, although completing education and access to employment is a critical part for the recovery of these patients, few studies have focused on this outcome.

Objectives: To determine the employment rate and its possible predictor factors in a FEP sample after 5 years follow – up.

Methods: 190 FEP treated between June 2010 and July 2013 at the ETEP Program at Hospital del Mar were included. Inclusion criteria were: 1) age 18-35 years; 2) fulfillment of DSM-IV-TR criteria for brief psychotic disorder, schizophreniform disorder, schizophrenia or unspecified psychosis; 3) no previous history of severe neurological medical conditions or severe traumatic brain injury; 4) IQ level < 80, and 5) no substance abuse or dependence disorders except for cannabis and/or nicotine use. All patients underwent an assessment at baseline including sociodemographic and clinical variables (substance use, DUP, PANSS and GAF). Moreover, employment status has recorded at 5 years follow – up as dichotomyc variable (being employment defined as having either a full-/part-time job, being a student at school or university, or being involved in a study/training program). SPSS program was used for statistical analyzes.

Results: In our FEP sample, the employment rate was 34.2%. We observed significant differences in sex (p = 0.013), cannabis use (p = 0.022) and GAF scores (p = 0.016) between un/employed patients. Nevertheless, in the logistic regression model (ENTER METHOD) only female sex remained as predictor of higher employment rate (95% CI 1.13 to 4.85; p = 0.022) at 5 years follow – up.

Conclusions: Our results suggest that females with a FEP have a better outcome in terms of employment rates, consistent with some previous studies. Some authors suggest that it could be explained by the fact that female patients used to have shorter DUP or more affective symptomatology, which has been also related to a better outcome. Nevertheless, we did not find any differences in these other variables in our sample. Employment not only provides financial independence but also structure and purpose, opportunities for socializing and developing new relationships, a sense of identity, self-worth and meaning in life. Thus, given its importance in FEP functional recovery, more studies in this field are needed to improve patients vocational achievements and determine which specific approaches would each of them need.

Reducing treatment delays of first episode psychosis through policy in Canada: a mixed methods analysis of service provider perspectives

F. Poukhovski-Sheremetyev^{1,2*}, Y. Pelling³, J. Denny⁴, A. Abdel-Baki⁵, S. Iyer^{1,2} and V. Noel²

¹Department of Psychiatry, McGill University; ²Douglas Hospital Research Centre, Montréal; ³SPOR National Training Entity, Quebec City; ⁴Cape Breton University, Nova Scotia and ⁵Department of Psychiatry and Addictions, University of Montréal, Montréal, Canada

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.795

Introduction: Young people with a first episode of psychosis can achieve full remission with prompt treatment. Throughout Canada, early psychosis intervention programs are implementing policies to

ensure timely delivery of services. One of Canada's first early intervention services, the Prevention and Early Intervention for Psychosis program, set the guideline that all youth referred should receive an appointment within 72 hours. The availability of early intervention programs has increased significantly but the standards these programs have adopted to ensure timely delivery of services remains unknown.

Objectives: This project aims to identify the policies and practices in early intervention programs that ensure timely delivery of services. Secondly, the project aims to understand the level of awareness of the 72-hour recommendation and the level of adoption of this recommendation. Thirdly, the project aims to identify the factors that facilitate and hinder a program's ability to reach and maintain their benchmarks for timely delivery of services.

Methods: Participants included 17 service delivery providers from four early intervention programs located in socio-culturally distinct regions in Canada. Participants completed a survey about their program's service delivery policies and practices. We led individual semi-structured interviews with seven service providers to identify the barriers and facilitators to delivering timely care. We conducted frequency analyses of the survey data and thematic analysis of the interviews to identify emerging themes.

Results: Forty-one percent of survey respondents indicated that their program implemented formal policies to minimize the delay to the first appointment, with benchmarks ranging from 72 hours to 12 weeks. The majority of program managers interviewed were aware of the 72-hour benchmark, voiced satisfaction with standards, and felt that establishing standards was helpful to delivering quality services. Average time between referral and first appointment ranged from 10 days to 12 weeks; however, more than half of survey respondents were unaware of the average delay in their program. Notable barriers to implementation included patient non-responsiveness, insufficient staffing, and missing patient contact information from referrals. The service providers reported engaged staff, flexible schedules, and team-based care as facilitators to meeting service delivery benchmarks.

Conclusions: Benchmarks such as the 72-hour recommendation are an excellent step in improving timeliness of delivery of early intervention services. Common barriers to meeting benchmarks, such as patient adherence and staff resources may be difficult to overcome; however, implementing standardized referral forms and processes, increasing staff engagement, providing flexible schedules, and encouraging team-based care could improve timely delivery of services.

doi: 10.1192/j.eurpsy.2024.796

Introduction: Psychotic disorders are serious mental illnesses that require long-term antipsychotic treatment that provides sufficient

efficacy, safety and therapeutic adherence. The latter is an essential factor that must be emphasized in clinical practice in order to avoid relapses. On this occasion, we have the need to know the long-term impact on our clinical practice and on the evolution of patients after the change in formulation of paliperidone palmitate 1 (PP1M) and 3 Month long-acting injectable antipsychotic (PP3M) to paliperidone palmitate 6 Month (PP6M).

Objectives: The present study describes a sample of patients with severe mental disorders (n= 100) treated with six-monthly paliperidone palmitate (PP6M) studying the diagnoses, socio-demographic characteristics, number of relapses, tolerability and treatment adherence of patients.

Methods: Prospective descriptive study with a sample selected by non-probabilistic consecutive sampling, retrospective type, in a time interval of 15 month (n= 100 outpatients). The patients selected were all those who received 6 monthly paliperidone palmitate treatment from May 2022 to September 2023. A descriptive analysis was performed. Mean and standard deviation were calculated for quantitative variables and N and percentage for categorical variables.

Results: Prospective study with consecutive sampling of 100 outpatients (62% men, 38% women; mean age 48 years) diagnosed with psychosis (76 % Schizophrenia, 21 % Unspecified psychosis, 3 % Delusional disorder) those who are administered PP6M long-acting injectable antipsychotic previously treated with PP1M (35%) and PP3M (65%).

After 15 months of the study, 4 patients (4%) have suffered a relapse, one of them (1%) requiring hospitalization. 5 patients (4%) declined to continue PP6M and have returned to their previous injectable. 1 patient (1%) has died of unknown causes outside the treatment. 90 patients continue treatment with PP6M (90% retention rate). 54 patients maintain antipsychotic monotherapy (54%). No additional adverse effects were reported after switching to PP6M. The subjective perception of satisfaction after the switch to PP6M by patients and caregivers was very high.

Conclusions: The present real clinical practice study shows that PP6M could be an effective and well tolerated treatment in patients with severe mental disorder, for patients diagnosed with psychosis, with a high rate of relapse prevention and high rates of compliance. Changing treatment from PP1M or PP3M to PP6M could help patients with severe mental disorder to normalize their lives and functionality.

The relationship between depression and overall, general psychopathology, positive, and negative symptoms in people with schizophrenia spectrum disorders: a cross-sectional study

F. Bartoli¹, A. Calabrese¹, F. Moretti¹, M. Castiglioni¹, L. Prestifilippo^{1*}, A. De Pietra¹, M. Gazzola¹, P. Camera², C. Crocamo¹ and G. Carrà^{1,3}

¹Department of Medicine and Surgery, University of Milano-Bicocca, Monza; ²Department of Mental Health and Addiction Services, ASST Nord Milano, Sesto San Giovanni, Milan, Italy and ³Division of Psychiatry, University College London, London, United Kingdom

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.797

Introduction: Depressive symptoms are a common occurrence in people suffering from schizophrenia spectrum disorders (SSDs), representing a separate domain that interacts in peculiar ways with positive and negative symptoms. Nonetheless, available evidence on the relationship between depression and key clinical dimensions of SSDs is limited.

Objectives: To increase the knowledge regarding depression in SSDs, we performed a cross-sectional study aimed to investigate the association of depressive symptoms with overall, general psychopathology, positive, and negative symptoms in individuals with SSDs.

Methods: Adult people with SSDs were recruited from two psychiatric inpatient units in the northern area of the Metropolitan City of Milan from May 2020 to March 2023. Study participants with a Calgary Depression Scale for Schizophrenia score >6 were rated as depressed. Symptom severity was assessed by using the Positive and Negative Syndrome Scale (PANSS). Variables associated with depression at the univariate level were included into two multiple logistic regression models to analyse the association between depression and PANSS overall score as well as General Psychopathology, Positive, and Negative sub-scores.

Results: A total of 231 subjects with SSDs were included. Among them, approximately one third ($N=78$; 33.8%) reported depressive symptoms. Multiple logistic regression models suggested that depression in individuals with SSDs was associated with higher overall ($p<0.001$) and General Psychopathology ($p<0.001$) PANSS scores. Conversely, an inverse relationship between depression and positive symptoms was found ($p=0.002$). Negative symptoms were not associated with depression ($p=0.210$).

Conclusions: Our findings suggest that people affected by comorbid SSDs and depression have more severe overall and General Psychopathology symptoms according to PANSS scores, as well as lower levels of positive symptoms. Further investigations are needed to evaluate the generalisability of these findings and to improve the clinical management of people with SSDs and depression.

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.798

Introduction: According to immunological theories of schizophrenia prenatal and postnatal exposure to pathogens may contribute to the etiopathogenesis, suggesting that chronically activated immune system cells (macrophages and T lymphocytes) constantly secrete proinflammatory cytokines which affect the development and function of central nervous system.

Objectives: In the present work we aimed to evaluate IL-1 β plasma levels in schizophrenic patients during their first psychotic episode and to compare the obtained results to those from healthy subjects.

Methods: Plasma was obtained from 32 drug-naive schizophrenic patients, without history of substance abuse or addiction, immediately after their admission to the medical ward, while the control samples were obtained from 20 healthy volunteers.

Results: Levels of IL-1 β were measured using ELISA assay, which measures IL-1 β protein in a range from 7.81 to 500 pg/ml. Results revealed that the levels of IL-1 β in patients with first psychotic episode were not increased and were below the limit of detection in all studied samples. The same was found in the samples belonging to the control group.

Conclusions: These data contribute to the poll of knowledge and a still unresolved dogma about the etiopathogenesis of schizophrenia since the results obtained by some studies are also questioning this marker. Thus, whether or not an increase of IL-1 β is congenital, acquired during the prodromal phase or absent until the time of first psychotic episode has not yet been investigated.

Increased emergency room visits without corresponding rehospitalizations in cannabis users with psychosis

O. Martin-Santiago^{1*}, M. Calvo-Valcarcel¹, P. Martinez.Gimeno¹, C. Alario-Ruiz¹ and B. Arribas-Simon¹

¹Hospital Clinico Universitario, Valladolid, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.799

Introduction: Epidemiological studies have established a complex relationship between cannabis consumption and a heightened risk of psychotic disorders, including schizophrenia. However, this connection is multifaceted, influenced by genetics, environment, and individual psychology. Surprisingly, despite a surge in emergency room (ER) visits associated with cannabis consumption and psychosis, there haven't been significant increases in hospital readmissions. This rise in ER visits can be attributed to the increasing social acceptance of cannabis and its legalization in some regions, increasing the likelihood of adverse effects. Furthermore, the higher potency of contemporary cannabis can trigger psychotic reactions, particularly in those consuming elevated levels of THC, its primary psychoactive component.

Objectives: This study aimed to compare the rates of readmissions and ER visits one year after hospital discharge among patients diagnosed with schizophrenia and other psychotic disorders, stratified by cannabis consumption.

Methods: We collected sociodemographic and clinical data from 109 patients after discharge from a psychiatric hospitalization unit.

Results: Patients who consumed cannabis ($N=35$) were younger than non-consumers ($M=31.4$; $SD=10.0$ vs $M=44.3$; $SD=11.4$; $t(107)=5.71$; $p<.01$), with no significant gender differences, hospital stay durations, or proportions of schizophrenia diagnoses (33.3%). The readmission rates and time to readmission were similar between both groups. Interestingly, 54.2% of cannabis consumers required emergency care ($X^2_{(1, N=109)}=4.1$, $p=.04$), with 73.6% not needing admission ($X^2_{(1, N=109)}=5.5$, $p=.01$), in contrast to 33.7% and 56% in the non-consumer group. The time to the first urgent care visit was shorter in the consumer group ($M=59.5$; $SD=56.3$) compared to the non-consumer group ($M=105.8$; $SD=93.1$; $t_{(107)}=1.92$; $p=.03$).

Conclusions: This study reveals that patients with psychosis and cannabis consumption tend to visit ER services more frequently despite utilizing fewer hospital resources like hospitalizations. Notably, despite the increased ER visits, there hasn't been a corresponding rise in hospital readmissions. These would be due to individuals experiencing cannabis-related psychotic episodes receiving suitable assessment and treatment in the ER, obviating the need for prolonged hospitalization. Furthermore, some psychotic episodes may naturally resolve over time, particularly with reduced or discontinued cannabis consumption. Our result highlights the need for personalized care approaches targeting this group, effectively addressing acute episodes related to cannabis use and psychosis. Addressing this trend requires a multidisciplinary approach involving mental health professionals, addiction specialists, and emergency response teams.

Clinical predictors of treatment effectiveness in late onset schizophrenia and schizophrenia-like psychosis

V. Pochueva^{1*}, T. Safarova¹ and V. Sheshenin¹

¹FSBSI "Mental Health Research Center", Moscow, Russian Federation

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.800

Introduction: Clinical features and structural changes in the brain of patients with late-onset schizophrenia and schizophrenia-like psychosis are important in predicting the effectiveness of treatment.

Objectives: Identification the dependence of effectiveness of psychopharmacotherapy on the clinical features and structural brain changes in late-onset schizophrenia and schizophrenia-like psychosis.

Methods: 111 patients, age from 52 to 89 years with ICD-10 diagnosis F20, F25, F22.8, F06.2 were investigated for 28 days. Clinical, psychometric methods with PANSS, CGI, HAMD, CDSS, MMSE scales were used. MRI/CT were performed. Effectiveness of treatment was measured in two ways: 1. Percentage ratio of reduction in total scores to the 1st value of scales. 2. The number of responders (patients with a decrease in PANSS by 30% or more).

Results: The effectiveness of treatment in the overall group was 29.4% on the PANSS scale (from -13.6% to 77.2%). The greatest

effectiveness was on subscale of positive syndromes (34.9%), the lowest – on the subscale of negative syndromes (18.6%). The number of responders (R) was 43 patients (38.7%), non-responders (NR) – 68 patients (61.3%). The responder group was characterized by a greater severity of acute psychosis before the begging of treatment. Early insomnia, excitement and anxiety, decreased appetite, valuated by HAMD scale were significantly more pronounced. Treatment effectiveness had negative correlates ($p<0.05$) with number of acute attacks, number of hospitalizations and the duration of current attack. The predominance of negative symptoms has a negative correlation with effectiveness by PANSS and CGI scales. According to the results of MRI/CT examination, cortical atrophy, vascular changes and leucoaraiosis were more often represented in NR group.

Conclusions: The connection between the effectiveness of treatment and the clinical and psychopathological features and structural changes in late onset schizophrenia and schizophrenia-like psychosis was shown.

Peer Support in Psychosis Care: A Valuable Resource for Recovery

F. Cunha^{1*}, I. Santos¹, N. Castro¹, R. Andrade¹, E. Almeida¹, J. Abreu¹, J. Martins¹, R. Vaz¹ and S. Borges¹

¹Centro Hospitalar Tondela-Viseu, Viseu, Portugal

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.801

Introduction: A variety of peer support workers have been integrated in the mental health workforce in several countries. The effectiveness of this approach is still inconclusive. However, some data reveals promising results. Some projects have integrated peer support intervention in the treatment of psychosis. In fact, UK clinical guidelines for psychosis advise the inclusion of peer support within Early Intervention in Psychosis services.

Objectives: The current study aims to evaluate how peer support may assist the intervention in psychosis and highlight challenges ahead in this field.

Methods: Narrative review of the available scientific literature.

Results: Research suggests that consistent and frequent peer support enhances social support and boosts self-confidence and the overall quality of life for people going through psychosis. Individuals diagnosed with severe mental illnesses who receive peer support reportedly experience an increased sense of control, hopefulness, and empowerment, enabling them to initiate positive changes in their lives. People going through psychosis experience internalized stigma. Destigmatization of psychotic experiences is a central theme of intervention in psychosis. Participants viewed peer support as a valuable form of assistance that could offer advantages to both peers (service users) and peer support workers.

Conclusions: Peer support makes a strong contribution to destigmatising psychosis. The available data is promising and supports the effectiveness of peer support in such instances. As projects of peer support in psychosis continue to be implemented, further

research should provide additional insight into the effectiveness and inherent challenges of this type of intervention.

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.802

Introduction: Patients' beliefs and attitudes about medications play a role in whether they adhere to their medications or not. Knowledge on how beliefs and attitudes about medications can be influenced is therefore important.

Objectives: The current study aimed to assess whether patients' perceived support from their therapists regarding use of medications was associated with their beliefs and attitudes about medications. Because non-adherence in patients with psychosis frequently results in relapses and emergencies, this knowledge may be very useful for therapists and patients.

Methods: This cross-sectional study included 310 patients diagnosed with psychosis from 31 clinical units in Norwegian mental health specialist care. We assessed beliefs about medications using the Beliefs about Medicines Questionnaire (BMQ). BMQ-specific consists of two subscales, BMQ-necessity and BMQ-concerns. Higher score on the necessity subscale indicates stronger beliefs in the necessity of taking the medicine. Higher score on the concern subscale indicates stronger concerns about taking the medicine. We used a newly developed self-report questionnaire, MedSupport, to assess the patients' perceived support from therapists in dealing with their medications. Higher score on the MedSupport means that the patient experienced more support with decisions related to medications. Linear mixed effect models were used to investigate possible associations of sociodemographic factors, clinical factors and patients' perceptions of medication support with BMQ.

Results: Patients' perceptions of medication support from therapists were positively associated with positive beliefs towards medications, $\beta = 0.20$, 95% CI [0.04 to 0.35], $p=0.012$, and negatively associated with concerns about taking the medications, $\beta = -0.31$, 95% CI [-0.44 to -0.17], $p < 0.001$, when other relevant variables were taken into consideration.

Conclusions: The present study shows that therapists may affect patients' beliefs and concerns about medications. Consequently, medication support may lead to improved adherence to medications prescribed.

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.803

Introduction: In recent years, mental health has gained prominence in public health, prompting thorough investigations into psychiatric condition trends. This study conducts a comprehensive epidemiological analysis of hospitalizations for Schizophrenia, Schizotypal, and Delirium Disorders in Rio Grande do Sul (RS) over the past five years. By revealing these patterns, it enhances our understanding of regional mental health dynamics and offers insights for intervention strategies, resource planning, and improved mental healthcare. The ultimate goal is to advance more effective and accessible mental healthcare in RS and beyond.

Objectives: This study aims to analyze the prevalence and epidemiological profile of hospitalizations due to psychiatric disorders to assist in the diagnosis and outcome of affected patients.

Methods: A cross-sectional, descriptive, retrospective, and quantitative study was conducted regarding hospitalizations for Schizophrenia, Schizotypal Disorders, and Delirium in the state of RS between January 2018 and November 2022. Data were collected from the Department of Informatics of the Brazilian Unified Health System (DATASUS) in the "Hospital Information System of SUS" section, focusing on the nature of care, age group, gender, and ethnicity of the patients. The information was aggregated over the five-year period based on the four mentioned descriptors and subsequently analyzed to establish a profile of hospitalizations during that period.

Results: The analysis spans from 2018 to 2022, encompassing a total of 28,345 hospitalizations. In 2019, there was the highest number of cases (22.21%), followed by 2018 (21.08%). Urgent care admissions constituted 85.34% of the total. The age group most affected was 35 to 39 years (11.8%). Men were more affected than women (60.18%), and the majority of hospitalizations were among the Caucasian ethnicity (75.12%). The average length of stay was 23.7 days, and the mortality rate stood at 0.26%.

Conclusions: The increasing trend in hospitalizations, peaking in 2019, highlights the need for preventive measures. Urgent admissions (85.34%) underscore the demand for accessible mental health resources. Men in the 35 to 39 age group are disproportionately affected, suggesting specific risk factors. The predominance of Caucasian ethnicity emphasizes the need for culturally sensitive

care. A longer average length of stay (23.7 days) underscores treatment complexity, while a low mortality rate (0.26%) signals effective medical care. In essence, these findings inform tailored mental health policies to enhance service quality and prioritize patient-centered approaches.

Sexuality in schizophrenia: Perception of signals of sexual interest

P. Biedková^{1,2*}, O. Vaníček², O. Novák^{2,3}, K. Ständer², E. Kolářová² and R. Androvičová²

¹1st Faculty of Medicine, Charles University; ²Centre for sexual health and interventions, National Institute of Mental Health and ³Faculty of Arts, Charles University, Prague, Czech Republic

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.804

Introduction: There is emerging evidence that people with schizophrenia (SCH) struggle to form romantic relationships and are often dissatisfied with their sex lives. Intimate relationships are perceived as normalizing and related to a person's recovery and better medication adherence. Nevertheless, this area remains scientifically unaddressed, and patients with SCH generally do not feel adequately supported in terms of their sexual health.

Objectives: The study aims to assess whether challenges in establishing sexual relationships could be connected to: a) decreased salience of sexual intimacy and/or b) compromised ability to detect, recognize, and react to signals of sexual interest.

Methods: Forty-three patients with SCH (29 males and 14 females) and a control group of twenty-four participants (11 males and 13 females) were exposed to our first experiment, the Circular attention task. This task was designed to evaluate the salience of erotic stimuli compared to neutral ones. At the beginning of each trial, a black fixation circle appeared in the middle of the screen. When a fixation of 250 ms or longer was detected within the circular area of interest (AOI) around the fixation circle, the fixation circle disappeared, and a pair of erotic/neutral pictures appeared. During the experiment, the eye movements were measured using the eye-tracking device Eyelink 1000plus. For data analysis, we used Wilcoxon signed-rank test to assess the differences between the mean latency to first fixation, mean duration of first fixation, and mean proportion of time spent gazing at the stimulus both for sexual and neutral pictures in the whole sample regardless of sex and patient status. More detailed analysis was performed using 2 (sex: male, female) x 2 (status: patient, control) two-way ANOVA.

Results: Considering the whole sample there was a significant difference in mean latency to first fixation ($W = 707$, $p = 0.007$, $r_{fb} = -0.379$) and mean duration of first fixation ($W = 1923$, $p < 0.001$, $r_{fb} = 0.739$). There was a shorter latency to first fixations towards sexual pictures ($M = 952.33$ ms) than to neutral pictures ($M = 1005.30$ ms). First fixations were longer for sexual pictures ($M = 280.96$ ms) than for neutral pictures ($M = 243.73$ ms). There was an effect overall in the sample towards the sexual pictures, but it was not different for participants based on their sex or patient status.

Conclusions: Findings revealed that interest in explicit sexual stimuli does not differ based on sex or patient status. Patients with

SCH appear to find explicit erotic signals sexually salient, suggesting their interest in sexual intimacy. Our study will further investigate whether persons with SCH are able to interpret, recognize and respond to signals of sexual interest. Based on our results, the guidelines for sexological remediation will be developed.

The study was supported by the Charles University, 1. LF project GA UK No. 56123.

doi: 10.1192/j.eurpsy.2024.805

Introduction: In patients affected by Schizophrenia and Bipolar Disorder disorders the use of antipsychotic drugs is essential in preventing the exacerbation of symptoms. The use of long-acting injectable (LAI) antipsychotics is considered an important treatment option. The aim of this study was to evaluate the incidence and predictors of relapse during antipsychotic treatment with LAIs in a sample of psychiatric outpatients up to a year after the start of long-acting therapy.

Objectives: The study included 103 adult patients admitted to the psychiatric unit of Sant'Andrea University Hospital in Rome.

Methods: We evaluated duration of untreated illness, previous treatments, substance abuse, suicidal status, LAI dose, and use of other medicines for association with new episodes of illness or of symptomatic worsening as well as hospitalization, using bivariate and multivariate analyses.

Results: Seventy-three patients were diagnosed with schizophrenia spectrum and 30 with bipolar disorders. Age at study entry averaged 36.7 years ($SD = 11.55$). 40.8% of patients were women. The mean age at onset were 23.11 ($SD = 7.0$). All the other information were reported in Table 1. On 103 patients undergoing with LAI treatment for a year only 9 (8.7%) patients had a relapse during the study period. The two groups differed according to the presence of hospitalization during the 12 months before the LAI treatment ($p = .022$), in particular patients with relapse were more hospitalized than patients with no relapse (62.5% vs. 21.7%). Moreover, group with relapse were more at risk of suicide during the 12 months before the LAI treatment than the other group, for both suicidal ideation (11.1% vs. 4.3%; $p = .015$) and attempt (25.0% vs. 3.2%; $p = .049$). Finally, the two groups differed according to the side effects reported during the year of LAI treatment ($\chi^2 = 38.48$; $p < .001$). Specifically, patients' group with relapse reported more side effects caused by parkinsonism (25.0% vs. 1.1%) and tremor (25.0% vs. 0%). No differences were found for the other variables (See table 1).

Image:

Variables	Mean or %		Statistic	p-value
	Relapse	No Relapse		
Cases (n)	9 (8.7)	94 (91.3)		
Women (%)	66.7	38.3		.154*
Age	37.22±9.88	36.70±11.74	U=402.5	.811
Onset age	25.89±7.28	22.84±6.97	U=299.5	.159
Diagnosis			$\chi^2 = 1.55$.213
SS	8 (88.9)	65 (69.1)		
BD	1 (11.1)	29 (30.9)		
Comorbidity	6 (66.7)	33 (35.1)		.079*
Substance abuse	2 (22.2)	25 (26.6)		1.0*
Family history (%)			$\chi^2 = 1.07$.585
Any psychiatric diagnoses	1 (11.1)	16 (17.0)		
Schizophrenia	3 (33.3)	18 (19.1)		
Untreated illness: DUI (mos)	45.77±90.7	17.25±48.16	U= 359.5	.419
Treatments before LAI (%)				
Any antidepressant	2 (22.2)	17 (18.1)		.670*
Mood-stabilizer	4 (44.4)	54 (57.4)		.499*
First gen. antipsychotic	3 (33.3)	26 (28.0)		.711*
Second gen. antipsychotic	9 (100)	67 (72.0)		.107 *
Hospitalized S12 mos before LAI	5 (62.5)	20 (21.7)		.022*
Hospitalized at start of LAI (%)	3 (33.3)	24 (25.8)		.696 *
Suicide risk S12 mos before LAI (%)				
Ideation	3 (37.5)	5 (5.4)		.015*
Attempt	2 (25.0)	3 (3.2)		.049*
Suicide risk at start of LAI (%)				
Ideation	1 (11.1)	4 (4.3)		.373 *
Attempt	0 (0.0)	2 (2.1)		1.0*
Side effects of LAI during 12 mos treatment			$\chi^2 = 38.45$	<.001***
Parkinsonism	2 (25.0)	1 (1.1)		
Tremor	2 (25.0)	0 (0.0)		
Hyperprolactinemia	0 (0.0)	3 (3.3)		
Metabolic disorders	0 (0.0)	2 (2.2)		
Post Injection Syndrome	0 (0.0)	1 (1.1)		

Conclusions: In conclusion, our observations confirm the importance of LAI therapy in real word. However, our results indicate that these drugs might not prevent subsequent exacerbations for a proportion of individuals whose illness is stabilised on continuous antipsychotic treatment. Extra pyramidal symptoms in particular might have pathophysiological implications for relapse.

Evaluation of daytime sleepiness and insomnia symptoms in OSA patients with a characterization of symptom-defined phenotypes and their involvement in depression comorbidity

A. Gabryelska^{1*}, S. Turkiewicz¹, P. Bialasiewicz¹, F. Grzybowski¹, D. Strzelecki² and M. Sochal¹
¹Department of Sleep Medicine and Metabolic Disorders and ²Department of Affective and Psychotic Disorders, Medical University of Lodz, Lodz, Poland
*Corresponding author.
doi: 10.1192/j.eurpsy.2024.806

Introduction: Recent studies have emphasized the importance of clinical manifestations, such as insomnia and sleepiness, in defining phenotypes of obstructive sleep apnea (OSA), shifting from a focus on OSA severity and sleep structure.
Objectives: The study aimed to characterize insomnia and sleepiness associated with OSA phenotypes and assess their involvement in depression symptoms (DS) in OSA.
Methods: A total of 181 participants undergoing polysomnography (PSG) were asked to fill out questionnaires, including Epworth Sleepiness Scale (ESS), Insomnia Severity Index (ISI), Pittsburgh Sleep Quality Index (PSQI), and Back Depression Index (BDI). They were categorized into phenotypes: insomnia-sleepiness (I+S; ESS≥11; ISI≥15; n=20), sleepiness (S; ESS≥11; ISI<15; n=22), insomnia (I; ESS<11; ISI≥15) and asymptomatic (A; ESS<11; ISI<15; n=55).
Results: A linear regression model for BDI score (R²=0.357, p<0.001) included ISI score and subjective to objective sleep latency ratio. ISI score was a predictive factor for mild and moderate DS (OR=1.226, p<0.001 and OR=1.392, p=0.002, respectively). I and I+S phenotypes are characterized by higher BDI scores (p<0.001 and p=0.015), longer subjective sleep latency (p=0.008 and p=0.041), and shorter subjective total sleep time (TST; p=0.049 and p=0.006), compared to A. Furthermore, the I and I+S groups had shorter subjective TST than S (p=0.028 and p=0.047). I and I+S had higher BDI scores than A (p<0.001 and p=0.015, respectively) and S (p<0.001 and p=0.017, respectively). I phenotype was associated with the risk of mild and moderate DS (OR=5.614, p<0.001 and OR=9.550, p=0.008 respectively). Moreover, the I+S phenotype presented an even greater risk for mild DS (OR=10.286, p<0.001).
Conclusions: The study suggests that using clinical features for OSA phenotyping holds promise for finding OSA individuals with increased risk for the occurrence of DS.

Psychiatric brain gain in Switzerland. Competency-based onboarding.

D. Gurrea Salas^{1*} and R. F. Palma Álvarez²
¹Department of Addictive Disorders, Psychiatric Services Aargau, Brugg, Switzerland and ²Department of Psychiatry, Hospital Universitari Vall d'Hebron, Barcelona, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2024.807

Introduction: In the last 30 years, Switzerland has been established as a destination country for psychiatric trainees. The needed competences for the work as a trainee deviate regarding colleagues from foreign countries though, hindering a viable solid development professional without specific on-boarding program. A similar approach to the figure of tutor anchored in the Spanish postgraduate medical training is still missing in the Swiss medical System. Hereby we performed a survey in the new colleagues who are part from the medical team in an observer status before beginning with the responsibilities as a trainee.
Objectives: Recognizing competences and needs of the onboarding in current trainees that are still allocating because of the work

conditions as stated in the following paper, (Bischof et al. Swiss Arch Neurol Psychiatr Psychother. 2021;172:w03198)

Methods: Survey with open questions collecting needs and competences expected to fulfil in Switzerland were distributed in 5 different medical colleagues in an observer status between August 2022 and September 2023.

Results: Response rate was 62,5 %. Main reasons for the migration were considering better perspectives in education and professional development in the goal country, coming push factors as the current work situation in the original country to the fore. Support regarding the local language and an overview of the interprofessional communication were outlined as the advantage of the internship prior to the duties as a psychiatric trainee.

Conclusions: An structured on-boarding program is a demand for the newcomers - majority of trainees from foreign countries - to step in better in the Swiss health system. Elements of the Spanish trainee system could be adapted for a suitable allocation and integration process in the goal country.

The Impact of Sleep Deprivation in the Treatment of Depression: A Literature Review

J. Camilo

Psychiatry, CHTMAD, Vila Real, Portugal

doi: 10.1192/j.eurpsy.2024.808

Introduction: Depression is a pervasive and debilitating mental health disorder that affects millions of individuals worldwide. Despite the availability of various treatment modalities, a significant proportion of patients continue to experience inadequate symptom relief and persistent emotional suffering. Sleep disturbance is a common symptom of depression, and emerging evidence suggests that manipulating sleep patterns through sleep deprivation may hold potential therapeutic benefits. This literature review aims to explore the role of sleep deprivation as an adjunctive treatment for depression, shedding light on its mechanisms and potential outcomes.

Objectives: To investigate the historical context and theoretical underpinnings of sleep deprivation in depression treatment; to examine the methods and protocols used in studies involving sleep deprivation as a therapeutic intervention for depression; to analyze the empirical evidence regarding the efficacy of sleep deprivation in ameliorating depressive symptoms; to assess the safety and feasibility of implementing sleep deprivation in clinical practice; to discuss the potential mechanisms underlying the antidepressant effects of sleep deprivation.

Methods: A systematic review of the literature was conducted.

Results: The review identified a diverse body of literature exploring the potential benefits of sleep deprivation in depression treatment. Preliminary findings suggest that acute sleep deprivation may lead to rapid and transient improvements in mood among individuals with depression. Various protocols, including total and partial sleep deprivation, have been investigated, demonstrating differential effects on depressive symptoms. Additionally, potential

mechanisms underlying these effects, such as alterations in neurochemical pathways and circadian rhythms, have been proposed.

Conclusions: Sleep deprivation as an adjunctive treatment for depression is a promising but complex intervention that requires further investigation. While some studies have reported significant improvements in mood following sleep deprivation, the sustainability of these effects and the potential long-term consequences remain uncertain. Moreover, the optimal protocols, safety guidelines, and patient selection criteria need to be established for clinical application. Future research should focus on elucidating the mechanisms involved and conducting well-designed randomized controlled trials to determine the efficacy and safety of sleep deprivation in the context of depression treatment. This review underscores the importance of considering sleep as a modifiable factor in the comprehensive management of depression.

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.809

Introduction: There is a growing interest in understanding the impact of duty hours and resting times on training outcomes and the well-being of resident physicians. Psychiatry resident's duty hours in Spain comprise a regular working schedule of 37.5h per week and a minimum of 4 mandatory on-call shifts. The most recent duty hours regulations in Spain were transposed from the European Working Time Directive (EWTd). According to Spanish Law, doctors cannot work for more than 48h per week and need to have resting times per day (at least 12h), per week (at least 36h) as well as annual leave (at least a month). However, there is practically no data on this situation in psychiatry resident physicians.

Objectives: Our aim is firstly, to describe the number of shifts performed by psychiatry resident physicians in Spain. Secondly, to describe compliance with the daily and weekly rests compared to those set in national and European law. Finally, to analyse the difference by demographic variables (gender and year of residency), in both the number of on-call duty shifts and compliance with rests.

Methods: A descriptive cross-sectional study was designed through an online survey adapted from the existing literature. The target population were Spanish psychiatry resident physicians undergoing PGT who started their specialist training during the years 2018–2021. The survey was disseminated through the Spanish regional medical councils to all active psychiatry resident physicians by mail as well as through informal communication channels. The study was authorised by the Spanish Medical Organization's General Assembly which is the highest ethical and deontological body of physicians in Spain.

Results: 55 responses were obtained, of which 61.82% identified as females. The mean number of on-call shifts in the last 3 months was 14.05. This mean was highest in women 14.32 and in the cohort of 2020 15.46 (first year of residency). Among the resident physicians surveyed, 66.07% exceeded the 48h per week limit set by the EWTD and 7% of them did not rest after a 24-h on-call shift. Furthermore, 22% of respondents did not have a day-off after a Saturday on-call shift. The mean working hours when not resting after an on-call-shift were 7 hours. The comparison by gender and year of residency of the main variables can be seen in figures 1 and 2 respectively.

Image:

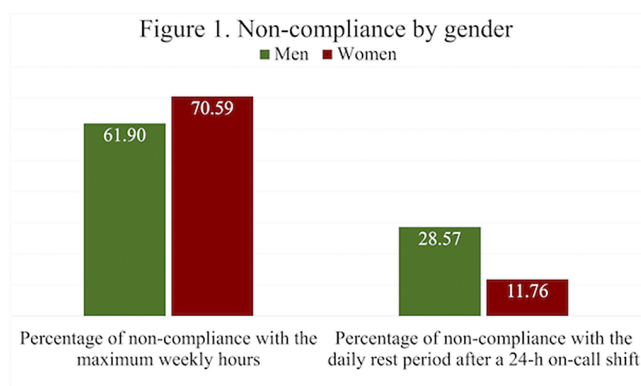

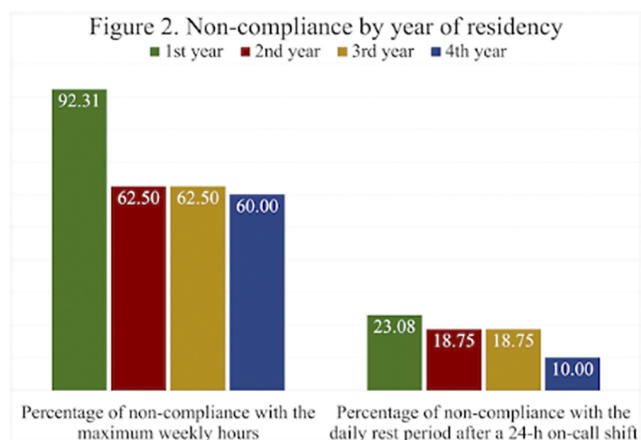

Image 2:

Conclusions: Psychiatry resident physicians in Spain greatly exceed the established 48 h/week EWTD limit. Likewise, non-compliance with labour regulations regarding mandatory rest after on-call duty and minimum weekly rest periods are observed. Differences can be seen by gender and year of residency. The situation described could potentially create a high-risk situation for the health and psychosocial well-being of resident physicians, hinder learning outcomes and could lead to suboptimal patient care.

Differences in habenula and septal nuclei and resting state functional connectivity (RSFC) in the presence or absence of clinically significant insomnia in patients with MDD

J.-M. Heo^{1*}, S.-G. Kang², S.-E. Cho¹, C.-K. Kang³ and J.-Y. Jung²

¹Psychiatry, Gil Medical Center, Gachon University College of Medicine; ²Health Science, Gachon University Graduate School and ³Radiological Science, College of Health Science, Gachon University, Incheon, Korea, Republic Of

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.810

Introduction: There are differences in clinical presentation with and without insomnia in MDD, and it is expected that there are brain biological differences that contribute to this, but functional MRI studies of MDD with insomnia vs MDD without insomnia are scarce. In particular, few studies have examined resting state functional connectivity (RSFC) seeding the habenula and septal nuclei, which play key roles in both mood and sleep.

Objectives: The purpose of this study is to determine whether there are differences in habenula and septal nuclei and RSFC in the presence or absence of clinically significant insomnia in patients with MDD.

Methods: To identify the effects of insomnia in MDD group, one-way ANCOVA covariate control was used to compare differences of RSFC between MDD_w/INS and MDD_wo/INS group. The potential confounders (i.e., age, sex, education years, and total score of HDRS-17) were adjusted in this analysis. To examine the relationship between RSFC and clinical sleep questionnaires (i.e., ISI and PSQI) in the participants with MDD, Pearson's partial correlation analysis controlling same potential confounders was performed by using Fisher-transformed correlation coefficients and scores of ISI and PSQI. For comparing the difference of RSFC between MDD and HC, the analysis was also performed with ANCOVA controlling for age, sex, education years.

Results: The analysis in this study included 36 in the MDD_w/INS group, 21 participants in the MDD_wo/INS group, and 38 in the healthy controls (HC) group. The main finding of this study was that MDD with insomnia showed increased RSFC in Habe_L - Rolandic_Oper_R, Habe_L - Cuneus_R, Habe_R - Thal_Pul_R,

and decreased RSFC in Septal - Cerebellum_Crus1_R compared to MDD without insomnia. All regions with significant results were significantly correlated with insomnia severity.

Conclusions: Since the RSFC of all pairs of regions that showed significant differences between the two groups in this study were significantly correlated with insomnia severity (i.e., ISI score), the association of these regions with insomnia in MDD is supported. The significance of this study is that there have been studies that have examined the RSFC in fMRI for insomnia, but there are few studies on MDD with insomnia, and since the habenula and septal nuclei play an important role in insomnia, sleep, and mood, it is meaningful to seed fMRI studies on these areas.

EPP0736

The relationship between neurotrophins and cognitive functions in the context of emotional response to sleep deprivation

M. Ditmer¹, A. Binienda², A. Tarasiuk², A. Gabryelska¹, P. Białasiewicz¹, S. Turkiewicz¹, F. F. Karuga¹, J. Fichna² and M. Sochal^{1*}

¹Department of Sleep Medicine and Metabolic Disorders and ²Department of Biochemistry, Medical University of Lodz, Lodz, Poland

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.811

Introduction: Studies conducted up to date on the subject of deprivation of sleep (DS) primarily focused either on its impact on certain cognitive abilities or mood-enhancing effects in patients with depression. A notable body of evidence suggests that both might be related to alterations in neurotrophin synthesis induced by DS. However, the role of NTs as an interface between DS, mood, and cognitive functions is unclear.

Objectives: The study aimed to investigate associations between cognitive abilities measured by Trail Making Test (TMT) and Stroop Color and Wort Test (ST), serum protein concentrations of brain-derived neurotrophic factor (BDNF), glial cell line-derived neurotrophic factor (GDNF), neurotrophin-3 (NT3), neurotrophin-4 (NT4) as well as the expression of their respective genes after a night of sleep deprivation.

Methods: Each participant (n=76) underwent a 24-hour DS under the control of actigraphy. Venous blood collection, TMT, and ST were carried out in the morning after DS. Mood was evaluated twice, after DS and in the preceding evening; based on the alleviation of depression symptoms participants were divided into respondents (RE; n=47) and non-respondents (NR; n=29). Serum protein concentration was determined using ELISA kits. Gene expression was evaluated by quantitative real-time polymerase chain reaction with gene-specific probes (reference gene: β -actin). Relative expression was calculated using the Livak formula. TMT is a neuropsychological instrument; Part 1 is thought to evaluate mostly attention, whereas Part 2 executive functions. ST is a 2-part

test applied in the assessment of response inhibition and complex attention.

Results: In RE, cognitive abilities were not associated with expression levels of any of the studied proteins or mRNA (all $p > 0.05$). In NR, BDNF and GDNF mRNA expressions negatively correlated with TMT Part 1 ($p = 0.017$, $p = 0.048$, respectively); scores obtained in TMT Part 2 bore a similar relation to BDNF, GDNF, and NT4 mRNA ($p = 0.034$, $p = 0.041$, $p = 0.026$, respectively). In this group, expression of all BDNF, GDNF, NT3, NT4 mRNA correlated negatively with both parts of ST ($p < 0.001$, $p = 0.009$, $p = 0.042$, $p = 0.009$ for Part 1; $p < 0.001$, $p = 0.003$, $p = 0.031$, $p = 0.014$ for Part 2, respectively).

Conclusions: Those results suggest that alterations in the synthesis of NTs might be an element of the molecular milieu characterizing different types of DS response. Negative correlations between test scores and NT mRNA expressions could imply that the reduction of the production of NT proforms might protect against the decline of cognitive functions in the aftermath of DS. Projects using a larger battery of tests as well as analyzing immature forms of NTs would be desirable in order to further investigate mechanisms underlying DS response.

Impact of Palestine-Israel War on Tunisian People's Sleep

N. Messedi¹, M. Sehli^{1*}, F. Guermazi¹, I. Chaari¹, F. charfeddine¹, L. Aribi¹ and J. Aloulou¹

¹Psychiatry B, Hedi Chaker University Hospital of Sfax, sfax, Tunisia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.812

Introduction: The Palestine-Israel War has reverberated across borders, transcending boundaries to affect individuals far beyond the conflict zone.

While much attention has been rightfully directed toward the immediate physical and psychological consequences within the war-torn regions, there is a growing need to explore the broader impact on the mental health of populations in neighboring countries including the sleep disorders among the Tunisian population during this war.

Objectives: To study the sleep disorders in Tunisian people related to the extensive war news broadcasting and to identify the factors associated to it.

Methods: It was a cross-sectional, descriptive and analytical study, conducted among Tunisians. Data were collected during October and November 2023, through an anonymous online questionnaire, spread throughout social media (Facebook/Instagram), using the Google Forms® platform. We used a socio-demographic and clinical data sheet and the Insomnia Severity Index (ISI) to measure the severity of insomnia.

Results: A total of 1091 participants completed the questionnaire. The participants' mean age was 32.7 ± 9.8 years, with a sex ratio (F/M) = 3.5.

The study revealed that 100% of the respondents followed the war, predominantly relying on social media (98.6%) with 55% closely monitoring the war via the media during more than 3 hours per day. 74.1% of the participants were Religious practitioners According to the (ISI): a significant insomnia was found in 75.2% of participants. The breakdown of insomnia severity indicated that 47.3% experienced subthreshold insomnia, 25.7% clinical insomnia of moderate severity, and 2.2% clinical insomnia of severe intensity. The factors significantly associated with severe insomnia were: a male population (p=0.018) and an increase in religious practices (p=0.031).

Conclusions: The impact of the Palestine-Israel war on Tunisian individuals' sleep patterns, predominantly mediated through increased exposure via social media with using increase in religious practices as a possible coping mechanism. The study highlights support initiatives to address the psychological repercussions of international conflicts on mental health. This suggests the importance of applying sleep hygiene rules and screening for sleep disorders.

Insomnia and Its Association with Successful Aging in the Older Indian Population: A Large Population-Based Study Based on LASI, Wave 1

S. Leng^{1*}, Y. Jin² and X. Tang¹
¹Sleep Medicine Center, Mental Health Center, Department of Respiratory and Critical Care Medicine and ²Department of Urology, West China Hospital, Sichuan University, Chengdu, China
*Corresponding author.
doi: 10.1192/j.eurpsy.2024.813

Introduction: Evidence regarding the link between insomnia and successful aging (SA) in the older generation remains scarce.

Objectives: The purpose of this study is to explore the relationship of insomnia with SA within a substantial sample of the community-dwelling Indian population.

Methods: Data were drawn from the Longitudinal Ageing Study in India (LASI), Wave 1, conducted during 2017-2018. Older participants aged 60 years and above who completed both the insomnia and SA surveys were included. Insomnia was determined by the presence of at least one of three symptoms: 1) difficulty in initiating sleep; 2) difficulty in maintaining sleep; or 3) early morning awakening, occurring 5 or more times per week. SA was

assessed by five components: 1) absence of chronic diseases; 2) low probability of disability; 3) high cognitive functionality; 4) low probability of depression; and 5) active social engagement. The association between insomnia and SA was examined through survey-weighted multivariable logistic regression, with adjustments made for potential covariates. Subgroup analyses were carried out to evaluate interactions with age, sex, alcohol use, and smoking status.

Results: A total of 31362 participants met the eligibility criteria. The overall weighted prevalence was 9.91% for insomnia and 23.94% for SA. In fully adjusted models, insomnia exhibited a negative association with SA (OR 0.70; 95% CI 0.63-0.78, see Table 1) and with each of SA's components, except for the absence of chronic diseases (OR 0.94; 95% CI 0.85-1.04, see Table 1). Subgroup analyses, stratified by age, sex, alcohol use, or smoking status, did not reveal any significant interactions between insomnia and SA (p for interaction = 0.098, 0.873, 0.704, 0.095, respectively).

Table 1. Relationship between insomnia and successful aging.

Insomnia	ORs (95% CIs)		
	Unadjusted model	Model 1	Model 2
No	Reference	Reference	Reference
Yes			
Successful aging	0.50 (0.45, 0.55)	0.54 (0.49, 0.60)	0.70 (0.63, 0.78)
Absence of chronic diseases	0.66 (0.61, 0.71)	0.65 (0.60, 0.70)	0.94 (0.85, 1.04) [†]
Low probability of disability	0.43 (0.40, 0.46)	0.45 (0.42, 0.49)	0.51 (0.47, 0.55)
High cognitive functionality	0.66 (0.61, 0.72)	0.75 (0.68, 0.83)	0.78 (0.71, 0.87)
Low probability of depression	0.33 (0.30, 0.36)	0.34 (0.31, 0.38)	0.38 (0.34, 0.42)
Active social engagement	0.79 (0.73, 0.86)	0.87 (0.80, 0.95)	0.86 (0.78, 0.94)

[†] p > 0.05; ORs, odds ratios; 95% CIs, 95% Confidence intervals. Model 1 adjusted for: age, sex, level of education, work status, marital status, place of residence, economic status, caste; Model 2 adjusted for: model 1 plus body mass index (BMI), alcohol use, smoking status.

Conclusions: Insomnia was negatively linked with SA within the older Indian population. Future prospective studies are warranted to validate these relationships, investigate underlying mechanisms, and enhance the understanding and promotion of SA.

Use of videogames, Internet Gaming Disorder, and Agressiveness in Emerging Adulthood

D. Silva¹ and B. R. Maia^{2*}

¹Universidade Católica Portuguesa and ²Universidade Católica Portuguesa, Center for Philosophical and Humanistic Studies, Braga, Portugal

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.814

Introduction: Internet gaming disorder has been associated with an excessive number of hours spent playing video games, which leads to a detriment of other daily activities and interests. In addition, it is associated with personality traits such as aggression and anger. In Portugal this relations are almost unexplored.

Objectives: To explore the relationship between video game use, internet gaming disorder and aggression.

Methods: This study was applied to a sample of 202 subjects, aged between 18 and 29 years old ($M = 22.5$, $SD = 3.006$). Subjects fulfilled a sociodemographic and videogame pattern questionnaire, and the Portuguese versions of the Internet Gaming Disorder Scale (short form), and the Buss-Perry Aggressiveness Questionnaire.

Results: In this study 20.3% ($n = 27$) of the males and 5.8% ($n = 4$) of the females use excessively videogames, considering the screen time recommended by the American Academy of Pediatrics. However, 81% ($n = 70$) of the sample have a positive self-perception of their use. 21.4% ($n = 45$) use videogames during day, 71% ($n = 49$) during night and 3.8% ($n = 8$) during dawn. The total score for internet gaming disorder was of 15.17 ($SD = 6.006$), but only 1 subject (0.5%) presented probable videogame disorder considering the cut-off points. A positive and significant correlation was found between internet gaming disorder and physical aggressiveness (.32**), verbal aggressiveness (.28**) and hostility (.45**). Finally, a positive correlation was found between internet gaming disorder and time spent playing video games.

Conclusions: Our results, despite being merely exploratory, show us the relationship that exists between the use of video games, internet gaming disorder and aggressiveness. In that sense it is important to continue to explore internet gaming etiology and consequences.

Alcohol addiction treatments for home resident in Switzerland: review and results of a transectional study

I. Gothuey^{1*} and F. Masdea²

¹Adult Psychiatric Sector and ²Old person psychiatric sector, Firourg Mental Health Network, Marsens, Switzerland

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.815

Introduction: In Switzerland, alcohol consumption is even decreasing, with an exception for old people after retirement. 35% of them have a heavy or addictive consumption (OFSP, consommation d'alcool en Suisse, fait et chiffres. 01.2023). This is also the case for home residents. The alcohol consumption by old people has negative consequences on the health (falls, fractures, cognitive disorders).

The authors conduct a cross-sectional enquiry in the homes of Fribourg area to identify addictive behaviour and different existing supports. After a review, the authors present the results of their enquiry

Objectives: Identify how much home-residents have a problematic or an addictive alcohol problem

Identify if there is existing support
Hinghlighting the training need for the staff

Methods: Crossectionnal enquiry was sent in 42 Home of the
Fribourg area, with 3 relances

Results: The preliminary result will be completed at the end of
2023:

- Every home identify at least 4-5 residents with a problematic alcohol consumption
- Most of them, the staff have no specific addictive training and no needs for it
- The staff authorise alcohol consumption in the home, to avoid alcohol withdrawal
- The psychiatric consultant in the home can help the staff to manage the counter-attitudes

Home residents are not eligible for specialized addictive care, while the generally respond well to motivational interviewing or to controlled consumption. The lack of staff training could be an hypothesis. The lack of interest in the negative consequences of alcohol on the health of people at the end of their lives is another hypothesis

Conclusions: Nursing home residents are not eligible for specialized addictive care. The enquiry results are astonishing: no need of specialized training, authorization of continuous drinking in the different homes, while the literature points to the effectiveness of motivational interviewing or controlled approaches by old people with addictive disorders.

Further studies are needed, ethical consideration on the management of alcohol addiction in the elderly should be proposed.

Cannabinoid syndrome in cannabis dependence: a case report

C. Pichilingue Reto*, A. M. Jose Rojo and M. B. Carrillo Reche

Psychiatry, Benito Menni CASM, Barcelona, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.816

Introduction: A 36-year-old man with a history of cannabis use disorder since age 16, consuming 8-10 units/day, experienced irritability and tremors upon reducing consumption. His psychiatric issues emerged in 2020, marked by anxiety, abdominal pain, and severe vomiting, leading to a dyspepsia diagnosis. Subsequently, he received psychiatric care at CAS Hospitalet, diagnosed with severe cannabis use disorder. No prior inpatient admissions occurred.

Objectives: Our project aims to show a case report and summarize the available evidence on cannabinoid hyperemesis syndrome (CHS).

Methods: In May 2023, he voluntarily sought admission to Barcelona's "Hospital Sant Pau," aiming for cannabis detox and treatment of cannabinoid hyperemesis. He'd endured years of intense abdominal pain, nausea, and vomiting, worsening over the last two years, with uncontrollable vomiting hindering daily life. Admission saw reduced cannabis use to 3-4 units/day. Inpatient care revealed anticipatory anxiety, rumination, and somatic anxiety, accompanied by distal tremors and internal restlessness due to abdominal discomfort, partially alleviated by 5-10 mg of diazepam.

Results: Treatment included domperidone 10mg/8h, haloperidol drops (5-10 drops/8h), capsaicin ointment, hot showers, and cryotherapy, resulting in gradual relief from abdominal pain. Moderate cravings for tobacco and cannabis led to acetylcysteine 600mg/12h and gabapentin up to 1200mg/8h. Gastric discomfort with SSRIs led to vortioxetine 10 mg/day, well-tolerated with a positive response. Consultation with the GI department confirmed the treatment's efficacy, emphasizing cannabis abstinence. Upon discharge, cannabinoid hyperemesis symptoms markedly improved, and the patient was referred to "Hospital de Dia."

Conclusions: CHS is a cyclic vomiting syndrome, preceded by daily to weekly chronic longstanding use of cannabis that can be difficult to diagnose and treat (1,3,4). It is unique in presentation, because of the cannabis's biphasic effect as anti-emetic at low doses and pro-emetic at higher doses, and the association with pathological hot water bathing (2). The major characteristics are as follows: history of regular cannabis for any duration of time (100%), cyclic nausea and vomiting (100%), resolution of symptoms after stopping cannabis (96.8%), compulsive hot baths with symptom relief (92.3%), male predominance (72.9%), abdominal pain (85.1%), and at least weekly cannabis use (97.4%) (1). Treatments such as topical capsaicin, haloperidol, benzodiazepines, and propranolol have shown symptom relief (3) whereas opioids should be avoided (4). Cannabis cessation appears to be the best treatment (1,3).

The role of the occupational therapist in treatment of patients with prescription medicine dependence

D. Iskendri^{1,2,*} and L. Štátná¹

¹Department of Addictology, Charles University, First Faculty of Medicine in Prague, Prague and ²University of West Bohemia, Faculty of Health Care Studies, Pilsen, Czech Republic

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.817

Introduction: The abuse of prescription drugs (especially sedatives, hypnotics and opioid analgesics) is a serious and increasingly common phenomenon occurring across addiction clinics. Medications are prescribed for the treatment of chronic pain, sleep difficulties or as mood stabilisers in response to the rush of time and demands of performance. The onset of addiction is often protracted and subtle, but has a major impact on the quality of life and the health, economic or social status of the user. Patients may experience, among other things, cognitive impairment, fatigue, sleep disturbances, irritability, loss of motivation, headaches or impaired coordination of movements. This study is focused on cognitive impairment due to prescription drug dependence and how this impairment affects patients in everyday life.

Objectives: This poster aims to introduce the audience to the possibilities of occupational therapy intervention in the context of addiction medicine.

Methods: Data will be taken using standardized tests and questionnaires dealing with cognitive function. It will be conducted upon the patient's admission to addiction treatment and again after six months of cognitive rehabilitation following the initial survey. Data are collected at the General University Hospital in Prague, Department of Addictology, Prague, Czech Republic.

Results: Data are being collected.

Conclusions: The case study manifests multidisciplinary approach in care of patients addicted of prescription medicine. The aim is a comprehensive view of all aspects of the patient's life affected by prescription drug abuse with cognitive impairment.

Grant affiliation: This paper was made possible by the institutional support programme Cooperatio, research area Health Sciences and Grant No. 260632 within the Specific Academic Research.

Psychoactive substance disorder: first experience In a comprehensive model of harm reduction model in Bogotá Colombia, 2017-2021

A. S. Quesada^{1*} and M. Cote^{2,3}

¹Psiquiatría, Universidad de los Andes; ²Psiquiatría, Universidad Nacional de Colombia and ³EPS Sanitas, Psiquiatra de adicciones de adicciones, Bogotá, Colombia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.818

Introduction: In Colombia the traditional treatment model implies the needing of a total cessation of consume to be able to access an inpatient and long stance rehabilitation program. However, literature in other countries experiences had suggested and used a harm reduction program with an outpatient rehabilitation program.

As this programs are more cost-effective and enables the patient to continue his daily life, perpetuate his life style, keep and enhance the psychosocial network, an outpatient comprehensive multimodal program was designed to adapt to a health promotion company (EPS for its Spanish acronym) and has been used since 2017.

Objectives:

- share the experience acquired in an undeveloped country of Latin America
- The typification in the main substance consumption in the development group as well as its differentiation in gender and age group

Methods: Experience and results

Results:

- The majority of patients are men over women
- the predominant age group is between 29-59 years old
- there is a difference between the age group depending on the substance of impact

Conclusions: The experience has shown that up to 30% of the population treated have gotten to a controlled consumption or the total suspension without the needing of an inpatient program. In general, the patient has shown motivation and adherence to an outpatient program.

Spironolactone in Alcohol Use Disorder (SAUD): Introduction to an ongoing double-blind, placebo-controlled, ascending dose, Phase 1b study

A. Leko^{1,2*}, M. Farokhnia¹, S. T. Weiss¹, C. A. Blake¹,
L. A. Farinelli¹ and L. Leggio¹

¹Translational Addiction Medicine Branch, NIDA and NIAAA, Baltimore and Bethesda, United States and ²Department of Psychiatry and Psychotherapy, Semmelweis University, Budapest, Hungary

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.819

Introduction: Efforts are critically needed to increase the armamentarium of options that clinicians can use to treat patients with alcohol use disorder (AUD). Numerous preclinical studies support the hypothesis that mineralocorticoid receptor (MR) pharmacological antagonism may represent a novel and promising treatment for AUD. Namely, the non-selective MR antagonist spironolactone dose-dependently decreased 1) the intake of alcohol in mice in a model of alcohol binge drinking procedure and 2) alcohol self-administration in dependent and non-dependent rats (Farokhnia, Rentsch, Choung *et al.*, *Mol Psychiatry* 2022; 27(11):4642-4652). Furthermore, two U.S.-based independent human pharmacoepidemiologic studies utilizing electronic health records data showed that patients treated with spironolactone for any indication reduced their weekly alcohol use in a primary care-type medical setting (Palzes *et al.*, *Neuropsychopharmacology* 2021; 46(12):2140-2147) and Alcohol Use Disorders Identification Test-Consumption (AUDIT-C) score in a Veterans Affairs medical setting (Farokhnia, Rentsch, Choung *et al.*, 2022; 27(11):4642-4652). In both studies, spironolactone-treated patients were compared to matched ones without spironolactone prescription using propensity score matching.

Objectives: We are conducting a Phase 1b human study to assess the pharmacokinetics and pharmacodynamics of spironolactone-alcohol co-administration and testing the safety and tolerability of spironolactone, alone and combined with alcohol in individuals with AUD.

Methods: Spironolactone in Alcohol Use Disorder (SAUD) is a double-blind, placebo-controlled, randomized, within-subject, ascending dose study with spironolactone (0, 100, 200, 400 mg/day) PO for 5 days to reach steady-state, followed by oral fixed-dose alcohol administration aimed at reaching a blood alcohol level of approximately 0.08 %. Our sample consists of 12 adults diagnosed with AUD.

Results: The primary endpoint is to measure spironolactone and alcohol PK during concomitant administration. Our secondary endpoints are 1) assessment of subjective and cognitive effects of acute alcohol administration during concomitant spironolactone treatment; 2) number and severity of adverse events (AEs) experienced, compared between placebo (0 mg/day) and all three spironolactone doses; 3) PK characteristic of spironolactone active metabolites, canrenone, 7- α -thiomethylspironolactone (TMS) and 6 β -hydroxy-7 α -thiomethylspironolactone (HTMS), before and after administration of alcohol. Recruitment is underway.

Conclusions: The above-mentioned preclinical and clinical evidence suggest that spironolactone may be repurposed for the treatment of AUD. Our Phase 1b study is a key step before moving to larger efficacy trials.

From wernicke-korsakoff to central pontine myelinolysis: the potentially irreversible risks of alcohol use

A. F. Silva*, R. M. Lopes, V. S. Melo, C. A. Rodrigues, P. M. Coelho, F. M. A. Santos, I. S. Fernandes and L. P. Delgado

Psychiatry and Mental Health Department, Centro Hospitalar Médio Tejo, Tomar, Portugal

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.820

Introduction: Sustained alcohol intake, when combined with incomplete treatment, can result in chronic structural changes in the Central Nervous System, including generalized cortical and cerebellar atrophy, amnesic syndromes like Korsakoff's syndrome, and white matter disorders such as Central Pontine Myelinolysis and Marchiafava-Bignami syndrome. It is crucial to prevent these complications due to their potential for irreversible and debilitating consequences. For Wernicke-Korsakoff syndrome, early recognition and thiamine administration for prevention are paramount, as it arises from thiamine deficiency due to malnutrition caused by persistent alcohol use. In the case of Central Pontine Myelinolysis, which is caused by abrupt fluctuations in serum osmolality, controlled sodium correction is essential.

Objectives: Through a clinical case and a review of published literature, this study aims to reflect on the importance of preventing neurological injuries associated with chronic alcohol consumption, specifically Wernicke-Korsakoff Syndrome and Central Pontine Myelinolysis.

Methods: A literature review was conducted by searching for articles on PubMed using the terms "Alcohol Use Disorder," "Wernicke-Korsakoff syndrome," and "Central pontine myelinolysis." A clinical case is presented, featuring a 50-year-old patient with alcohol use disorder who developed Wernicke-Korsakoff syndrome and Central Pontine Myelinolysis. Considering this case, we reflect on the primary approaches that could have been beneficial in preventing these complications and propose a straightforward method for doing so.

Results: A 50-year-old patient presented with poor general condition, characterized by low weight, significant loss of strength in the limbs and arms, and incoherent speech with anterograde amnesia and confabulation. This condition had progressed to a point where the patient could no longer walk, perform basic self-care tasks such as bathing, dressing, and eating independently, underscoring the severity of his condition. The diagnoses of Wernicke-Korsakoff syndrome and Central Pontine Myelinolysis were established based on clinical manifestations and the presence of hyperintense lesions observed in the central pons on T2/FLAIR axial MRI scans. This clinical case highlights the importance of proper and precocious prevention of complications in patients with alcohol use disorder. The foremost step in preventing these complications is to treat alcohol dependence effectively, even when faced with patient resistance. It's vital to remain vigilant about potential complications and implement suitable prophylactic measures.

Conclusions: The devastating effects of complications arising from Alcohol Use Disorder, such as Wernicke-Korsakoff syndrome and Central Pontine Myelinolysis, underscore the importance of

enhanced attention that clinicians should provide when approaching these patients at all clinical interactions.

Different facets of addiction from a systemic perspective: a case report

A. Osiak*, U. Altunoez, M. Anthoff, G. Rietig, M. Bald, S. Akbas and I. T. Graef-Calliess

KRH Wunstorf Psychiatric Hospital, Wunstorf, Germany

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.821

Introduction: Many individuals who suffer from one or multiple substance use disorders often also struggle with another co-morbid psychiatric condition, primarily anxiety disorders. As substance dependency develops, the loss of self-control becomes a pivotal issue, leading to challenges in self-esteem and self-respect. These challenges subsequently give rise to problems in interpersonal communication and close relationships. In addition to the biological model of substance use problems and highly manualized approaches, it is crucial to have a systemic understanding of the patient's situation and appropriate treatment settings. This understanding allows for the proper consideration of individual differences and requirements, ultimately enabling better treatment and prevention strategies.

Objectives: Our aim is to present a comprehensive case that shows various facets of addiction and introduce a systemic therapy concept of an integrative/systemic day clinic from Germany.

Methods: Through a detailed case presentation, we will introduce a systemic-psychotherapeutic day-clinic concept from a psychiatric training hospital in Wunstorf, Germany.

Results: Case: In the case of a 48-year-old female patient initially diagnosed with recurrent depressive disorder, it was later revealed that she also deals with alcohol addiction and its interconnectedness with sex addiction. Shame and a lack of self-esteem in relationships played a central role in her journey. She does not perceive herself to be loved but to be harmed, which led to many violent sexual acts that increased her feelings of shame. Systemic therapeutic approaches like family constellations were applied, helping her to experience her child-ego states. This profound insight propelled her willingness to change. She began prioritizing self-care, learning to like, accept, and eventually love herself. Aromatherapy aided in calming and maintaining focus. The patient learned to redefine her emotions, aligning them with reality, thereby enabling the adaptive fulfillment of her needs.

Conclusions: Our interdisciplinary team at the day clinic employs therapeutic approaches like dynamic, cognitive-behavioral, and systemic therapy to thoroughly understand the patients and their conditions. This case underscores the significance of an individually tailored treatment drawing from diverse therapeutic concepts, especially in patients with addiction. The combination of different therapeutic approaches facilitates a profound engagement with the patient, potentially resulting in more intensive therapeutic work and a higher rate of success which should be evaluated in future studies.

Women's addiction : experiences at Arrazi Psychiatric Hospital in Morocco

A. KHALLOUK

Arrazi Psychiatric Hospital, salé, Morocco

doi: 10.1192/j.eurpsy.2024.822

Introduction: Drug addiction, also called substance use disorder, is a disease that affects a person's brain and behavior and leads to an inability to control the use of a legal or illegal drug or medicine. there is a complex interplay of neurobiology, genetics, and the environment –nature and nurture– that play into the development of addiction, alcohol, and other drug use disorder. Substances such as alcohol, marijuana and nicotine also are considered drugs. Research has shown that women often use drugs differently, respond to drugs differently, and can have unique obstacles to effective treatment as simple as not being able to find child care or being prescribed treatment that has not been adequately tested on women.

Objectives: describe the socio-demographic and clinical characteristics of female patients admitted to the addictology department of Arrazi Hospital in Salé

Methods: Retrospective study with descriptive and analytical aims on the files of women who were admitted to the addictology service since its opening in 2000, with the aim of specifying the prevalence and the characteristics of addictive behaviors in the female population.

Results: in progress

Conclusions: in progress

Combating Gaming Disorder in 2024: A Survival Manual

D. M. Ribeiro* and D. Teixeira

Departamento de Psiquiatria e Saúde Mental, Centro Hospitalar Universitário do Algarve - Hospital de Faro, Faro, Portugal

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.823

Introduction: Gaming Disorder (GD) has not been officially recognized as a diagnostic entity in the DSM-5, being listed in the “conditions for further study” section. However, it is described in the ICD-11, and clinically, it is observed that an increasing number of individuals, particularly the younger population with easier access to technology, are affected by this issue. Nefarious consequences include loss of performance at school/work and a potential for failing other responsibilities such as in the familiar and social spheres.

Objectives: Despite its harm, psychiatrists are generally less familiar with this entity when compared to other psychiatric disorders. Thus, our main goal was to establish a comprehensive and holistic review of its approach.

Methods: A bibliographical research on the topic was conducted from the available scientific literature on the topic, with the utmost prioritization of evidence-based sources.

Results: The overall prevalence of Gaming Disorder is challenging to assess precisely, but it is estimated to be around 3%, making it comparable to obsessive-compulsive disorder and some substance use disorders. It is more common than pathological gambling. Clinically, GD is characterized by an excessive preoccupation with gaming that supersedes all aspects of life. It may also involve a compulsion to play and the presence of withdrawal symptoms from periods when there are no gaming activities. The behavior is driven by the ACE triad (anonymity, convenience, and escape). Often, individuals with GD do not seek treatment. Although there are no specific pharmacological agents, antidepressants, mood stabilizers, and naltrexone have shown some success. In psychotherapies, cognitive-behavioral therapy has the strongest evidence.

Conclusions: There is a limited amount of information on GD, and when researching the topic, one primarily encounters information on other substance-related addictive disorders and, in the case of behavioral disorders, gambling. However, as young people are increasingly exposed to screens and video games with potential harmful effects on their development, and in adults, inhibiting them from taking on work and family responsibilities, it is essential to conduct more studies on the subject to prevent these deleterious consequences.

Alcohol withdrawal seizures, epilepsy and brain trauma

G. Dzhupanov¹*, V. Nikolov¹ and G. Slaveykov²

¹State psychiatric hospital for treatment of drug addiction and alcoholism and ²University multiprofile hospital for active treatment in neurology and psychiatry St Naum, Sofia, Bulgaria

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.824

Introduction: Alcohol addiction can lead to withdrawal seizures, but most patients do not develop epilepsy. In some cases a permanent complication occurs - symptomatic epilepsy. In other cases epilepsy precedes alcohol addiction. Comorbidity may pose serious challenges to treating clinicians. There are conflicting data regarding relationship between alcohol use, seizures and epilepsy (Scorza CA et al., CLINICS 2020;75:e1770). Other factors like brain trauma may have impact in genesis of epileptic states as well.

Objectives: Evaluation of interplay between seizures, epilepsy and brain trauma in patients with alcohol use disorder.

Methods: Analysis of a case series in a hospital setting and review of relevant literature.

Results: In our series of cases the number of patients who have suffered epilepsy before the onset of alcohol use is small. In most of the hospitalized patients epilepsy occurred after the development of alcohol use disorder. In this group we observed that head and brain trauma play role in genesis of seizures and epilepsy and in some instances the reverse happens.

Conclusions: Our data indicate the potential role of brain trauma as predisposing and complicating factor in patients who developed seizures and epilepsy. Seizures sometimes increase the risk of brain trauma. Seizures and trauma are important factors in typology of Lesch (Lesch et al. 2011) and a serious evaluation in this direction is important, because its diagnostic, therapeutic and prognostic implications. Further clarification in this field is necessary.

Addiction to budda blues : About 2 clinical cases

I. Belabbes

arazi hospital, sale, Morocco
doi: 10.1192/j.eurpsy.2024.825

Introduction: Buddha Blue, or PTC for “Pète Ton Crâne”, is a synthetic drug particularly popular with young people. It is sold as a liquid to be inhaled in electronic cigarettes.

Objectives: To discuss the clinical manifestations and psychopathology associated with PTC.

Methods: We shed light on PTC addiction through clinical vignettes of patients who were hospitalized in pediatrics at the Gonesse hospital.

Results: We received two male patients with manifestations of PTC intoxication or withdrawal. One of the patients presented with an acute delirious flush requiring long-term treatment, while the second presented with somatic manifestations of pain and vomiting, as well as psychiatric manifestations such as hallucinations, without meeting the criteria for a psychiatric disorder. Both cases required addictological follow-up and child psychiatric therapy.

Conclusions: PTC addiction can lead to life-threatening complications, hence the importance of prevention and screening in order to institute early and effective treatment.

Prevalence and factors associated with smoking among university staff

I. Sellami^{1,2*}, A. Feki^{2,3}, A. Abbes¹, M. Masmoudi¹, M. Hajjaji¹ and K. Jmal Hammami¹

¹Occupational medicine, Hédi Chaker Hospital; ²Medecine university and ³Rheumatology, Hédi Chaker Hospital, Sfax, Tunisia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.826

Introduction: Smoking among university professionals could influence student smoking behavior, making it important to understand the associated factors to prevent this phenomenon.

Objectives: To determine the prevalence of smoking among University staff in Sfax, Tunisia, and identify its associated factors.

Methods: We conducted a cross-sectional survey using a self-administered questionnaire distributed to 100 university staff. The questionnaire included socio-professional characteristics, assessment of physical workload using the Borg CR-10 scale, and evaluation of nicotine dependence using the Fagerström test.

Results: Our study included 62 participants, with 67.7% of them being women. Active smoking was reported by 50% of male participants. We observed symptoms of severe to very severe depression, anxiety, and stress in 6.4%, 22.5%, and 9.7% of our participants, respectively. Nicotine dependence, as assessed by the Fagerström test, was high to very high in half of the smokers. Bivariate analysis

indicated a significant association between smoking and male gender, perceived workload (33.9%), and body mass index.

Conclusions: Smoking among university staff is a prevalent phenomenon, especially among male participants. The association of smoking with perceived workload suggests the need for preventive measures to reduce these physical constraints. It is paramount to take actions to encourage smoking cessation among university staff.

Smoking Prevalence and its Association with Work-Related Factors in an Electricity and Gas Company

I. Sellami^{1,2*}, A. Feki^{2,3}, A. Abbes¹, M. A. Ghrab¹, K. Jmal Hammami¹, M. L. Masmoudi¹ and M. Hajjaji¹

¹Occupational medicine, Hedi Chaker Hospital; ²Medecine university and ³Rheumatology, Hedi Chaker Hospital, Sfax, Tunisia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.827

Introduction: In the workplace, a smoke-free environment is crucial to guaranteeing the health of workers and those around them. Understanding the relationship between smoking and work is a prerequisite for implementing effective tobacco control measures.

Objectives: To assess the prevalence of smoking in an electricity and gas company in Sfax and to determine the relationship between workers' nicotine dependence and perceived workload.

Methods: We conducted a cross-sectional survey evaluating the smoking behavior of 100 employees of an electricity and gas company. The survey was carried out from July to December 2022 using a two-part questionnaire. The first part was completed by the participants, and the second was administered by the interviewer. Nicotine dependence was assessed using the Fagerström test, while perceived workload was evaluated using the raw NASA-TLX questionnaire.

Results: Our study population consisted of 82 male participants. Active smoking was reported by 45.1% of participants. Among smokers, 40.5% had moderate to high nicotine dependence as assessed by the Fagerström test. According to the raw NASA-TLX questionnaire, the mean scores for mental, physical, and temporal demands were 88.8±13.5, 63.6±24.7, and 59.1±28.4, respectively. The mean scores for effort, performance, and frustration were 83.8±14, 85.4±13.1, and 34.5±28.1, respectively. Bivariate analysis indicated an inverse correlation between nicotine dependence and physical demands at work. However, a significant positive correlation was found between nicotine dependence and frustration at work.

Conclusions: Smoking among electricity and gas company workers is a prevalent issue, highlighting the urgent need for smoking cessation interventions. The association of smoking with perceived workload underscores the importance of preventive measures to reduce work-related stress.

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.828

Introduction: Internet use can become uncontrollable, leading to physical and psychological suffering and what is known as cyber-addiction.

Objectives: To assess the frequency of cyberaddiction in a population of young doctors.

Methods: We conducted a cross-sectional, descriptive study of a population of young doctors. We collected socio-professional and medical data using a Google Forms self-questionnaire. The Young scale was recommended for screening for cyberaddiction. A score ≥ 5 indicates Internet addiction. The Hospital Anxiety and Depression Scale (HAD) was adopted to reveal anxiety-depressive disorders.

Results: A total of 45 physicians responded to our survey. The mean age was 29.93 ± 4.8 years. The sex ratio (M/F) was 0.3. Participants were single in 69% of cases. Residents represented 64% of the population. Physicians were family medicine residents in 11% of cases. The mean Young's score was $3.13 \pm 1.97/8$. Cyberaddiction was noted in 24% of cases. A definite anxiety-depressive disorder was found in 6.7% and 13.3% of cases respectively. Internet addiction was significantly associated with female gender ($p < 0.05$) and a positive HAD (A) score ($p = 0.03$).

Conclusions: According to the results of our study, cyberaddiction is common among medical staff. A preventive strategy is needed to counter the harmful effects of this addiction.

Alcohol and tobacco dependence among medical practitioners

A. Belkahla¹, D. Brahim¹, I. Yaich^{2*}, C. Ben Said², A. Ghenim¹, M. Mersni¹, H. Ben Said¹, N. Mechergui¹, I. Youssef¹, G. Bahri¹, N. Bram² and N. Ladhari¹

¹Occupational pathology and fitness for work, Charles Nicolle Hospital, Tunis and ²Forensic Psychiatry department, Razi Hospital, Mannouba, Tunisia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.829

Introduction: Excessive use of tobacco, alcohol and other illicit drugs has a negative impact on the physical and mental health and work capacity of users. Physicians are no exception to these dreadful practices.

Objectives: To assess tobacco and alcohol use among medical staff and the factors associated with these uses.

Methods: Descriptive cross-sectional study of physicians practicing in different Tunisian hospitals. The levels of tobacco and alcohol dependence were assessed by the Fangerström and AUDIT tests. Anxiety and depression disorders were screened by the hospital anxiety and depression scale (HAD)

Results: A total of 45 physicians participated in our study. The average professional seniority was 3.36 ± 3.5 years. The mean age was 32.11 ± 6.08 years with a sex ratio (M/F) of 0.32. The participants were medical residents in 64% of the cases. The frequency of smoking was estimated at 24%. The level of smoking dependence was high in 9% of cases. Men were more addicted to nicotine than women ($p = 0.014$). Alcohol consumption was 18%, made up of 62% of women; with a strong dependence rate in 25% of users. Definite anxiety disorders were found in 7% of cases and definite depressive disorders were present in 13% of cases. No correlation between medical specialty, grade, anxiety disorders and level of dependence was observed.

Conclusions: Doctors seem to be particularly affected by addictive behaviours and psycho-emotional disorders which could sustain these practices. Awareness-raising sessions and special monitoring must be introduced to combat these scourges.

Prevalence and determinants of internet addiction among children with depression: A study in a school setting in Tunisia

K. Mayssa^{1*}, H. Imen¹, K. Ali¹, B. Jaweher¹, B. T. Donia¹, A. Hela¹, K. Khaoula¹ and M. Yousr¹

¹Department of Child Psychiatry, University Hospital of Hedi Chaker, Sfax, Tunisia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.830

Introduction: Child depression is a public health problem. Its association with internet addiction (IA) could increase the frequency of complications and have a significant impact on the child's psychological well-being, schooling, family and social life.

Objectives: To study the clinical profile and associated factors of IA in a population of primary school children with depressive disorders.

Methods: This was a descriptive and analytical cross-sectional study of 182 children with depression attending four primary schools in the government of Sfax. The study took place from 1 March 2022 to 30 June 2022. In the present study, we administered the following psychometric scales: Internet Addiction Test (IAT), Revised Children's Anxiety and Depression Scale (RCADS- 47), Birlson Depression Scale Questionnaire and the Rosenberg Self-Esteem Scale.

Results: The mean age of the children studied was 9.9 ± 1.17 years and the sex ratio was 0.8. Mean score of Internet Addiction Test was 40 ± 4.46 . In addition, Internet addiction was identified in 73.6% of students with depression ($N = 143$). Following a univariate analysis, internet addiction among depressed Childrens was positively correlated to individual factors such as the absence of leisure activity, the number of hours per day spent on the internet (1.63 VS 3.25 , $P < 0.001$) and interest in accessing Tiktok ($p = 0.002$). Internet addiction in depressed children also depended on family factors. Internet addiction was more common among childrens with a medium to

high family socio-economic level ($P < 0.001$) in cases where parent-child communication was deemed unsatisfactory ($P = 0.002$) and in cases of verbal violence ($P < 0.001$). We were also able to establish a significant link between internet addiction among depressed pupils and significant symptoms of anxiety ($P=0.019$) and low self-esteem ($P<0.001$). Multivariate analysis using binary logistic regression revealed that medium to high socio-economic level, unsatisfactory parent-child communication, absence of leisure activities and significant symptoms of social phobia were independent predictors of Internet addiction in children with depression.

Conclusions: Our study highlighted the high frequency of IA in children with depression and demonstrated the implication of certain variables such as medium to high socio-economic status, disruption of the family environment, anxiety and low self-esteem. The identification of these different factors would make it possible to identify a group at risk of IA. This raises the case for introducing prevention and awareness-raising campaigns on IA among depressed children, targeting these groups and targeting health professionals and parents.

Addiction and pregnancy: case report on gender perspective.

L. Bueno Sanya*, O. De Juan Viladegut, L. Olivier Mayorga, H. Andreu Gracia and P. Barrio Giménez

Psychiatry and psychology, Hospital Clínic de Barcelona, Barcelona, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.831

Introduction: In recent years, interest has grown in understanding the particularities of addiction in women. One of these singularities, with an important impact on public health, is pregnancy. Substance use during pregnancy has increased in recent decades. Given that addiction is mainly a chronic disease of the brain circuits of reward, motivation and memory, an event such as pregnancy does not exempt people who suffer from substance use disorder (SUD) from the difficulties of achieving abstinence. Moreover, as addiction often involves cycles of relapse and remission, pregnant women can also suffer a relapse even if they previously had achieved abstinence. On the other hand, given that addiction is a disease with a significant social component, we can find patients in precarious economic and social situations who suffer unwanted and therefore unplanned pregnancies.

Objectives: To describe the case of a pregnant woman with SUD for multiple drugs who is admitted to the inpatient ward of the Hospital Clínic of Barcelona for detoxification. Also to reflect, taking in to account gender perspective, on the particularities of substance use in women on childbearing age.

Methods: We present the case of a 25-year-old woman, six weeks pregnant and homeless, who was admitted to the inpatient ward for presumed psychotic symptoms. Even if the patient had a history of intravenous heroin, cocaine, and methamphetamine use, during the admission she only admitted current alcohol consumption (3 UBE/day). During admission, the patient decided to undergo a legal voluntary abortion. Regarding this case, we did a literature review on the consequences of different substances use to pregnancy (to both the fetus and the mother's health). Likewise, we reflected on

interventions that could be carried out in community mental health facilities to detect cases like the one exposed and provide help.

Results: Poor obstetric outcomes are six times higher in patients who use substances. Newborns can have withdrawal syndrome, spontaneous abortion, pre-term birth, fetal malformations and fetal growth restriction. More than 50% of women of reproductive age use drugs, mainly alcohol. Routine screening and education of women of reproductive age is the best way to reduce substance use during pregnancy.

Conclusions: We consider it essential for a better management of these patients to remember that the evidence suggests that the decisions that addicts make are mainly driven by a pathology, not by a moral failure. However, pregnancy can be a moment of greater motivation to stop using drugs, given that it is a high risk situation for the mother and the fetus.

The Relationship Between Problematic Internet Use (PIU) and Psychological Distress: A cross- sectional study

M. Theodoratou^{1,2*}, M. Varvitsioti¹, G. A. Kougioumtzis^{2,3}, G. Tsitsas⁴, A. Kaltsouda⁵, K. Flora⁶ and C. Papathanasiou¹

¹Social Sciences, Hellenic Open University, Patras, Greece; ²Health Sciences, Neapolis University Pafos, Pafos, Cyprus; ³Psychology, National and Kapodistrian University; ⁴Psychology, Harokopion University, Athens; ⁵Psychology, University of Ioannina, Ioannina and ⁶Psychology, Macedonian University, Florina, Greece

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.832

Introduction: Problematic Internet Use (PIU) has emerged as a widespread social challenge and is characterised by an individual's inability to regulate their internet use, culminating in a negative impact on their daily life. It is vital to explore the possible mediating relationship between psychological distress and unregulated Internet use.

Objectives: The study aims to explore the relationship between problematic Internet use, psychological distress and quality of life.

Methods: In this cross-sectional study, participants engaged in a structured data collection process using Google Forms, responding to a series of questions developed through a quantitative methodology using a Likert scale questionnaire.

The K-6 Distress Scale and the World Health Organisation Quality of Life (WHOQOL) were used in conjunction with questions about demographics and problematic internet use. The integration of these multiple measures aimed to provide comprehensive insights into the effects and patterns of Internet use and its association with different levels of distress and demographic variables.

Results: Statistical data analysis revealed notable associations between psychological distress and several variables, including age, education, employment status and health, but no significant associations were found with place of residence or marital status. Significant associations were also found between problematic Internet use (PIU) and variables such as age, education, employment, marital status and health. However, no significant association was found with place of residence. Quality of life was also found to be correlated with age, employment status and health, but not with marital status or educational attainment. In addition, the analysis revealed a strong association between problematic internet use (PIU) and psychological distress. A concurrent

increase in reported psychological distress was observed as PIU levels escalated, reinforcing the relationship between excessive internet use and psychological wellbeing. This suggests that PIU may be associated with increased levels of mental distress in the population studied.

Conclusions: In conclusion, this study provides valuable insights into the multifaceted dynamics of mental distress, PIU, and quality of life in relation to demographic factors. It underscores the importance of holistic approaches to mental health that consider individual characteristics and behaviors, with a particular focus on addressing the challenges posed by problematic internet use. Further research and tailored interventions are needed to better understand and support people facing these complex issues.

Psychotropic substance use among medical residents: prevalence and characteristics

H. Ktari, M. Moalla*, N. Smaoui, I. Gassara, R. Feki, S. Omri, L. Zouari, M. maalej bouali, M. Maalej, J. Ben Thabet and N. Charfi
Psychiatry C, Hedi Chaker Hospital of Sfax, Sfax, Tunisia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.833

Introduction: Psychotropic substance use among medical residents represents a critical concern due to its potential impact on patient care and practitioner well-being. This topic looks into the prevalence and characteristics of psychotropic substance use, including prescription medications and illicit drugs, among individuals pursuing medical residency. Understanding the scope of the problem and its distinctive features is essential for developing targeted interventions and support mechanisms within the medical community.

Objectives: To assess psychotropic substance use among medical residents, describe its characteristics and determine the prevalence of problematic use.

Methods: We conducted a cross-sectional and descriptive study among Tunisian medical residents over a three-month period (August - September 2022) using an online survey. Different specialties and levels of residency were included. An online self-questionnaire was used including a data collection form and the DAST-10 (Drug Abuse Screening Test) scale. The data was analyzed using the SPSS 20th version software

Results: Among the 80 residents in our study, 19 (23.8%) reported psychotropic substance use, and 12 (15%) reported that they had misused psychotropic drugs at least once in their lives (without a prescription and/or with a prescription but not following the instructions). The most commonly psychotropic drugs used were benzodiazepines, followed by amphetamines, analgesics, anesthetics, and pregabalin (28%, 16%, 12%, 12%, 12%, respectively). Consumption was regular for 41.7% of those who reported psychotropic drugs misuse. The initiation of psychotropic use followed a desire to experiment various substances (41.7%), a medical prescription (33.3%), or their availability due to medical practice (25%). Self-medication and recreational use were the most common reasons for use (41.7% each). Furthermore, 31.6% of consumers revealed a problematic substance use as assessed by the DAST-10 scale.

Conclusions: Our study showed a concerning prevalence of psychotropic substance use among medical residents, benzodiazepines being the most prevalent. Notably, 15% acknowledged misuse and a

significant proportion displayed problematic substance use. These results highlight the potential health risks and the importance of addressing this issue within the medical community.

The relationship between cannabis use, depression, anxiety and self esteem among Tunisian young adults living abroad

M. Moalla^{1*}, N. Charfi², H. Ktari¹, S. Omri², N. Smaoui², I. Gassara², R. Feki², L. Zouari², M. maalej bouali², J. Ben Thabet² and M. Maalej²

¹Psychiatry C, Hedi Chaker Hospital and ²Psychiatry C, Hedi Chaker Hospital of Sfax, Sfax, Tunisia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.834

Introduction: Cannabis use is very common worldwide. Its consumption could be explained by recreational purposes as it can be motivated by some psychiatric disorders such as depression, anxiety or low self-esteem.

Objectives: This study aims to explore the relationship between cannabis use, depression, anxiety and self-esteem among a population of Tunisian adults living abroad.

Methods: A cross-sectional online survey was carried out using a self-administered questionnaire on young Tunisians people who have completed their secondary studies at the pilot high school of Sfax and currently residing abroad. The survey questionnaire was designed on Google Forms. It included a data collection sheet and psychometric scales "Cannabis Abuse Screening Test" (CAST), "Hospital Anxiety and Depression Scale" (HADS) and "Rosenberg's self-esteem scale".

Results: The sample consisted of 35 Tunisian young adults. 17 participants (48.6%) reported a cannabis use behavior. It was done with friends in a festive setting in 88% of cases (N=15). According to the CAST, 17,6% (N=3) of cannabis users were at high risk of cannabis dependence. Anxiety was present in 17,6% (N=3) and depression in 17,6% (N=3) of participants. Self-esteem was low in 23,53% (N=4) of participants.

Cannabis use was not associated with the presence of current emotional disorders such as anxiety and depression ($p=0.894$ and $p=0.933$ respectively). It was also not associated with lower self-esteem ($p=0.585$).

Conclusions: Cannabis use is relatively common among young Tunisian emigrants without evolving towards dependence in several cases. This behavior seems to be more influenced by social factors and misrepresentations about cannabis than by psychological disturbance.

Disclosure of Interest: None Declared

EPV0032

Profile of cannabis users among a population of Tunisian young adults residing abroad

M. Moalla^{1*}, N. Charfi², S. Sellami¹, I. Gassara², R. Feki², N. Smaoui², S. Omri², L. Zouari², J. Ben Thabet², M. maalej bouali² and M. Maalej²

¹Psychiatry C, Hedi Chaker Hospital and ²Psychiatry C, Hedi Chaker Hospital of Sfax, Sfax, Tunisia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.835

Introduction: Tunisian emigrants may consume psychoactive substances in other countries. This community is exposed to sociocultural and legal contexts different from those in Tunisia and the degree of acculturation would tend to increase over time. However, data on the use of psychoactive substances, particularly cannabis, in this particular population are scarce.

Objectives: This study aims to determine the profile of Tunisian young adults residing abroad who use cannabis.

Methods: We conducted a cross-sectional, descriptive and analytic study. It was carried out in the form of an online survey. We focused on young Tunisians people who have completed their secondary studies at the pilot high school of Sfax and currently residing abroad. Data collection was through Google Forms administered questionnaire.

Results: Thirty-five participants were included in our study. Cannabis use behavior affected 48.6% of them (N=17)) and it was done with friends in a festive setting in 88% of cases (N=15). Cannabis use was more common among people who were single ($p=0.001$), living alone ($p=0.047$), had a psychiatric history ($p=0.032$) and hanging out with friends who also smoked cannabis ($p=0.032$). Cannabis use was also more common among cigarette smokers ($p=0.000$) and alcohol consumers ($p=0.000$). It was significantly more common among people who shared erroneous beliefs about cannabis, that it is a mild drug ($p=0.024$) and that it does not cause dependence ($p=0.042$).

Conclusions: Cannabis use among Tunisian young adults residing abroad seems to be a form of poly-consumption, more common among singles, living alone and having a psychiatric vulnerability. These findings underscore the need for targeted interventions and educational initiatives to address cannabis use within this specific population.

HCV screening, investigation and management in persons with SUD admitted to Mount Carmel Hospital, Malta

M. A. Apap Bologna*, K. Sant, A. Camilleri and G. Grech

Mount Carmel Hospital, Attard, Malta

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.836

Introduction: Individuals who suffer from substance use disorder (SUD) are at increased risk of Hepatitis C (HCV). Mount Carmel Hospital (MCH) is the only public service in-patient mental health care facility on the island of Malta. Individuals with SUD are referred to MCH for support with comorbid mental health conditions.

Objectives: To assess whether current practice meets the UK Clinical Guidelines on Drug Misuse and Dependence (2017) recommendations- yearly screening for HCV, further testing and referral to infectious disease specialists for those who screen positive for HCV. To compare current practice at MCH, Malta with other countries in the European Union and United Kingdom.

Methods: Retrospective analysis of HCV screening, investigation and referral practices as recorded on iSoft Clinical Manager records for SUD-related admissions to MCH under the care of addiction specialists in 2022 ($n=120$). Admissions data were provided by the data protection office, with permission from the Chairman of the Department of Psychiatry, and de-identified at source to safeguard patient confidentiality.

Results: 60% ($n=72$) of the SUD inpatient population underwent screening for HCV according to guideline recommendations. 37% ($n=44$) of this cohort has received a positive HCV antibody result. 32 persons had HCV RNA load records, 34% ($n=11$) of whom had a detectable viral load. 50% ($n=17$) of those who screened positive for HCV were offered an appointment with an infectious disease specialist within the year, 7 attended. The table below compares HCV status between our group and published data for the UK, Austria and Greece. Despite heterogeneity in study designs and populations (we describe an inpatient cohort with diagnosed SUD, not all of whom inject drugs) comparable proportions have undergone HCV screening in the preceding twelve months and similar proportions have chronic HCV infection.

	% Tested in past year for HCV	% HCV antibody positive	% HCV RNA detectable	% HCV cleared
Malta (MCH 2022)	60	37	34	66
England, Wales, N. Ireland (UAMS 2021)	43	57	26	74
Scotland (NESI 2020)	58	55	81	19
Austria (EMCDDA 2019)	59	85	44	56
Greece (EMCDDA 2019)	/	61	54	46

Conclusions: Most SUD inpatients at MCH undergo HCV screening according to guideline recommendations but current practice falls short of ideal coverage and follow-up care. Current screening practices and chronic HCV infection rates at MCH are comparable to other countries in the EU and UK.

Prevalence, sociodemographic factors and psychological distress related to compulsive buying online

M. Mnif, F. Guermazi, D. Mnif, W. Abid*, I. Feki, I. Baati and J. Masmoudi

CHU Hedi Chakeur psychiatry A department, Sfax, Tunisia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.837

Introduction: Since that the online commerce provides an important shopping environment, it has been argued that traditional buying-shopping disorder may migrate into the online market.

Objectives: The aims of the current study were to investigate the prevalence of online buying-shopping disorder, and to determine sociodemographic and psychological factors related to this addictive behavior.

Methods: A cross-sectional, descriptive and analytical study was conducted among subjects who had already made at least one online shopping. Data was collected using a self-questionnaire published by GOOGLE FORMS. Assessment included the short version of the Internet Addiction Test modified for online shopping sites (s-IATshop). The Hospital Anxiety and Depression Scale (HADS) has been used to assess anxiety and depression.

Results: A total of 137 participants aged 34.62 ± 9.82 years completed the online questionnaire.

Only 4 (2.9%) participants had a probable compulsive buying shopping on line.

The HADS-A score ranged from 0 to 14, with a mean of 6.85 ± 3.49 and almost half of the participants (44.5%; N=61) had anxiety symptoms.

A high s-IAT shopping score was correlated with secondary or university education ($p=0.046$). We also found that women, who were younger and had higher incomes, had the highest scores on the s-IAT-shopping scale, without however confirming statistical significance.

Conclusions: Our study has shown the potential vulnerability factors for compulsive online shopping disorder. Thus, this behaviour deserves to be taken into account in behavioural addictions.

Disclosure of Interest: None Declared

EPV0035

Assessment of self-esteem among Tunisian cannabis users

M. Kacem*, W. Bouali, M. Henia, S. Brahim and L. Zarrouk

Psychiatric department, Taher Sfar Hospital of Mahdia, Mahdia, Tunisia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.838

Introduction: Self-esteem plays a role in the adaptive functioning of the human being. It could be a protective factor regarding multiple risks particularly substance use.

Objectives: The aim of this study is to assess self-esteem among a group of young Tunisian users of cannabis.

Methods: The total study sample was composed of 137 participants, who took part of a transversal descriptive study during two months (January and February 2020). These partakers were comprehensively recruited among Emergency patients of Mahdia Hospital. Thereupon, the main criteria for the selection of these patients was their consumption of cannabis, regardless of their primary health care seeking reason or purpose. The research was carried out upon their declaration of cannabis consumption and their compliance to be part of such a study. Thus, Data were collected on a pre-determined data sheet that included various information (age, sex, lifestyle, personal and family psychiatric history, age at which they started their cannabis consumption and the rate of cannabis use ...). Accordingly, Self-esteem was assessed using the Rosenberg Self-Esteem Scale (RSES). Consequently, the interview took place after the subject's verbal and informed consent and the assurance of anonymity and confidentiality of the interview content.

Results: In our study population, the cannabis consumers were young adults aged between 18 and 35 years old, with a male predominance of 71%. Among those users, 65.9% were single and 29.7% dropped out of school or experienced academic failure. On a socio-economic level, we concluded to a rate of 5.8% (lower class),

60.9% (middle class) and 33.3% (upper class). Besides, 40.8% were employed. In total, 23.2% had a psychiatric history. Furthermore, the use of other substances was also prominent and frequent as follows: alcohol 72.5%, tobacco 74.6%, ecstasy 41.3% and 25.4% cocaine. The use of cannabis was considered as a means of indulgence and pleasure for 66.7%, as an anxiolytic for 26.8% and as a sedative for 23.9%. Self-esteem, among those cannabis users, was very low in 20% of cases, low in 38% of cases, medium in 15% of cases and high in 25% of cases. Consequently, more than half of the study population remains below the medium average according to RSES.

Conclusions: These results lead us to question the relation between cannabis and self-esteem. The question that is evolved about the use of cannabis is the following: Is it used as a remedy or is it the cause of self-esteem deficiency?

Disclosure of Interest: None Declared

EPV0036

Post-traumatic stress disorder in crack/cocaine users

N. Ait Bensaid*, Y. Bensalah, M. Sabir and F. El Omari

Psychiatric hospital ArRazi, salé, Morocco

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.839

Introduction: Cocaine use has become popular in the form of crack and has spread throughout the world. Crack/cocaine use is often linked to serious social and psychiatric disorders, including post-traumatic stress disorder, and users appear to be at increased risk of physical and mental illness and social harm.

Objectives: To determine the prevalence of post-traumatic stress disorder in patients followed and hospitalized in the addictology department at the Arrazi psychiatric hospital in Salé for management of crack/cocaine use disorder.

Methods: This is a descriptive cross-sectional study using a questionnaire including sociodemographic and clinical criteria and a post-traumatic stress scale (PCLS) to investigate the existence of post-traumatic stress disorder in patients monitored and hospitalized for crack/cocaine use disorder in the addictology department at the Arrazi psychiatric hospital in Salé.

Results: We collected 77 participants. The majority of patients were born in the city. The average age of the participants was 27, with a male predominance (67%). The majority were unemployed at the time of the study, single, separated or divorced. For more than 50%, the start of drug use was more than 4 years ago. The smoked route (crack) is the most predominant, followed by the inhaled route and 1% for the injectable route. Some 37% were hospitalized in an addictology unit. Almost 65% of participants had a history of post-traumatic stress disorder.

Conclusions: Co-morbidity between crack/cocaine use disorder and post-traumatic stress disorder is frequent among patients monitored and hospitalized in the addictology department at the Arrazi psychiatric hospital in Salé. There seems to be a need to develop new therapeutic strategies and to adapt existing programs to patients' needs. In addition, understanding the profiles of patients suffering from this comorbidity in mental health facilities could help clinical staff to better accept their problems and behaviours, thus promoting treatment adherence and better outcomes.

EPV0037

Exploring treatment specifics of addictive disorder in a young adult living in a post-war middle income country with rapid social and cultural transition: a qualitative case report

N. Agani

of Psychiatry, University Clinical Centre of Kosova, Pristina, Kosovo
doi: 10.1192/j.eurpsy.2024.840

Introduction: Addictive disorder, characterized by the tendency to abuse an illicit substance or manifest a repeated risky behavior, is a fairly common phenomenon occurring in the last 50 years, predominantly in middle and high income countries. While psychotherapy has an evident positive impact in the treatment of the disorder, data has shown that it is often not sufficient to achieve full remission and have optimal positive impact in the quality of life compared to simultaneous use of psychotherapy, pharmacotherapy and psychosocial rehabilitation.

Objectives: The aim of the study is to highlight different specifics of the inpatient treatment of “Mr. E”, living in a post-war middle-income country with rapid social and cultural transition.

Methods: Subject of this case study is “Mr. E” a 17 year old student with a history of family trauma with a long history of abuse and ambulatory psychiatric treatment. Data has been analyzed from the medical history of the patient treated in 2023, in the substance abuse unit of the Department of Psychiatry, University Clinical Center of Kosova. Semi structured interviews, daily abstinence symptoms evaluation and self - report measures were used to gather qualitative data throughout the treatment process. Treatment protocol consisted on: detoxification, pharmacotherapy and simultaneous supportive individual and group psychotherapy, with the goal to evaluate, treat and reintegrate “Mr. E” into the society free of illicit substance abuse. Comorbidities are correlated with underlying causes, while a healthy lifestyles are promoted through the work on behavior changes that will support optimal social reintegration in a rapid changing social and cultural environment.

Results: The findings revealed several significant therapeutic objectives such as: Enhanced self – awareness; Reduced ruminations and increased self-control; Enhanced quality of life; and Decreased substance abuse. Detoxification protocol in the treatment of addictive disorder in inpatient psychiatric treatment was essential for abstinence symptom management during crisis. Strengthening the body parallel to healing the mind was found as an important stepping stone.

Conclusions: Combined, detoxification, psychopharmacological, and psychotherapeutic approach was essential for successful treatment of a young adult in a post-war middle income country with rapid social and cultural transition.

Orthorexia Nervosa and exercise addiction in a sample of Tunisian athlete students

N. Smaoui, O. Bouattour*, R. Feki, I. Gassara, S. Omri, M. Maalej, L. Zouari, M. Maalej, J. Ben Thabet and N. Charfi

psychiatry C department, Hedi chaker University hospital, Sfax, Tunisia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.841

Introduction: Orthorexia and exercise addiction can lead to serious health problems, such as malnutrition and exercise-related injuries.

Objectives: The aims of our study were to assess the prevalence of exercise addiction and orthorexia nervosa in Tunisian students at the Institute of Physical Education in order to investigate the relationship between these different health dimensions.

Methods: An anonymous self-administered questionnaire was distributed to students in the Sfax and Gafsa sports sections during March 2023. The orthorexic tendency was assessed using the ORTO-15 questionnaire. An ORTO-15 score below 40 points indicates orthorexic tendencies. The Exercise Addiction Inventory (EAI) was used to study exercise addiction

Results: In our study, 240 students were included. Mean scores on the ORTO-15 and EAI scales were 38.6 ± 8 and 16.6 ± 4.1 respectively. Participants at risk of exercise addiction had a statistically significant tendency towards orthorexia ($p < 0.001$). Among the students, 82.5% had engaged in regular physical activity at a gym in the last two years. The reasons given by students for going to the gym were muscle strengthening (57.9%) and preparation for a sporting competition (37%).

Among students taking part in sports activities at the gym, the mean ORTHO-15 score was significantly lower among those doing so to prepare for a sports competition ($p = 0.005$). Participants who believed that they were addicted to sport had a statistically greater tendency towards orthorexia ($p = 0.012$).

Conclusions: Our study revealed an association between addictive exercise and orthorexic eating in Tunisian athlete students.

Liquor for breakfast, fighting against alcohol consumption

N. Navarro Barriga, P. Marqués Cabezas*, M. B. Arribas Simón, B. Rodríguez Rodríguez, C. Alario Ruiz, G. Guerra Valera, A. Aparicio Parras, M. J. Mateos Sexmero, M. Fernández Lozano, P. Martínez Gimeno, M. A. Andreo Vidal, M. Calvo Valcárcel, M. P. Pando Fernández, M. D. L. A. Guillén Soto, T. Jimenez Aparicio, M. D. C. Vallecillo Adame and C. De Andrés Lobo

Hospital clínico universitario de Valladolid, Valladolid, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.842

Introduction: The harmful consumption of alcohol is known for how tortuous its management can be in mental health, encouraging introspection of it as a serious problem is perhaps the main key to starting to battle against its damaging influence on the development of a functional and full life.

Objectives: To describe a clinical case showing an unpredictable complication in an alcohol detoxification process.

Methods: 54-year-old man, native of Cádiz, widowed for half a decade, without children. He resides with his parents in the family home. Currently unemployed for approximately a year. He has previously worked in the IT sector. As a notable somatic history, we found long-established arterial hypertension and a total hip

replacement. He has been under irregular follow-up with a mental health team for anxiety-depressive symptoms in the context of grief. He goes to the emergency service brought by his family to begin the detoxification process in the hospital setting. He acknowledges ethanol consumption since he was widowed, which began when he awakes; quantities that ranged between one or up to three bottles of distilled liquor per day, generally consumption is in the home environment. A little less than a year ago, he began to isolate himself in his room and abandon his self-care, eating increasingly insufficient food intake, refusing to receive professional care to quit the habit, mainly because he did not recognize it as disruptive.

The patient was admitted to hospital with symptoms suggestive of withdrawal, making it extremely difficult to control blood pressure levels. On the third day of admission to the acute care unit, fever peaks, blood pressure levels well below normal parameters, and compromised level of consciousness began to be evident.

Results: Blood tests were performed that, together with the clinical picture, suggested imminent septic shock, so critical care was contacted for transfer and stabilization. A germ of probable urinary etiology sensitive to a broad spectrum of antibiotics was isolated in blood cultures, and the medication of the detoxification process was progressively optimized. Once clinical stability was achieved at all levels, an inpatient cessation resource was managed, which the patient accepted and considered suitable for his complete recovery.

Conclusions: A holistic approach to the alcoholic patient is important, since serious problems of an organic nature often arise. This is why a multidisciplinary intervention is necessary, as well as a holistic approach to care, involving both classic pharmacology and assiduous long-term psychotherapeutic intervention.

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.843

Introduction: In recent years, there has been an increase in the prevalence of illicit use of fentanyl and other opioids in the United States population. This has led to an increase in medical, psychopathological and abuse-associated comorbidity, an increase in deaths and a decrease in the age of consumption, and has become a serious emerging problem in young people.

We present the case of an 18-year-old woman from the United States who recently settled in Spain and started a follow-up in Mental Health due to opioid and other substance abuse problems.

Objectives: To address the growing problem surrounding the illicit use of fentanyl and opioids as drugs of abuse based on the presentation of the clinical case mentioned above.

Methods: Bibliographic search and description of a clinical case of a patient under follow-up by Mental Health at the "Hospital Clínico Universitario de Valladolid".

Results: An 18-year-old woman from the United States who has been living with her father in Spain since the summer of 2023, having moved to Spain due to problems related to substance abuse. With no previous medical or surgical history and with a history of follow-up in Mental Health in her country of origin for depressive symptomatology, dysfunctional personality traits and abuse of different toxic substances since adolescence.

After a brief and erratic follow-up in Psychiatry for anxious-depressive symptoms reactive to a complex and conflictive relationship with his mother and marked academic difficulties during the first years of adolescence, at the age of 15 he started using cannabis and alcohol, thus beginning a period marked by relationships with marginalized sectors of the population, substance abuse and school failure.

As his cannabis consumption intensified, he began to consume fentanyl prescribed to his mother, as well as other opioids to which he had access illegally, for which reason he had to be admitted twice to detoxification centers without results, which is why his family finally decided to move him to Spain.

Conclusions: In recent years, fentanyl abuse has become a serious public health problem that is mainly centered in the young population. High levels of impulsivity and lack of frustration tolerance predispose to the use of illicit substances for elusive purposes.

Substance abuse carries with it not only an important organic comorbidity, but also a marked socio-familial and economic repercussion.

Cannabinoid hyperemesis syndrome: a case report and literature review

P. Veloso*, M. Gomes, R. Lopes de Dios and F. Pereira

Psychiatry, Hospital de Braga, Braga, Portugal

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.844

Introduction: Cannabis is the most used recreational drug worldwide. Cannabinoids have long been known for their anti-emetic properties. Paradoxically, chronic cannabis consumption has been linked to inducing refractory nausea and vomiting, a condition called cannabinoid hyperemesis syndrome (CHS). CHS remains inadequately acknowledged by clinicians.

Objectives: Report a CHS case and discuss this syndrome's diagnosis, pathophysiology, and management.

Methods: Collection of clinical information and review of the literature.

Results: We share the case of a 38-year-old male who repeatedly recurred to the emergency department (ED) due to persistent vomiting, nausea, and abdominal pain. The patient had experienced similar intermittent episodes over the past 12 years. Interestingly, the use of hot showers provided symptomatic relief. Urine drug tests consistently showed positive results for cannabinoids. During acute phases, he required supportive treatment involving fluid therapy. Long-term treatment included cannabis abstinence. CHS is defined by episodic vomiting, following prolonged excessive cannabis consumption, which is alleviated by sustained cessation of cannabis. During the acute phase of the condition, patients often find relief using hot baths and showers, which is a common behavior observed. CHS-related complications encompass acute kidney injury and severe electrolyte disturbances. CHS can result in multiple ED visits, frequent hospitalizations, extensive

diagnostic evaluations, and elevated healthcare expenditures. Although the exact pathophysiology of CHS remains unclear, some mechanisms have been proposed. These include reduced gastric motility by gastrointestinal cannabinoid receptors 1 (CB1) over-riding, cannabinoid lipid buildup, endocannabinoid system dysregulation, dysregulated stress response, changes in thermoregulation, modifications in the transient receptor potential vanilloid system and genetic polymorphisms in the P450 system. In the acute phase, the foremost concern is providing supportive care including intravenous hydration and electrolyte corrections. The most effective treatment for CHS is cannabis cessation. Nevertheless, there are alternative treatments that have shown promise in alleviating symptoms, such as hot water hydrotherapy, topical capsaicin, haloperidol, benzodiazepines, propranolol and aprepitant.

Conclusions: As cannabis usage becomes increasingly prevalent, it becomes imperative for healthcare providers to acknowledge the long-term effects of cannabinoids, specifically regarding CHS. This diagnosis should be contemplated when evaluating patients who experience recurrent and incoercible vomiting coupled with a history of cannabis consumption. The compulsion to take hot baths or showers can serve as a noteworthy indicator for diagnosing CHS.

Technological Addictions: The New Frontier in Addiction Psychiatry

P. Levounis

Psychiatry, Rutgers New Jersey Medical School, Newark, United States
doi: 10.1192/j.eurpsy.2024.845

Introduction: Addiction to video games, cybersex, internet gambling, social media, texting and emailing, and online auctions can be as addictive as substances. These technological addictions have real-world ramifications and lead to the loss of jobs, money, and loved ones. As technology becomes integrated into many facets of modern life, the appreciation of such addictions has become increasingly challenging. This session will explore the addictive potential of technology and discuss the legitimacy of technological addictions as psychiatric conditions worthy of medical assessment, diagnosis, and treatment.

Objectives:

- 1. List five forms of Technological Addictions as they appear in the scientific literature of 2023.
- 2. Describe the psychology and culture surrounding Internet Gaming addiction.
- 3. Distinguish between normal use and addiction.

Methods: Lecture and discussion

Results:

- 1. Research on the phenomenology and nosology of these illnesses helps us further elucidate the distinction between problematic and nonproblematic use of technology, especially in children and young adults.
- 2. Another area of new research involves emerging technologies. By the time clinicians get a firmer grasp of today’s ailments, the

technology of tomorrow—such as virtual reality and smart devices powered by artificial intelligence—will be commonplace enough to bring about a host of new problems.

Conclusions: Though data on the prevalence of technological addictions are sparse, most people use computers, tablets, and smartphones regularly with great benefits and no serious adverse consequences. We will need to be ready to guide our patients, our colleagues, and the general public on how to best handle technology with an eye on maximizing its enormous potential for fulfillment, gratification, and happiness while minimizing its significant risks for dissatisfaction, misery, and despair.

Correlations between Clinic Preferences and Alcohol Use Disorder: an Alcohol Cohort Study in Northern Taiwan in 2022

W.-Y. Su¹, S.-C. Wang^{2*} and S.-Y. Yeh²

¹National Yang Ming Chiao Tung University, Taipei City and

²Department of Psychiatry, Taoyuan General Hospital, Taoyuan City, Taiwan, Province of China

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.846

Introduction: Chronic alcoholism can result in severe liver conditions such as fatty liver disease and cirrhosis, potentially leading to life-threatening complications and premature death.

Objectives: This study investigated the age-sex distribution of patients with alcohol addiction and aimed to identify differences in clinic department preferences based on their principal and additional diagnoses in Taiwan, in 2022.

Methods: We conducted a comprehensive analysis of the diagnostic patterns of 334 patients with alcohol addiction from the Taoyuan General Hospital, Ministry of Health and Welfare.

Results: **Figure 1** depicts patient demographics, highlighting 297 male and 37 female patients with alcohol-related disorders. Males aged 41-60 years were particularly dominant, as shown in **Figure 2**. Principal diagnoses, including alcoholic liver disease and acute pancreatitis, are detailed in **Table 1**. Additional diagnoses, such as chronic pancreatitis and esophageal varices, are presented in **Table 2**. For departmental preferences, **Table 3** reveals the Gastrointestinal (GI) department as the top choice, followed by Kidney, Neurological, and Cardiovascular/Chest.

Table 1. Top 5 Principal Diagnoses of Alcohol Addiction Patients.

ICD-10-CM	Principle diagnosis	Times	Rank
K70	Alcoholic liver disease	43	1
K85	Acute pancreatitis	27	2
F10	Alcohol related disorders	18	3
A41	Other sepsis	14	4
K86	Other chronic pancreatitis	11	5

Table 2. Top 5 Additional Diagnoses of Alcohol Addiction Patients.

ICD-10-CM	Additional diagnosis	Times	Rank
F10	Alcohol related disorders	40	1
K86	Other chronic pancreatitis	18	2
I85	Esophageal varices	16	3
K70	Other sepsis	16	
E87	Other disorders of fluid, electrolyte and acid-base balance	15	4
R65	Symptoms and signs specifically associated with systemic inflammation and infection	10	5

Table 3. Top 5 Departments for Alcoholism Patient Presentation.

Department	Times	Rank
Gastrointestinal	162	1
Kidney	39	2
Neurological	25	3
Cardiovascular Chest	15	4

Image:

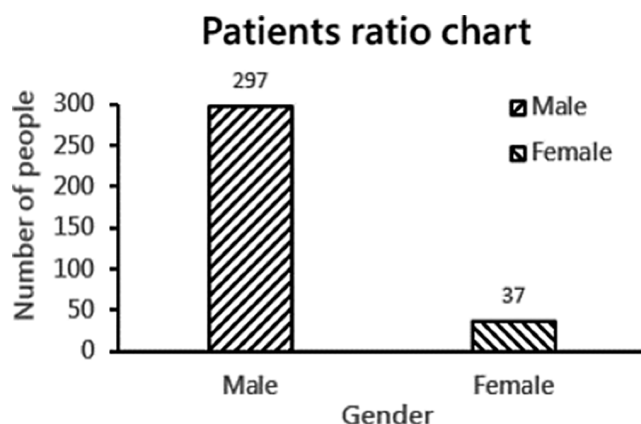

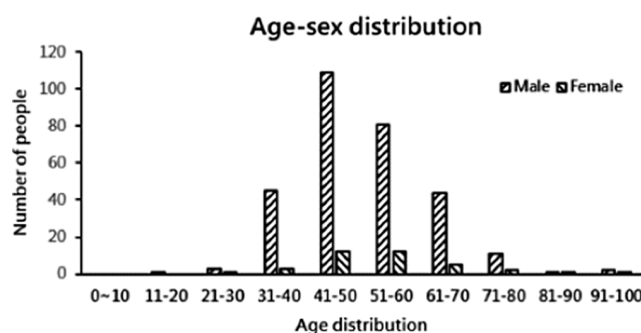

Image 2:

Conclusions: The study revealed that patients with alcohol addiction often delay seeking psychiatric help instead of presenting for medical care only after liver or gastrointestinal complications occur. This underscores the crucial need for better health education regarding

the relationship between alcohol addiction and liver disease. Prompt recognition and early intervention for substance addiction can significantly reduce these risks and improve patient outcomes.

EPV0051

The amount of drunk days and its relationships with other characteristics of alcoholic behavior of the respondents

V. Kuzminov^{1*}, I. Linskiy¹, O. Minko¹, M. Denisenko¹, T. Tkachenko¹, V. Zadorozhny¹, N. Malykhina¹, O. Minko¹, R. Lakinskiy¹, O. Vasilyeva¹, B. Herasymov¹, D. Herasymov¹ and O. Yurchenko¹

¹Emergency psychiatry and narcology and narcology, SI "Institute of Neurology, Psychiatry and Addiction of the NAMS of Ukraine", Kharkiv, Ukraine

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.847

Introduction: Alcohol abuse is a multifaceted problem. Its harmful effects on the individual have been more studied. Less studied is the influence of a drinking person on his microsocial environment. Having an abusing person in his space makes it interesting to study the influence of some quantitative and qualitative indicators of his alcohol consumption on the microsocial environment.

Objectives: 1532 people were examined during 2018-2022, who belonged to three comparison groups: patients with alcohol dependence (AD) (401 people); healthy relatives of AD patients (725 people); representatives of the general population comparable with the representatives of the first two age groups (406 people).

Methods: The main research instruments were the questionnaire of the international research consortium "GENAHTO" (Gender, Alcohol, and Harms to Others), as well as the Alcohol Use Disorders Identification Test (AUDIT). The obtained data were processed by methods of mathematical statistics (variance, correlation and regression analysis).

Results: An algorithm for regression analysis in conditions of high dispersion of the initial data has been developed. Using this algorithm, it was shown that the regression dependence of the main characteristics of alcohol behavior on the frequency of DD is non-linear, while for typical and maximum doses of alcohol it is optimally described by polynomials of the second degree, and for the severity of disorders due to alcohol use (AU), the time spent on AU, as well as self-assessment of the negative impact of AU by respondents on their environment - by polynomials of the third degree. It was found that for men (on average) to reach the border of risky-dangerous AU (according to the criteria of the AUDIT test), a lower frequency of DD is sufficient than for women, which indicates a greater vulnerability of men (compared to women) to the formation of disorders due to AU.

Conclusions: It was established that for men (on average) to reach the limit of risky and dangerous (according to the criteria of the AUDIT test), a lower frequency (2-3 times a week) is enough than for women (3-4 times a week), which once again indicates greater vulnerability of men (compared to women) to the formation of due to psychological problems and mental disorders.

Psychiatric comorbidities among patients hospitalized in the addictology department of Ar Razi hospital in Morocco

Y. Bensalah*, M. Sabir and F. Elomari

psychiatric hospital Ar Razi, Salé, Morocco

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.848

Introduction: Comorbidity between psychiatric disorders and disorders linked to psychoactive substance use is common and represent a real public health problem.

The association of a psychiatric disorder can, in certain cases, modify the treatment methods and also the evolution of the addictive behavior.

Objectives: Determining the prevalence of psychiatric comorbidities in patients with substance use disorder Identify the socio-demographic and clinical characteristics of patients hospitalized in the addictology department.

Methods: We conducted a cross-sectional study with descriptive and analytical aims, in order to study psychiatric comorbidities in 150 patients with substance use disorder hospitalized in the addictology department of Ar Razi hospital in Salé over a period from June 1, 2022 to August 30, 2023.

Data collection was done using a questionnaire including clinical and socio-demographic characteristics, the prevalence of problematic use of psychoactive substances and the comorbidity of psychiatric disorders (diagnoses assessed by DSM 5 criteria).

Results: A male predominance was noted (80%). The main substances consumed in the last 12 months were tobacco (98%), cannabis (74%), alcohol and benzodiazepines.

The majority of patients presented at least one psychiatric comorbidity (80%), with a predominance of depressive disorder and anxiety disorders.

Personal history of suicide attempts was found in 30% of the sample Substance dependency that prompted initially the consultation was higher in patients with psychiatric comorbidity ($p < 0.05$)

Post-traumatic stress disorder was significantly associated with the presence of problematic cocaine and alcohol use. Social phobia is associated with the absence of a criminal record.

Conclusions: Addictive behaviors are often associated with psychiatric disorders. The most common psychiatric comorbidities are depression, anxiety and personality disorders, hence the need for simultaneous treatment of psychiatric pathologies and addictive behavior

Disclosure of Interest: None Declared

EPV0053

Sociodemographic and clinical characteristics of patients on Methadone followed at Ar Razi hospital in Morocco

Y. Bensalah*, M. Sabir and F. Elomari

Psychiatric hospital Ar Razi, Salé, Morocco

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.849

Introduction: Opioid substitution treatments, notably methadone, now represent the standard treatment in the management of opioid

dependence, making it possible to reduce illicit opioid consumption, crime, infections linked to administration practices and improve socio-professional integration

Objectives: Determine the socio-demographic and clinical characteristics of the patients Evaluate the quality of life of these patients

Methods: A cross-sectional, descriptive and analytical study was conducted with 60 patients receiving methadone followed at Ar-Razi Hospital in Salé between 01 June 2023 and 30 August 2023. A questionnaire was used to assess the socio-demographic and clinical characteristics of the patients. Quality of life was assessed using the 36-item Short Form Health Survey SF-36 scale

Results: The average age of our patients was 34 years with a male predominance

Most of our patients were single and unemployed Somatic disorders were found in 15% of the sample

The majority of them had an associated depressive disorder

The main types of new psychoactive substances consumed were benzodiazepines (62.3%) and cannabis.

Quality of life was impaired in 60% of patients treated with methadone

Conclusions: The population using methadone is precarious and presents somatic and psychiatric vulnerability. Forms of misuse and associated consumption of other psychoactive substances and illicit drugs are recorded, hence the need for early detection in order to improve care

Disclosure of Interest: None Declared

EPV0054

Socio-demographic and clinical profile of opioid users

Z. bencharfa*, R. zahir, I. El Hamoumi and F. El omari

Ar-razi psychiatric hospital, Salé, Morocco

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.850

Introduction: Opioid use disorder is a pattern of problematic opioid use, leading to impaired functioning or clinically significant suffering. Morocco, a pioneer in the Arab world in the field of opiate substitution, is no exception to this rule, and has found itself confronted with a situation where opiate use is much more widespread in the north of the country. Morocco's geographical proximity to Europe and the multiple interactions fostered by migratory population flows undoubtedly contribute not only to the spread of hard drug use, particularly heroin, but also to the diversification of consumption methods (injection drugs)

Objectives: The main objective of our work was to study socio-demographic and clinical profile of opioid users in Morocco, but also their quality of life after treatment in Morocco, before concluding with recommendations for improving the overall management of the patient.

Methods: We conducted a cross-sectional, analytical study in the Addictology Department at Ar-razi Hospital in Salé, which provides oral methadone substitution therapy for around 80 patients.

Results: The total number of patients responding to the questionnaire was 60 participants.

The population of methadone-treated patients in our study was 83.33% (n = 50) male and 16.67% female (n = 10).

The most common age group in our study was between 31 and 45 (71.67%). 36.67% were married (n=22), 80% (n=48) lived with their family, 83.34% (n=50) had a secondary school education or higher, while the vast majority 63.33% (n=38) had no fixed occupation.

96.7% (n=58) of participants were of Moroccan nationality, against only 3.3% who were foreigners (n=2).

The main indication for methadone withdrawal in our patients was heroin use (66.67%), followed by Codeine, then Tramadol. The daily doses of methadone delivered ranged from 04 to 200 mg/patient, with an average of 75 mg.

The main adverse effects reported by our patients were libido disturbance, constipation, fatigue and sleep disturbance.

63.33% (n=38) of patients continued to use other psychoactive substances on a regular basis, mainly tobacco, followed by cannabis. 13.33% (n=8) reported persistent craving, and the vast majority claimed to be supported by a family member (70%, n=40).

Conclusions: For several years, quality of life has been a major preoccupation of healthcare professionals in a bio-psycho-social approach. In this vision of care, quality of life should now be part of the clinical criteria for monitoring patients on methadone.

EPV0055

Ekbom síndrome (Parasitosis delirium): Cocaine Use vs. Psychotic Depression. A case report

E. Arroyo Sánchez*, J. Gimillo Bonaque, P. Setién Preciados and C. Díaz Mayoral

Hospital Universitario Príncipe de Asturias, Madrid, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.851

Introduction: Parasitosis delirium represents a rare mono-symptomatic psychosis characterized by the delirious firm belief of the patient, against all evidence, of being infested by cutaneous parasites. The syndrome affects in particular middle-aged women, and can be the single manifestation of psychological uneasiness or represent one of the aspects of a more complex psychiatric case, compromising almost totally any normal daily work and/or social activity. It is often accompanied by a refusal to seek psychiatric care. This condition can be associated with various underlying causes, including substance use disorders and psychotic depression. Understanding the differences and similarities between delirium of infestation in the context of cocaine use and psychotic depression is crucial for accurate diagnosis and effective treatment.

Objectives: This study aims to compare and contrast the clinical features, etiology, and treatment approaches of delirium of infestation in individuals with cocaine use and those with psychotic depression. By examining these two distinct populations, we can gain insights into the unique challenges and considerations associated with each condition.

Methods: A case report of a 44-year-old woman with delirium of parasitosis, depressive symptoms and cocaine use in the last three days. Also a comprehensive literature review using the PubMed database to identify relevant clinical articles on delirium of infestation, cocaine use, and psychotic depression.

Results: Cocaine use and psychotic depression can both cause delirium of infestation. Cocaine-induced delirium is characterized by agitation, paranoia, and delusions of infestation. Psychotic depression is characterized by a depressed mood, delusions, and hallucinations. Delusions of infestation are a common feature of both conditions. However, the underlying mechanisms and treatment approaches differ. Cocaine-induced delirium is primarily associated with the acute effects of cocaine on the central nervous system, while psychotic depression involves a complex interplay of biological,

psychological, and environmental factors. Treatment for cocaine-induced delirium involves addressing the underlying cocaine use, while treatment for psychotic depression involves antidepressant and antipsychotic medications. Otherwise, Anti-Parkinson drugs were most frequently associated with delusional infestation

Conclusions: Delirium of infestation can occur in individuals with cocaine use and those with psychotic depression, albeit with different etiologies. Clinicians should consider the underlying cause when diagnosing and treating patients with this condition. Further research is needed to explore the specific neurobiological mechanisms and optimal treatment strategies for delirium of infestation in these distinct populations.

Drug-induced psychosis and intravenous drug use in chemsex context

J. Curto Ramos^{1,2*}, A. Rodríguez Laguna², P. Barrio², L. Ibaguchi², A. García², I. Azqueta² and H. Dolengevich Segal³

¹Department of Psychiatry, Clinical Psychology and Mental Health, La Paz University Hospital; ²Apoyo Positivo and ³Dual Disorders Program. Department of Psychiatry, Henares University Hospital, Madrid, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.852

Introduction: Several studies have called attention to the mental health disorders associated with chemsex -the intentional use of drugs before or during sexual intercourse GBMSM (gay, bisexual and men who have sex with men) population-. Sexualized intravenous drug use is also known as slam or slamsex. There are few studies that analyze the mental health differences between intravenous drug users compared to non-intravenous drug users in chemsex context.

Objectives: We aim to analyze the relationship between the practice of slamsex and the development of drug-induced psychosis.

Methods: A cross-sectional descriptive analysis of a sample of users attended by the non-governmental organization Apoyo Positivo in the program "Sex, Drugs and You" between 2016-2019 was performed.

Results: We included 217 participants. Drug-induced psychosis was found in 80 participants. Drug-induced psychosis was significantly higher in the intravenous drug use group compared to the non-intravenous drug use group (p<0.05).

Conclusions: Previous studies have reported that MSM who practiced chemsex were more likely to experience from different mental health disorders, being psychosis one of the most frequent psychiatric diagnoses. In our study, drug-induced psychosis was higher in participants who engaged in intravenous drug use. Further studies analyzing the relationship between slamsex and drug-induced psychosis are needed.

Disclosure of Interest: None Declared

EPV0057

Group therapy for problematic chemsex in Ngos community treatment settings in Spain

J. Curto Ramos^{1,2*}, N. Sanz Velasco³, L. Carballeira⁴, I. López Álvarez⁵, P. Barrio², L. Ibaguchi², A. García² and H. Dolengevich Segal⁶

¹Department of Psychiatry, Clinical Psychology and Mental Health, La Paz University Hospital; ²Apoyo Positivo; ³Department of Psychiatry, Hospital Clínico San Carlos; ⁴Department of Psychiatry, Hospital Doce de Octubre, Madrid; ⁵Department of Psychiatry, Hospital Universitario Marqués de Valdecilla, Santander and ⁶Dual Disorders Program. Department of Psychiatry, Henares University Hospital, Madrid, Spain
*Corresponding author.

doi: 10.1192/j.eurpsy.2024.853

Introduction: The intentional use of drugs before or during sexual intercourse (chemsex) is a phenomenon of special importance in the MSM (men who have sex with men) population due to its impact on mental, physical and sexual health. Group therapy has been included in several programs for chemsex users.

Objectives: To describe and to compare the different group therapy treatments for problematic chemsex users in NGOs community treatment settings in Spain.

Methods: We conducted several interviews with key informants from 5 NGO in Spain. A qualitative analysis of the different group therapy treatments for problematic chemsex was performed.

Results: Different models of groups were described including: psychoeducational, support, interpersonal process, harm reduction and mindfulness-based cognitive groups. Most of the group interventions developed were support and psychoeducational based. There were fewer interpersonal group and relapse prevention group therapy. The different models of group intervention were considered useful and necessary for deliver information in a culturally sensitive context and for reducing drug use, social isolation and loneliness.

Conclusions: Chemsex is a phenomenon that needs a multidisciplinary approach, including individual and group therapy. Group therapy for problematic chemsex has several advantages over individual model treatments, including the reduction of sense of isolation, loneliness, information and feedback from peers. More research is needed to analyze the implementation and efficacy of group therapy for chemsex users in different contexts.

EPV0058

Pathophysiology and Management of Amphetamine-Related Psychiatric Disorders

T. Jupe*, N. Stamoulis and A. Varsamis

Psychiatric Hospital of Attica, Athens, Greece

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.854

Introduction: Amphetamines may induce symptoms of psychosis very similar to those of acute schizophrenia spectrum psychosis. This has been an argument for using amphetamine-induced psychosis as a model for primary psychotic disorders. To distinguish the two types of psychosis on the basis of acute symptoms is difficult. However, acute psychosis induced by amphetamines seems to have a faster recovery and appears to resolve more completely compared to schizophrenic psychosis.

Objectives: The objectives of this e-poster is to identify the pathophysiology of amphetamine-related psychiatric disorders and

outline the available treatment and management options for amphetamine-related psychiatric disorders.

Methods: A bibliographical review was performed using PubMed platform. All relevant articles were found using the keywords: psychotic episode, amphetamines, pathophysiology and management.

Results: Amphetamines inhibit monoamine (dopamine, norepinephrine, epinephrine, serotonin) reuptake, leading to increased monoamine concentrations in the neuronal synapse. Amphetamines can also lead to increased monoamines in the cytosol by interactions with vesicular monoamine transporter 2. Dopamine and norepinephrine release in the nucleus accumbens results in a feeling of euphoria and a reward feedback loop, which may result in addiction. Studies also suggest increased dopaminergic pathways lead to glutamate excesses in the cerebral cortex, altering the function of cortical GABAergic neurons. This damage leads to dysregulation of glutamate in the cerebral cortex, a precursor to psychosis. Prior psychiatric studies have found that GABAergic cortical dysfunction seems to relate to schizophrenia. Generally, acutely agitated psychotic patients are treated with intravenous benzodiazepines (lorazepam, diazepam, or midazolam) as first-line agents. However, if a second-line agent is needed, antipsychotic medicines like risperidone, haloperidol, ziprasidone, and olanzapine have been successful in managing amphetamine-associated psychosis. Lipophilic beta-blockers, such as metoprolol and labetalol, have also been used successfully to resolve agitation and hyperadrenergic vital signs.

Conclusions: Compared to schizophrenic psychosis, amphetamine-induced acute psychosis induced appears to demonstrate a more rapid recovery. It also seems to resolve with substance abstinence; however, this recovery may be incomplete.

Wellbeing after Brief Alcohol Interventions in Male Inpatients in a General Hospital in Singapore

Z. W. Lew*, C. S. Lim, H. S. Ong, R. M. Ong, Y. C. Ng, W. L. Teo and L. H. Peh

Department of Psychological Medicine, Changi General Hospital, Singapore, Singapore

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.855

Introduction: Harmful alcohol consumption has significant cost on health and is associated with lower quality of life (e.g., Lu *et al.* BMC Public Health 2022; 22:789). In Singapore, a significant proportion of the adult population exhibit alcohol misuse behaviours (e.g., Lim *et al.* BMC Public Health 2013; 13:992). Many patients admitted into general hospitals have excessive alcohol consumption and related problems. These admissions can be an opportunity for intervention due to accessibility to the individuals and their time (Saitz *et al.* Ann Intern Med 2007; 146 167-176). Some studies have suggested that brief alcohol interventions (BAI) delivered in general hospitals can be effective in reducing alcohol use. However, there has been less support for the benefits of BAI on wellbeing.

Objectives: This study investigated the effectiveness of BAI in improving perceived sense of wellbeing among male alcohol users admitted to a general hospital in Singapore.

Methods: 108 male inpatients in various medical wards received BAI by the hospital's addiction counsellors and completed the Personal Wellbeing Index (PWI) questionnaire. At a one-year follow-up via telephone, the PWI was again administered.

Results: Average PWI scores were higher at follow-up ($M = 7.83$, $SD = 1.16$) than during baseline admission ($M = 7.60$, $SD = 1.12$), $p < 0.01$. Further analyses found that scores improved significantly on PWI items related to standard of living ($M = 7.36$, $SD = 1.41$ vs $M = 7.09$, $SD = 1.65$; $p < 0.05$), health ($M = 7.42$, $SD = 1.74$ vs $M = 6.62$, $SD = 1.87$; $p < 0.01$) and achievement ($M = 7.43$, $SD = 1.44$ vs $M = 6.98$, $SD = 1.64$; $p < 0.01$). There were no significant differences in scores on the other PWI items between baseline and follow-up.

Conclusions: The results suggest that BAI can be beneficial in improving patients' sense of wellbeing.

EPV0061

Transition from methadone to subcutaneous buprenorphine depot in patients with opioid use disorder - a case report

M. Delic

Center for Treatment of Drug Addiction, University Psychiatric Clinic Ljubljana, Ljubljana, Slovenia
doi: 10.1192/j.eurpsy.2024.856

Introduction: Opioid dependence is a complex condition that often requires long-term treatment and care. Methadone, a synthetic full opioid agonist, and buprenorphine, a partial agonist at the opioid receptor, are most commonly used for substitution therapy of opioid dependence and typically administered orally as a liquid and sublingual tablets. Transition from methadone to sublingual buprenorphine may precipitate withdrawal and is usually performed only in patients on low dose of methadone (<30-40 mg). Microdose induction is proposed as a possible solution to ease the transition to buprenorphine.

Objectives: To present a rapid transition from methadone to sublingual buprenorphine and after that to buprenorphine depot.

Methods: A case report of a patient who was switched from methadone 60 mg to sublingual buprenorphine 8 mg using microdosing and after that switched to buprenorphine depo 16 mg weekly.

Results: Patient was successfully switched to sublingual buprenorphine and after that to buprenorphine depot. The transition was completed without withdrawal symptoms.

Conclusions: This report supports the use of a microdose induction to initiate buprenorphine. Additionally, this approach may be significant for patients stabilized on high doses of methadone who may not be able to tolerate a traditional buprenorphine induction.

An exploration of the most frequent comorbidities in patients with mobile phone addiction

O. Vasiliu^{1*} and D. G. Vasiliu²

¹Psychiatry, Dr. Carol Davila University Emergency Central Military Hospital and ²Regina Maria Foundation, Bucharest, Romania

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.857

Introduction: Mobile phone addiction (MPA) has been associated in the literature with various psychiatric comorbidities and psychological risk factors, which indicates the need to screen these patients for multiple disorders. However, a clear protocol for the evaluation of individuals with an MPA does not yet exist, therefore, investigating the most prominent risks for comorbidities is considered necessary from the perspective of developing structured methods of assessment.

Objectives: The main objective of this review was to determine the available existence able to describe the most common comorbidities in individuals presenting with MPA.

Methods: Data regarding MPA were collected from the main medical electronic databases (PubMed, Cochrane, Clarivate/Web of Science), but also from other sources (main engines research and grey literature). All published papers between January 2000 and July 2023 were included in the primary selection, if they corresponded to the paradigm „mobile phone addiction”/”cell phone addiction”/”mobile phone dependence” and „comorbidity”/”dual diagnosis”.

Results: Based on the review of six papers, the most frequently reported comorbidity in MPA patients were substance use disorders (mainly nicotine and cannabis) and other behavioral addictions (especially problematic Internet use). Other symptoms or syndromes reported in the literature as co-occurring with MPA were anxiety, depression, high levels of stress-related pathology, sleep disturbances, emotional instability, and somatization. Overall lower levels of mental health were reported in patients with MPA. A heterogeneity in the results of these epidemiological studies was observed because of the different instruments administered and the populations explored.

Conclusions: The screening for detection of comorbid disorders or psychological problems in patients with MPA is important because the case manager should integrate all this information into a therapeutic strategy.

EPV0063

The awareness of behavioral addictions in general practitioners- An epidemiological report

O. Vasiliu

Psychiatry, Dr. Carol Davila University Emergency Central Military Hospital, Bucharest, Romania

doi: 10.1192/j.eurpsy.2024.858

Introduction: Although the research on behavioral addictions (BAs) is continuously developing, the awareness about this category

of disorders and their important negative consequences still remains a problem for many physicians. This phenomenon is associated with delayed diagnosis and treatment initiation, lack of valid epidemiological data about these pathologies, and overall lower quality of life in these patients.

Objectives: The main objective of this study was to explore the awareness of GPs on the general diagnosis criteria of BAs.

Methods: An online questionnaire addressed to general practitioners (GPs) investigated the level of their knowledge regarding the main criteria for diagnosis in five more commonly reported BAs, i.e., gambling disorder, problematic Internet use, cell phone addiction, food addiction, and shopping addiction. The questionnaire included 50 items and required 20-25 minutes to complete. The answers were anonymized.

Results: Answers from 12 GPs were analyzed, with an 80% completion rate. Gambling disorder was the only diagnosis recognized by all the respondents, followed by shopping addiction (50%) and abusive Internet use (33.3%). Lack of time to screen for these disorders was the most frequently invoked reason for not including instruments dedicated to BAs in the regular visits to the GPs. The Internet was admitted by all the respondents as their source of information about BAs.

Conclusions: There is an acute need to improve the knowledge of GPs about the existence and consequences of BAs in order to increase the probability of early detection and treatment initiation for these patients. It is expected that Internet-based campaigns for increasing GPs will benefit BAs patients in the long term.

Drama-based therapy program in the recovery of adults with addictive disorders

M. Krupa^{1*} and A. Balogh-Pécsi²

¹Department of Hungarian and Applied Linguistics, University of Szeged, Szeged and ²University of István Széchenyi, Győr, Hungary

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.859

Introduction: Following the pandemic, we can find many new communication situations. Social relationships have changed a lot and are developing differently due to digital development, new lifestyles, and the effects of COVID-19. These components: social media, the transformation of interpersonal relationships, and the use of the platforms provided by the internet can lead to addictive disorders as risk factors.

Objectives: In this presentation, we review studies investigating the relationship between the new digital techniques, social connection, and communication development of adults with addictive disorders. We attempt to provide a summary of new theories and the areas currently being researched around the topic. Another aim of our research is to present the new drama-based therapy theories and methods in adults with addictive disorders.

Methods: To learn about recent international results, we conducted a literature search in 3 databases (PubMed, Medline, Web of Science) using the following keywords: drama therapy, addiction, emotion regulation, and adults, over the past 5 years. Empirical journal articles in English were used to prepare the literature review.

Exclusion criteria were: the appearance publication before the year 2017 and the adolescent population.

Results: Changes in social behavior, emotion regulation, and addictive disorder were correlated. The studies examined social communications and loneliness in primarily cross-sectional studies design. The escapism from interpersonal relations and low self-esteem is the highest motivation to start regular videogame playing or using social media without control which becomes an addictive disorder.

Conclusions: Problematic social media use and changes in social connection threaten adults' mental health. The diagnosis of emotion dysregulation, low self-esteem, and social disconnection is the detection of risk factors for addictive disorders. The new methods and tools of drama-based therapy are new prevention possibilities for these risk factors. In this way, it is a relevant issue in the field of education science.

Revolutionizing Addiction Medicine: The Role of Artificial Intelligence

S. Poudel^{1*}, J. Choudhari¹, N. Panta², H. Kumar³, D. Leszkowitz⁴ and S. S. Ahmed¹

¹Department of Research & Academic Affairs, Larkin Community Hospital, South Miami; ²Kathmandu Medical College, Kathmandu, United States; ³Dow University of Health Sciences, Karachi, Pakistan and ⁴Department of Addiction Medicine, Larkin Community Hospital, South Miami, United States

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.860

Introduction: Addiction medicine is becoming more of an issue as addiction-related problems continue to plague people all over the globe, resulting in serious health consequences. Addiction has become increasingly prevalent in recent years, as have addiction-related disorders. For efficient care and improved patient outcomes, this growing pandemic requires early and precise identification. In the field of addiction medicine, artificial intelligence (AI) looks to be a feasible tool. This systematic review examines the current state of research on the use of AI in addiction medicine, including a variety of AI techniques, their efficiency compared to conventional diagnostic methods, and their potential influence on addiction therapy. While AI has great potential for transforming addiction treatment, further research is needed to assess its use fully.

Objectives: The objective of this review is to assess the current state of research on the use of artificial intelligence in addiction medicine, focusing on its diagnostic efficacy and potential for revolutionizing addiction therapy.

Methods: To evaluate the effectiveness of AI in addiction medicine, we conducted an extensive search of the PubMed database. Our search encompassed articles published in the English language from January 2013 to March 2023. Inclusion criteria encompassed studies reporting the utilization of AI for addiction diagnosis in human patients.

Results: The initial PubMed search produced 100 papers, of which 15 were included after meticulous analysis and screening.

These studies assessed diverse types of data, including patient records and behavioral patterns, employing various AI techniques, such as machine learning and deep learning. The findings indicate that AI can accurately and swiftly identify addiction-related issues, boasting high sensitivity and specificity rates. Additionally, AI demonstrates potential in identifying specific addiction subtypes and forecasting patient outcomes. Nevertheless, these studies also underscore certain limitations of AI, such as the requirement for extensive data and susceptibility to overfitting.

Conclusions: Artificial intelligence holds the potential to revolutionize addiction medicine by enabling faster and more precise diagnostics, pinpointing specific addiction subtypes, and predicting patient outcomes. However, further research is imperative to validate AI's efficacy across diverse patient populations and address challenges related to data accessibility, communication, and integration into clinical practice.

EPV0066

Cannabinoids Hyperemesis Syndrome – An Urgent Call for Timely Diagnosis, Management, and Future Directions– A Case Report and Review of the Updated Literature

S. Poudel^{1*}, J. Choudhary¹, N. Panta², H. Kumar³, S. Ahmed¹ and D. Leszkowitz⁴

¹Department of Research & Academic Affairs, Larkin Community Hospital, South Miami, United States; ²Kathmandu Medical College, Kathmandu, Nepal; ³Dow University of Health Sciences, Karachi, Pakistan and ⁴Department of Addiction Medicine, Larkin Community Hospital, South Miami, United States

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.861

Introduction: Cannabinoid Hyperemesis Syndrome (CHS) is distinguished by a pathognomonic cyclic pattern of hyperemesis characterized by recurring episodes of severe vomiting every few weeks to months, as well as obsessive thoughts and compulsive behavior, such as a proclivity to take frequent hot baths or showers. It is largely accepted as the most commonly used illicit drug in the United States, with estimates ranging from 42% to 46% lifetime consumption. Despite greater awareness of CHS, practitioners continue to lack comprehension, resulting in an unfortunate delay in patient identification and treatment.

Objectives: The aim of this article is to bring attention to CHS in order to enable clinicians, and more specifically, addiction medicine specialists and psychiatrists, to diagnose it as quickly as possible and thus avoid unnecessary additional invasive examinations and investigations. This will save the patient's time, prevent financial burdens and mental health stresses, and increase their overall quality of life.

Methods: A thorough screening and data extraction of the relevant articles was conducted using PubMed, Cochrane, and Embase. Databases were used to search for articles on CHS published between January 2021 and September 2023, yielding relevant articles. Keywords used were "hyperemesis", "cyclical vomiting", "cannabis" and "cannabinoid".

Results: We present a case of 20-year-old teens who came to emergency with severe dehydration and vomiting of more than 40 episodes at home. He had multiple admissions for abdominal pain, nausea, and vomiting in the past and was evaluated and diagnosed with gastritis, PUD, and H. pylori infection. A more detailed medical history revealed a frequent use of cannabis over the past few years and symptoms manifestation and worsening is associated with the use of cannabis. After the complete cessation of cannabis, there have been no new symptomatic episodes reported in the patient and the patient is stable clinically.

Conclusions: Cannabinoid Hyperemesis Syndrome (CHS) is a serious health hazard that requires immediate discovery and treatment. Despite the widespread use of cannabis, CHS is often misdiagnosed, resulting in unnecessary medical treatments and complications for patients. Given their special knowledge of linking chronic cannabis use to this syndrome, this case report and literature review highlight the critical role of addiction medicine experts and psychiatrists in quickly detecting and treating CHS. Early detection and treatment, particularly complete cannabis abstinence, are critical in alleviating symptoms, minimizing recurrent hospitalizations, and ultimately improving patients' overall quality of life.

EPV0067

What Do Case Studies Tell Us About Addictions and Psychiatric Comorbidities? A Survival Story: The necessity for a transdiagnostic and holistic approach

B. D. Ulug^{1*} and H. C. Ozden¹

¹Psychiatry, Hacettepe University, Ankara, Türkiye

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.862

Introduction: Comorbidities in addiction: It is a rule rather than an exception. The story starts in childhood; even before, in infancy, may be in utero. The dimensional traits have been already there, existing obviously far before any DSM-5 diagnosis. Developmental qualities of stress sensitivity, impulsivity and emotion dysregulation are the leading ones. Besides, comorbidity research (NESARC being one of the prominent) (Hasin and Grant. Soc Psychiatry Psychiatr Epidemiol, 2015;50 (11): 1609-1640) addressed childhood abuse, neglect or other childhood adverse experiences as a definite risk factor for adolescence and adult mental disorders, particularly substance use disorders. Developmental and environmental adversities in a mutually amplifying pattern make a vicious cycle in which the individual finally finds an illusionary exit, a pathway to addiction.

Objectives: This presentation aims to discuss the complexities and challenges for the diagnosis and treatment of a patient with a twenty five year follow-up, a survival period for the patient herself as well as for the therapeutic alliance (Ulug, Arch Neuropsychiatr, 2015;52: 213-215).

Methods: Case study: The history and the life chart of her, diagnosed as having at least seven DSM diagnoses, indicate the depth of psychopathology and the intensity of interventions, most of which failed due to the lack of a transdiagnostic and holistic perspective. A specific focus of the case study will be on the problematic use of Borderline Personality Disorder formulation/diagnosis and its

negative, somehow short-coming, impact on the treatment, course and recovery.

Results: The challenges brought by comorbid transdiagnostic cases, similar to the subject of this presentation, have become a common practice for addiction professionals. While big data or empirical large datasets can have their own limitations to help the practitioner for overcoming such challenges, as stated in Stein's article "it is important to recognize the value of a wide range of complementary research designs including the age-old single-case study, which may sometimes provide clinical insights that outweigh those from big data analyses." (Stein et al. *World Psychiatry*, 2022; 21(3): 393-414).

Conclusions: The case study indicates the necessity for transdiagnostic and holistic approach in the management and long term treatment of such difficult-to-diagnose and difficult-to-treat patients.

EPV0068

Cortisol Levels Correlated with Exposure to Alcohol Related Visual Stimuli in Patients with Alcohol Use Disorder

A. Mihai^{1*} and M. Valeriu²

¹Psychiatry, University of Medicine, Pharmacy, Technology and Science and ²Mureş County Hospital, Targu-Mures, Romania

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.863

Introduction: The mechanism of craving is not yet fully understood. It implies numerous factors contributing to the decisions an individual has to ponder when faced with a stimulus that has resemblance with the previous experiences related to it. Neural pathways implying the reward mechanism play a significant role in the interpretation of visual, auditory, olfactory stimuli, polarizing the perception towards positive or negative experiences with that substance of abuse.

Objectives: In this study we focus on the cravings related to alcohol use, in a sample of patients admitted in hospital due to alcohol use disorder pathologies, providing the fact that Romania has the 2nd highest prevalence of heavy episodic drinking at least once a month (35% of adults, in a statistic published by Eurostat in 2019).

Methods: We included 30 patients with alcohol use disorder. The PACS (Penn Alcohol Craving Scale) was used to assess the severity of craving in the week prior to the hospital admission. Before visualising any alcohol related cues using VRET, patients will have a half hour of group therapy to lower levels of anxiety. Cortisol and blood sugar will be measured after this half hour to set a baseline. Afterwards, using VRET, subjects will be asked to watch a number of visual stimuli that will include cues to alcohol consumption and different types of beverages. Half hour after visualising cues of alcohol, the craving will be assessed by measuring blood sugar and salivary cortisol levels once again. Completing these measurement, patients will be asked to complete the PACS scale one more time to correlate the patients craving with the biological findings. Blood sugar levels will be measured with a blood glucose meter with test strips. Cortisol levels will be measured using salivary levels of cortisol. We choose measuring the salivary

levels of cortisol, due to the fact that using this method, the biological active, free cortisol. Measurements of the serum cortisol indicate the total quantity, but not the biologically effective cortisol.

Results: Visual stimuli of alcohol, with the help of VRET modifies the autonomous glucocorticoid secretion, and provide objective information complementary to the each individual's craving assessment

Conclusions: There are a great number of strong ties between alcoholic craving in patients and endogenous shifts in cortisol secretion. We aimed towards a better understanding on craving in patients hospitalised for AUD. Other directions for future research are to find out if it possible to consider craving a form of stress or if we could limit craving, by limiting stress.

Motives for MDMA Use: A Comparative Study with Alcohol and Cannabis

D. Zullino^{1*}, L. Penzenstadler², S. Rothen¹, F. Seragnoli¹, A. S. Girardet¹, G. Calzada¹ and G. Thorens¹

¹Service d'addictologie and ²Hôpitaux Universitaires de Genève, Genève, Switzerland

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.864

Introduction: While research on drug use motives has primarily focused on widely used substances like alcohol, tobacco, and cannabis, understanding the motivations behind MDMA use is crucial for developing targeted therapeutic, preventive, and harm reduction strategies.

Objectives: The objective of this study is to present the findings of an online survey that evaluates the motives behind the use of 3,4-methylenedioxymethamphetamine (MDMA) and draws comparisons between these motives and those for alcohol and cannabis consumption.

Methods: Data were collected through an online survey, available in both English and French, with 99 participants. The survey included five sections, including a substance abuse screening test (ASSIST) and the Pahnke-Richards Mystical Experience Questionnaire. The primary focus was on motives for MDMA use, assessed using an adapted version of the Marijuana Motives Measure (MMM), comparing them with alcohol and cannabis motives.

Results: The most reported motive for MDMA use was enhancement, followed by expansion motives. Social motives were the third most common, while coping motives ranked fourth, and conformity was the least common motive. Comparisons with alcohol and cannabis use motives revealed differences in motives for each substance. MDMA showed a unique pattern of motives.

Conclusions: Enhancement emerged as the most prevalent motive for MDMA use, consistent with previous research on MDMA motive use. Expansion motives, which involve altering perceptions and increasing self-awareness, ranked second, reflecting the growing interest in MDMA-assisted therapy for conditions like PTSD. Surprisingly, social motives were less common for MDMA

compared to alcohol and cannabis, suggesting unique social dynamics associated with MDMA use. Conformity motives were also less significant for MDMA users, possibly due to the age of initiation and user maturity.

Understanding the motives behind MDMA use is essential for designing effective interventions and harm reduction strategies. The distinct motives for MDMA, as compared to alcohol and cannabis, highlight the need for tailored approaches to address its use. Further research should explore the complex interplay of motives, age of initiation, social context, and cultural factors to inform comprehensive strategies related to MDMA use.

EPP0354

Kambó as a drug that can induce psychotic or manic symptoms. A case report

E. Arroyo Sánchez*, C. Díaz Mayoral and P. Setién Preciados

Hospital Universitario Príncipe de Asturias, Madrid, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.865

Introduction: Kambó, also known as the “frog medicine,” is a traditional Amazonian medicine derived from the secretions of the Phyllomedusa bicolor tree frog. It has gained global attention for its purported therapeutic properties, including its use in addressing mental health issues. However, the psychiatric effects of kambó remain poorly understood, particularly concerning manic symptoms or psychosis.

Objectives: The primary objective of this review is to comprehensively analyze and evaluate the available literature regarding the connection between kambó use and psychosis or manic symptoms. Specifically, this review seeks to determine the prevalence of psychosis among kambó users, identify potential risk factors for the development of psychosis or manic symptoms in this context, explore the mechanisms underlying any observed psychiatric effects, and provide insights into the clinical implications of kambó use.

Methods: A case report of a 34-year-old man with chronic delusional disorder who presented to the emergency department with manic symptoms coinciding in time with the use of Kambó.

Results: The findings of this bibliographical review suggest that there is limited empirical evidence to establish a direct link between kambó use and psychosis. Most available studies are anecdotal or based on qualitative reports, making it challenging to draw definitive conclusions. While some case reports and interviews suggest that kambó use may be associated with transient psychotic-like symptoms, including visual and auditory hallucinations, more rigorous research is needed to confirm and characterize these effects. Several case reports and qualitative studies suggest that individuals who have undergone kambó ceremonies may experience transient manic-like symptoms, such as elevated mood, increased energy, and impulsivity. However, these reports lack systematic assessment and standardized measurement of manic symptoms. Mechanisms underlying these effects remain speculative, with some researchers proposing altered neurotransmitter systems as a potential explanation.

Conclusions: In conclusion, this review underscores the scarcity of scientific literature on the potential association between kambó use and psychosis or manic symptoms. Although anecdotal reports and qualitative studies suggest a link, there is a notable lack of robust empirical research to support or refute this claim. Future research should focus on conducting controlled studies to elucidate the psychiatric effects of kambó, including its potential to induce psychosis and manic symptoms, while also considering cultural and individual factors that may influence outcomes. Such research would contribute to a more comprehensive understanding of kambó's psychopharmacological profile and its implications for mental health.

Anxiety Disorders and Somatoform Disorders

EPV0071

Nomophobia and psychological distress in a sample of young adults and adults

S. Pinheiro¹ and B. R. Maia^{2*}

¹Universidade Católica Portuguesa and ²Universidade Católica Portuguesa, Center for Philosophical and Social Sciences, Braga, Portugal

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.866

Introduction: Nomophobia comes from the term “no-mobile-phone phobia” and describes the discomfort, stress, or anxiety caused by the absence of a cell phone or any other virtual communication device in individuals who use these devices frequently. Research, although scarce, points to a statistically significant relationship between nomophobia and psychological distress factors such as anxiety, depression, and stress.

Objectives: To explore the relationship between nomophobia and psychological distress in a sample of young adults and adults

Methods: The sample was composed of 194 Portuguese subjects, aged between 18 and 30 years old ($M = 22.08$, $DP = 2.89$), who fulfilled a sociodemographic questionnaire, and the Portuguese version of the Nomophobia Questionnaire, and of the Anxiety, Depression, and Stress Scale.

Results: The entire sample showed some type of nomophobic symptomatology, specifically 59.3% ($n = 106$) had moderate nomophobia and 24.2% ($n = 40$) had severe nomophobia. Positive and statistically significant correlations, with strong magnitude, were found between nomophobia and anxiety (.46**), depression (.58**), and stress (.50**) subscales. Females presented significantly higher nomophobia levels ($Md = 109.35$) compared to males ($Md = 71.66$), $U = 2480.50$, $p < .001$, with an high effect size ($d = .69$). A significant and negative correlation was found between nomophobia and age ($-.18^*$).

Conclusions: Nomophobia was present in all the sample, and it is related to psychological distress. Females and younger subjects presented higher nomophobia levels. Further studies are needed to clarify their etiology, but some preventive and remediative actions need to be developed in order to minimize its emergence and their negative psychological impact.

EPV0072

Exploring the Impact of 2023 Wildfires on Generalized Anxiety Disorder Symptoms among Residents in Alberta and Nova Scotia

G. Obuobi-Donkor^{1*}, R. Shalaby², B. Agyapong²,
R. D. L. Dias¹ and V. I. O. Agyapong^{1,2}

¹Department of Psychiatry, Dalhousie University, Halifax and

²Department of Psychiatry, University of Alberta, Edmonton, Canada

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.867

Introduction: Raging wildfires are rising in diverse areas, leading to significant environmental and psychological repercussions that are drawing growing concern.

Objectives: This study seeks to assess the prevalence of likely Generalized Anxiety Disorder (GAD) and investigate the factors contributing to its occurrence amidst the wildfires in Alberta and Nova Scotia.

Methods: Data were collected online through a cross-sectional survey from May 14 to June 23, 2023. Alberta and Nova Scotia participants self-subscribe to the program by texting 'HopeAB' or 'HopeNS' to a designated short code, respectively. The GAD-7 validated scale assessed likely GAD symptoms among the participants.

Results: There were 298 respondents in this study, with a majority residing in Alberta/Nova Scotia areas affected by recent wildfires (62.3%). Among the respondents, 41.9% were likely to experience Generalized Anxiety Disorder (GAD) symptoms. Those living in regions recently impacted by wildfires in Alberta/Nova Scotia were found to be twice as likely to have GAD symptoms, with an odds ratio of 2.4 and a confidence interval of 95% ranging from 1.3 to 4.3.

Conclusions: The study's findings highlight a relationship between living in areas affected by wildfires and the likelihood of experiencing generalized anxiety disorder (GAD). Exploring potential predictors through additional research could aid in developing strategies to alleviate the mental health impact of natural disasters.

Disclosure of Interest: None Declared

EPV0073

Factors Affecting Student Anxiety estimated by linear regression

T. Urtnasan* and N. Namdag

¹Mental health, Etugen, Ulaanbaatar, Mongolia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.868

Introduction: This study was conducted to estimate anxiety levels at the university level to address the issues of changing the healthy lifestyle of students, promoting health, spending their free time properly, being healthy, and developing good habits.

Objectives: The aim is to study the factors affecting student anxiety.

Methods: The study was conducted by random sampling of 1356 students from the 1st to 5th year of the medical school of Etugen University in the academic years 2020-2022.

Results: 4.3%(58) of students' inherent anxiety was low, 62.3% (845) was moderate, and 33.4%(453) were high, while 4.2%(57)

had low anxiety and 42.4% (575) were anxious due to the student's situation. had moderate anxiety and 53.4% (724) had high anxiety.

According to the research, 69.9% (948) had a low level of motivation, 23.4% (317) had a below-average level, 5.6% (76) had an average level, and 1.1% (15) had an above or higher level.

There is a weak inverse relationship between congenital anxiety and the course of study ($r=-0.054^*$), and a weak inverse relationship between age ($r=-0.048$). There is a weak ($r=-0.125^{**}$) inverse relationship between situational anxiety and the course of study, and a weak ($r=-0.127^{**}$) inverse relationship between age.

When examining the relationship between students' natural anxiety and the factors influencing it, there is a moderate ($r=0.630^{**}$) direct correlation between natural anxiety and situational anxiety. According to the one-factor linear regression analysis of students' congenital anxiety ($B=-1.964$; 95%CI (-3.07 - 0.858); $p<0.01$), increasing the age by one increases congenital anxiety by 1.964 times, $p<0.01$, which means that the linear model is good, indicating a match.

Multivariate linear regression analysis showed that situational anxiety ($B=3.845$; 95%CI (6.288 - 347.90); $p<0.01$) or a one-level increase in situational anxiety increased congenital anxiety 3.845 times $p<0.00$. is relevant

Conclusions: According to the multivariate analysis, there is a linear significant relationship between one increase in student age, and -1.256-fold decrease in situational anxiety, and a -5.464-fold decrease in situational anxiety when not suffering from mental illness.

Disconnecting from my heartbeat: About a case of derealization in a critically ill patient

C. Alario Ruiz*, M. S. Oscar, N. Navarro Barriga, R. R. Beatriz and R. V. Claudia

Hospital Clínico Universitario de Valladolid, Valladolid, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.869

Introduction: Depersonalization/derealization encompasses a series of symptoms that are difficult to describe by the patient, as well as complex to diagnose by the professional, and can go through multiple diagnoses prior to the diagnosis of certainty.

Objectives: It is proposed, through a clinical case, to know the characteristics of this disorder, evolution, differential diagnosis and therapeutic possibilities

Methods: 62-year-old male, history of harmful alcohol consumption and a previous admission to a psychiatric short hospitalization unit for self-injury (superficial cuts in the context of severe mental illness of his wife) post-transplantation who is required by ideas of death, anhedonia and lack of collaboration in patient, The day before the evaluation, refusal to take oral treatment, selective mutism. Pre-transplant evaluation where no psychopathological alteration was observed.

Results: What is initially assessed and treated as a confusional episode of inactive type, through a correct psychopathological examination and with subsequent continuous interviews, with

mood fluctuations throughout the admission, is subsequently oriented as an acute stress disorder, adaptive reaction with an anxious-depressive component and finally concluding that we are facing a dissociative disorder, highlighting the depersonalization/derealization on a dysfunctional personality base.

Conclusions: Characteristic of depersonalization is the great difficulty in describing symptoms, the feeling of being disconnected from one's own body, emotions and reality. The latest studies on etiopathogenesis with MRI show an inhibitory response on the limbic system by hyperactivation of the ventrolateral prefrontal cortex as well as a decrease in the autonomic response, the initial result being the attenuation of the processing of emotions. Among the differential diagnoses: post-anxiety illness disorder, major depressive episode, other dissociative disorders, panic disorder, psychotic disorder, substance-induced disorder. There are several partially effective treatments, although the results so far are poor. SSRIs, quetiapine and naltrexone have been tried. Partial efficacy with lamotrigine together with SSRIs and, if high levels of anxiety coexist, SSRIs together with clonazepam. There are studies where psychodynamic psychotherapy, behavioral therapy and hypnosis have obtained partially effective results.

Quality of Life Assessment in Patients with Knee Osteoarthritis

A. Feki^{1,1*}, I. SELLAMI², F. Ellouze³, M. Yahya³, S. Baklouti¹ and M. H. Elleuch³

¹Rheumatology; ²Occupational medicine, Hedi Chaker Hospital and ³Physical Medicine and Functional Rehabilitation, Habib Bourguiba Hospital, Sfax, Tunisia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.870

Introduction: Osteoarthritis is one of the most common diseases and a leading cause of functional limitation and dependence, significantly impacting the quality of life (QOL).

Objectives: The aim of this study was to evaluate the impact of knee osteoarthritis on QOL and identify associated factors.

Methods: This prospective cross-sectional descriptive study was conducted in the Physical Medicine and Functional Rehabilitation Department over a 4-month period, involving patients with symptomatic bilateral knee osteoarthritis (according to the American College of Rheumatology (ACR) criteria). Sociodemographic data, comorbidities, and characteristics of knee osteoarthritis were collected. The assessment of QOL and the functional impact of knee osteoarthritis were based on the KOOS (Knee Injury and Osteoarthritis Outcome Score) self-questionnaire, Lequesne Index, and modified WOMAC (Western Ontario and McMaster Universities Osteoarthritis Index) Score. The KOOS questionnaire included 5 subscales: pain (KOOS-Pain), symptoms other than pain (KOOS-Symptoms), activities of daily living (KOOS-ADL), sports and recreational function (KOOS-Sport), and QOL (KOOS-QOL).

Results: We included 30 patients with an average age of 59.27 ± 6.3 ; the male-to-female ratio was 0.15. Sixty percent of patients lived in urban areas, with varying levels of education: primary (n=10),

secondary (n=4), and university (n=4), while the majority were illiterate (40%). Most of our patients were employed, with 64.28% engaging in significant physical activity, resulting in an average of 6 ± 2 days of work absenteeism every 3 months due to knee pain. The mean duration of knee osteoarthritis was $7.97 \text{ years} \pm 3.14$. The average pain visual analog scale (VAS) score was 5.2 ± 0.4 . Knee osteoarthritis was classified as stage 2 in 40% and stage 3 in 60% of cases. Regarding functional impact, the mean WOMAC global index was 16.6 ± 4.68 , and the mean Lequesne Index was 11.05 ± 3.45 ; moderate disability was observed in 16.7%, significant disability in 50%, and severe disability in 16.7% of patients. Furthermore, the KOOS questionnaire revealed decreased KOOS-Sport and KOOS-QOL scores, with mean values of 35 ± 10.2 and 37 ± 8.9 , respectively. Our study identified factors associated with a poor quality of life: age > 65 years ($p < 0.05$), disease duration ($p = 0.02$), and VAS pain > 5 ($p = 0.02$).

Conclusions: Improving the quality of life is an essential therapeutic goal in managing knee osteoarthritis. Our study demonstrates that advanced age, longer disease duration, and high pain intensity can negatively impact quality of life.

The impact of Obstructive Sleep Apnea Hypopnea syndrome severity on depression and anxiety disorders

A. Fki^{1*}, A. Ben Lazreg², R. Bouchech³, R. Ben Cheikh³ and G. Sakly³

¹occupational medicine, Sahloul university hospital; ²Faculty of medicine and ³department of neurophysiology, Sahloul university hospital, Sousse, Tunisia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.871

Introduction: Obstructive sleep apnea hypopnea syndrome (OSAHS) is a chronic source of stress that can alter the emotional state of affected patients.

Objectives: This study aimed to assess the impact of OSAHS severity on depression and anxiety disorders in a Tunisian population of apneic patients.

Methods: We conducted a cross-sectional study, involving 40 patients diagnosed with OSAHS by polysomnography in the Sleep unit, department of Neurophysiology at Sahloul university hospital in Sousse, Tunisia. Anxiety and depressive disorders were detected using the Arabic version of the HADS (Hospital Anxiety and Depression Scale).

Results: The mean age was 49.7 ± 7.87 years with a sex ratio of 1.1. The mean apnea-hypopnea index (AHI) was 29.72. OSAHS was mild, moderate and severe in 40%, 22.5% and 37.5% of cases respectively. One third (30%) of patients received a treatment with continuous positive airway pressure (CPAP). The prevalence of depression in the study's patients, according to the HADS, was 56.4% and that of anxiety was 59%. There was a positive linear relationship between AHI and scores of depression and anxiety ($p = 0.045$ and $p = 0.037$ respectively). Similarly, a significant association was found between HAD scores and treatment with CPAP ($p < 0.05$).

Conclusions: These results show a high frequency of anxiety-depressive disorders in patients with OSAHS. Severity of OSAHS

and CPAP treatment proved to be determining factors in anxiety and depressive disorders, hence the importance of detecting these disorders in order to improve patients' quality of life.

Non-Adaptive Defense Mechanisms and Their Relationship to Psychosomatic Disorders among a Sample of University Students

D. M. M. M. Almajali and N. S. G. Abdelrasheed*

Education, dhofar University, dhofar, Oman

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.872

Introduction: In the university stage, the student is exposed to many psychological changes, pressures, and conflicts, which makes him resort to many non-consensual psychological defense mechanisms such as (repression, justification, projection, relapse, denial, delusional illness, reverse transference, day-dreaming), which causes an imbalance in the personality and its psychological functions. This may lead to cognitive and mental distortions and physiological imbalances, and the appearance of symptoms that cause psychosomatic disorders that are not due to organic physiological imbalances or bacterial diseases, but rather as a result of imbalances in the psychological functions of the ego, Which increases the symptoms of headache, vomiting, poor digestion, irritable bowel syndrome, shortness of breath, rapid heartbeat, hormonal imbalance, facial redness, and others.

Objectives: 1. Identifying the degree of use of non-consensual psychological defense mechanisms among university students, and the differences in this according to the variable (gender and degree of academic achievement)

1. Revealing the correlation between the degree of use of non-consensual psychological defense mechanisms and the emergence of disturbed psychosomatic symptoms in the functions of (the respiratory system, the digestive system, the cardiac system, the muscular system, sleep disorders, and bodily disorders).

Methods: The correlational analysis approach was used to study the relationship between the variables of the study. The sample consisted of 300 male and female university students. A scale for psychological defense mechanisms was constructed, and a scale for psychosomatic disorders prepared by Diop (2011) was adopted, and its psychometric properties were verified.

Results: The responses in the degrees of non-consensual psychological defense mechanisms were varied, with a high degree in (justification, projection, repression, and delusional illness) and a moderate degree in (relapse, daydreaming, denial, and reverse transference). Differences appeared between males and females in favor of males, while differences in academic grades were in favor of the lowest grade. The results also showed a statistically significant correlation between psychological defense mechanisms and the appearance of psychosomatic symptoms, as it was high in disorders (respiratory system, cardiac system, muscular system, sleep disorders), and moderate in (emotional disorders and somatic disorders).

Conclusions: There is a positive correlation between the degrees of use of non-consensual psychological defense mechanisms and the

emergence of psychosomatic disorders, in the functions of several bodily systems and behavioral and emotional disorders.

Interrelations of phantom ringing related anxiety and personal self-esteem in undergraduate university students

E. L. Nikolaev¹ and M. Alhasan^{2*}

¹Department of Social and Clinical Psychology and ²Medical Faculty, Ulianov Chuvash State University, Cheboksary, Russian Federation

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.873

Introduction: Manifestations of phantom ringing syndrome are widely seen in healthy population. Are there any interrelations between this phenomenon and personal psychological characteristics that are connected with the level of their mental health?

Objectives: To determine the specificity of interrelations of phantom ringing syndrome related anxiety and personal self-esteem in university students

Methods: The anonymous survey covered 546 undergraduate university students. The questions were centered on the students' patterns of their personal smartphone use.

Results: The research showed that manifestations of phantom ringing syndrome is available in 189 students, or in every third student (34.6%), who use mobile phones. It is equally represented in males (49.7%) and females (50.2). Clinically, it is characterized by a higher level of anxiety, which reliably correlates ($p < 0.01$) with the level of stress ($r = .17$), level of nervousness caused by absence of a mobile phone ($r = .18$), the frequency of headache ($r = .15$), the frequency of medication consumption related to chronic somatic disease ($r = .15$). We also established valid negative interrelations between the level of phantom ringing syndrome related anxiety and the personal self-esteem based on the parameters of religious belief ($r = -.15$), personal attractiveness ($r = -.16$), mind ($r = -.17$), happiness ($r = -.24$), liveliness ($r = -.25$) and well-being ($r = -.15$). We have not found any proof of valid interrelations with self-assessment of health.

Conclusions: The received results prove that phantom ringing syndrome related anxiety is connected with the personal self-esteem, the level of the perceived stress and some other clinical manifestations

EPV0081

Pimozide as an effective treatment for obsessive symptoms related to physical discomfort in the context of somatoform symptomatology.

P. Del Sol Calderon^{1*}, A. Izquierdo de la Puente¹, R. Fernández² and M. García Moreno¹

¹Psychiatry, Hospital Puerta de Hierro and ²Psychiatry, Hospital Universitario Infanta Cristina, Madrid, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.874

Introduction: The patient was a 34-year-old male admitted to the psychiatric inpatient unit for high anxiety and suicide ideation due to severe toothache.

Objectives: To show how the antipsychotic pimozide can be an effective option for the treatment of anxiety and obsessive symptoms around physical complaints within the spectrum of somatoform disorders

Methods: Case report and literature review

Results: The patient comes to the emergency room with high anxiety and active self-harming ideation. He reports that for months he has been experiencing mouth pain that is becoming more and more intense. He has seen multiple professionals without finding a cause that justifies the pain. In the past she has a history of multiple ailments (knee, abdominal pain...). He is being treated with sertraline 150, clonazepam 3 mg per day and olanzapine 5 mg at night. During admission, treatment with pimozide up to 4 mg per day was started. The patient is progressively less distressed and with more distance from the ideas about pain, being able to carry out more activities during the day. There is remission of suicidal ideation

Conclusions: There is evidence in the literature that the use of pimozide was effective in different psychotic disorders. It has been seen to reduce the intensity of symptoms in cases of delusional disorders with delirium of somatic type or those such as delusions by parasitization. The use of pimozide has also been effective in the treatment of complex tic disorder. In this case it is effective and could be explained by the close relationship of obsessive symptoms with psychotic symptoms.

EPV0082

The Effect of the Apollo Neuro Device on Anxiety Among Participants who Underwent Ketamine Assisted Therapy

V. Tsang

UBC, Vancouver, Canada

doi: 10.1192/j.eurpsy.2024.875

Introduction: The study aimed to evaluate the effectiveness of a device called “Apollo” in reducing anxiety, as compared to a control group. Participants were divided into two groups: the intervention group (receiving the “Apollo” device) and the control group (receiving no intervention).

Objectives: The primary outcome measure was the change in Generalized Anxiety Disorder 7-item (GAD-7) scores, calculated as the difference between post-GAD-7 and pre-GAD-7 scores.

Methods: Participants were recruited from two different cohorts, with the intervention group derived from the “Apollo” dataset and the control group derived from the “KaT Cohort 9” dataset. Matching was performed based on Age, Sex, and pre-GAD-7 scores to create comparable groups.

For those with full datasets, a total of 4 (out of 5) participants from the “Apollo” group were matched with 15 (out of 45) participants from the “Control” group, based on the selected criteria. Data cleaning was performed to handle missing values and non-numeric entries. Propensity score matching was used to match participants from the “Apollo” and “Control” groups based on Age, Sex, and pre-GAD-7 scores. An independent samples t-test was conducted to compare the mean change in GAD-7 scores between the two groups. Since propensity score matching requires complete data on

matching factors (age, sex, pre-GAD-7), those without full datasets were excluded.

Results: The median change in GAD-7 scores in the “Apollo” group was -8.5 , indicating a median reduction in anxiety symptoms. The independent samples t-test revealed no statistically significant difference in the change in GAD-7 scores between the “Apollo” and “Control” groups ($t = -0.889$, $p = 0.387$). Therefore, the study so far did not conclude a significant difference.

Conclusions: Ketamine assisted therapy remains a promising way to decrease anxiety among patients with generalized anxiety disorder and elevated GAD-7 scores. Ways to potentially improve these results are increasing the number of Apollo patients and having more balanced numbers between groups.

Cannabis Use and Its Interaction with Anxiety Disorders

F. Varino*, T. Duarte, F. S. Silva, P. Froes, A. M. Fernandes and P. Baronet

Psychiatry, Centro Hospitalar Universitário Lisboa Norte, Lisbon, Portugal

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.876

Introduction: Cannabis use has been reported to cause a myriad of acute adverse reactions, including those linked to anxiety disorders, such as panic attacks and derealization. Notably, in the emergency department, anxiety makes up a significant proportion of the complaints related to cannabinoid consumption. Several reports show these symptoms can persist after the cessation of cannabis consumption. Consequently, some questions have arisen regarding the role of cannabinoids as precipitators for anxiety disorders in vulnerable individuals. Alternatively, it has been hypothesized that patients with anxiety disorders are more prone to using cannabis.

Objectives: We aim to understand whether there is an established relationship between anxiety disorders and cannabis use. Moreover, we intend to identify what are the factors which make an individual more likely to experience anxiety following cannabis consumption.

Methods: A search was conducted in the PubMed database using the MeSH terms “cannabis”, “panic disorder”, “anxiety”, “panic” and “generalized anxiety disorder”. Articles published in the last ten years were considered. Publications were selected after careful reading of their abstract. A non-systematic review of the selected articles was performed.

Results: Eight articles were included in this review. While a majority of these publications did not find a significant association between cannabis use and anxiety disorders, a small subset of analyzed articles found that cannabis use may increase anxiety severity in general, devoid of specific diagnostic association. Individuals who presented to the emergency department with anxiety complaints after cannabis use were likely to be young and to have ingested edible cannabis. History of psychiatric disease, especially substance use disorder, was common in this population.

Conclusions: Most available data suggest cannabis use is not clearly linked to anxiety disorders. However, information around this topic is scarce and heterogenous. Further research is needed focusing on the natural evolution of acute anxiety after cannabis use. Factors such as young age, presence of psychiatric comorbidities and

consumption of edible cannabis appear to contribute to a significantly increased risk of experiencing acute anxiety after cannabis use.

Role of Virtual Reality in Treating Anxiety in Child & Adolescent

K. Shah^{1*}, P. Reddy², A. Giri³ and S. Srinivas⁴

¹Wake Forest University; ²Baptist Health - UAMS Medical Education Program PGY-4 Psychiatry Resident; ³Dhaka University and ⁴Baptist Health and the University of Arkansas for Medical Sciences (BH-UAMS), Winston-Salem, United States

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.877

Introduction: Anxiety disorder affects nearly 9.4% of children aged 3-17 years. Virtual Reality (VR) provides an alternative for managing anxiety due to immersive, multisensory, and excellent distraction.

Objectives: The aim is to evaluate the efficacy of VR therapy in managing anxiety in children.

Methods: We searched PubMed, Medline, Embase, Web of Science, and Biosisdatabases with the keywords "Virtual Reality" in the context of "Anxiety Disorders" and included 8 relevant studies published in English until February 10, 2023, for our qualitative synthesis.

Results: The VR-Guided relaxation (VR-GR) effectively decreased anxiety immediately after administration. In another trial, 4 of the 9 patients completely overcame their fears, and 8 of 9 saw an improvement in target behaviors in the autism population even after six weeks after the therapy, and the effect lasted 1 year post-treatment. In another study, VR-based therapy helped reduce anxiety and behavioral scores significantly in the VR group vs. the control. In another study, they found during pediatric intravenous catheter placement, patients who received VR therapy showed significantly less anxiety and pain compared to those who did not. In another study, they found VR therapy helped reduce anxiety during the induction of pre-operative anesthesia in children undergoing elective surgery.

Conclusions: A study discovered benefits with statistically significant results in reducing anxiety in children immediately after VR-based therapy. To explore the full spectrum of benefits and efficacy of VR-based therapy for anxiety as a standalone or adjunct to pharmacotherapy, we recommend future trials with robust study designs.

Results of anxiety disorders in a medical professional

P. Sarantuya^{1*}, B. Putev¹ and T. Myatav²

¹Medical department, Etugen university and ²Avicenna science center, Ulaanbaatar, Mongolia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.878

Introduction: Anxiety is the most prevalent disease in the world. Symptoms of anxiety disorders affect everyone. The symptoms are worse after a long period of time and more severe disease than normal. A study was conducted to support the assumption that it is an opportunity to improve healthcare services.

Objectives:

1. Anxiety disorders of doctors and medical specialists of Selenge Province General Hospital
2. Determine the relationship between certain factors and certain factors of anxiety disorders

Methods: The GAD7, SRQ20, and PHQ9, sleep system detection questionnaire methods issued by WHO for doctors of primary health care institutions were analyzed by analytical research snapshot model from 03.15 to 04.05, 2023.03.22. /1/01 was obtained and the survey was conducted.

Results: In the study, 23-65-year-olds received medical care, and the average life expectancy was 37.05 years. 30% (27) of the respondents did not have anxiety disorders, 36.67% (33) had mild anxiety disorders, 18.89% (17) had moderate anxiety disorders, and 14.44% (13) had severe health problems. 6.67% (6) of the respondents had no depression, 10% (9) had very mild depression and could cope on their own, 24.44% (22) had moderate depression and could cope, and 27.78% (25) with healthy depression. 24.44% (22) had major depressive disorder and 6.67% (6) had major depressive disorder. According to correlation analysis, GAD7 score with SRQ20 stress score $r=0.76$ and PHQ9 mood score with $r=0$. the inverse association was statistically significant at $p=0.00$. PHQ9 depression score had a strong effect on SRQ20 stress score $r=0.74$, $p=0.00$, and GAD7 score $r=0.46$, $p=0.0000$. $r=-0.40$, $p=0.00$ had a moderate inverse relationship with age, and $r=-0.24$, $p=0.00$ had a weak inverse relationship with age. In linear regression analysis, the GAD7 anxiety disorder score increased by 48.8% ($p=0.00$) when fixed at one, which was statistically significant. In logistic regression analysis, PHQ9 depression score increased by 35.08% ($p=0.01$) per entry. In composite logistic regression analysis, the PHQ9 depression score was statistically significant $OR=4.07$ ($p=0.01$) multiplied by one.

Conclusions: Doctors and medical professionals include psychological health research, testing, treatment, psychological counseling, and health care. Anxiety disorders are related to stress, depression, satisfaction, and age, while depressive disorders are anxiety disorders.

Disclosure of Interest: None Declared

Features of cognitive functions in generalized anxiety disorder: narrative review

E. L. Isakulyan^{1*} and M. P. Marachev^{1,2}

¹Neurocenter of medical and psychological correction and rehabilitation and ²Moscow Scientific Research Institute of Psychiatry Branch of V. Serbsky National Medical Research Centre for Psychiatry and Narcology, Moscow, Russian Federation

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.879

Introduction: Generalized anxiety disorder (GAD) is characterized by excessive and uncontrollable worry and anxiety about several activities or events. Although some cognitive symptoms are common in GAD patients, there are still controversial results from their linkage. Some studies indicate intact cognitive functions in GAD patients, while others suggest that anxiety and its cognitive aspect, worry, are associated with reduced performance in several cognitive domains.

Objectives: To assess the linkage and contribution of cognitive impairment to the maintenance and severity of GAD; to determine which specific domains of cognitive function are impaired in patients with GAD; and to examine age differences regarding cognitive impairment in GAD patients

Methods: A systematic literature search was executed using the PubMed and Google Scholar databases from 1960 to 2023 and the keywords “generalized anxiety disorder”, “anxiety disorder”, “cognitive function”, “cognitive dysfunction”, “cognitive impairment”, “late-life”, “young”, “adult”, and their combination.

Results: Anxiety and worry, as main characteristics of GAD, were shown to be linked and manifested by deficient attentional control, a main function of working memory. Attentional control functions are biased toward threats, which, in turn, hinders cognitive processing efficiency. Moreover, several structural and electrophysiological impairments could be linked to cognitive dysfunction in people with GAD. For example, patients with GAD showed reductions in gray matter volumes, especially in the regions of the hip, midbrain, thalamus, insula and superior temporal gyrus. The hippocampus, middle cingulate gyrus, putamen and head of the caudate nucleus also showed lower activity in response to the neutral words. Also, GAD patients have better inhibitory control, which may be associated with more severe symptomatology. These results are consistent with attentional control theory, which posits that worry might negatively impinge on inhibition and set-shifting. In terms of age differences, we observed that GAD in elderly patients is associated with impairment of short-term and delayed memory. In young adults, GAD is associated with various cognitive impairments, particularly in selective attention, working memory, cognitive flexibility, planning ability or efficiency, and other executive functions (EF).

Conclusions: To sum up, we observed that GAD is associated with worse cognitive functioning in several domains. Further research into cognitive dysfunction in GAD is needed to better understand the impact on daily living and to allow more tailored treatment strategies including medication, therapy and interventions targeted to improve specific cognitive domains.

Disclosure of Interest: None Declared

EPV0089

Treatment of Misophonia with Cognitive Behaviour Therapy: A Case Report

K. B. Avanoğlu^{1*} and C. Kılıç²

¹Department of Psychiatry, Yalova State Hospital, Yalova and ²Department of Psychiatry, Hacettepe University Hospitals, Ankara, Türkiye

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.880

Introduction: Misophonia is a condition characterized by extreme emotional reactions, such as irritation or anger, triggered by specific sounds. Despite its prevalence, there is a lack of evidence-based treatment methods for misophonia.

Objectives: This case report aims to explore the effectiveness of combining psychoeducation with Cognitive Behavioral Therapy (CBT) in the treatment of a misophonic patient. The focus is on reducing the patient's emotional distress and improving their quality of life.

Methods: The patient is a 28-year-old woman employed as a salesperson in a busy city. Mouth smacking, gum chewing and clock

ticking are the sounds that bother her the most. She has never used any medications or attempted any methods to alleviate her misophonia. Neither she, nor her family has a history of a psychiatric disorder. The therapeutic intervention spanned eight sessions, each lasting around half an hour. The first two sessions, a patient history was taken and Misophonia Interview Scale (MIS) was conducted. MIS comprised the Misophonia Checklist (MCL), which involved reading fifty misophonic sounds to the patient one by one. She then rated her discomfort in response to each sound on a four-point Likert-type scale. From the MCL responses, a total severity score (Misophonia Total Score - MTS), was calculated.

The treatment commenced with a psychoeducational component focused on enhancing the patient's comprehension of misophonia. This phase aimed to elucidate the neurobiological underpinnings of the condition, common triggers, and the emotional reactions associated with it.

Then, CBT was employed to identify and challenge the patient's negative automatic thoughts (NATs) linked to her misophonia. Three sessions primarily concentrated on identifying and managing NATs associated with her misophonia. These sessions equipped the patient with the skills to recognize and confront NATs through structured discussions and practical assignments.

The last three sessions centered on exposure therapy, with the goal of reducing emotional and physiological responses to triggers. Homework assignments during this phase encouraged the patient to independently practice exposure exercises.

Results: The initial MTS was 54, indicating significant distress. After the interventions, the final MTS decreased to 35 and the impact of misophonic symptoms on her life decreased from severe to moderate.

Conclusions: Misophonia is a challenging disorder to treat due to its limited evidence-based interventions. This case report demonstrates that a combination of psychoeducation and CBT methods may hold promise in managing misophonic symptoms. However, it is essential to acknowledge the need for further research in this area, as misophonia's treatment strategies require more robust empirical support. This case highlights the potential benefits of psychoeducation and CBT, emphasizing the need to explore and develop effective treatments for this debilitating condition.

Anxiety disorders and Quality of life: The Role of Occupational Therapy

V. Moraiti^{1*}, A. Kalmanti², A. Papadopoulou³ and G. N. Porfyri⁴

¹Early Intervention in Psychosis (EIP), Ikelos NGO (Collab. Attikon University Hospital); ²2nd Department of Psychiatry, Medical School, National and Kapodistrian University of Athens, “Attikon” University Hospital; ³2nd Department of Psychiatry, Medical School, National and Kapodistrian University of Athens, “Attikon” University Hospital, Athens and ⁴Psychiatric Department, General Hospital of Papanikolaou, Thessaloniki, Greece

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.881

Introduction: Anxiety disorders represent the most common mental illnesses, which are listed among the ten most important causes of disability worldwide. According to DSM-5, they are defined as “disorders that share characteristics of excessive fear and anxiety and

related behavioral disorders". Patients exhibit low levels of quality of life. Their daily routine is affected negatively. However, Occupational Therapy has been proven to play a crucial role in their treatment, improving quality of life through the involvement in occupations.

Objectives: To highlight the contribution of Occupational Therapy in ameliorating the quality of life in anxiety disorders.

Methods: A review of 50 articles -from 2013 to 2023- on PubMed and Google Scholar, regarding the beneficial impact of Occupational Therapy in the Anxiety Disorders' treatment.

Results: Occupational Therapists can intervene in many negatively affected -by the disease- life domains such as: Activities of Daily Living, Education, Work, Play, Social Interaction and Sleep. The most effective Occupational Therapy methods are based on the cognitive behavioral approach and include: Psychoeducation, Relaxation techniques, Social skills training and Systematic desensitization.

Other methods involve training in Activities of Daily Living such as feeding, maintaining good personal hygiene, and using public transport. Furthermore, Art Therapy (visual arts, use of clay) has been shown to reduce feelings of anxiety, while promoting creativity and enhancing self-esteem.

Conclusions: Additional research is needed regarding the effectiveness of Occupational Therapy in improving the quality of life for patients suffering from Anxiety Disorders. The important "take home message" is that the amelioration of the patients' quality of life should be the main goal of the therapeutic intervention and not a secondary result of it.

The multimodal psychotherapy of the anxiety disorders patients

V. Mishyiev¹, B. Mykhaylov^{1*}, Y. Grynevych¹ and V. Omelyanovich^{1,2}

¹Shupyk National Healthcare University of Ukraine and ²Bogomolets National Medical University, Kyiv, Ukraine

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.882

Introduction: Anxiety disorders are a common type of mental pathology with severe social and medical consequences in the lives of people suffering from them. General population studies indicate their prevalence ranges from 1.7% to 4.7% of the population. According to data from a US national study among the population aged 15 to 54 years, only 2.7% and 4.7%, respectively, suffered from panic disorder, one of the common types of anxiety disorders, during their lifetime. At the same time, the features of the emotional structure of anxiety disorders and the effectiveness of their psychotherapy among the population of low-income countries, especially in countries in a situation of prolonged bloody war and environmental disaster, remain poorly studied.

Objectives: The purpose of the study was to identify the features of the emotional symptomatic structure of anxiety disorder and evaluate the effectiveness of their psychotherapeutic correction. For this purpose, 180 patients with anxiety disorders who were hospitalized in Ukraine (during the period 2022 - 2023) were examined.

Methods: The basic method was group psychotherapy with elements of rational, positive, suggestive and family psychotherapy. Regarding emotional disorders, cognitive behavioural therapy (CBT) was used for phobic-depressive and anxiety-depressive syndromes.

Results: Most patients experienced a decrease in the level of general anxiety and internal anxiety. Almost no spontaneous occurrence of fear was observed. During active interviewing, patients stated that their previous anxieties and fears had lost their relevance and acquired clear emotional overtones. There was also a significant decrease in the symptoms of the depressive cycle, and patients began to feel joy and optimism.

Conclusions: To correct emotional dysfunction in patients with episodic paroxysmal disorders, generalized anxiety disorders and mixed anxiety-depressive disorders, it is optimal to use a system of psychotherapeutic correction built on stepwise and multimodal principles.

Effects of adding acupuncture to group psychotherapy for anxiety

L. Mehl-Madrona

Native Studies, University of Maine, Orono, United States

doi: 10.1192/j.eurpsy.2024.883

Introduction: Acupuncture has long been used in treating anxiety, and a literature exists on its effectiveness. However, acupuncture is rarely covered by government insurance (Medicaid or Medicare) or even by many commercial insurance carriers in the United States, making it inaccessible to those who cannot pay separately.

Objectives: We asked if adding acupuncture to an anxiety group would improve outcome.

Methods: We provided acupuncture during group psychotherapy for anxiety as a non-billable service. This was feasible since patients were already being billed for group psychotherapy. A physician and a social work intern led the group. At the start of the group, the physician went around the circle of group members and inserted acupuncture needles, using points in the ears, head, hands, feet, and, in the summer, arms and lower legs). The size of the group ranged from 4 to 12 people. We used Battlefield auricular points, the four gates (Large Intestine 4 and Liver 3, bilaterally), and GV24, GV29, Ht7, and Sp6. Sometimes, other points were added for other symptoms (back pain, neck pain, etc.) People sometimes joined the group without anxiety as a core problem in getting access to acupuncture. A core group of patients formed who came weekly while others came and went. The Hamilton Anxiety Scale measured anxiety after treatments 4, 8, and 12. The group lasted 90 minutes and consisted of mindfulness training, guided imagery, and CBT for anxiety. All patients met the criteria for generalized anxiety disorder. The t-test procedure was used to compare the differences between the means for the two groups.

Results: Thirty-five patients received acupuncture, while another 55 patients attended the group and did not elect to receive acupuncture. All patients were covered by MaineCare health insurance, Maine's version of Medicaid. All patients had multiple other medical problems, which was why they were referred to the group. Seventy percent of the patients were women, and 30% were men. The average age was 40.1 years. Anxiety ratings on the Hamilton Anxiety Scale decreased by the last time measured for those not receiving acupuncture by an average of 5.17 points (S.D. 2.9; n = 55). Anxiety ratings for those receiving acupuncture decreased by an average of 7.19 points (S.D. 2.5, n = 35). The difference of the means was -2.02 (S.E. 0.595; 95% CI = -2.203 to -0.837; t = -3.394; p = 0.001).

Headaches, shoulder pains, and upper back pain also decreased. Patients reported high levels of benefit from the acupuncture and encouraged other patients to continue to come and try the acupuncture. Usually, the needles could be placed within the first third of the group.

Conclusions: Acupuncture improved anxiety ratings for people in group psychotherapy for anxiety over group alone, though the possibility of a placebo effect cannot be eliminated. Patients chose acupuncture, which could also present a potential bias.

Using Virtual Reality Assisted Therapy to Reduce Cognitive Test Anxiety and Dysfunctional Metacognitions

F. Obuća^{1*}, P. Ünal-Aydın¹ and O. Aydın¹

¹Psychology, International University of Sarajevo, Sarajevo, Bosnia and Herzegovina

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.884

Introduction: Cognitive test anxiety and dysfunctional metacognitions can significantly impact an individual's performance and overall mental health. However, the effectiveness of various treatment strategies, including Virtual Reality (VR) therapy, is yet to be fully explored.

Objectives: This study aimed to examine the effectiveness of VR therapy in reducing cognitive test anxiety and dysfunctional metacognitions in adults.

Methods: A total of 64 participants were enrolled in the study, with 40 in the treatment group and 24 in the control group. Data were collected using the Metacognition Questionnaire-30, Cognitive Test Anxiety Scale, and a sociodemographic questionnaire. Paired samples t-tests were used to compare pretest and posttest scores, while independent samples t-tests were used to compare the means between the groups.

Results: The findings suggest that the treatment group experienced a significant reduction in cognitive test anxiety and negative metacognition scores following VR therapy. No significant changes were observed in the control group, and there were no significant differences in pretest scores between the treatment and control groups.

Conclusions: The study indicates that VR therapy may be an effective treatment strategy for reducing cognitive test anxiety and dysfunctional metacognitions. Further research is recommended to validate these findings and explore the potential of VR therapy in treating other psychological disorders.

Perfectionism, self-efficacy and mindfulness as predictors of test anxiety among university students

S. Tvrtkovic

Psychology, International University of Sarajevo, Sarajevo, Bosnia and Herzegovina

doi: 10.1192/j.eurpsy.2024.885

Introduction: Test anxiety includes subjective experience of intense physiological, cognitive and/or behavioral symptoms

during test-taking situations such as pacing, headaches, excessive feelings of fear, anger, troubles concentrating, sudden forgetfulness and negative self-talk. Especially students who are striving for flawlessness, have overly critical self-evaluations and beliefs that other expect perfection are sensitive to experiencing these feelings. On the contrary, individuals who believe in their ability, are present in the moment and are open to experiences tend to be more resilient to stressors and anxiety symptoms.

Objectives: The aim of this study was to investigate perfectionism, self-efficacy, and mindfulness as predictors of test-anxiety among undergraduate and postgraduate students of different study fields.

Methods: 525 undergraduate and postgraduate students from the fields of Natural, Medical Sciences and Engineering, Social Sciences, Humanities and Art, and Economics, Business and Administration Studies participated in the study. A sociodemographic form, the Test Anxiety Inventory (TAI), 15-Item Five Facet Mindfulness Questionnaire (FFMQ-15), Scale of General Self-efficacy (GSES) and Frost Multidimensional Perfectionism Scale-Brief (FMPS-Brief) were used. Descriptive statistics were used to show the sociodemographics of our sample, while correlational analyses were performed to assess the associations between the variables. To further validate the findings, multiple linear regression analyses were performed.

Results: Higher perfectionistic evaluative concerns and lower self-efficacy showed associations with test-anxiety and were proven as predictors among undergraduate and postgraduate students. In addition, being younger and female in postgraduates, and having perfectionistic strivings and being Mindful-Observe in undergraduate students proved to be significant predictors of test-anxiety.

Conclusions: The found associations of perfectionism and self-efficacy, as well as its predictor roles further validate the information we have in literature, but widen the sample to postgraduate students and various study fields which help us generalize the findings more. What adds the most value in theoretical and practical aspects is the findings associated with mindfulness. Mindfulness techniques are very popular intervention methods for anxiety related symptoms, and the positive relationship of Mindful-Observe with test anxiety opens new viewpoints to mindfulness-based interventions. Particularly focusing on Mindful-Observe while treating test-anxiety may yield better outcomes in alleviation of symptoms.

Lithium withdrawal and relapse in bipolar disorder when kidney function deteriorates

C. De Andrés-Lobo, M. D. C. Vallecillo Adame, T. Jiménez Aparicio, A. Rodríguez Campos*, N. Navarro Barriga, M. J. Mateos Sexmero, B. Rodríguez Rodríguez, M. Fernández Lozano, M. Calvo Valcárcel, M. Andreo Vidal, P. Martínez Gimeno, M. P. Pando Fernández, L. Rojas Vázquez, G. Lorenzo Chapatte, M. Ríos Vaquero and A. Monllor Lazarraga
Psychiatry, HCUV, Valladolid, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.886

Introduction: Lithium was the first mood stabilizer and today continues to be a first-line treatment in the treatment of bipolar disorder despite its adverse effects, which make it important to monitor blood levels and control kidney function.

Objectives: Presentation of a case of lithium withdrawal and relapse in bipolar disorder. Literature review relating to the risk of relapse when lithium treatment is interrupted.

Methods: We present a clinical case of a patient who suffers a deterioration in renal function that requires the withdrawal of lithium and who consequently suffers a relapse. We conducted a bibliographic research of articles in Pubmed on this topic.

Results: A 49-year-old male, with a history of multiple admissions to UHB since the age of 18 with a diagnosis of bipolar disorder and treatment with lithium. Decompensations towards the manic pole have always been related to interruptions in lithium treatment. On several occasions when the patient was feeling well emotionally, he believed himself to be "cured" and abandoned the treatment, triggering a manic episode, showing verbal aggression, increased self-esteem and delusional ideation of harm. Remission was usually achieved with the reintroduction of lithium and the addition of high-dose quetiapine. Between episodes, constant overvalued ideas of economic scarcity seemed to persist, which were accentuated in the form of delusional ideas of ruin in depressive decompensations. After 7 years of stability, control analysis showed blood litemia of 2.2 mEq/L with deterioration of kidney function and generalized tremor was observed, without improvement after serum therapy. He was admitted for dialysis and lithium was suspended. Treatment with valproate was started and a consultation scheduled in a week to adjust the dose. The patient did not attend that consultation and was admitted three days later to Psychiatry Hospitalization showing a challenging attitude, evident dysphoric mood, accelerated speech, with derailments and echolalia. Delusional ideation of harm with auditory hallucinations. Insomnia and hyporexia. Chronic renal failure persisted.

Conclusions: Lithium is a very effective drug but with a narrow therapeutic range that requires adequate monitoring due to the possible consequences of its use at different organs and systems of the body. when lithium is found in the blood at toxic levels with deterioration of kidney function and glomerular filtration fails to recover, lithium treatment should be suspended. Sudden withdrawal of lithium significantly increases the risk of relapse due to rebound effect. More than 50% of patients experience a recurrence within 10 weeks of withdrawal.

Factors influencing stigma in bipolar disorder type I

A. Adouni*, Y. zgueb, I. bouguerra, F. ben othman and R. jomli psychiatry department A, Razi hospital, Manouba, Tunisia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.887

Introduction: Given the recurrence of mood episodes, with their negative repercussions such as high suicidal risk, significant cognitive decline and the persistence of residual signs with a negative impact on the patient's family, social and professional functioning,

Bipolar Disorder is a mental disorder with a significant social stigma.

Objectives: Identify the socio-demographic and clinical factors that may influence the experience of stigma in bipolar disorder type I

Methods: We conducted a cross-sectional, comparative study over a six-month period at the aftercare unit of Razi Hospital's psychiatric ward "A", including patients treated for TB I according to DSM 5 criteria and stable on treatment.

The study was conducted in two stages: first, sociodemographic and clinical characteristics were collected using a pre-established form. The DISCUS scale, validated in Arabic, was then administered.

Results: We included 100 patients (60 men and 40 women) with a mean age of 43.55 years.

The median DISCUS stigma score was 6 (0-19).

The mean value of the DISCUS scale was high for patients of urban origin ($p=0.042$), with a low socioeconomic level ($p=0.001$), and poor family dynamics ($p<0.001$).

The presence of a comorbid personality disorder was significantly associated with stigma ($p=0.006$). The DISCUS scale was positively associated with the number of years of follow-up, the number of hospitalizations, the number of manic episodes, the number of depressive episodes and the number of episodes with psychotic or melancholic features.

Conclusions: This stigma can have a negative impact on patients' quality of life in a whole range of ways, including limiting their opportunities for education, employment and housing. Intensive therapeutic interventions should be considered for vulnerable patients to limit the consequences.

EPV0097

The Dilemma of Lithium Discontinuation in Bipolar Disorder During Pregnancy Planning: A Case Report and Literature Review

B. Orgaz Álvarez*, E. Jiménez Sola, M. Velasco Santos, P. Ibáñez Mendoza, Á. de Vicente Blanco and S. Cebolla Lorenzo Hospital Universitario La Paz, Madrid, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.888

Introduction: Lithium is considered the gold standard mood stabiliser for bipolar disorder, yet its use during pregnancy remains controversial, demanding careful consideration of potential risks and benefits. Classically, it has been associated with an increased risk in congenital heart defects, however, recent studies point towards a much lower absolute risk than was previously believed. Furthermore, discontinuation of lithium before or during pregnancy poses a high risk of destabilisation and lithium has been shown to reduce the risk of relapse both in pregnancy and in the postpartum period. Hence, treatment planning is of the utmost importance in this patient group and individual risk stratification should be undertaken for patients to make informed decisions about their treatment.

Objectives: To describe the case of a patient with bipolar disorder who discontinued lithium treatment while attempting to conceive and subsequently presented with a manic episode and to expand the scientific knowledge on this topic.

Methods: Case report and brief literature review.

Results: A 41-year-old patient with a diagnosis of bipolar disorder, previously on lithium 900mg/day, was admitted to the emergency department with symptoms suggestive of a manic episode. One month prior, the patient had discontinued treatment with lithium due to her desire to pursue pregnancy and interrupt treatment while trying to conceive. The patient had a history of postpartum psychosis followed by various depressive and manic episodes with psychotic symptoms, leading to a bipolar disorder diagnosis and commencing treatment with lithium. Her consultant psychiatrist had informed her of the individualised risks of interrupting treatment with lithium and had advised to continue treatment alongside frequent follow-up due to the high-risk of relapse. Despite her consultant's recommendation, she decided to interrupt treatment and hence a personalised lithium tapering regime and advice to continue treatment with quetiapine 200mg/day was given.

During the ED stay, treatment with olanzapine was introduced which helped to stabilise her symptoms. Lithium levels were subtherapeutic (lithium serum level 0.11 mmol/L). Inpatient psychiatric admission was avoided due to rapid symptom improvement, strong social support in the community and her preference for ambulatory care. Lithium was gradually reintroduced and antipsychotic treatment was adjusted at follow up appointments, which ultimately led to the resolution of symptoms and stabilisation.

Conclusions: This case highlights the significance of considering continuing lithium treatment in bipolar disorder during pregnancy planning. Decisions about medication in pregnancy are multifaceted, making appropriate risk stratification imperative in order to inform individualised care plans to minimise the risk of relapse in these patients.

Neuropsychiatric symptoms and arachnoid cysts: tracing the association regarding a case report

C. Regueiro Martín-Albo*, F. M. Sanabria, E. E. Durán, M. F. Fariña and N. R. Criado

Hospital Clínico San Carlos, Madrid, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.889

Introduction: In the review of recent literature, we found very few presentations of case reports in which the presumed association between psychiatric disorders and arachnoid cysts is discussed. Arachnoid cysts are rare brain tumors with little apparent symptomatic impact and in most cases, they are diagnosed incidentally. We present the case of a 15-year-old adolescent with a personal history of a previous severe depressive episode, as well as suspicion of serious mental pathology in the family. It presents a subacute onset episode, in the context of regular cannabis consumption, consisting of intense emotional lability and psychomotor restlessness, a tendency toward irritability, decreased sleep needs, and the appearance of delusional ideas of harm and self-referential interruption. During the study of the case, and incidentally, the cranial magnetic resonance imaging revealed the presence of an arachnoid

cyst located in the left frontotemporal location, approximately 4 cm in diameter.

Objectives: (1) To describe the clinical particularities of this case, focusing on the diagnostic difficulties we faced. (2) To review current scientific evidence regarding the possible association between neuropsychiatric symptoms and arachnoid cysts.

Methods: A review of the patient's clinical history was carried out and complementary tests were performed. Likewise, a review of the available scientific literature was also performed in relation to the appearance of neuropsychiatric symptoms associated with the presence of arachnoid cysts.

Results: The literature regarding the possible association between psychosis and arachnoid cysts is scarce. However, it is proposed that arachnoid cysts may be associated with various neuropsychiatric alterations, such as affective alterations, schizophrenia-like psychosis or amnesic symptoms. The atypicality in the symptoms sometimes leads us to suspect an organic origin of the condition, with some features such as associated memory deficits, emotional incontinence, movement disorders or neurological focal data; some of which are present in the case at hand.

Conclusions: There is controversy among different sources regarding the role of the cyst in the development of symptoms or, on the contrary, its presentation only as a chance finding. Further investigation focusing on clinical observations and neuroimaging is needed.

EPV0099

Lithium nephropathy in Bipolar Disorder: a clinical challenge

C. Alario-Ruiz*, B. Arribas-Simon, P. Martinez.Gimeno, M. Calvo-Valcarcel and O. Martin-Santiago

Hospital Clínico Universitario, Valladolid, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.890

Introduction: Lithium nephropathy can occur in long-term lithium-treated bipolar disorder patients. Key risk factors include duration of lithium exposure, cumulative dose, acute intoxication episodes, advanced age, and comorbidities such as hypertension, diabetes mellitus, hyperparathyroidism, and hyperuricemia, along with concurrent use of antipsychotics. The clinical presentation is gradual, with mild proteinuria, often accompanied by arginine vasopressin resistance. Histological studies show a correlation between interstitial fibrosis and cumulative lithium duration. Approximately 15 to 25 per cent of exposed patients may experience a gradual decline in glomerular filtration rate. The outcome after lithium discontinuation varies.

Objectives: This case study aims to analyze and document the clinical presentation, diagnosis, and management of lithium nephropathy in a patient with Bipolar Disorder.

Methods: We gathered data on the medical history, lab results, and treatment approach for a patient with Bipolar Disorder.

Results: The patient, a 50-year-old woman, had been under the care of Psychiatry since 2008 due to a diagnosis of Bipolar Disorder Type I. During this time, she had experienced depressive and manic episodes but had not presented significant symptom

decompensation for the past 14 years, successfully managed with lithium at a current dose of 600 mg per day. However, on this occasion, the patient sought hospitalization due to recent behavioural disturbances, including restlessness, disinhibition, abrupt changes in behaviour, pressured speech, sleep problems, agitation, and aggression. The patient also reported an increased sense of polyuria and polydipsia. Evaluation in the emergency department revealed elevated lithium levels of 1.47 mmol/L and hypokalemia, that justified lithium withdrawal. After lithium levels decreased, an estimated glomerular filtration rate remained low. She was diagnosed with lithium nephropathy, an adverse effect of long-term lithium therapy. Treatment with lithium changed to sodium valproate. Treatment with asenapine started and sustained for two months. Over the following two years, the patient experienced four additional hospital admissions in Psychiatry due to manic episodes.

Conclusions: Long-term lithium therapy can lead to lithium nephropathy with symptoms such as polyuria, polydipsia, and acute kidney failure. Consistent monitoring of patients receiving lithium is crucial to detect potential adverse effects. This case highlights the challenges in managing bipolar patients, as discontinuing lithium exacerbated symptoms despite switching to sodium valproate for nephropathy prevention. Long-term lithium treatment, while effective for bipolar disorder, poses significant renal risks. We emphasize continuous renal function monitoring and assessing the risk-benefit of lithium treatment while actively researching lithium nephropathy and its impact on glomerular function.

Childhood trauma in bipolar disorder: experience of Arrazi hospital

H. Boukidi*, H. Ballouk, M. Sabir, N. Ait bensaid and F. Elomari
Arrazi psychiatry hospital, Sale, Morocco

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.891

Introduction: Bipolar disorder is a chronic, recurrent, and disabling condition that typically begins in late adolescence or early adulthood. It is characterized by alternating phases of depression, mania, or hypomania. Childhood traumas are more frequently found in adults with bipolar disorder, suggesting their contribution to its development. They are also associated with more severe and complex clinical forms and a less favorable prognosis.

Objectives: Our objective is to assess the prevalence of childhood trauma rates in adults with bipolar disorder and to study the impact of childhood traumas on the clinical course of bipolar disorder, in comparison with a group of patients with bipolar disorder who did not experience trauma during their childhood.

Methods: This is a descriptive cross-sectional study using a questionnaire comprising sociodemographic criteria and the Childhood Trauma Questionnaire Short Form (CTQ-SF) to evaluate the connection between physical and psychological traumas during childhood and bipolar disorder. The study also examines the types of these traumas and their impact on the course of bipolar disorder in these categories.

Results: Data were collected from 54 patients with bipolar disorder at Ar-Razi Psychiatric University Hospital. Among this sample, 60% were female and 40% were male. The age of the participants in our study ranged from 18 to 54 years. According to the Childhood Trauma Scale, approximately one-third of patients with bipolar disorder had experienced childhood trauma. Moreover, most participants who had survived childhood trauma experienced more relapses than patients who had not experienced traumatic incidents during their childhood.

Conclusions: Childhood traumas and bipolar disorder appear to have a significant causal association, both in the development of the disease and its course. The results of our study support evidence published in articles to better clarify the nature of this association. However, our study has several limitations, including a limited sample size and difficulties in long-term follow-up during the disease. Therefore, further studies exploring this subject are desirable for better management of this condition.

Difficulties in assessing the medical fitness of workers with mood disorders : A study of 101 cases

S. Chemingui¹, D. Brahim², M. Mersni², N. Mechergui², M. METHNI^{1*}, H. Ben Said², I. Youssef², G. Bahri², I. YAICH³, C. Ben Said³, N. BRAM³ and N. Ladhari²

¹Occupational pathology and fitness for work department, Charles Nicolle Hospital; ²Occupational pathology and fitness for work department Charles Nicolle Hospital, tunis, Tunisia and ³Forensic Psychiatry department, Razi Hospital, La Manouba, Tunis, Tunisia
*Corresponding author.

doi: 10.1192/j.eurpsy.2024.892

Introduction: Assessing the medical fitness of workers with mood disorders remains a topical issue, because of its organizational, socioeconomic and professional impact.

Objectives: To assess the medical and occupational characteristics of workers with mood disorders.

To evaluate the impact of these psychiatric disorders on the medical decision of fitness for work.

Methods: Descriptive and retrospective study, over six years (January 1, 2018 to August 30, 2023) including all medical records of workers with mood disorders (bipolar disorder, anxiety disorder, and depression), referred to the occupational department of the Charles-Nicolle Hospital in Tunis for a medical fitness for work.

Results: The study included 101 patients, mostly female (sex ratio = 0.4), with a mean age of 43.3 ± 9.2 years. The most represented sector of activity was health care. The participants were mainly nurses (25%), followed by technicians (22%) and workers (21%). The mean job seniority was 16.5 ± 9.3 years. A pathological history was found in 74.3% of cases, of which 47.5% were psychiatric disorders. Mood disorders identified in our population were: bipolar disorder (53.5%), anxiety disorder (43.5%), and depression (3%). After medical examination and the decision of treating physician, 39% of the patients (N=39) were declared fit for work, and 31.4% (N=32) were fit with ergonomic adjustments. These accommodations consisted mainly of night shift exemptions in 75% of cases. Temporary unfitness was declared in 24 patients (23.6%).

Job mutation was recommended for four patients. Early retirement due to invalidity was proposed for two patients.

Conclusions: The decision on the medical fitness of workers with psychiatric disorders remains a delicate issue that requires the attention of both legislators and occupational health practitioners.

Proteomic analysis of blood serum in bipolar disorder

L. Smirnova^{1*}, A. Seregin¹, E. Dmitrieva¹, M. Zavialova² and S. Ivanova¹

¹Laboratory of Molecular Genetics and Biochemistry, Mental Health Research Institute, Tomsk National Research Medical Center, Russian Academy of Sciences, Tomsk and ²Advanced Mass Spectrometry Core Facility, Skolkovo Institute of Science and Technology, Moscow, Russian Federation

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.893

Introduction: Bipolar disorder (BD) often has symptoms similar to other mental disorders (BD), and there are no paraclinical criteria for differential diagnosis. (Geoffroy *et al.* Bip Dis 2017; 5 7). Published work on MD proteomics is scarce and focused on schizophrenia. (Dmitrieva *et al.* PeerJ. 2022; 10 e13907). Therefore, it is important to study potential biomarkers of BD using easily accessible material—blood serum (Rhee *et al.* *Transl Psy* 2023; 13 44). Identification of proteins involved in the pathogenesis of BD will help in the study of the pathogenetic mechanisms of BD, the development of differential diagnostic methods and pathogenetically based drugs.

Objectives: Carrying out a comparative proteomic analysis of blood serum from patients with BD and healthy individuals to identify potential biomarkers

Methods: We analyzed the protein spectrum of the blood serum of 14 patients with BD who were admitted during a depressive episode at the age of 32 [21;52] years with a disease duration of 8[5;11] years. The control group consisted of 10 mentally and somatically healthy individuals corresponding to the gender and age of the BD group. Blood serum was purified from 14 major proteins using affinity chromatography and separated by electrophoresis using the Laemmli method. After trypsinolysis, proteins were identified using HPLC/mass spectrometry on an Orbitrap instrument. Mass spectrometric analysis was performed on the Advanced Mass Spectrometry Core Facility of Skolkovo Institute of Science and Technology. Protein identification was carried out using the UniProtKB database using the Mascot search engine. The results were tested for significance using the nonparametric Fisher exact test with Yates correction.

Results: In patients with BD, qualitative mass spectrometry revealed differential expression of 21 neurospecific proteins. Among them: Protein dispatched homolog 3, Ceroid-lipofuscinosis neuronal protein 6, SWI/SNF complex subunit SMARCC1, Neurogenic differentiation factor 4, Protein furry homolog-like, REST corepressor 1 – are involved in the proliferation, development and differentiation of neurons; Hemicentin-2, Dystrophin, Voltage-dependent L-type calcium channel subunit alpha-1D, Syntaxin-

binding protein 5, Small conductance calcium-activated potassium channel protein 1– participate in synaptic transmission of ion transport and form receptors.

Conclusions: Studying the role of these proteins in BD and their quantitative content in a larger number of patients is promising. This will help in the development of new diagnostic criteria and targets for drug therapy for BD.

Support by the Russian Science Foundation grant No. 23-75-00023.

EPV0107

Clinical Characteristics and Aggression in Unipolar and Bipolar Course of Affective Disorders

L. Smirnova^{1*}, O. Roshchina² and A. Seregin¹

¹Laboratory of Molecular Genetics and Biochemistry and ²Affective States Department, Mental Health Research Institute, Tomsk National Research Medical Center of the Russian Academy of Sciences, Tomsk, Russian Federation

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.894

Introduction: The diagnosis and treatment of depression are complex due to its diverse forms. Recent focus in clinical practice has been on identifying markers for mono- and bipolar depression, as early diagnosis significantly impacts treatment.

Objectives: To identify clinical characteristics of unipolar and bipolar depressive disorders and assess their correlation with aggression levels in patients.

Methods: We studied patients at the Mental Health Research Institute of Tomsk NRMC: ICD-10 codes: Bipolar Affective Disorder (BD) (n=28), Recurrent Depressive Disorder (RDD) (n=33). Patients with BD were older (49 (33; 52) years) than those RDD (40 (31; 51) years) (p=0.018). The current depressive episode duration was shorter for BD (3 (2; 7) months) compared to RDD (5 (2; 12) months) (p=0.018). Gender distribution was comparable (p=0.568). We measured clinical symptoms (depression, anxiety, anhedonia) using psychometric tools (HAM-D, HAM-A, SHAPS) at admission and after 3 weeks of therapy. Aggression was assessed with the Buss-Durkee Hostility Inventory (BDHI) at admission.

Results: Patients with RDD demonstrated a higher severity of depressive symptoms upon admission (Table 1).

Table 1. Clinical Characteristics of Unipolar and Bipolar Depression Course

Severity of Symptoms	Bipolar Depression	Unipolar Depression	p (U-test)
HAM-D on admission	19 (15.5; 24)	22 (18; 26)	0.044
HAM-D after 3 weeks	4 (2; 6)	4 (3; 7.75)	0.219
HAM-A on admission	16 (12; 25)	19.5 (13; 26.75)	0.098
HAM-A after 3 weeks	3 (2; 6.5)	4 (3; 7.75)	0.219
SHAPS on admission	5 (1.25; 9)	3 (0; 10)	0.7
SHAPS after 3 weeks	1 (0; 4)	1 (0; 3)	0.44

The severity of some aggressive patterns was higher in patients with bipolar disorder (Table 2).

Table 2. The severity of aggressiveness in unipolar and bipolar depression.

BDHI subscale	Bipolar Depression	Unipolar Depression	p (U-test)
Aggressiveness index	19 (13; 24)	18.5 (12; 24)	0.745
Hostility index	9 (7; 13.75)	9 (7; 11)	0.139
Assault Hostility	4 (2; 6)	4 (2; 6)	0.618
Indirect Hostility	5 (5; 6)	4 (4; 6)	0.015
Irritability	6 (4; 8)	5 (3; 7)	0.081
Negativism	2 (1; 4)	2 (1; 4)	0.262
Resentment	5 (4; 6)	5 (3; 6)	0.113
Verbal Hostility	7 (6; 8)	6 (5; 8)	0.008

As a result of the study, no statistically significant correlations were found ($p>0.05$, Spearman’s test).

Conclusions: The conducted research did not yield convincing data that would allow us to make judgments about specific clinical patterns in the course of unipolar and bipolar depression. Thus, the problem of searching for unique biological markers of the courses of affective disorders remains relevant. Support by the Russian Science Foundation grant No. 23-75-00023.

EPV0108

Neuropsychiatric symptoms in Multiple Sclerosis (MS): Case Report of a First Manic Episode in a Patient with Suspected MS

M. A. N. C. Pais^{1*}, T. M. F. Fernandes¹ and M. Cagigal²
¹Department of Psychiatry, Centro Hospitalar e Universitário de Coimbra, Coimbra and ²Department of Psychiatry, Centro Hospitalar e Universitário de Coimbra, Coimbra, Portugal
*Corresponding author.
doi: 10.1192/j.eurpsy.2024.895

Introduction: Multiple Sclerosis (MS) is an inflammatory disease affecting primarily the central nervous system, characterized by focal lesions of white-matter demyelination. It can present with a variety of neurological symptoms, including monocular vision loss, sensory loss, paresthesias, limb weakness, ataxia and bladder dysfunction, and has a typically chronic and progressive course. Neuropsychiatric manifestations including depressive or manic symptoms, anxiety disorders and psychosis, are also frequently observed, and are of particular importance to mental health practitioners.

Objectives: To describe a case of a 45-year-old female patient with a history of suspected MS presenting with manic symptoms, and to discuss the possible neuropsychiatric manifestations of Multiple Sclerosis.

Methods: Clinical case report and literature review.

Results: A 45-year-old woman was brought to the emergency department presenting with severe acute agitation, irritable mood, rapid speech and persecutory delusions. She had no prior history of neuropsychiatric symptoms, but her medical history was notable for a suspected diagnosis of MS, having suffered an episode of optic neuritis 16 years before the present episode. Magnetic

Ressonance Imaging performed 3 months before emergency admission documented non-specific white-matter lesions presenting as hyper-intense in long TR sequences, as well as a cervical lesion of atypical characteristics, representing possible spondylo-tic myelopathy or demyelination. A head CT performed at emergency admission did not reveal relevant acute findings. The patient was hospitalized and initiated risperidone and valproic acid therapy. She responded favorably to medication, with progressive stabilization of mood and remission of delusional ideas over three weeks.

Conclusions: Neuropsychiatric symptoms are a common and concerning manifestation of Multiple Sclerosis. The present case illustrates that clinicians should be on alert for signs of mood and psychotic symptoms in patients with suspected or confirmed MS, as these can manifest at any point during the disease course.

Our old friend lithium and encephalopathy: a case report

M. P. Cameira^{1*}, C. F. dos Santos², M. Pereira¹, M. V. Lisboa¹, M. R. Soares¹ and P. Abreu¹
¹Psiquiatria and ²Centro Hospitalar Psiquiátrico de Lisboa, Lisbon, Portugal
*Corresponding author.
doi: 10.1192/j.eurpsy.2024.896

Introduction: Lithium is a well-established mood stabilizer used in the management of bipolar disorder, that is generally well-tolerated; however, it is associated with rare but potentially severe neurological side effects. Lithium-induced encephalopathy is characterized by a spectrum of symptoms, ranging from subtle cognitive deficits to severe manifestations such as altered mental status to overt delirium, seizures and coma. Risk factors include advanced age, concomitant medication and underlying renal impairment. This symptoms do not consistently correlate with lithium concentrations.

Objectives: This abstract aims to provide an overview of the clinical characteristics, underlying mechanisms, and management of lithium-induced encephalopathy.

Methods: We discuss a case of a 62-years-old woman diagnosed with bipolar disorder under treatment with lithium and olanzapine, without recent changes of posology. She presented to emergency department with subacute and fluctuating neuropsychiatric symptoms, including confusion, disorientation in time and space, complex visual hallucinations, delusional ideas, alteration in memory and logic thinking, dysarthria and dyspraxia. Neuroimaging showed no structural abnormalities, blood tests were normal and serum lithium levels were within the therapeutic range (0.8 mEq/L). Upon discontinuation of lithium, the patient exhibited a gradual resolution of symptoms. We conducted a comprehensive search of medical databases, including PubMed, to identify relevant articles related to lithium encephalopathy published up to September 2023.

Results: This case challenges the conventionally established threshold of elevated serum lithium levels in the development of encephalopathy. The underlying pathophysiology is complex and multifactorial, with proposed mechanisms including alterations

in neurotransmitter balance, oxidative stress, mitochondrial dysfunction and individual susceptibility to idiosyncratic reactions. Early diagnosis is challenging, necessitating a high clinical suspicion, neuroimaging and exclusion of other etiologies. Management strategies involve discontinuation of lithium, even when serum lithium levels are within the therapeutic range, supportive care, and, in severe cases, hemodialysis to reduce lithium levels rapidly.

Conclusions: Clinicians should maintain a high index of suspicion of lithium-induced encephalopathy, especially in patients presenting with neurological symptoms while on lithium treatment. Early recognition and intervention are essential for minimizing morbidity and preventing potentially irreversible neurological damage. Further research is needed to better understand the precise mechanisms underlying it, risk factors and to refine treatment strategies.

EPV0110

Multifactorial etiology of manic episodes. About a case

M. Valverde Barea^{1*}, F. Vilchez Español¹,
L. Soldado Rodríguez¹ and M. O. Solis Correa²

¹Psychiatry, H.U. Jaén, Jaén and ²Psychiatry, USMC Baza, Baza, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.897

Introduction: Manic episodes have a multifactorial etiology, with frequent association with genetic factors, comorbidities such as systemic diseases or secondary to infectious diseases, and environmental exposure factors. The prevalence of bipolar disorder is markedly higher in patients with autoimmune disease. The risk of developing bipolar disorder in some studies has been seen to be higher among patients with rheumatoid arthritis, therefore chronic inflammation would be a potential mechanism and could be a modifiable risk factor for bipolar disorder. Growing evidence indicates that Sars-CoV-2 may also trigger the acute onset of mood disorders or psychotic symptoms.

Objectives: We present the case of a patient who presents symptoms compatible with an acute manic episode after an outbreak of rheumatoid arthritis and comorbid COVID infection.

Methods: 52-year-old patient. She went to the hospital emergency room presenting affective symptoms compatible with a manic episode and psychomotor agitation. Personal medical history: rheumatoid arthritis, antiphospholipid syndrome. Psychiatric personal history: Depressive disorder under follow-up by a private psychiatrist under treatment with antidepressants. During the interview, the patient presented accelerated speech, with great emotional incontinence. Saltigrade thought and tachypsychia. She verbalizes delusional ideas of megalomaniacal and mystical and religious characteristics. She verbalizes that she is the reincarnation of the holy spirit, that God has taken her body and speaks through her. In the emergency room, a Sars-CoV-2 infection that the patient was unaware of was diagnosed. She is admitted to the hospital in the mental health unit, in the first interviews the patient maintains speech with delusional ideas "I notice the stigmata of Christ on my body".

Results: The patient recovers after treatment for the COVID infection, remaining asymptomatic. It was decided to start lithium to stabilize mood and the patient presented good tolerance and treatment with antipsychotics. The patient presented a favorable response, remitting the psychotic symptoms of which she was critical and stabilizing the affective symptoms. The patient is diagnosed with Severe Manic Episode with Psychotic Symptoms, as the main diagnosis and we could conclude the diagnosis of Bipolar Disorder since she has presented 2 depressive episodes in the past that have required treatment and follow-up by psychiatry.

Conclusions: Manic episodes have a multifactorial etiology and require an individualized approach, and comorbid medical conditions must always be assessed in order to establish a therapeutic plan with patients.

Carbamazepine-induced toxidermia: Case report and a literature review

R. Jbir*, M. Maalej, S. Omri, N. Charfi, R. Feki, I. Gassara,
N. Smaoui, L. Zouari, J. Ben Thabet and M. Maalej

Psychiatry C department, Hedi Chaker university hospital, Sfax, Tunisia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.898

Introduction: Carbamazepine is effectively used in treatment of bipolar disorder for its thymoregulatory virtues, but it can induce numerous side effects, including skin eruptions that can be severe sometimes.

Objectives: To study the relationship between toxidermia and treatment with carbamazepine.

Methods: We report the case of a patient who developed a toxidermia following the intake of carbamazepine.

Results: Mr. AD, 19 years old, with medical history of diabetes, has been diagnosed with bipolar disorder since the age of 17. He was initially treated with risperidone with an irregular follow-up.

He was hospitalized in our department for a manic episode with psychotic features with agitation and refusal of treatment.

The patient was put on injectable treatment 15 mg/day of Haloperidol and 20 mg/day of diazepam.

After 5 days in hospital, we switched to the oral route, gradually increasing haloperidol doses to 30mg, reducing diazepam doses and introducing carbamazepine for thymoregulatory purposes.

Carbamazepine was progressively increased up to a dose of 800mg per day.

Fourteen days after the introduction of carbamazepine, the patient presented a generalized rash requiring the discontinuation of this medication. He was treated with an anti-histamine and local corticosteroids, on the advice of dermatologists.

In the days following discontinuation of carbamazepine, skin lesions regress and then disappear.

Biologically, we observed a rise in eosinophilic polynuclear cells to 580, followed by a gradual decrease after stopping the treatment.

A pharmacovigilance opinion was sought, concluding that carbamazepine was responsible for the toxidermia, given the delay in

onset and the favorable evolution after discontinuation of the incriminating treatment. Moreover, this undesirable effect is well described in the literature.

Hence the contraindication to further use of carbamazepine in Mr. AD.

In addition, the patient was put on sodium valproate with good tolerance.

Conclusions: Each prescribed drug must be considered as potentially capable of causing cutaneous reactions as an adverse effect. Both the prescriber and the patient must be made aware of this phenomenon. The attitude can be modulated on a case-by-case basis, after specialist advice, depending on the severity of the rash and the disease to be treated.

Exploring maladaptive early schemas in adults with bipolar disorder

Z. Bencharfa*, H. Ballouk, I. Katir, F. Laboudi and A. Ouanass

Ar-razi Psychiatric Hospital, Salé, Morocco

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.899

Introduction: Bipolar disorder is a severe and chronic mental pathology, with an estimated prevalence of 1% in the general population. It is a complex pathology, encompassing a wide variety of severe and contradictory symptoms, with harmful repercussions on the patient's personal, emotional, social, professional and conjugal life, precipitating relapse. By improving our knowledge of bipolar disorder, we can support and accompany patients, helping them to understand their illness, to be able to manage it, to resolve the problems that may arise from it, and to prevent relapses and the occurrence of further episodes.

Objectives: The aim of our work is to explore maladaptive early patterns in people with bipolar disorder in the intercritical period in relation to their symptomatology and functional disability, given that consideration of maladaptive early patterns (IAPs) could lead to better identification, understanding and management of bipolar disorder.

Methods: We conducted a cross-sectional, descriptive and analytical study. The sample in our study consisted of 40 bipolar adults and 40 control adults, recruited from the various inpatient and outpatient departments of our hospital. They were all university graduates, aged between 20 and 60, followed for at least 06 months and stabilized on treatment. After collecting the various socio-demographic and clinical data, we used the Young schema questionnaire-short form (YSQ-S1).

Results: Our study sample seemed to be characterized by certain specificities: high "self-sacrifice", "high demands" and "exaggerated personal rights". Feelings of dependence and incompetence were also high among our patients, especially those with type I bipolar disorder, leading to a marked decline in self-esteem and autonomy.

Conclusions: The data we have retained from this work show us the importance of drug, psychotherapeutic and family management in

achieving thymic stability and psychological and relational well-being.

Corticosteroid-induced mania, review and case report

M. GARCÍA MORENO^{1*}, A. DE COS MILAS²,
L. BEATOBE CARREÑO², A. IZQUIERDO DE LA PUENTE¹ and
P. DEL SOL CALDERON¹

¹Psychiatry, Hospital Universitario Puerta de Hierro Majadahonda and

²Psychiatry, Hospital Universitario De Móstoles, Madrid, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.900

Introduction: Corticosteroid treatment has been associated with the appearance of psychiatric symptoms such as depression, mania or psychosis. It is believed that manic symptoms appear with lower doses than psychotic ones. Furthermore, manic symptoms are usually associated with brief treatments against depressive ones that often appear with chronic administration of corticosteroids. The symptoms can persist for to 2 months, with an average duration of 3 weeks. The prognosis is favorable with a complete remission of symptoms in more than 90% of patients. Treatment initially consists in reducing or removing corticosteroids. However, sometimes symptomatic treatment with antipsychotics or mood stabilizers is necessary.

Objectives: To review about corticosteroid-induced mania

Methods: We carry out a literature review about corticosteroid-induced mania, accompanied by a clinical description of one patient previously diagnosed of bipolar disorder who presents a manic episode after corticosteroids treatment.

Results: A 25-year-old male was admitted to the short-term hospitalization unit from the emergency department due to manic symptoms. He had a previous diagnosis of attention deficit hyperactivity disorder sin adolescence and also a diagnosis of bipolar disorder established 7 years ago. During the last year he had received treatment with asenapine 10 mg and lamotrigine 200 mg, with good response. Several weeks before his admission he received corticosteroid treatment during several days, due to an respiratory infection. In this context he appeared more nervous, dysphoric, hyperthymic, impulsive, with increased speech pressure, insomnia and tachypsychia. Despite the withdrawal of corticosteroid treatment, manic symptoms persisted. During admission, asenapine's dose was increased with a complete remission of the manic symptoms.

Conclusions: Corticosteroids are associated in a high percentage with the appearance of manic symptoms. The prognosis is usually favorable after the withdrawal of corticosteroid treatment. However, sometimes the symptoms do not disappear despite withdrawal - mainly due to individual vulnerability - or this one is not possible. In these cases, treatment with antipsychotics or mood stabilizers is indicated.

Bipolar disorder, Deafness and Culturality in Psychiatric Home Hospitalization: A Clinical Case

J. Marti Bonany*, G. De Iturbe Catania, R. Romar Navia, D. Tolosa Merlos, C. Montserrat Diez, E. Pechuan Martínez, R. Rodriguez Seoane, L. Gil Martinez and D. Garcia Hernandez
Salut Mental Institut, Hospital del Mar, Barcelona, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.901

Introduction: Mental health in the deaf community is a complex issue. Challenges in diagnosis and treatment arise from a lack of experienced interpreters and difficulties in translating Sign Language to spoken language. Deaf individuals, due to auditory limitations, are more vulnerable to abuse, increasing their risk of mental health disorders, including bipolar affective disorder (BPAD). BPAD is a prevalent, debilitating condition with varied prevalence estimates. Managing it is tough due to its lifelong, unpredictable nature. A new approach called Psychiatric Home Hospitalization Unit aims to provide acute mental health care at home as an alternative to hospitalization.

Objectives: To show the management of severe bipolar disorder with comorbidity from a Psychiatric Home Hospitalization Unit

Methods: A clinical case of bipolar disorder with deafness attended at the Psychiatric Home Hospitalization Unit of our hospital is presented.

Results: A 24-year-old deaf woman borned in Pakistan and later moving to Catalonia, she faced educational challenges but ultimately completed her studies with sign language support. Afterward, she struggled to find suitable employment, and her family had a history of bipolar disorder.

She exhibited a sudden change in behavior, characterized by irritability, paranoia, and distrust. Communication was challenging due to her speech difficulties, but assessments using sign language and observation were conducted. Her physical examination was normal, but her speech was disorganized and pressured, suggesting possible auditory hallucinations and thought disturbances. She was hospitalized and diagnosed with bipolar disorder with psychotic features.

During her initial hospitalization, she received lithium, olanzapine, clonidine and benzodiazepines. After discharge, she continued treatment through a home hospitalization service during almost 4 month. During follow-up she presented a course with high affective instability, rapid cycling alternating brief periods of stability with other presenting manic and mixed features with high disorganization.

Due to the rapid cycling pattern Valproic acid was considered. Valproic acid was introduced up to 700 mg/d (97.1 mcg/mL). Treatment with lithium carbonate 800 mg/d (0.91 mEq/L) was maintained. Previous antipsychotic regimen was changed to quetiapine 400mg/d, olanzapine 5mg/d. Her condition improved significantly with the adjusted treatment regimen. She was discharged to an outpatient service.

Conclusions: Diagnosing and treating bipolar affective disorder (BPAD) in a deaf and mute patient posed unique challenges. The rapid mood cycling pattern and complexity of her case made treatment challenging. Family information and interpreter support were vital. Cultural factors were considered, and home hospitalization was crucial in managing symptoms that lasted over four months.

Sleep Disturbance in Bipolar Disorder. Treatment Implications

T. Jupe*, A. Roumpou and K. Provi

Psychiatric Hospital of Attica, Athens, Greece

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.902

Introduction: Relationship between sleep and bipolar disorder involves the following aspects: decreased need for sleep is a fundamental marker of the manic state, sleep deprivation is one cause of mania and may in fact be a fundamental etiological agent in mania, total sleep time is a predictor of future manic episodes, and total sleep time may be a marker of response as well as a target of treatment in mania.

Objectives: This e-poster aimed to summarize evidence regarding the sleep disturbance in Bipolar Disorder.

Methods: Bibliographical review was performed using PubMed platform. All relevant articles were found using the keywords: sleep disturbance, bipolar disorder, mania.

Results: Sleep disturbances are frequent in BD patients in different phases of illness, including the euthymic state and remission. These sleep aberrations are represented not only by insomnia but also by sleep-wake rhythm disorders, especially delayed sleep-wake phase disorders. During the manic state, most patients experience a reduced need for sleep and longer sleep onset latency. Likewise, in the depressive state, insomnia and hypersomnia are commonly observed. Meta-analyses of trials conducted on remitted BD patients demonstrated prolonged total sleep time, increased awakenings after sleep onset, greater variability of sleep-wake variables, and reduced sleep efficiency.

Conclusions: Overall, all kinds of sleep disorders and parasomnias are very common especially in youth patients with BD. Thus, compared to the general population, youth with BD exhibit lower sleep efficiency, longer slow wave sleep, and reduced REM sleep, features that could affect the genesis and prognosis of the disorder. Sleep disturbances may also be used as predictors of the onset of BD in a subset of high-risk young subjects.

EPV0117

Use of aripiprazole long-acting injectable release as a stabiliser. About a case

A. Izquierdo De La Puente^{1*}, P. del Sol Calderón¹, R. Fernandez Fernandez², M. V. da Silva³ and M. Garcia Moreno¹

¹Psychiatry, Hospital Universitario Puerta de Hierro de Majadahonda, Majadahonda; ²Psychiatry, Hospital Universitario Infanta Cristina, Parla and ³Psychiatry, CSM San Carlos, El Escorial, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.903

Introduction: A 56-year-old patient diagnosed with bipolar affective disorder type II, who remains stable, with no manifest episodes, thanks to aripiprazole 60mg daily.

Objectives: The aim is to carry out a brief review of the use of the drug as the only stabiliser in bipolar affective disorder.

Methods: A 56-year-old patient, who has been suffering from episodes of hypomania since the age of 40, with episodes of depression. After poor tolerance to the use of the usual stabilisers, and the impossibility of using antidepressants due to hypomanic swings, it was decided to start treatment with aripiprazole orally, up to a maximum of 60mg daily. Despite the fact that the patient, with this treatment, had no side effects and remained more stable psychopathologically, the patient did not comply adequately with the correct dosage, due to his rotating work shifts. This fact explained that although he acknowledged an improvement, he continued with episodes of depressive symptoms lasting several days followed by episodes of hypomanic characteristics.

Results: For this reason, it was decided to change treatment to aripiprazole long-acting injectable, in order to ensure linear blood levels of the drug. Initially, it was decided to prescribe 400mg every 28 days. However, after the first administration, 20 days later, the patient began to show dysphoric mood, with marked emotional lability, living in an egodystonic manner. For this reason, the dose was increased to 600mg on a monthly basis. Since then, after a year and a half with the same treatment, the patient has been stable and in line. There has been no further decompensation of the underlying psychopathology and no side effects.

Conclusions: Aripiprazole in TAB is superior to placebo in type I patients, mainly affecting manic and mixed episodes, but not so much in depressive episodes. It has also been observed that it not only acts in the acute phases, but also has a stabilising function, preventing manic episodes.

One study showed that up to 65% of patients on oral aripiprazole in whom it was replaced by AOM remained clinically stable. In the same study, approximately 50% of those who completed 52 weeks of follow-up were able to maintain clinical stability.

Sleep disorders in patients with bipolar disorder: age and tobacco consumption correlates

K. Razki^{1*}, C. Najar¹, S. Ben Aissa¹, M. Oumaya² and R. Bouzid²

¹Razi Hospital, LaManouba and ²Mental Health Department, Tahar Maamouri Hospital, Nabeul, Tunisia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.904

Introduction: Sleep disruptions are frequently observed in individuals with bipolar disorder and have been linked to various unfavorable consequences, such as an elevated risk of relapse and lower quality of life. Nonetheless, the impact of sociodemographic factors on the development and progression of these disruptions remains largely unexplored. Gaining insight into the relationship between sleep disruptions and sociodemographic factors is essential for designing effective interventions and enhancing clinical outcomes for individuals affected by bipolar disorder

Objectives: The objective of this study is to examine the association between sleep disorders in patients with bipolar disorder II (BDII) and sociodemographic characteristics.

Methods: This is a cross-sectional, descriptive, and analytical study that was conducted over a one-month period from October 1 to

October 31, 2022, with patients attending the follow-up unit of the mental health department at Nabeul Hospital, Tunisia. The study employed a questionnaire as a tool for data collection, and participants provided voluntary and informed consent before responding. The protection of participant confidentiality and anonymity was carefully observed during all stages of the study.

Results: In this study, we enrolled patients who satisfied the following eligibility criteria: age range of 18 to 60 years, a confirmed diagnosis of type II bipolar disorder based on DSM V criteria, and psychiatric stability as demonstrated by no hospitalization within the preceding 6-month period.

Our study included a sample of 40 male patients diagnosed with type II bipolar disorder. The participants had a mean age of 36 ± 13.2 years, and the majority were unmarried and living with their families or alone. Over two-thirds of the participants had attained a university level of education, while a large proportion of the patients, specifically 80%, reported being regular smokers.

The results of the study revealed that the mean global score on the Pittsburgh Sleep Quality Index (PSQI) was 7.28 ± 3.35 , indicating an overall low quality of sleep. The majority of the participants, that is 65% (26), had poor sleep quality scores (> 5), while 45% (18) reported experiencing poor sleep ($PSQI \geq 8$).

Our analyses further demonstrated that there was a significant association between tobacco consumption and PSQI scores ($p=0.003$). Additionally, we found that participants who were above 40 years old had a higher likelihood of experiencing sleep disturbances ($p=0.0017$).

Conclusions: According to the findings of our study, it appears that patients diagnosed with type II bipolar disorder may experience impaired sleep quality, which can be influenced by age and tobacco consumption. These results underscore the need for a holistic approach to patient care that addresses both the biological and sociodemographic factors that can impact sleep in this population.

Sleep and cognition in Bipolar Disorder in full or partial remission

K. T. Svee^{1*}, H. Kallestad², G. Morken², T. I. Hansen³ and A. Engum¹

¹Division of Mental Healthcare, St. Olavs Hospital; ²Department of Mental Health, Norwegian University of Science and Technology, NTNU and ³St. Olavs Hospital, Trondheim, Norway

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.905

Introduction: Cognitive impairment in Bipolar Disorder (BD) is frequent and is associated with reduced function in several areas. Close to half of the patients with BD have persistent cognitive dysfunction. The causes of cognitive impairments and factors associated with normal cognitive function are not clearly described. Some preliminary evidence links sleep disturbances and cognition impairment in BD. A limited number of studies have investigated the link between sleep and cognitive function in BD using objective measures.

Objectives: We aim to investigate associations between sleep and objective and subjective cognitive function in patients with BD in full or partial remission.

Methods: This is a cross-sectional study. The participants will be 90 adults meeting criteria for DSM 5 BD type 1 or type 2 in full or partial remission. Participants are recruited from psychoeducational groups for BD and from a specialist outpatient clinic. Diagnoses are set with SCID-5 and are confirmed in a consensus meeting with at least two psychiatrists and/or specialists in psychology. Symptoms of depression and mania are measured with Montgomery Asberg depression rating scale (MADRS) and Young Mania Rating Scale (YMRS). Sleep is measured subjectively with Insomnia Severity Index (ISI) and objectively with actigraphs which participants wear on their non-dominant hand for ten days. Subjective cognition is measured with Cognitive Complaints in Bipolar Disorder Rating Assessment (COBRA). Participants undergo neurocognitive testing with a self-administered validated web-based neuropsychological test platform. The testing is carried out in the participant's home on their smart phones. The tests include measures of learning, storing, recalling, and recognizing visual and verbal information, working memory and reaction time. Normal cognitive function is defined as scores within or above mean on all cognitive subtests. The test-platform has been validated.

We will use descriptive statistics to examine distribution of demographic characteristics. We will test for correlations between sleep factors and subjective and objective measures of cognitive function.

Ethics: The Regional Committees for Medical and Health research ethics approved the study.

Results: Results will be presented at the conference. So far, 74 out of 90 participants have been included.

Conclusions: We anticipate that normal sleep may be associated with good cognitive functioning. The findings of this study could offer supplementary insights into BD heterogeneity and potential treatment targets.

The role of cannabis in bipolar disorder relapse: a prospective study of hospital acute readmissions

L. Olivier^{1*}, A. Giménez¹, H. Andreu Gracia¹, L. Bueno¹, Ó. De Juan Viladegut¹, T. M. Fernández¹, I. Ochandiano¹, S. Salmerón¹, L. Bracco², L. Tardón Senabre¹ and I. Pacchiarotti³

¹Institut de Neurociències, Hospital Clínic de Barcelona, Barcelona, Spain; ²Department of Pathophysiology and Transplantation de Neurociències, University of Milan, Milan, Italy and ³Bipolar Disorder Unit, Hospital Clínic de Barcelona, Barcelona, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.906

Introduction: With the rapid changes of attitude, investigation and legislation around cannabis and its subproducts in the Western world, there is a need to profoundly examine the consequences of its use in the general population and, specifically, in people affected by mental disorders. There is a clear relationship between cannabis use and psychosis, but there is also growing evidence of its relationship with manic episodes (Sideli et al, 2019).

A systematic review published by the CANMAT Task Force in 2022 examined again the relationship between cannabis use and bipolar

disorder (BD), establishing association with worsened course and functioning of BD in frequent users (Tourjman et al., 2023). On the other hand, some recent papers have highlighted the role of the endocannabinoid system (ECS) in BD, suggesting even possible beneficial effects, mainly through the CB2 receptor (Arjmand et al, 2019).

Objectives: To describe the impact of cannabis in the psychiatric readmission in BD and to approach the differences in course in cannabis users with regards to non-users.

Methods: We conducted a prospective cohort study including the patients admitted to our acute psychiatric unit with the diagnosis of manic or mixed episode during the period between 2015 and 2019 (including patients with one of both final diagnosis: BD or schizoaffective disorder). We established a follow-up of 3 years from the date of admission in which hospital readmissions are examined.

Results: The study, which included 309 patients, concluded that cannabis users were admitted and had the first episode at a younger age ($p=0.005$), a higher percentage of them did not have a previous diagnosis ($p=0.026$) nor a previous history of mental health issues ($p=0.019$) and it was more likely to be their first admission ($p=0.011$) and to suffer psychotic symptoms ($p=0.002$).

As of treatment, the results were statistically significant regarding the fact that a lower proportion of patients had received previous psychiatric treatment ($p=0.004$) and previous electroconvulsive therapy ($p=0.003$). There was a higher chance of them being non-adherent with medication ($p<0.001$) and to be administered extended-release antipsychotic treatment during admission ($p<0.001$).

The study did not find a statistically significant relationship with cannabis use and a higher rate of readmission in the 3 years of follow-up.

Conclusions: Although a higher relapse rate could not be proven in our study, other previously identified factors related to a worse illness course (Sajatovic et al., 2009) did show a significant association with cannabis use, which could lead to one suggesting that our results are compatible with the actual evidence and that cannabis products are detrimental to people who suffer from BD and schizoaffective disorder.

Disclosure of Interest: None Declared

Bipolar disorder and Quality of life assessment using the SF-12 health survey

N. Gannoun¹, G. Bahri¹, N. Mechergui¹, H. Ben Said¹, D. Brahimi¹, M. Mersni¹, M. Bani¹, Y. Imene¹, N. Ladhari¹, M. METHNI^{2*}, C. BEN SAID² and N. BRAM²

¹Occupational Medicine health department, Charles Nicolle hospital and ²Forensic psychiatry département, Razi hospital, la Manouba, Tunis, Tunisia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.907

Introduction: Bipolar disorder (BD) is a severe and chronic mental illness characterized by recurrent major depressive episodes and mania (BD-I) or hypomania (BD-II). In addition to the burden of the disease and its consequences, people living with BD, like many

other people suffering from mental illness, must deal with their difficulty of integration which can influence their personal and professional life and consequently their quality of life (QOL).

Objectives: The aim of our study is to assess the QOL among working patients with BD.

Methods: A cross-sectional study was carried out in the occupational medicine department of the Charles-Nicollé hospital in Tunisia. Sociodemographic and occupational data were collected from the medical records of patients with bipolar disorder who consulted our department during the period 2022 to 2023. and a telephonic survey was carried out to complete the SF 12 international scale, which is a general health questionnaire that consists of 12 questions which investigates the patient's state of health via 8 different dimensions: General health perception, Physical health, Limited physical role function, Physical pain, Vitality, Mental health, Limited emotional role function and social functioning.

Results: We enrolled a total of 46 cases where 76% with BD type 1 with an average age of 43 ± 9 years. Most participants were female (76%) and the most frequent sectors of activity were healthcare and administration (80% and 12% respectively). BD was well balanced in 39% of cases with an average bipolar history of 7 years. The median annual absence due to psychiatric problems was 92 ± 61 days per year. The average score was 44 ± 18 for the General Health, 57 ± 35 for physical health and 67 ± 18 for mental health.

Conclusions: This study revealed that people living with BD's QOL seems to be altered. Clinicians need to be attentive to the QOL of their patients, its assessment, and its empowerment in their daily clinical practice. Future work is required to establish valid strategies to fight low QOL among patients suffering from BD.

Disclosure of Interest: None Declared

EPV0123

Diagnostic Challenges in Affective Disorders: Delirious Mania - A Case Report and Literature Review.

P. Herrero Ortega^{1*}, A. Oliva Lozano¹, J. Garde González¹ and M. A. Morillas Romerosa¹

¹Psychiatry, La Paz University Hospital, Madrid, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.908

Introduction: Affective disorders exhibit diverse clinical manifestations, and one distinctive subtype is delirious mania. Despite its exclusion from formal diagnostic manuals, delirious mania frequently emerges in everyday clinical practice. Recognizing it within the realm of differential diagnosis is crucial. Delirious mania is characterized by acute onset of excitement, grandiosity, emotional lability, delusions, and insomnia typical of mania, combined with disorientation and altered consciousness characteristic of delirium. Some authors consider delirious mania as a variant of classic bipolar disorder, while others associate it with catatonia. Additionally, some link it to underlying medical or neuropsychiatric causes.

Objectives: To describe the clinical case of a patient with delirious mania and emphasize the importance of recognizing this as a potential diagnosis in patients with abrupt alterations in mental state.

Methods: Clinical case report and literature review.

Results: A 61-year-old female patient with a history of a unique depressive episode over 20 years ago, treated with Carbamazepine up to 750 mg, is admitted to the Emergency Room with acute symptoms consistent in global disorientation, aggressive behavior, mutism, bradyphrenic and repetitive incoherent speech, along with visual hallucinations, all of which had developed over a few days. The gradual withdrawal of Tegretol over an 8-month period preceded her admission to the ER.

Relevant medical tests, including cranial CT, EEG, blood tests, and urine analysis, were conducted during her ER stay, all of which yielded normal results. Neurological evaluation ruled out acute neurological pathology, leading to her subsequent admission to the Psychiatry department. Throughout her admission, the patient exhibited irritability and expressed derogatory comments filled with offensive language. She gradually became more expansive, with her thought content becoming megalomaniac in a delirious range. Her speech was incoherent, verbose and had loose associations.

Treatment was reintroduced with Carbamazepine up to 600 mg/day and Olanzapine up to 20 mg/day, resulting in a rapid and comprehensive improvement of her symptoms, ultimately leading to the complete resolution of her condition.

Conclusions: This case highlights the concept of delirious mania, characterized by alterations in attention, orientation, memory, confusion, behavioral and thought fluctuations, and psychomotor disturbances which can manifest abruptly, as observed in this patient. This clinical case underscores the significance of considering delirious mania in the differential diagnosis of patients with abrupt alterations in mental state, particularly those of advanced age with a history of affective episodes. A global understanding of this condition is essential for its timely recognition and appropriate management.

EPV0124

Unipolar and Bipolar Depression : Which Differences?

M. Turki¹, A. Labyadh^{2*}, W. Abid¹, N. Halouani¹, S. Ellouz¹ and J. Aloulou¹

¹Psychiatry B department and ²Psychiatry C department, Hedi Chaker Hospital, Sfax, Tunisia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.909

Introduction: Depression is a common mental disorder whose management remains delicate, given the trans-nosographic nature of this syndrome. Two common types of depression are bipolar and unipolar depression. Although they share many similar symptoms, several differences between the two pathologies are suggested in prior studies.

Objectives: We aimed to compare the disease characteristics and evolution of unipolar and bipolar depressed patients.

Methods: We conducted a retrospective descriptive and analytical study among medical records of 167 patients hospitalized for a depressive episode (DE) at the Psychiatry "B" Department, Hedi Chaker University Hospital (Sfax, Tunisia), during the period

between 2015 and 2017. Patients were divided into two groups according to DSM-5 criteria: those with bipolar disorder I or II (bipolar depression) versus those with major depressive disorder (unipolar depression).

Results: The mean age of our patients was 37.6 years, with a female predominance (sex-ratio F/M =1.7). The age of onset of the disease was earlier in bipolar depressed patients (29.36 versus 31.89), without a significant relationship. Family psychiatric history was significantly more prevalent in bipolar disorder patients (73.5% versus 37.3%; $p<0.001$). Bipolar patients are more likely to be unemployed (65.3% versus 50.8%), but without a significant relationship.

Bipolar patients were more likely to be hospitalized for suicide attempts (44.9% versus 35.6%; $p=0.2$).

Conclusions: Distinguishing between major depressive disorder and bipolar disorder is important because there are differences in the optimal management of these conditions.

EPV0125

Manic episode in a patient with pancreatic adenocarcinoma: a case report

J. I. Mena Garcia*, H. Andreu, S. Salmeron, I. Ochandiano and E. Cesari

Psychiatry and Psychology Service, Hospital Clínic, Barcelona, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.910

Introduction: Psychiatric comorbidity is common in cancer patients, emphasizing the need for comprehensive care. While depressive symptoms in pancreatic cancer (PC) have been studied, there is limited attention given to manic symptoms. This case report aims to contribute to the knowledge of PC psychiatric comorbidities by describing a case of a 61-year-old patient with stage IV PC, with no personal or family psychiatric history, who presented a sudden onset manic episode.

Objectives: Our goal is to contribute to the growing knowledge of psychiatric comorbidities of PC focusing on manic symptoms by describing the case of a patient with stage IV PC without previous psychiatric history who presented a sudden onset of a manic episode.

Methods: We describe the mentioned clinical case. We also searched for previous case reports of maniac episodes in pancreatic cancer using a PubMed query.

Results: The patient, a 61-year-old male with stage IV PC, presented at the Emergency Room with abrupt behavioural changes suggestive of a manic episode of two weeks of evolution. The patient had been undergoing chemotherapy and short 3-day cycles of corticosteroids for the past 9 months but had been off this treatment for 20 days when the episode began. Acute organic causes were ruled out. The patient was admitted to the psychiatric unit, where organic screening was expanded and treatment with antipsychotics and a mood stabilizer was initiated with subsequent remission of symptoms after two weeks.

This article describes the case of a man with a PC diagnosis who had no prior psychiatric history and was admitted to the inpatient psychiatry unit due to a manic episode involving high-risk

behavioral disturbances and megalomaniac psychotic symptoms. Several factors may have contributed to the onset of these symptoms, including corticosteroid use after chemotherapy and certain chemotherapy agents. However, due to temporal factors, these factors do not fully explain the episode.

The exact biological mechanisms behind the manic symptoms remain unknown, but hypotheses include gene-environment interactions in bipolar disorder and immunodysregulation related to the production of inflammatory cytokines. We found in the literature four cases that have reported new-onset mania as an initial symptom of PC, but the causal relationship is unclear.

Conclusions: Notably, this case differs from others due to the rapid remission of symptoms and the use of lithium therapy. While the underlying mechanisms are still unclear, this case contributes to understanding this rare complication of PC and may help in developing consensus on clinical management. Future research will further explore the pathophysiology of psychiatric symptoms in PC and appropriate therapeutic approaches.

This case shows a manic episode as a rare psychiatric complication in PC. In the literature reviewed, four other similar cases have been observed.

Case Series: The use of Lithium in Bipolar Affective Disorder and End-Stage Renal Disease

K. Corrigan^{1*}, D. Larkin¹, G. Giusti², M. Gallagher¹ and A. Guerandel¹

¹St Vincent's University Hospital, Dublin, Ireland and ²The University of Pisa, Pisa, Italy

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.911

Introduction: Lithium is a highly effective treatment in the management of Bipolar Affective Disorder (BPAD) however it is associated with increased risk of developing chronic kidney disease. There is a lack of clear guidance on alternative approaches to managing those individuals that require cessation of lithium due to progression to end stage renal disease (ESRD).

Objectives: We discuss two patients with BPAD on lithium therapy who have developed ESRD. In both cases, lithium was discontinued due to ESRD, with alternatives trialled. In one case, the patient continues to be managed without lithium, whereas in the second, a decision was made to recommence lithium at a low dose. We reviewed the literature to provide meaningful context to the cases.

Methods: Case 1 This patient with a long history of BPAD and multiple medical co-morbidities experienced progressive decline in renal function. A decision was made to cease lithium therapy with close monitoring for signs of affective relapse. The patient was stabilised using a combination of sodium valproate and quetiapine. Since cessation of lithium, the patient has required a significant increase in support from the CMHT and more frequent admissions to manage mood and anxiety symptoms that cause significant subjective distress.

Results: Case 2 This patient had a long history of stable BPAD, with no episodes of illness for over 30 years. Unfortunately they developed CKD and despite a significant reduction in lithium over time, they developed ESRD requiring haemodialysis. Lithium was discontinued leading to a manic relapse of BPAD requiring a prolonged admission and a combination of carbamazepine, olanzapine, escitalopram and clonazepam to stabilise their mental state. Following discharge home, their mental state failed to reach baseline and they reported significant anxiety symptoms and memory impairment. Following protracted assessment and support they were deemed unfit for renal transplant and a decision was then made by the patient, their family, nephrology and psychiatry to recommence lithium therapy whilst on haemodialysis. Their anxiety and functioning improved significantly following the reintroduction of low dose lithium, allowing the withdrawal of other neuroleptics.

Conclusions: Both cases required an individual approach to balance physical and mental health considerations. There are no clear markers to predict if a patient will respond to alternative mood stabilisers, nor is there a guarantee that kidney function will improve or stop declining when lithium is discontinued. Decisions should reflect patient preference and balance risks associated with relapse and of declining ESRD.

Sex differences in neurocognitive performance in older adults with bipolar disorder

S. Martín-Parra^{1*}, C. Torrent², A. Ruiz¹, M. Bort¹, G. Fico¹, V. Oliva¹, M. D. Prisco², J. Sanchez-Moreno², E. Jimenez², A. Martinez-Aran², E. Vieta³, B. Sole² and L. Montejo²

¹Bipolar and Depressive Disorders Unit, Hospital Clinic of Barcelona, IDIBAPS, University of Barcelona; ²Bipolar and Depressive Disorders Unit, Hospital Clinic of Barcelona, CIBERSAM, IDIBAPS, University of Barcelona and ³Bipolar and Depressive Disorders Unit, Hospital Clinic of Barcelona, CIBERSAM, IDIBAPS, Departament de Medicina, Facultat de Medicina i Ciències de la Salut, University of Barcelona, Barcelona, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.912

Introduction: In recent years, research has focused on the older adults with bipolar disorder (OABD), aged 50 years and over, a constantly growing population due to the increased of life expectancy. Actually, some authors suggest that these individuals constitute a distinct subtype with a specific and different needs such as seen in epidemiologic, clinical and cognitive features. Further research has revealed significant differences between females and males with BD in clinical and cognitive variables in middle-aged and young patients, but this topic among OABD population remains unclear.

Objectives: The aim of this study is to identify the distinctive profile in clinical, functional and neurocognitive variables between females and males in OABD.

Methods: A sample of OABD and Healthy Controls (HC) were included. Euthymic patients or in partial remission were included. Neurocognition was measured with a battery of tests that included premorbid intelligence quotient, working memory, verbal and visual memory, processing speed, language and executive functions. Independent t-test and Chi-squared test analysis were performed as appropriated.

Results: According to the analysis, statistically significant differences were seen between females and males. A more impaired cognitive profile is observed in women. They performed worse in the subscales of Arithmetic ($F = 6.728, p = <0.001$), forward digits ($F = 0.936, p = 0.019$) and Total Digits ($F = 1.208, p = 0.019$) of the WAIS-III, in the Stroop Color Word Test, color reading ($F = 0.130, p = <0.001$), in the Continuous Performance Test, block change measure ($F = 2.059, p = 0.037$), in the Rey-Osterrieth Complex Figure-copy ($F = 0.005, p = 0.029$) and in the Boston Naming Test ($F = 0.011, p = 0.024$). Nor significant differences were found in clinical neither in psychosocial functioning variables.

Conclusions: In view of the following results, and since no differences were observed between women and men in terms of clinical and functional outcomes, it could be said that the differences observed in cognition cannot be explained by disease-related factors. Furthermore, these results highlight the need to develop a gender-specific cognitive interventions in OABD population. In this way, we could have an impact on the course of the illness to reach a better quality of life.

The Effect of Social Support on Recovery and Treatment Adherence in Individuals Diagnosed with Bipolar Disorder

R. Aydar*, M. C. Aktaş and C. H. Ayhan

Van Yüzüncü Yıl University, Van, Türkiye

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.913

Introduction: Social support have affected the recovery and adherence with treatment in bipolar patients.

Objectives: This research aims to understand the contribution of social support mechanisms to treatment adaptation processes in individuals struggling with bipolar disorder and the effects of these support mechanisms on recovery. In this way, the importance of the social support factor will be tried to be understood in order to provide more effective and customized support to individuals living with bipolar disorder.

Methods: This study will planned to descriptive correlational design. The data will collect to using the Morisky Treatment Adherence Scale (MTAS), the Multidimensional Scale of Perceived Social Support (MSPSS), the Recovery Process Inventory (RPIS), and the Sociodemographic Data Form from individuals diagnosed with Bipolar disorders. By filling out these scales, participants will evaluate their treatment compliance, perceived social support levels, and recovery processes. The data will be subjected to appropriate methods for statistical analysis and will be used to understand the relationships between social support and treatment compliance and recovery processes.

Results: Data extraction is still on going in detailed style by principal authors. Description of studies and the key findings will be presented.

Conclusions: It is thought that the results obtained from this research will be an important guide in providing more effective support to individuals with the level of social support, treatment adherence and recovery processes in individuals struggling with bipolar disorder

Key Words: bipolar disorder, social support, treatment adherence, recovery.

Disclosure of Interest: None Declared

Introduction: Bipolar I disorder (BD-I) is a chronic and recurrent mood disorder characterized by alternating episodes of depression and mania; it is also associated with substantial morbidity and mortality and with clinically significant functional impairments. While previous studies have used functional magnetic resonance imaging (fMRI) to examine neural abnormalities associated with BD-I, they have yielded mixed findings, perhaps due to differences in sampling and experimental design, including highly variable mood states at the time of scan.

Objectives: The purpose of this study is to advance our understanding of the neural basis of BD-I and mania, as measured by fMRI activation studies, and to inform the development of more effective brain-based diagnostic systems and clinical treatments.

Methods: We conducted a large-scale meta-analysis of whole-brain fMRI activation studies that compared participants with BD-I, assessed during a manic episode, to age-matched healthy controls. Following PRISMA guidelines, we conducted a comprehensive PubMed literature search using two independent coding teams to evaluate primary studies according to pre-established inclusion criteria. We then used multilevel kernel density analysis (MKDA), a well-established, voxel-wise, whole-brain, meta-analytic approach, to quantitatively synthesize all qualifying primary fMRI activation studies of mania. We used ensemble thresholding ($p < 0.05$ -0.0001) to minimize cluster size detection bias, and 10,000 Monte Carlo simulations to correct for multiple comparisons.

Results: We found that participants with BD-I ($N=2,042$), during an active episode of mania and relative to age-matched healthy controls ($N=1,764$), exhibit a pattern of significantly ($p < 0.05$ -0.0001; FWE-corrected) different activation in multiple brain regions of the cerebral cortex and basal ganglia across a variety of experimental tasks.

Conclusions: This study supports the formulation of a robust neural basis for BD-I during manic episodes and advances our understanding of the pattern of abnormal activation in this disorder. These results may inform the development of novel brain-based clinical tools for bipolar disorder such as diagnostic biomarkers, non-invasive brain stimulation, and treatment-matching protocols. Future studies should compare the neural signatures of BD-I to other related disorders to facilitate the development of protocols for differential diagnosis and improve treatment outcomes in patients with BD-I.

doi: 10.1192/j.eurpsy.2024.915

Introduction: Investigation expectations for children and adolescents with cancer is an important issue for their psycho-emotional development as well as their quality of life.

Objectives: To investigate the expectations of children suffering from cancer.

Methods: 102 questionnaires were collected from pediatric patients suffering from neoplasia disease (62 boys and 40 girls) with a median age of 13 years, covering the multidimensional expectation questionnaire (MEQ) suitable for children with cancer in a 4-point Likert scale. The MEQ was then evaluated using the SPSS.21 statistical package, which resulted in 13 questions. The questionnaire of expectations highlighted three factors that referred to the "family life expectations", "daily life / daily routine and career prospects", and "expectations of networking friendship", respectively. The statistical results were obtained by multi-line regression analysis, with the Stata 12.1 statistical package, while ethical issues were complied with and licensed.

Results: MEQ reliability (Cronbach's alpha) for the entire scale was 0.82 and for agents ranged from 0.65-0.84. Overall, pediatric cancer patients delivered a fairly high average score of $3,33 \pm 0,42$ questions in the expectation's questionnaire, while the mean scores were $3,29 \pm 0,63$, $3,51 \pm 0,45$ and $3,19 \pm 0,54$, respectively. From the results of the analysis of multiple regression, it appeared that, as the age increases, the patients with neoplastic disease have overall 76 lower expectations ($p = 0.014$), while the satisfaction of the doctors-nursing staff in the total expectations is positive ($p = 0.018$). In the family life expectancy factor, the age of children appears to play a negative role in increasing age ($p = 0.019$), while positive body image and satisfaction with doctors-nursing staff ($p = 0.040$, $p = 0.006$) respectively. It appeared that children aged > 13 years have worse outcomes in expectations of the daily routine and career prospects with ($p = 0.037$).

Conclusions: The MEQ has proven to be a valid and reliable tool that can provide pediatric staff and researchers with information about the expectations of children and adolescents with cancer that require long-term health care.

Pattern of video game usage and video game disorder in Portugueses adolescents: A study about parental and peer attachment, parenting styles, and communication in parenting

A. M. Ribeiro¹ and B. R. Maia^{2*}

¹Universidade Católica Portuguesa and ²Universidade Católica Portuguesa; Center for Philosophical and Humanistic Studies, Braga, Portugal

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.916

Introduction: Video game disorder has been a subject of increasing interest, being associated with patterns of insecure attachment and authoritarian and permissive parenting styles. However, there is still a gap concerning the relationship between video game disorder and parent-child communication, one of the fundamental components of attachment to parents. Particularly in the Portuguese context, research on these topics and

their interrelations is still scarce, thus remaining relatively unexplored.

Objectives: To explore the pattern of video game usage and video game disorder, as well as their relationships with parental and peer attachment, parenting styles, and communication in parenting within a sample of Portuguese adolescents.

Methods: 150 Portuguese teenagers, recruited at public Portuguese schools, aged between 10 and 19 years old (mean age = 14.37, DP = 3.12; 52.7% girls (n = 79), and mostly living with both parents (79.7%, n = 106) fulfilled a sociodemographic and an academic questionnaire, a questionnaire on video game use patterns, the Video Game Disorder Scale - Short Version 9, the People in My Life Questionnaire, the Portuguese hetero-report version of the Parenting Styles and Dimensions Questionnaire: Short Version and the Perception Scale of Parenting Communication.

Results: The majority of the sample indicated 3rd childhood (n = 81, 54.0%), specifically at 8 years old, as the age of video game initiation and a playtime of less than or equal to 2 hours (n = 111, 74.0%), with only 2 participants found to have a video game disturbance index (1.3%). A positive association was found between video game disturbance and the average hours of gameplay, as well as a negative association with the age of game initiation. Additionally, relationships were explored, revealing that video game disturbance is negatively related to lower quality of attachment to parents and peers, positively related to an authoritative parenting style, and negatively related to less available, open, and affectionate parent-child communication.

Conclusions: This study provides an in-depth understanding of adolescents' behavior regarding video games, contributing to the knowledge of the topic in the Portuguese context. Furthermore, the identification of factors associated with video game disturbance allows for the development of remediation and prevention programs for this addictive disturbance, which are essential tools in psychological practice.

Attachment representations in high intellectual potential (HIP) children compared to non-HIP children during development

S. Hamdioui¹ and L. Vaivre-Douret^{1,2,3,4,5*}

¹Faculty of Medicine, University of Paris-Saclay, UVSQ, INSERM Unit 1018-CESP, Villejuif; ²Faculty of Health, Department of Medicine, University of Paris Cité; ³Chair of Neurodevelopmental Clinical Phenotyping, Institut Universitaire de France (IUF); ⁴Necker Enfants Malades University hospital, AP-HP. Centre and ⁵Department of Endocrinology, Necker-Enfants Malades Hospital, IMAGINE Institute, Paris, France

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.917

Introduction: The studies about developmental bases of attachment in healthy children with high intellectual potential (HIP) are rare. Moreover, the literature underline socio-emotional disorders in HIP and difficulties with behavioral adjustment of parents.

Objectives: We aimed to explore the developmental trajectory of attachment in HIP children without psychological or learning disorders.

Methods: The french version of the Adolescent-Unresolved-Attachment-Questionnaire (QANRA: internal consistency=0.74-0.82; test-retest =0.58-0.83) was analyzed in 80 healthy children (50 HIP with IQ>130 vs. 30 non-HIP), aged 7-to-13-years-old (mean 10y; SD 1.8). All children were recruited in private and public schools in Paris.

Results: There was no significant difference between the groups. However, when we looked at the developmental trajectory by distinguishing the period of adolescence [7-10 years (56% in the HIP group vs. 53% in the non-HIP); 11-13 years (44% in the HIP group vs. 47% in the non-HIP)], we have noted a significantly early integration of resolved attachment in the HIP children that seems to remain stable in adolescence.

Conclusions: Our findings highlight the early onset of attachment with a harmony of intellectual/psycho-affective development in HIP children without skipping stages, but more quickly and effectively. This could potentially be explained by their cognitive abilities, particularly the theory of mind and the executive functions, known to be significantly more efficient in HIP children without neurodevelopmental disorders.

EPV0134

Developmental organization of the graphic gesture with a pre-scrptural task to assess handwriting

L. Vaivre-Douret^{1,2,3,4,5*} and C. Lopez³

¹Faculty of Health, Department of Medicine, University of Paris Cité;

²Chair of Neurodevelopmental Clinical Phenotyping, Institut Universitaire de France (IUF), Paris; ³Faculty of Medicine, University of Paris-Saclay, UVSQ, INSERM Unit 1018-CESP, Villejuif; ⁴Necker Enfants Malades University hospital, AP-HP. Centre and ⁵Department of Endocrinology, Necker-Enfants Malades hospital, IMAGINE Institute, Paris, France

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.918

Introduction: The literature mainly focused on spatio-temporal and kinematics parameters of tracing letters or words using digitizing tablets, no recent research has previously studied the developmental prerequisites of the organization of handwriting.

Objectives: We aimed to aimed to investigate and validate the developmental organization of the graphic gesture with a pre-scrptural task.

Methods: 122 typically developing right-handed elementary school children (grades 1st to 5th) aged from 6 to 11;3 years old were recruited. The axe postural and arm gestural features were video-recorded with analysis in 2D reconstruction. Spatial (length, size, regularity, slope of the line...), temporal (drawing time, pause time) and kinematic measures (velocity, peak velocity) were collected with a digital pen independent connected to an analysis software tool. External validity was studied in relation with the standardized handwriting scale BHK. The child has to draw a line of cycloid loops (from left to right drawn in an anti-clockwise direction) across the width of an A4 size unlined half sheet of white paper (containing non-visible watermarks to provide the location of the pen) free to move on the table, after observing the dynamic model on the iPad placed in front of him.

Results: Five main patterns of inter-segmental displacement gestures were found for the production of the line of loops with a significant developmental progress from grades 1st to 5th. Findings showed significant economic rotation movement with forearm rotation around the elbow in 4th and 5th grade, with the elbow tending significantly to be static on the table ($p = 2.43e-16$), wrist on the table and ($p = 0.02$) and in half-supine position ($p = 0.001$), tri-digital grasp of the pen ($p = 3.81e-08$). Moreover, the mean pressure applied on the pen decrease at 4 and 5th grades and it is correlated to deleterious spatial-temporal and kinematic parameters.

Conclusions: The results of our study provide the first developmental grade and age-related normative data in the developmental genesis of the graphomotor gesture and with the spatio-temporal / kinematic measures. The more mature the gesture, the more there is a decrease in degrees of freedom of movement and stabilization of the joints that is fixed, as well as the presence of a distal flexion movement extending fingers in synergy with the rotation of the arm around the elbow. Furthermore, the task of copying of loops in ecological settings appears to be a good predictor for legibility and writing speed. Those data can account for the mechanisms of motor programming necessary to the automatization of the future gesture of handwriting.

EPV0136

Trends in Youth Fatal Drug Overdose and Suicide Intentionality

Y. Kaminer

Psychiatry, University of Connecticut, Farmington, United States
doi: 10.1192/j.eurpsy.2024.919

Introduction: Fatal youth overdose (FYO) in the US has been driven by fentanyl and polysubstances since 2016. Youth suicide have also been increasing since the year 2000. The manner of FYO may be accidental, intentional or undetermined, Psychoactive drug use including opioids has been known to increase suicidality in youth.

Objectives: Examine and compare the rate of intentional and accidental FYO as well as specific drug toxicology in youth under 26 years of age in the state of Connecticut, USA; between the years 2016-2018 (Kaminer et al. JCASA 2020;29 80-87) and 2019-2021.

Methods: We reviewed N=286 consecutive FYO case files of youth who died between 2019-2021, from the Connecticut office of the Chief Medical Examiner.

Results: Comparing the periods of 2019-2021 2016-2018: A) FYO attributed to fentanyl increased significantly; B) Intentional FYO rates doubled from 3.8% to 7.7%; C) No gender differences were found between and within age groups; and D) hispanic rates increased significantly while caucasian rates decreased significantly; F) for the first time FYO of youth under the age of 15 years was recorded and G) the age group of 15-19 years old constitute 10% of the FYO and remained unchanged.

Conclusions: The use of lethal drugs leading to youth accidental and intentional FYO should be addressed by developing prevention-intervention approach. Focus on acute modifiable high-risk is

prudent. The increase of intentional (i.e., suicidal) determined YFO is a major public health concern.

Conversive and Factitious disorders: Differential diagnosis based on a case report

M. Fernandez Lozano, B. Rodriguez Rodriguez, N. Navarro Barriga, M. J. Mateos Sexmero, C. Alario Ruiz*, L. Rodriguez Andrés, G. Medina Ojeda, T. Jimenez Aparicio, C. Vallecillo Adame, C. De Andres Lobo, M. A. Andreo Vidal, P. Martinez Gimeno, M. Calvo Valcarcel, M. P. Pando Fernández, L. Rojas Vazquez, M. Rios Vaquero, G. Lorenzo Chapatte and A. Monllor Lazarraga

Hospital Clínico Universitario de Valladolid, Valladolid, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.920

Introduction: Conversive disorder is characterised by the presence of one or more involuntary neurological symptoms that are not due to a clear medical pathology. On the other hand, consciously simulated illnesses fall into two diagnostic categories: factitious disorders and malingering, which are differentiated by both the motivation for the behaviour and the awareness of that motivation. Factitious disorder behaviours are motivated by an unconscious need to assume the sick role, whereas malingering behaviours are consciously driven to achieve external secondary gains.

Objectives: Study of the differences between conversion disorder and factitious disorder and their repercussions from a case of difficult diagnosis.

Methods: Bibliographic review of scientific literature based on a relevant clinical case.

Results: We present the case of a 14-year-old male patient. Adoptive parents. Studying in high school. Social difficulties since childhood. He comes to the emergency department on several occasions referring stereotyped movements and motor tics in the four extremities with left cervical lateralization. Increase of these symptoms in the last month, so it was decided to admit him to the pediatric hospital. After observation and study of the patient's movements with normal complementary tests he should return home. The following day he returned to the emergency department after an episode of dizziness, mutism and emotional block. It was decided to admit him to Psychiatry for behavioral observation and differential diagnosis.

Conclusions: In the assessment of patients it is essential to make an appropriate diagnosis taking into account the patient's symptomatology and the patient's background and life context. Conversion disorder is the unintentional production of neurological symptom, whereas malingering and factitious disorder represent the voluntary production of symptoms with internal or external incentives. They have a close history and this has been frequently confounded. Practitioners are often confronted to medically unexplained symptoms; they represent almost 30% of neurologist's consultation. The first challenge is to detect them, and recent studies have confirmed the importance of "positive" clinical bedside signs based on incoherence and discordance. Multidisciplinary therapy is

recommended with behavioral cognitive therapy, antidepressant to treat frequent comorbid anxiety or depression, and physiotherapy. Factitious disorder and malingering should be clearly delineated from conversion disorder. Factitious disorder should be considered as a mental illness and more research on its pathophysiology and treatment is needed, when malingering is a non-medical condition encountered in medico-legal cases.

Smith-Magenis Syndrome associated with Autism Spectrum Disorder with delayed diagnosis due to B12 deficiency: a case report

A. N. Orpay*, H. A. Güler and S. Türkoğlu

Child and Adolescent Psychiatry, Selcuk University Faculty of Medicine, KONYA, Türkiye

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.921

Introduction: Smith-Magenis syndrome (SMS) is a complex genetic disorder characterised by distinctive physical features, developmental delay, cognitive impairment and a typical behavioural phenotype. SMS is caused by interstitial 17p11.2 deletions (90%) involving multiple genes, including the retinoic acid-induced 1 gene (RAI1), or by pathogenic variants in RAI1 itself (10%).

Objectives: In this case report, we present a case of Smith-Magenis syndrome with Autism Spectrum Disorder with karyotype 46,XX, 17p 11.2 gene deletion confirmed by Autism Spectrum Disorder, who was followed up in a paediatric neurology outpatient clinic with neuromotor developmental delay and whose diagnosis was delayed due to B12 deficiency. We also update scientific developments in Smith-Magenis syndrome.

Methods: We describe an 18-month-old male with Smith-Magenis syndrome and Autism Spectrum Disorder who was seen in our paediatric psychiatric outpatient clinic and who received B12 replacement with developmental delay.

Results: The patient was followed up in the paediatric neurology outpatient clinic with delay in neuromotor developmental milestones and this delay was thought to be due to B12 deficiency (B12<100 ng/L). The initial examination revealed delay in neuromotor and behavioural milestones, speech delay, wide and high nasal bridge and hypertelorism. Further physical examination revealed syndactyly of the second and third toes bilaterally and crossed lower teeth. Clinical and psychometric testing (Ankara Developmental Screening Inventory) by 2 consultants and 1 research assistant resulted in a diagnosis of intellectual disability and an additional diagnosis of Autism Spectrum Disorder due to social deficits that could not be explained by intellectual disability.

Conclusions: Smith-Magenis syndrome is a well-known disorder involving the deletion of chromosome 17p11.2, which contains the RAI1 gene. This condition is associated with neuromotor and behavioural delay, as well as distinctive dysmorphic features. Clinicians should consider Smith-Magenis syndrome in the differential

diagnosis for patients with delayed neuromotor and behavioural milestones, even in the presence of documented blood parameters (such as B12 deficiency) that may account for the delay.

Specific intervention program for ARFID comorbid with ASD in a Children's Youth Autism Day Hospital

A. Alvarez^{1*}, N. Santamaria², V. Bote¹, R. Medina¹, B. Sanchez², I. Mendez², J. A. Monreal² and A. Hervas²

¹University Hospital Mutua Terrassa, Terrassa, Spain and ²Mental Health, University Hospital Mutua Terrassa, Terrassa, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.922

Introduction: Children and adolescents with ASD are more likely to have eating problems compared to the general population of the same age, one of the disorders whose prevalence is increased in people with ASD is avoidant/restrictive eating disorder Food (ARFID) ARFID is characterized by a lack of interest in eating or avoidance of food intake, which in the case of people with ASD is usually related to impaired sensory processing and cognitive rigidity. For this reason, the Autism Day Hospital carries out a specific food intervention program.

Objectives: To retrospectively evaluate the results of the Food Program of the Autism Day Hospital during the year 2022.

Methods: A retrospective analysis of the cases of patients admitted to the Food Program of the Autism Day Hospital during the year 2022 is carried out. Results of the sensory pattern and presence of genetic alterations of each one of the patients are compared. And the results of the intervention are evaluated by quantifying the new foods introduced into the diet at the end of the admission.

Results: The sample is made up of a total of 5 children (4 boys and 1 girl) aged between 7 and 12 years. All of them meet diagnostic criteria for Autism Spectrum Disorder and present comorbidity with ARFID. Of the total sample, 1 of the patients presented in the genetic study a microdeletion S. in 15q13.3, duplication in 2q13 and duplication in 5p12-p11, with the genetic studies in the rest of the patients in the sample being normal. Regarding the results of the sensory pattern (Infant/Toddler Sensory profile test), all the patients presented differences in relation to other children of their age in the oral sensory pattern, this difference being definitive in 3 of the 5 patients in the sample. All the patients included in the program presented a satisfactory evolution, introducing at least 15-20 new foods into their usual diet, including different textures and consistencies.

Conclusions: The therapeutic approach to ARFID in children with ASD carried out from a multidisciplinary perspective; sensory integration, behavioral approach and, if necessary, psychopharmacological, has shown, based on the results obtained from the food program of the ASD Day Hospital, a favorable evolution of the eating disorder. For this reason, we consider the detection of this typical comorbidity of ASD and its referral to specific therapeutic programs to be of special importance.

EPV0141

Clinical and electroencephalographic particularities of children and adolescents with behavioral disorders

R. Bouchech¹, A. Fki^{2*}, I. Kammoun¹ and K. Masmoudi¹

¹Functional explorations department, Habib Bourguiba hospital, Sfax and ²Occupational medicine department, Sahloul hospital, Sousse, Tunisia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.923

Introduction: Behavioral disorders are a frequent reason for consultation in child psychiatry. Children and adolescents with epilepsy are at risk of behavioral disorders that can affect their quality of life.

Objectives: The aim of this study was to investigate the electroencephalographic aspects of children with behavioral disorders and to determine the prevalence of comorbidity with epilepsy.

Methods: This was a retrospective descriptive study conducted from January 2019 to May 2022. We included all children and adolescents referred to the functional explorations department at Habib Bourguiba hospital, Tunisia for Electroencephalogram (EEG) as part of a workup to explore a behavioral disorder.

Results: A total of 117 patients were included in the study. The mean age was 14 ±4.2 years. The sex ratio was 1.29. Agitation was reported in 66.7% of patients. One case of attempted suicide was noted. Among these patients, 29.9% reported audiovisual hallucinations. Concentration difficulties were associated with 59% of cases. Ten patients had a history of epileptic seizures. Of the 117 EEGs performed, 59.8% were pathological. The abnormalities observed were paroxysms in 67.1% of cases and focal slowing in 25.7%. Five patients had a rapid rhythm on the EEG. An absence-type electro-clinical seizure was recorded in one patient. Patients with visual hallucinations had epileptiform abnormalities of occipital location in 41.7% of cases, and slow waves of anterior location in 50% of cases. Patients with auditory hallucinations had parietal epileptiform abnormalities in 89% of cases.

Conclusions: Ictal and interictal manifestations seem to play a part in the genesis of behavioral disorders in children and adolescents. An EEG would therefore be preferable in this age group, for better management.

Disclosure of Interest: None Declared

EPV0142

Study of EEG sensitivity and specificity in loss of consciousness in adolescents

R. Bouchech¹, A. Fki^{2*}, I. Kammoun¹, I. Kammoun³ and K. Masmoudi¹

¹Functional explorations department, Habib Bourguiba hospital, Sfax;

²Occupational medicine department, Sahloul university hospital, Sousse and ³functional explorations department, Hedi chaker hospital, Sfax, Tunisia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.924

Introduction: Although the etiological diagnosis of loss of consciousness is essentially based on a careful history and clinical examination, electroencephalography (EEG) remains an important investigative tool.

Objectives: The aim of this study was to identify the value of EEG in the management of adolescents with recurrent bouts of fainting

Methods: This was a retrospective descriptive study conducted from January 2019 to May 2022. We included all adolescents referred to the functional explorations department at Habib Bourguiba hospital, Tunisia for Electroencephalogram (EEG) as part of a workup to explore recurrent episodes of loss of consciousness.

Results: A total of 55 adolescents were included in this study, with a mean age of 15.4 ± 2.3 and a 72.4% female proportion. The delay between the EEG and the onset of the seizure was greater than one week. 67.3% of patients were referred by the child psychiatry department. 29.1% of the 55 EEG reports were pathological. Epileptiform discharges were noted in 56.3% of adolescents. Slow waves were found in 43.7% of cases. The location of the abnormalities was predominantly frontal. Patients with temporal EEG anomalies had a notion of ascending epigastric pain preceding loss of consciousness in 90% of cases. Adolescents with EEGs containing epileptiform abnormalities had a history of paroxysmal movements in 30% of cases. The sensitivity of the EEG was estimated to be around 25%, and the specificity around 79%.

Conclusions: Although the clinical examination is of great importance in the etiological diagnosis of loss of consciousness, the EEG remains a complementary examination of non-negligible interest in the etiological investigation.

Anxiety, Depression, and Stress on School-Aged Children and Adolescents in 2021: An Urgent Need for Comprehensive Intervention and Support

A. Romero^{1*}, M. Petro² and E. P. Ruiz³

¹CORDOBA, Universidad de Cordoba; ²CORDOBA, GEORGES NOBLE SCHOOL and ³CORDOBA, Universidad Pontificia Bolivariana, MONTERIA, Colombia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.925

Introduction: In the year 2021, there was a notable increase in behaviors associated with anxiety, depression, and stress among school-aged children and adolescents, possibly attributed to the pervasive effects of social isolation and confinement measures.

Objectives: This study conducted a thorough analysis of cases involving students aged 11 to 17 years who exhibited risk factors, anxious and depressive symptoms, and mood disturbances.

Methods: This study focused on students aged 11 to 17 years and employed a comprehensive approach to assess the impact of anxiety, depression, and stress. Cases were meticulously analyzed, and key categories were established to characterize the multifaceted challenges faced by the students. These categories included the availability of family support, utilization of psychopharmacological

treatment, engagement in psychological therapies, participation in psychopedagogical interventions, and patterns of school absenteeism.

Results: The analysis revealed a concerning prevalence of anxiety, depression, and stress-related symptoms among the student population. Many students exhibited risk factors that warranted immediate attention, including social isolation, disrupted routines, and uncertainty about the future. Furthermore, a significant portion of students displayed anxious and depressive symptoms, often leading to altered mood and behavioral challenges. In the context of family support, it was apparent that students with robust familial backing tended to cope more effectively with the psychological strain induced by the pandemic. However, a noteworthy number of students lacked adequate family support systems, exacerbating their mental health struggles. Students in need of such interventions benefited significantly from their implementation, demonstrating improved emotional well-being and a reduction in symptom severity. Nonetheless, the accessibility of these services remained a concern, with disparities in access evident among different demographic groups. Psychopedagogical interventions played a pivotal role in addressing issues related to school absenteeism and facilitating a smoother transition to remote learning. Students who engaged in these interventions showed positive progress in terms of school attendance and academic performance.

Conclusions: The findings of this study underscore the urgency of a holistic approach to addressing anxiety, depression, and stress in school-aged children and adolescents. It is imperative that consultations with child and adolescent psychiatry specialists be conducted promptly and in a manner that considers the unique contextual factors influencing each student's mental health. Moreover, efforts should be directed toward enhancing family support, expanding access to psychopharmacological treatment and psychological therapies, and promoting the implementation of psychopedagogical interventions.

Risk factors and personality characteristics of nonsuicidal self-injurious behavior in clinical sample of female adolescents

A. Osváth^{1*}, C. Hankó¹, M. Csáki¹, E. Molnár¹, J. Pahocsa¹, S. Kocsor¹, K. Tóth¹, D. Fertő¹, K. A. Sándor-Bajusz², T. Dergez³ and G. Csábi¹

¹Child and Adolescent Psychiatry; ²Division of Child and Adolescent Psychiatry, Department of Pediatrics, Medical School and Clinical Center and ³Institute of Bioanalysis, Medical School and Clinical Center, University of Pécs, Pécs, Hungary

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.926

Introduction: Nonsuicidal self-injury (NSSI) is a self-damaging behavior with typical onset in early adolescence, and shows greater prevalence in females. NSSI is defined by recurrent episodes of intentional self-inflicted damage to body tissue, without suicidal intent. These recurring self-inflicted injuries are done by the individual to relieve oneself from negative feelings, to resolve interpersonal difficulties, or to induce positive feelings.

NSSI in DSM-5. has been included among the conditions in need of further study.

NSSI can be interpreted as a maladaptive coping mechanism that can be regarded as an emotional dysregulation. Adverse childhood experiences including physical abuse, neglect or sexual abuse are the strongest predictors of the NSSI. Research has repetitively found strong associations between NSSI and identity diffusion and/or distorted personality traits.

Objectives: The aim of our study was to assess the association between childhood traumatization, personality characteristics including stages of identity development, and self-injurious behavior among female adolescents that experience difficulties with emotional regulation.

Methods: We compared our results to a Hungarian normative sample. The sample consisted of inpatients adolescents, age between 14 and 18, with a diagnosis consisting of „Emotional disorders with onset specific for childhood” or „Mixed disorders of conduct and emotions” with chronic nonsuicidal self-injurious behavior.

Childhood traumatization was measured with the short version of Childhood Trauma Questionnaire (H-CTQ-SF). Identity development and identity diffusion were measured with the Assessment of Identity Development in Adolescence Questionnaire (AIDA). Temperament and character factors were measured with the Junior Temperament and Character Inventory (JTIC).

Results: Adolescent patients with NSSI reported severe and multi-plex childhood traumatization. These patients scored higher on novelty seeking and harm avoidance and scored lower on the persistence, self-directedness, and cooperativeness factors in the JTIC. These results were compared with the Hungarian normative sample. Adolescents scored higher on the Discontinuity and Incoherence scales of the AIDA.

Conclusions: Our preliminary results suggest that childhood traumatization predicts self-injurious behavior in adolescent females. Additionally, we have found associations between signs indicative of personality disorder, including lower level of self-cohesion, self-integration and self-directedness.

Therapy program assisted with therapy dogs for children with Autism Spectrum Disorder (ASD)

A. Huguet Miguel^{1*}, N. Cornudella Solans¹, P. Vergés Balasch¹, J. Bergadà Bell-lloc² and V. Pera Guardiola¹

¹Children and Adolescent Mental Health Service, Sant Joan de Deu Terres de Lleida and ²Ilerkan Association, Lleida, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.927

Introduction: Autism spectrum disorders (ASD) is a neurodevelopmental disorder with an estimated lifetime prevalence of at least 1%. Some studies suggest that approximately 60% of children with ASD show emotional dysregulation and 44-86% sleeping disorders. Studies suggest that cognitive behavioral therapy and animal-assisted therapy AAT can be an intervention strategy to promote emotional and behavioral dysregulation and sleep disturbances.

Objectives: The purpose of this study was to investigate the effect of a therapy program assisted with dogs (AAT) together with cognitive behavioral therapy (CBT) on behavioral and emotional regulation and sleep disorders in children diagnosed with ASD.

Methods: The sample was composed of 24 children between 7 and 10 years old diagnosed with ASD randomized into two groups (CGT group (control group) and AAT + CBT group (experimental group)). Inclusion criteria: communication level of simple sentences, mild-moderate difficulties in behavioral and emotional regulation and sleep disturbances. Exclusion criteria: intellectual disability, children with specific dogs phobia. Assessment included ADOS-2, WISC-V, CGAS. dysregulation profile of Achenbach scale and Sleep Disturbance Scale for Children-Bruni. A program of 12 sessions (weekly one-hour sessions) focusing emotional and behavioral regulation and sleep disturbance was designed (Behavior Emotional Sleep Treatment Program. A pre-post evaluation was performed.

Results: Participants were 20 boys and 2 girls (2 participants dropped out), with a mean age of 9. Regarding the socio-demographic and clinical characteristics, no significant differences has been observed between both groups in the global functioning measured with the Children's Global Assessment scale (CGAS) ($p=0.832$), nor in the cognitive capacity (QI) neither in reference to the associated comorbidities ($p=0.103$) nor in the variable prescription pharmacological treatment ($p=0.142$). In emotional self-regulation, a significant improvement in emotional regulation difficulties was observed after treatment in both groups (experimental group: $p=0.014$; control group: $p=0.012$). However, the comparison between the pre-post intervention results between groups, regarding the emotional regulation variable, a greater improvement is observed in the experimental group ($p=0.013$). Significant improvements were also observed in sleep disorders (Bruni scale total score and in the sleep conciliation and maintenance difficulties scale) in both groups.

Conclusions: To conclude, although this is a pilot study with a small sample size and further research is needed, results suggest that a therapy program assisted with therapy dogs and CBT have positive effects on emotional dysregulation and sleep disturbances in children with ASD and offers a possible intervention strategy.

Antipsychotic use in under 25's - think carefully!

D. Collins¹, R. Holdsworth², T. Nebunu³ and J. Beezhold^{1*}

¹CYFP, NSFT, Great Yarmouth; ²NHS and ³Pharmacy, NSFT, Norwich, United Kingdom

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.928

Introduction: Antipsychotic use for adolescents (defined here as under 25 year olds) must be done with caution, giving due thought to advantages and potential side effects. Antipsychotics are extremely useful and effective drugs, but have side effects and many of these are problematic.

It has been noted that Risperidone is often used for this age group, despite the UK guidance being cautious about its use.

Objectives: To assess the extent of Risperidone prescribing in Norfolk/Suffolk for this patient group and to consider the monitoring of this.

Given that bone mass density is set down in teens – mid 20's, this is a particularly concerning issue when given to this age group. Additionally, distressing side effects and issues with fertility should be considered. If risperidone is used, Maudsley is very clear that this must be monitored: baseline/annual prolactin levels done, and action should be taken if these are elevated and/or the patient symptomatic.

Methods:

- 1) Evaluate numbers of adolescents, under 2ndry care Mental health service who have been prescribed Risperidone
- 2) Consider who prescribed it and the indication
- 3) to consider if routine monitoring had been completed (specifically, baseline prolactin and then annual prolactin levels)
- 4) to consider if these patients had developed side effects

Results: Almost 20% of 18-25 years olds, due to be seen in Youth Community Service had been prescribed Risperidone. Of these, only 44% had had prolactin levels done, despite the guidance. This equates to the over half not having prolactin checked. 60% of patients reviewed had symptoms of hyperprolactinemia. Indications for use included emotional dysregulation/EUPD, psychosis, ADHD, OCD/ASD and depression

Conclusions: Risperidone should be used with extreme caution in this patient group. Medication can be very useful for some young people experiencing distressing symptoms but, as Hippocrates advises, “do no harm” and seek not to cause iatrogenic harm.

Given that many of the young people seen by mental health services are experiencing emotional dysregulation (not necessarily an abnormal state in adolescent, when much is in flux), it is tempting to consider medication as one means of trying to alleviate distress. There is no clear treatment for dysregulated feelings, and most would accept that psychological support is more appropriate.

Early Onset Schizo-Obsessive Disorder: A Case Series of 7 Inpatient Children

E. Yerlikaya Oral* and G. Karacetin

Department of Child and Adolescent Psychiatry, University of Health Sciences, Bakirkoy Prof. Dr. Mazhar Osman Research and Training Hospital for Psychiatry, Neurology and Neurosurgery, Istanbul, Türkiye

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.929

Introduction: Schizo-obsessive disorder (SOD) is a complex psychiatric condition characterized by exhibiting symptoms of schizophrenia and obsessive-compulsive disorder (OCD)(Schirmbeck *et al.* Front Pharmacol. 2013 Aug 9;4:99). Some researchers prefer to describe this condition as a spectrum called “schizo-obsessive spectrum” and state that clinical representations such as OCD with poor insight, OCD with schizotypal personality disorder, schizophrenia with obsessive-compulsive symptoms and schizophrenia

with OCD are included in this spectrum(Poyurovsky *et al.* J Psychiatr Res. 2005 Jul;39(4):399-408). There is limited literature available on early on-set schizo-obsessive disorder in child and adolescent sample.

Objectives: This case series aimed to describe the clinical characteristics, phenomenology, diagnostic process and treatment response of SOD in a sample of inpatient adolescents and illuminate the intricate symptomatology between schizophrenic and obsessive-compulsive features.

Methods: A retrospective review was conducted of 7 adolescent patients who met DSM-V criteria for both schizophrenia and OCD in our inpatient clinic over the past year. Data were collected from medical records, including demographic information, clinical presentation, treatment history and response to treatment. All data were anonymized to maintain patient confidentiality.

Results: The sample consisted of 5 females and 2 males, with a mean age of 15,4 years. All patients presented with a mixed symptomatology of hallucinations, delusions and obsessive-compulsive symptoms. Many common points observed about clinical characteristics and psychiatric history of the patients. In most of the patients, the first psychiatric complaints started with obsessive-compulsive symptoms. It was observed that obsessions evolved into over-valued ideas and delusions in the course of time. Patients responded late and inadequately to pharmacological treatment, multiple drug use was necessary. Hospitalization lasted longer, the average time was 53 days. Most of the patients required augmentation with cognitive-behavioral therapy due to partial response or intolerable side effects. Unfortunately, no patient experienced full remission or returned to premorbid functioning.

Conclusions: This case series underscores the complexity of diagnosing and treating schizo-obsessive disorder in a pediatric population. It appears that a combined approach using both pharmacotherapy and psychotherapy may yield the most beneficial results. However, given the small sample size and retrospective design, these findings need to be interpreted with caution. Further research are crucial to corroborate our findings and refine treatment strategies.

EPV0149

Treatment Resistant Early-Onset Schizophrenia: A Tale of Two Siblings

E. Yerlikaya Oral

Department of Child and Adolescent Psychiatry, University of Health Sciences, Bakirkoy Prof. Dr. Mazhar Osman Research and Training Hospital for Psychiatry, Neurology and Neurosurgery, Istanbul, Türkiye

doi: 10.1192/j.eurpsy.2024.930

Introduction: Early-Onset Schizophrenia (EOS) is a rare and severe form of schizophrenia that begins in childhood and it is often associated with genetic risk factors, poorer prognosis, and increased treatment resistance compared to adult-onset schizophrenia (Hatzimanolis *et al.* Eur Psychiatry 2020;63(1):e44). This case report presents two siblings diagnosed with EOS and treated at the same inpatient clinic in different years.

Objectives: The aim is offering a perspective on the clinical characteristics, genetic and environmental implications, and treatment challenges of two siblings with EOS and seeking to enhance understanding of EOS's complexity, particularly in the context of treatment resistance.

Methods: A comprehensive retrospective review of the siblings' all medical records was conducted, focusing on their psychiatric history, symptoms, treatment trials, and responses of treatment. Both cases' current clinical situations were evaluated cross-sectionally.

Results: *Older sibling:* 19 year-old male, was diagnosed with EOS following the onset of symptoms as social withdrawal, negativism and suspiciousness at the age of 14. He referred to the inpatient clinic with the cause of drug intake refusal. Risperidone treatment started but there was no significant response. Risperidone to olanzapine switch made and clinical remission observed. After his discharge, 4 more hospitalisations in 5 years needed due to low socioeconomic status, parental neglect and him having no insight and stopped taking his medications repeatedly. Several depot form antipsychotic injections started to prevent recurrent hospitalisation. Despite that he needed several hospitalisations to adult psychiatry inpatient clinics. *Younger sibling:* 14 year-old female, were diagnosed with EOS following the symptoms as auditory hallucinations, suspiciousness, disorganised speech and behaviours at the age of 13. She referred to the same inpatient clinic with suicidal risk after 2 years of his brother's last hospital stay. She responded good to olanzapine treatment like her brother's, during her first stay. After 2 weeks of her discharge, her psychotic symptoms started again with no specific reason. Second hospitalisation needed due to her homicidal and suicidal risk. Clozapine and aripiprazole treatment started and she discharged in partial remission. She is being followed in outpatient clinic, with low functioning.

Conclusions: Despite trials of multiple antipsychotic medications and adjunctive treatments, both siblings demonstrated significant treatment resistance. These sibling cases underscore the complexity and challenges in managing EOS, particularly when it presents with treatment resistance. The shared familial environment and potential genetic factors demand further investigation to elucidate the pathogenesis of EOS and optimize therapeutic approaches.

Disclosure of Interest: None Declared

EPV0150

Effective Use of Clozapine in Managing Treatment-Resistant Conduct Disorder in an Adolescent Patient: An Unconventional Approach

E. Yerlikaya Oral

Department of Child and Adolescent Psychiatry, University of Health Sciences, Bakirkoy Prof. Dr. Mazhar Osman Research and Training Hospital for Psychiatry, Neurology and Neurosurgery, Istanbul, Türkiye

doi: 10.1192/j.eurpsy.2024.931

Introduction: This case report elaborates an unconventional approach to the management the use of clozapine, typically used in treatment-resistant Schizophrenia, in a 17-year-old female

patient with treatment-resistant Conduct Disorder, Attention Deficit and Hyperactivity Disorder and Intellectual Disability.

Objectives: The aim is to demonstrate the potential effectiveness and applicability of clozapine in treating severe, treatment-resistant behavioral problems associated with Conduct Disorder, even without the presence of psychosis, by detailing the clinical course, treatment strategy and outcome of this unique case.

Methods: A 17-year old female patient was referred to inpatient clinic due to escalating aggression towards her family members and risky sexual behaviors despite undergoing treatments before as risperidone, haloperidole, olanzapine, lithium, clonidine or aripiprazole. She was running away from home repeatedly and under the risk of sexual abuse. After comprehensive clinical and psychopathological assessment, a decision was made to initiate treatment with clozapine, closely monitoring the patient for adverse effects, and assessing its impact on the patient's aggressiveness and other behavioral problems. During her stay, clozapine dose titrated to 250 mg/day in addition to her current treatment as amisulpiride 800 mg/day and valproic acid 500 mg/day. Atropine solution as mouthwash used for salivary hypersecretion. No other side effects observed. Cognitive and behavioural therapy interventions made for anger management and impulsivity. Also focused on family-based interventions about establishing healthy boundaries.

Results: A significant reduction in aggressive behavior was noted under the treatment of clozapine. The patient's overall conduct and interaction with family improved remarkably. The treatment was well-tolerated except sialorrhea, leading to a successful integration back into her family and community.

Conclusions: This case highlights the potential of clozapine as a viable treatment option for managing severe, treatment-resistant behavioral problems in patients with conduct disorder, even in the absence of psychosis. A randomized-controlled trial showed that clozapine was more effective than risperidone in conduct externalization factors, delinquency trait and global functioning in children and adolescents (Juárez-Treviño *et al. Clin Psychopharmacol Neurosci.* 2019;17(1):43-53). While it necessitates careful monitoring due to its side-effect profile, this unconventional use of clozapine may open up new avenues for the management of treatment-resistant conduct disorder, thereby improving patient outcomes and quality of life. Further controlled studies are warranted to ascertain the safety and efficacy of this approach.

Cyber victimisation and depression among adolescents in Tunisia: a case report study and review of literature

E. Bergaoui^{1*}, A. Touiti^{1,2}, A. Maamri^{1,2}, A. Hajri^{1,2} and H. Zalila^{1,2}

¹Faculty of medicine of Tunis, University Tunis Manar, Manar and

²Outpatient psychiatry department, Razi hospital, Manouba, Tunisia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.932

Introduction: Cyber victimization is a form of violence that is perpetrated through social media, and its victims are primarily

adolescents and young adults. This can have a negative impact on their psychosocial well-being.

Objectives: To investigate the relationship between cyber victimization, depression, and suicide, identifying risk factors, prevention and intervention strategies through an case report.

Methods: We report the clinical case of a 16-year-old Tunisian man who developed a depressive disorder after being cyber-victimized. We also conducted a literature review in PubMed database keywords: depression, suicide, cybervictimisation, adolescents to identify risk factors, prevention and intervention strategies.

Results: The adolescent was a member of a youth group called The Gung, which organized climbing challenges that were then broadcast on Facebook. He was the victim of cyberbullying after failing a challenge that was broadcast live. As a result, he was rejected by his group of friends and subjected to death threats and bullying. A clinical examination revealed major depressive disorder, low self-esteem, and low self-assertion. The patient was treated with a combination of medication and psychotherapy, and he had a good outcome with social and educational reintegration.

Several studies have found that cyber victimization is associated with depressive disorders, anxiety disorders, and suicidal behavior among youth. Several risk factors have been identified, including low socioeconomic status, disrupted family dynamics, low self-esteem, and psychiatric disorders. Prevention and intervention strategies involve families, educational institutions, civil society, and health professionals.

Conclusions: The seriousness of cyber victimization among youth is undeniable. Early and personalized intervention is necessary to prevent suicidal behavior and restore the well-being of adolescents.

EPV0155

ADHD: Development of a printable poster for parents, teachers and healthcare professionals

I. Belabbes

hospital arazi, sale, Morocco
doi: 10.1192/j.eurpsy.2024.933

Introduction: ADHD is a very frequent reason for consultation in child psychiatry. It affects 2.5% of children and 5% of adults. Diagnosis is clinical. Treatment is based on medication combined with psychosocial interventions.

Objectives: Develop an ADHD guide for caregivers.

Methods: We carried out a literature review covering the last 5 years using the google scholar and pubmed search engines, including the key words ADHD, in order to produce a printable guide for caregivers working with children, in particular school teachers and healthcare personnel.

Results: Attention deficit hyperactivity disorder (ADHD) is a neurodevelopmental disorder affecting 5% of school-age children. It is characterized by abnormally high levels of developmental inattention, hyperactivity and impulsivity, leading to impaired personal, social, academic or occupational functioning. Because of its pervasiveness, ADHD can interfere negatively with general well-being, as well as with social life, academic performance and the development of social skills, which can lead to low self-esteem.

ADHD has multiple etiologies. It is thought to be due to a complex interaction between genes and environment. In fact, genetic vulnerability predisposes to the disorder which, under the influence of an unfavorable environment, expresses itself in clinical symptoms represented by 2 dimensions: inattention, hyperactivity and impulsivity. Diagnosis is essentially clinical, and treatment is based on medication combined with psychosocial interventions.

Conclusions: ADHD is one of the most frequently encountered disorders in general practice, pediatrics and child psychiatry. Early recognition of the disorder enables appropriate management, while limiting the impact of the disease on the functioning of the young person and his or her family.

EPV0157

Assessment of Sleep Habits and Problems in Children Aged 7 to 10: An Observational Study.

J. Camilo

Psychiatry, CHTMAD, Vila Real, Portugal
doi: 10.1192/j.eurpsy.2024.934

Introduction: Appropriate sleep habits play a pivotal role in the physical and psychological development of children. However, sleep deprivation or sleep problems can have a significant impact on children's mental health and daily functioning. This study investigates the sleep habits and problems in children aged 7 to 10 who attend the Child and Adolescent Psychiatry Service at CHTMAD, Vila Real, Portugal.

Objectives: The primary objective of this study is to assess the sleep habits and problems in children aged 7 to 10, aiming to establish data that can guide the development, implementation, and reevaluation of future interventions tailored to this age group.

Methods: This study is observational in nature and involved the participation of 21 patients from the Child and Adolescent Psychiatry Service at CHTMAD, Vila Real, Portugal, throughout the year 2022. Questionnaires related to sleep habits were administered to this population. Parents were invited to complete the Children's Sleep Habit Questionnaire (adapted from the Children's Sleep Habit Questionnaire by Prof. Owens, 2000), while the children (patients) were asked to fill out the Sleep Self Report-PT (adapted from Owens 2000 Research Version) and the Strengths and Difficulties Questionnaire (SDQ-Por, by Robert Goodman, 2005).

Results: As of now, the results of this study are still being processed. The data collected from the questionnaires will be analyzed to gain insights into the sleep habits and issues of children aged 7 to 10 years attending the Child and Adolescent Psychiatry Service in Vila Real, Portugal. Findings will be discussed, and any significant observations or trends will be highlighted.

Conclusions: This research aims to provide valuable insights into the sleep patterns and problems experienced by children in the specified age group. By understanding these issues, we can develop and implement targeted interventions to improve sleep quality and overall mental well-being. The conclusions drawn from this study will contribute to the development of evidence-based strategies for enhancing the sleep health of children in the Child and Adolescent Psychiatry Service at CHTMAD, Vila Real, Portugal.

Neurobiological Correlation Between Autism Spectrum Disorder and Anorexia Nervosa in Children

K. Shah^{1*}, P. Reddy², A. Giri³ and S. Srinivas⁴

¹Wake Forest University; ²Baptist Health - UAMS Medical Education Program PGY-4 Psychiatry Resident; ³Dhaka University, Winston-Salem and ⁴Baptist Health and the University of Arkansas for Medical Sciences (BH-UAMS), Little Rock, United States

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.935

Introduction: Anorexia Nervosa (AN) is common in adolescents and has a high mortality and morbidity rate with a lifetime prevalence of 0.5% to 2%.^{1,2} We aim to review the neurobiology correlation of Anorexia Nervosa in Autism Spectrum Disorder as they are often associated together.

Objectives: 1. Understand the correlation between the neurobiology of Autism Spectrum Disorder (ASD) and Anorexia Nervosa. 2. Assess the association and prevalence of Anorexia nervosa in the ASD population.

3. To focus on the implications for the pathogenesis of Anorexia Nervosa and treatment of this disorder in the ASD population.

Methods: We searched PubMed, APA PsycINFO, Embase, CINAHL, and Google scholar databases with the keywords Autism Spectrum Disorder AND Anorexia Nervosa and included 6 relevant human studies out of 187 published in English.

Results: Neilson et al. studied the outcome of ASD in teenage onset AN, and a statistically significant negative dose-response relationship is found in all the 3 Morgan-Russell Outcome Assessment Schedule (MROAS) domains in stable ASD over time, and the results on the subscales 'mental state,' 'psychosexual state' and 'socio-economic state,' 'personal contacts,' 'social activities' and 'employment record.'³ The outcome of AN onset in adolescence is generally favorable regarding mortality and the persistence of eating disorders in adulthood. A study by Pruccoli et al. noted a high prevalence of ASD traits in a group of young AN patients, predominantly seen in 4 specific EDI-3 subscales and independent of BMI.⁴ Margari et al. found only AN diagnosis had a statistically significant difference ($p = 0.04$) in females vs. males when comparing sex differences for comorbidities.⁵

Conclusions: Morphological changes in brain areas are linked to social cognition and increase the risk of eating disorders in ASD. We recommend future studies with robust study design to explore the full spectrum of pathogenesis and association of AN in ASD.

EPV0159

Association Between Maternal Diabetes and Childhood Neurodevelopmental Disorders

K. Shah^{1*} and C. Thomas²

¹Wake Forest University, Winston-Salem and ²East Tennessee State University, Mountain Home, United States

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.936

Introduction: The prevalence of metabolic disorders is rising, diabetes prevalence doubled during 1990-2017. In 2020, 7.8% of US pregnancies were complicated by Gestational Diabetes Mellitus (GDM). Our aim is to assess the impact this increase has on childhood developmental disorders and understand the link between maternal metabolic disorders and neurodevelopmental disorders in children with focus on Autism Spectrum Disorder (ASD) and ADHD.

Objectives: Our aim is to assess the impact this increase has on childhood developmental disorders and understand the link between maternal metabolic disorders and neurodevelopmental disorders in children with focus on Autism Spectrum Disorder (ASD) and ADHD.

Methods: A literature search was conducted using medical subject heading (MeSH) terms in PubMed, database from Jan 1 2014 to Feb 15, 2023. Only large-scale ($n > 20,000$) were reviewed. A total of 3 articles were included in our final qualitative synthesis review.

Results: An increased rate of ASD and ADHD are observed in children of mothers with insulin resistance, demonstrated by Type 2 Diabetes (T2DM) and GDM (Kuan-Ru Chen, et al.). T2DM had the strongest association with ASA and ADHD when looking at other neurodevelopmental disorders (Chen, et al.). GDM severity correlates to increased risk of ADHD (Xiang, et al.). Maternal obesity as a risk factor for ASA and ADHD has confidence intervals in the same ranges as immune dysregulatory disorders including Asthma and Autoimmune disorders (Woelfenden, et al.).

Conclusions: Pathomechanism of neurodevelopmental disorders involves maternal oxidative stress and inflammation. Maternal T2DM and obesity are pro-inflammatory states that can be targeted as modifiable risk factors of ASD and ADHD in children. Preconception metabolic optimization and tight glycemic control in pregnancy are two ways clinicians can start to address the rates of rising ASD and ADHD.

Early language intervention and IQ of children with non-syndromic orofacial clefts

K. A. Sándor-Bajusz^{1*}, E. Molnár¹, T. Dergez², K. Hadzsiev³, A. Vástyan⁴ and G. Csábi¹

¹Pediatrics, Division of Child and Adolescent Psychiatry; ²Institute of Bioanalysis; ³Department of Medical Genetics and ⁴Pediatrics, Division of Pediatric Surgery, University of Pécs, Medical School and Clinical Center, Pécs, Hungary

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.937

Introduction: Children with non-syndromic orofacial clefts are at higher risk for developmental difficulties. Speech and language are commonly affected developmental domains in these children.

Objectives: The aim of the current study was to explore the effects of early interventions for speech and language on later cognitive outcomes in this patient population.

Methods: A combined retrospective/prospective-comparative study was carried out at the Department of Pediatrics of the University of Pécs in Hungary. The participants were children between 6 and 16

years of age. The study consisted of a self-designed demographic questionnaire and an IQ test (WISC-IV).

Results: A total of 41 children with non-syndromic orofacial clefts and 44 age-matched controls participated in the study. Children of the cleft group were examined by pedagogical professional services and required special education plans significantly more often than controls ($p < 0.001$ and $p = 0.02$, respectively). Participants of the cleft group who received early speech and language therapy score higher on the Verbal Comprehension Index ($p = .005$). Full-Scale IQ score was also higher for cleft participants who received therapy, however not significant but borderline ($p = 0.08$).

Conclusions: Early language and speech interventions for children with non-syndromic orofacial clefts may have a positive effect on verbal skills and overall cognitive development. Future longitudinal studies examining baseline cognitive functioning of infants are needed to provide more conclusive evidence on the effects of interventional programs on speech and language development in cleft patients.

EPV0162

Emotion dysregulation in adolescents: the associations with clinical symptoms, risky-behaviors, and environmental factors

L. Pedrini* and S. Meloni

UO Psichiatria, IRCCS Centro San Giovanni di Dio Fatebenefratelli, Brescia, Italy

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.938

Introduction: Emotion dysregulation (ED) is transdiagnostic domain that plays a pivotal role in the emergence and persistence of numerous mental disorders. Examining the extent of ED within non-clinical populations may shed light on whether ED is indeed linked to symptoms as observed in clinical settings. This investigation constitutes a crucial milestone toward the development of preventive strategies.

Objectives: To investigate the correlations between ED, psychopathological symptoms, risky behaviors, and environmental factors in adolescent students.

Methods: A total of $N = 610$ students (16 years; 72% females) completed self-report standardized questionnaires measuring depression, anxiety, impulsivity, childhood trauma, relations with classmates, and family functioning. Lifetime risky-behaviours were recorded using an ad-hoc checklist, and ED through Difficulties in Emotion Regulation Scale (DERS). The sample was then divided into subgroups based on percentiles of DERS Total scores: $N = 210$ low ED, $N = 187$ moderate, $N = 214$ high.

Results: Participants exhibiting high ED displayed higher level of depression, anxiety and impulsivity (Table 1). There was an observable trend linking higher levels of ED with a greater proportion of youths reporting risky behaviors (Table 2). The high ED group reported an increased frequency of childhood traumatic

experiences, less favorable relationships with family members and classmates (Table 3).

Table 1. Clinical symptoms by level of ED in students ($N = 610$)

	low	moderate	high	Sig.
Patient Health Questionnaire (depression)	5.33(± 3.51)	8.94(± 4.05)	14.57(± 5.53)	<.001
Screen For Child Anxiety Related Emotional Disorders (anxiety)	59.27 (± 9.61)	68.61 (± 10.88)	79.39 (± 11.61)	<.001
Barratt Impulsiveness Scale-Brief (impulsivity)	15.14 (± 3.52)	16.70(± 3.81)	18.01(± 4.17)	<.001

Table 2. Risky behaviors by level of ED in students ($N = 610$)

	low	moderate	high	Sig.
Binge drinking	$N = 73$ (29.6%)	$N = 78$ (31.6%)	$N = 96$ (38.9%)	.097
Self-harm ideation	$N = 35$ (13.4%)	$N = 73$ (28%)	$N = 153$ (58.6%)	<.001
Self-harm	$N = 30$ (15%)	$N = 49$ (24.5%)	$N = 121$ (60.5%)	<.001
Binge eating	$N = 60$ (22.9%)	$N = 78$ (29.8%)	$N = 124$ (47.3%)	<.001

Table 3. Environmental factors by level of ED in students ($N = 610$)

	low	moderate	high	Sig.
Childhood Trauma Questionnaire (trauma)	30.99 (± 6.89)	35.39(± 9.1)	39.54(± 10.94)	<.001
Child And Adolescent Social Support Scale (classmate)	51.19 (± 11.7)	46.55 (± 10.96)	44.91(± 12.4)	<.001
Family Assessment Device (family functioning)	117.58 (± 14)	108.8 (± 17.48)	103.38 (± 20.11)	<.001

Conclusions: Findings provide robust support for the association between ED and compromised personal functioning, even within a non-clinical sample. The trend observed in the relationship between ED, clinical symptoms and risky behaviors is consistent across all variables. Overall, these results contribute to the growing body of evidence advocating for preventive interventions aimed at addressing ED in adolescents.

EPV0163

A multidisciplinary approach to the treatment of children and adolescents with Beckwith-Wiedemann syndromeM. Tripković^{1*}, I. Bakija², D. Horvat¹, P. Lederer¹ and I. Begovac¹¹Department of Psychiatry and Psychological Medicine, University Hospital Centre Zagreb and ²Department for Integrative Psychiatry, Psychiatry Clinic Sveti Ivan, Zagreb, Croatia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.939

Introduction: Beckwith-Wiedemann syndrome (BWS) is a rare and complex congenital disorder characterized by a spectrum of symptoms and somatic findings. The prevalence of classic BWS is 1:26,000 births in Europe, and is equal in both sexes. The causes of the disorder are complex and are related to alterations in the expression of one or more genes in the region of chromosome 11. The heterogeneity of the clinical picture results in a spectrum of clinical features, the most common of which include: excessive growth of one side or certain parts of the body, macroglossia, abdominal wall deficits such as umbilical hernia, hypoglycemia, enlarged abdominal organs and an increased risk of developing certain types of tumors in adulthood.

Objectives: The aim of this article is to highlight the importance of an early multidisciplinary approach in the management of children and adolescents with BWS.

Methods: Using clinical practice and a review of the existing limited literature, we examined the complexity of the disease and the importance of psychiatric, psychotherapeutic, and psychological interventions in the treatment of children and adolescents with rare diseases such as BWS.

Results: According to our clinical practice, a number of uncertain physical symptoms and possible complications may in some children with BWS lead to psychomotor retardation and lack of self-confidence due to the often impaired physical appearance. Affected children and adolescents are more likely to be exposed to abuse at school, show more behavioral and learning difficulties, difficulties in social adjustment, and resultant emotional difficulties. After initial genetic and pediatric treatment and subsequent regular monitoring, it is necessary to pay additional attention to the development of psychological sequelae in order to involve them and their families in psychotherapeutic treatment, and intervene in a timely manner so that they can achieve or maintain psychological stability and functionality. Many adolescent patients with BWS do not have significant somatic difficulties that would require pediatric intervention, but often present with symptoms of mental illness.

Conclusions: Psychological stress in children and adolescents suffering from rare somatic diseases represents a negative experience of an emotional and social nature, which affects the course of the disease and interferes with the treatment. Due to a number of possible physical manifestations and outcomes of such diseases, extensive psychological support and care by child and adolescent psychiatrists and the entire medical team is required. A multidisciplinary approach is crucial in the treatment of these patients and results in improved functionality and quality of life.

EPV0165

ADHD symptoms are associated with bully victimization in non-clinical populations tooM. R. Glans^{1*} and S. Bejerot²¹Örebro University, School of Medical Science and ²Örebro University, School of Medical Sciences, Örebro, Sweden

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.940

Introduction: Individuals with ADHD are at higher risk of being bullied than individuals without ADHD^{1,2,3}. Over the past decades, there has been a shift from a categorical to a dimensional conceptualization of ADHD⁴. It remains unknown if the association between ADHD and bullying also extends to non-clinical populations.

Objectives: To assess if subclinical ADHD symptoms associates with bully victimization in childhood and adolescence.

Methods: 1557 non-clinical adults completed the 6-item Adult Self-Report Scale Screener (ASRS) and answered questions concerning bully victimization. ADHD and ASD diagnoses served as exclusion criteria. Prevalence rates of bully victimization (defined as bullied \geq twice monthly) were compared at different time periods between those with- and without a positive ASRS-screener (cut-off score $\geq 4/6$) by chi-square tests. Moreover, logistic regression evaluated the association while adjusting for candidate covariates age and sex.

Results: Out of the total sample 1332 individuals (mean age=42, 60% female) scored negative and 217 individuals (mean age=36, 70% female) scored positive on the ASRS-screener while 8 had missing data on age or sex. Prevalence rates of bully victimization comparing those with- and without a positive score were as following: 20% vs 11%, $p < .001$ at 7-9 years, 26% vs 15%, $p < .001$ at 10-12 years, 20% vs 13%, $p = .005$ at 13-15 years and 6% vs 2%, $p = .002$ at 16-18 years. The statistically significant associations seen in the prevalence comparisons up until working life remained in the logistic regression models.

Conclusions: More pronounced subclinical ADHD symptoms were associated with approximately twice as high prevalence of bully victimization in childhood and adolescence. Thus, ADHD characteristics appear to have serious consequences across the full clinical and non-clinical parts of the spectrum.

EPV0167

Exploring Early Autism Markers in High-Risk Infants: Implications for Timely InterventionM. Negm¹ and N. Khoweiled^{2*}¹Health Education England, Birmingham and Solihull Mental Health Foundation Trust, Birmingham, United Kingdom and ²University of Strasbourg, Strasbourg, France

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.941

Introduction: Autism Spectrum Disorder (ASD) is a neurodevelopmental condition characterized by challenges in social

communication and behaviour. Timely identification of ASD is pivotal for effective intervention. However, significant gaps persist in our understanding of early signs and biomarkers, particularly among infants with older siblings already diagnosed with ASD. Furthermore, factors during the perinatal and neonatal period remain underexplored.

Objectives: This systematic review aims to investigate early autism markers within this specific cohort and assess their potential impact on intervention strategies.

Methods: A thorough search of electronic databases, including PubMed, PsycINFO, and Scopus, was conducted, initially identifying 161 relevant papers related to ASD and resilience published from 2013 to 2023. After excluding studies focused on environmental determinants of resilience in ASD, 75 papers remained. We concentrated on studies examining early identification of autism, especially in infants with older siblings with ASD, biomarker discovery, or predictive factors within this unique population. The search strategy employed a diverse set of keywords encompassing ASD, genetics, neurobiology, and the perinatal period to ensure comprehensive coverage of pertinent studies. Quality assessment of each study followed standardized criteria, and data synthesis utilized a thematic analysis approach.

Results: Our systematic exploration revealed a spectrum of early markers associated with ASD in high-risk infants, spanning behavioural, neurodevelopmental, genetic, and perinatal domains. Recognizing these early indicators offers promise for timely and potent intervention strategies, potentially refining long-term outcomes for children at risk of ASD.

Discussion: The synthesis of existing research in this systematic review underscores the significance of studying early markers within high-risk populations. Early intervention, guided by these markers, holds the potential to enhance the quality of life for at-risk children with ASD and their families. This review contributes to our understanding of the early identification of autism and emphasizes the imperative need for continued research in this critical area.

Conclusions: This systematic review sheds light on the current state of research on early signs and biomarkers of autism in infants with older siblings diagnosed with ASD. The findings carry significant implications for the development of targeted interventions that can be implemented at an earlier stage of development. Future research should further investigate these markers and their potential role in guiding early and effective intervention strategies. Keywords: Autism Spectrum Disorder, early signs, biomarkers, infants, older siblings, early intervention, high-risk population.

EPV0168

Food intake restriction in patient with autism spectrum disorder and Moebius syndrome, a strong association. A case report

P. Del Sol Calderon^{1*}, A. Izquierdo de la Puente¹, R. Fernández², M. García Moreno¹ and A. Erdocia¹

¹Psychiatry, Hospital Puerta de Hierro and ²Psychiatry, Hospital Universitario Infanta Cristina, Madrid, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.942

Introduction: A 7-year-old male diagnosed with autism spectrum syndrome and moebius syndrome was admitted to the psychiatric inpatient unit for a 3-week history of food restriction

Objectives: To show the importance of exploring symptoms of autism in patients diagnosed with moebius syndrome in order to optimize the intervention of the difficulties that may arise.

Methods: Case report and literature review

Results: This is a patient with a history of Moebius Syndrome, who required trauma surgery for a clubfoot in April 2019. In early childhood he needs early psychomotor care. He has an IQ of 91. A diagnosis of autism was made in 2018 highlighting high difficulty for social interaction and communication, with repetitive patterns of behavior and marked restricted interests. The patient came to the emergency room after 3 weeks of food restriction. His parents explain that about a month ago the patient witnessed one of his classmates having an episode of vomiting. Since then he has been afraid that he might vomit. They explain that he constantly asks about food expirations, needing to ask before each meal if it will sit well in his stomach. He has noticeably decreased the amount of food he eats and is becoming more selective with food. In the last week he has lost 2 kilograms. During the hospitalization we worked with the patient on his fears about intakes, achieving a weight recovery and normalizing his eating habits.

Conclusions: This case points out the association between Moebius syndrome and autism spectrum disorder. In addition, it reflects the importance of early diagnosis, since in this case it was essential to know the patient's tendency to literalism and rigid thinking in order to receive effective treatment to achieve renutrition. Moebius syndrome is a rare congenital disorder with a prevalence of less than 0.05%, characterized by congenital facial paralysis associated with absence of abduction of the eyes due to alterations of the VI and VII cranial nerves. It presents multiple craniocephalic, musculoskeletal, neurological or ophthalmological manifestations. Different studies have found an association between autism spectrum disorder and Moebius syndrome, with comorbidity between 25-40%, varying according to the studies.

Vortioxetine as an effective drug in the treatment of depression in adolescents with long QT index. A case report

P. Del Sol Calderon^{1*}, A. Izquierdo de la Puente¹, R. Fernández² and M. García Moreno¹

¹Psychiatry, Hospital Puerta de Hierro and ²Psychiatry, Hospital Universitario Infanta Cristina, Madrid, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.943

Introduction: This is a 13-year-old female patient admitted to the psychiatric unit active suicidal ideation.

Objectives: the objective is to show through a clinical case how vortioxetine can be safe in adolescents.

Methods: Case report and literature review

Results: She has a history of daily consumption of at least 2 units of cannabis per day. She presents high emotional distress secondary to academic failure, consuming the substance as a coping strategy. Due to prohibition and control by her parents, the patient stopped taking the substance, presenting severe depressive symptoms, self-injury and suicide ideation. For this reason she is admitted to the inpatient psychiatric unit. The electrocardiogram performed on admission shows a corrected QT index of 524. Exploring physical symptoms, she recognized episodes of syncope and palpitations. Coordination was made with cardiology, who performed an echocardiogram with normal results and began follow-up with them without prescribing medication. It was agreed not to use drugs that could prolong the QT index. Evaluating the clinical situation, it was decided to start treatment with Vortioxetine up to 10 mg. With this treatment there was no worsening of the electrocardiogram and the patient's mood improved, anxiety and ideas of death were remitted.

Conclusions: This work aims to show how vortioxetine has been effective and safe at the cardiological level in the case of moderate-severe depression in an adolescent with prolonged QT index

Disclosure of Interest: None Declared

Psychopharmacological management in patients with Di George syndrome

L. Rojas Vázquez, P. Marqués Cabezas*, G. Lorenzo Chapatte, M. Ríos Vaquero, A. Monllor Lazarraga, M. P. Pando Fernández, M. A. Andreo Vidal, M. Calvo Valcárcel, P. Martínez Gimeno, M. J. Mateos Sexmero, B. Rodríguez Rodríguez, M. Fernández Lozano, N. Navarro Barriga, T. Jiménez Aparicio, C. De Andrés Lobo, C. Vallecillo Adame, L. Sobrino Conde, M. D. L. Á. Guillén Soto and A. Aparicio Parra

Psiquiatria, Sacyl - Hospital Clínico Universitario Valladolid, Valladolid, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.944

Introduction: It is widely described in the scientific literature that patients who suffer from some type of congenital syndrome such as Di George Syndrome are more likely to present some type of psychopathological alteration during their development that may require intervention and treatment by infant and juvenile mental health teams in coordination with neuropsychiatry (1). On this occasion, we will present the clinical case of a patient who regularly attends psychiatry consultations for management of anxious symptoms with impulse control deficits associated with intellectual disability, diagnosed since childhood with tetralogy of Fallot and later with Di George syndrome. In this type of case, treatment is usually considered taking into account possible comorbidities at the organic level (since there may be cardiological involvement, which can be an added difficulty when taking into account the adverse effects of some psychotropic drugs) (2).

Objectives: This is followed by the presentation of the clinical case, which can serve to exemplify this type of case and clarify any doubts that may arise regarding treatment.

Methods: Presentation of the clinical case and review of updated scientific literature on the subject.

Results: Patient who first came to the infantile-junior consultations at the age of 8 years due to delay in the acquisition of verbal language and impulsivity. The patient had a history of pediatric follow-up since birth for different physical symptoms that finally led to the diagnosis of Di George syndrome.

Given the difficulties he presented both at home and at school, different psychometric tests were performed and it was determined that it could be beneficial to initiate treatment with extended-release methylphenidate. Prior to treatment, psychomotor restlessness (without aggressiveness) and difficulty in concentration prevailed, which improved significantly after upward adjustment of the dose to a guideline corresponding to his age and weight. It was not necessary in this case to administer other treatments (the possibility of starting Aripiprazole in case of episodes of agitation was considered, but it was not necessary). The patient has continued to be monitored by cardiology to assess the possible side effects of the treatment (since it can increase heart rate and blood pressure (3), but so far no complications have been detected).

Thanks to psychotherapeutic and educational intervention, language acquisition was achieved, although to date he still requires support due to the difficulties he still presents.

Conclusions: It is important to take into account the possible side effects of psychopharmacological treatment in patients with an associated congenital syndrome. Intensive and comprehensive follow-up by psychiatry and pediatrics (and later by their primary care physician) should be performed.

Disclosure of Interest: None Declared

EPV0171

Case-study: Patient with acquired epileptic aphasia in childhood

P. Terziianova^{1*}, A. Ushkova¹, K. Petkova¹, D. Borisova¹, A. Popova¹ and P. Marinov^{1,2}

¹Mental Health Centre "Prof. Nikola Shipkovenski" LTD and ²Sofia University "St Kliment Ohridski", Medical Department of Psychiatry, Sofia, Bulgaria

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.945

Introduction: Acquired epileptic aphasia or Landau-Kleffner syndrome (LKS) is a disorder with onset in the childhood between the ages of 2 and 8 years. The main defining psychopathological symptom of Landau-Kleffner syndrome is the acquired aphasia with epileptiform electroencephalographic abnormalities. The aphasia has both receptive and expressive features. The onset is usually subacute and the course is usually progressive with spontaneous improvements and exacerbations. The electroencephalographic abnormalities include pathological findings in the temporal and parieto-occipital brain regions.

Objectives: An 11 year old girl with generalized tonic-clonic and partial seizures is referred to our child and adolescence outpatient service due to language impairment. Her first generalized seizure has been at the age of 11 months old, caused by high temperature. The presence of articulation difficulties has raised suspicion for intellectual disabilities. She has been diagnosed with Epilepsy, grand mal seizures and has had continuous treatment with sodium valproate since the age of 3 years.

Methods: We used medical history, EEG-recordings, clinical observation and psychological assessment.

Results: Patient's language development has been normal till the age of 3 years old. She has started using single words properly at the age of 1 year and 6 months old. Her first simple sentences have appeared at the age of 2 years old. At the age of 3 years old after severe generalized tonic-clonic seizures she has stopped talking for a month. After this month she had started vocalizing and using simple words, but she had lost her ability to form sentences. She has had some mild difficulties in understanding verbal information and following instructions. Her speech has had bad articulation and deficits in the verbal fluency. Her gross and fine motor development, her social skills and problem-solving abilities have all been intact and age-appropriate. She has worked with speech therapist for 5 years and achieved partial recovery from the acquired aphasia. She continues to have problems with the articulation – the speech is still with mild dysarthria. We used WISC-IV to assess her IQ (IQ=108).

Conclusions: The patient has already developed age-appropriate speech prior to the onset of the language impairment. Considered as secondary or acquired, the observed aphasia together with the medical data for her epileptic seizures allows us to diagnose the patient with Acquired epileptic aphasia or Landau-Kleffner syndrome. Later development will be presented and discussed.

First episode psychosis in a young person with a diagnosis of Autistic Spectrum Disorder: A Case report

P. Raghvani*, C. Inogbo and V. Damle

Hope Unit, Pennine Care NHS Foundation Trust, Bury, Manchester, United Kingdom

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.946

Introduction: Psychotic disorders are significant comorbidities in young people with Autistic Spectrum Disorder (ASD). Evidence suggests that ASD & psychosis present with overlapping clinical features & cognitive symptoms leading to misdiagnosis (Trevisan *et al.* Front.Psych 2020;11:548). Clinicians encounter diagnostic dilemma during assessment of psychosis in adolescents with ASD.

Objectives: To discuss the clinical challenges in the assessment & treatment of young people with ASD & comorbid psychosis.

Methods: A case report of a young girl with ASD & comorbid psychotic illness.

Results: A young girl with ASD was admitted to CAMHS inpatient Unit with unusual beliefs & perceptual disturbances. She reported hearing the voice of 'Hydrogis' who was talking to her about his girlfriend. She made a voodoo doll & tried to set it on fire, as she believed that this would kill the girlfriend. She also heard voices of characters from a TV show, discussing her in third person. She absconded from home due to the distress associated. She attempted suicide by tying a ligature. She was seen responding to external stimuli, laughing incongruously & was thought disordered. Despite never being to USA, she spoke in American accent. She lacked insight & struggled to differentiate reality from fantasy. The aim of admission was to determine if the symptoms were part of ASD or a

psychotic disorder. She had medication free assessment but continued to be very distressed. We commenced Aripiprazole which was optimised. She responded well to the treatment & was discharged to the care of Early Intervention in Psychosis team with partial remission of symptoms.

Conclusions: Historically psychotic illnesses & ASD were thought to be closely linked. Research suggest that they are two separate disorders with specific onset, progress, signs & symptoms. ASD might be misdiagnosed as psychosis as difficulties in communication may resemble thought disorder, 'melt down' may mimic catatonia & difficulties in recognising others' intentions may mimic paranoia. Our patient was experiencing first episode psychosis in late adolescence. This age of onset is consistent with research findings. A study to differentiate between ASD & psychosis found that positive symptoms like hallucinations & delusions were suggestive of psychosis while odd emotional gestures, stereotyped speech & restricted interests indicated ASD. Our patient predominantly had positive symptoms of delusions, hallucinations & thought disorder, hence our diagnosis of psychotic episode. In some cases, it is difficult to differentiate childhood fantasies from delusional beliefs (Ribolsi *et al.* Front.Psych 2022;13:768586). Bleuler explains that children with ASD replace imperfect realities with imaginations & hallucinations but Michael Rutter claims that autistic children lack fantasy. There are varying views on this subject & this is the challenge we faced when treating this young person.

EPV0175

Worsening symptoms in ADHD children caused by increased parental stress before, during and after Covid-19

R. Tarazhi

Child and Adolescent Psychiatry, Mother Theresa University Hospital, Tirana, Albania

doi: 10.1192/j.eurpsy.2024.947

Introduction: Attention Deficit Hyperactivity Disorder (ADHD) is a neurodevelopmental disorder characterized by high levels of inattention, hyperactivity, and impulsivity that are present before the age of seven, seen in a variety of situations, inconsistent with the child's developmental level and that cause social or academic damage. Parents may respond with high levels of verbal aggression and disciplinary measures to disruptive behaviors, which causes their children to respond negatively, influencing a bidirectional process of participating of a vicious circle. The pandemic has been a huge battle for everyone. Their anxiety in this extraordinary situation can also increase the children's psychological and behavioral problems.

Objectives: This literature review aims to explore the connection between the increase of parental stress among parents of ADHD children and worsening symptoms of ADHD, before and during COVID-19 outbreaks.

Methods: The literature review was performed by searching the following electronic databases (for all available years from 2005-2021): PubMed, PubMed Central, Springer Open, Hindawi, Google Scholar. We included studies with a primary focus on parenting stress in families that have children, aged 6-12 years old, with a clinical diagnosis of ADHD that was made by a specialist using the

diagnostic criteria of DSM-III/DSM-IV/DSM-V or ICD-10. The search was organized in chronological order by selecting studies published in the time period before, during and after the pandemic. **Results:** Parents of children with ADHD tend to use inappropriate parenting styles, they are more disapproving, critical and exhibit poorer monitoring and more corporal punishment than parents of children without ADHD who try to control disruptive behaviors. These parenting styles can affect the course of the disease, worsen its manifestations and cause the secondary development of psychiatric and maladaptive behaviors. In some of the studies, during the outbreak of the COVID-19 pandemic, is observed a high prevalence of depressive symptoms (62.5%) among caregivers, while 20.5% and 36.4% indicated anxiety and stress symptoms, respectively. Some parents reported deterioration of general well-being in their children and this manifested as oppositional/defiant attitudes and emotional outbursts, sleep problems and anxiety in this context. **Conclusions:** The pandemic has had psychological influences on parents with ADHD that affected their children's compliance with the medication and, consequently worsened their symptomatology. Society can be exposed to chronic stressors like Covid-19 anytime soon, so the main focus must be identifying needs to inform future interventions designed to support parents and ultimately their children. Psychoeducation of parents should be promoted in order to cope with the symptomatology of ADHD in the field of normality or under a chronic stressor.

Prevalence and comorbidities of disruptive mood dysregulation disorder

S. Riam

Arrazi University Psychiatric Hospital, Rabat Faculty of Medicine and Pharmacy Mohammed V University, Rabat, Morocco
doi: 10.1192/j.eurpsy.2024.948

Introduction: Following the release of DSM-5 in 2013, a newly introduced diagnostic category emerged in psychiatric classification—the disruptive mood dysregulation disorder (DMDD). DMDD is a depressive disorder that begins in childhood and is marked by a consistently irritable or angry mood, frequently accompanied by temper outbursts that are notably severe.

Objectives: It is to study the prevalence and comorbidities of DMDD in Morocco, specifically at Arrazi University Psychiatric Hospital

Methods: Data were collected from youths aged 6 to 18 years who underwent a systematic assessment of symptoms. This assessment was extended to all patients consulting at Arrazi Hospital in Salé within the pediatric department over a period of four months (sample accrued from July 2023 to October 2023). The diagnosis of DMDD was established utilizing the diagnostic criteria outlined in DSM-5

Results: About 31% of the young participants met the operational criteria for DMDD. Those with DMDD exhibited increased comorbidity rates with attention-deficit/hyperactivity disorder (ADHD), another Depressive disorder and conduct disorder compared to those without DMDD. Additionally, they displayed elevated symptoms of aggressive behavior, rule-breaking, social issues, anxiety/depression, attention problems, and thought problems in comparison to all other participants without DMDD. It's noteworthy that youth with DMDD presented with at least one psychiatric comorbidity.

Conclusions: Given that DMDD is accompanied by other comorbid psychiatric disorders, particularly depression and anxiety, and appears to impact familial and occupational status in adulthood, the early detection and subsequent effective treatment of DMDD symptoms are of utmost importance.

Attentional Bias to Angry Faces: Contrasting Responses in Typically Developing Children and Children with Autism Spectrum Disorder

S.-Y. Kim* and Y. Choi

Psychology, Duksung Women's University, Seoul, Korea, Republic Of
*Corresponding author.
doi: 10.1192/j.eurpsy.2024.949

Introduction: Human faces generally attract immediate attention. However, it has been found that children with autism spectrum disorder (ASD) tend to allocate relatively less attention to faces. Previous research showed that typically developing children (TD) exhibited an attentional bias to angry faces, regardless of their anxiety levels, but it's unclear if this applies to children with ASD. Therefore, the present study aims to investigate attentional bias induced by angry and/or happy faces in children with ASD.

Objectives: We explored attentional bias toward angry faces in both TD children and children with ASD. We hypothesize that while TD children will show attentional capture effects in response to angry faces, children with ASD will not exhibit such attentional bias to facial stimuli, irrespective of their emotional content.

Methods: By now, five ASD participants (all male) and 34 TD participants (17 male), aged 6-12, have completed a continuous performance task. In this task, irrelevant distractors (angry or happy faces) appeared and disappeared abruptly, while the orientation of the target changed every 1,250 ms. Participants were asked to respond as quickly and accurately as possible to the orientation of the target. We designated the time when the distractor first appeared as T1, and subsequent time intervals at 1,250 ms increments were labeled as T2, T3, and T4. The time intervals when no distractor was present were labeled as TB (baseline). If the reaction time (RT) at T1 was significantly slower compared to TB, it indicated attentional bias by the distractor.

Results: For the RT data, separate repeated measures ANOVAs with 2 (emotion) * 5 (time) factors were conducted for each group. The results revealed a significant main effect of time ($F(4, 132) = 17.59, p < .01$) and a significant interaction between emotion and time ($F(3.27, 107.74) = 4.92, p < .01$) only in TD. Post hoc t-tests indicated that TD children exhibited significantly slower RT at T1 compared to TB, but this difference was observed only for angry faces ($t(33) = 4.84, p < .01$). In contrast, no significant effect was found in children with ASD. In other words, TD demonstrated attentional bias only when exposed to angry faces, while ASD children did not exhibit attentional bias to either emotion.

Conclusions: This study aimed to investigate attentional bias to angry faces in both TD and ASD children. The results indicate that TD children exhibited an attentional bias when exposed to angry faces, whereas ASD children did not display such bias. These findings are consistent with previous research suggesting that TD

children tend to show attentional bias towards angry faces, regardless of their anxiety levels. Furthermore, the absence of attentional bias to angry faces in ASD suggests that their characteristic of reduced attention to faces may contribute to the lack of attentional bias towards angry faces.

Attitudes on pharmacotherapy among parents of children with autism spectrum disorders

V. Mandic Maravic^{1,2*}, M. Vlasisavljevic¹, S. Lestarevic¹, J. Vasic¹, R. Grujicic¹ and M. Pejovic Milovancevic^{1,2}

¹Institute of Mental Health and ²Faculty of Medicine, University of Belgrade, Belgrade, Serbia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.950

Introduction: Parent-mediated interventions for children with autism spectrum disorder (ASD) have been recognized as very valuable (1). There is a significant effect of parental attitudes towards treatment on treatment outcomes (2).

Objectives: To evaluate parental attitudes and need for professional support regarding pharmacological treatment of children with ASD.

Methods: We interviewed 67 parents (83.6% mothers) of children with ASD who are regularly treated at our institution. We created a questionnaire with sociodemographic information, clinical characteristics of the child, and parental experience/attitudes on pharmacological treatment.

Results: The average child age was 20.06 ± 4.43 ; 80.6% were male. The child clinical characteristics and parental sociodemographics are shown Table 1.

Table 1. Clinical characteristics of children with ASD/parental sociodemographics

Clinical characteristics – children	N	Valid %	X	SD
Speech - 4 words or more	35	52.2		
Epilepsy	13	19.4		
Intellectual disability	21	31.3		
Parental sociodemographics				
Current age of parent (informant)			50.93	6.91
Parent (informant) education				
Primary and secondary school	25	37.3		
Attended/finished university or postgraduate degree	42	62.7		
Parent (non-informant) education				
Primary and secondary school	31	47		
Attended/finished university or postgraduate degree	35	53		

Parental attitudes and feelings when child is treated with medication are shown in Graph 1.

Graph 1. Parental attitudes on medication

We also examined what would help parents in reaching the decision on pharmacotherapy for their children (the results shown in Graph 2).

Graph 2. Parental need of support for decision on medication

In our further analysis, it was shown that the feeling of guilt and helplessness was significantly more present in parents who feared side-effects of medication ($p=0.016$ and $p<0.001$, respectively).

Image:

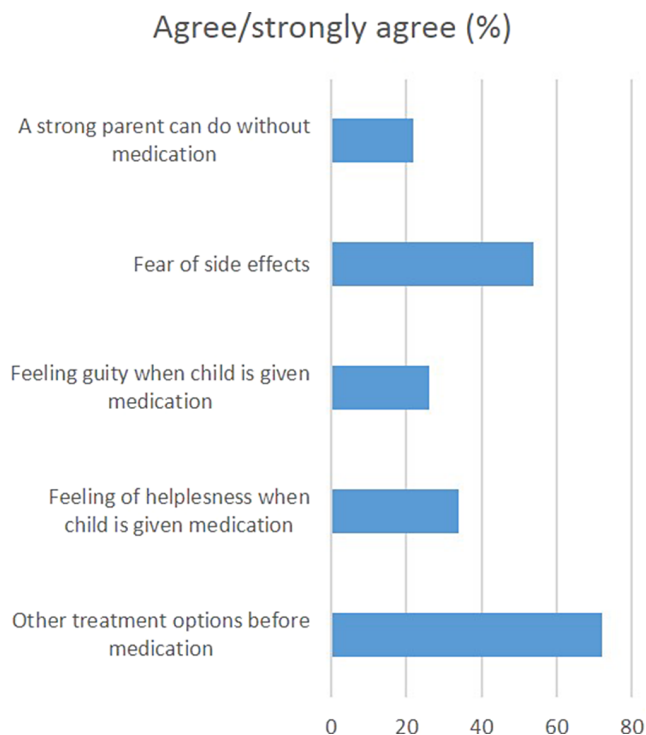

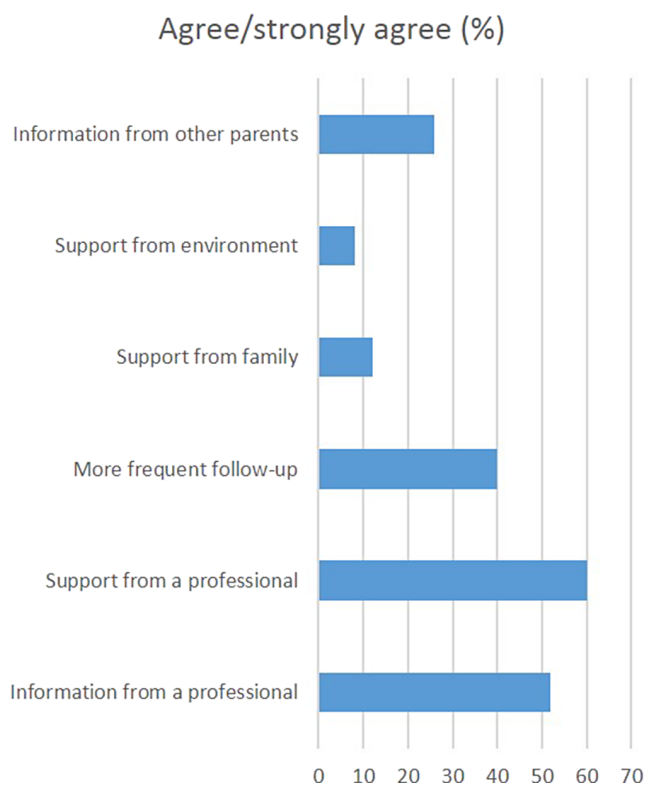

Image 2:

Conclusions: A significant number of parents battle with feelings of helplessness and guilt when medication is introduced in the treatment of their children. There is a great need for information provided by the clinicians as well as psychological support in reaching shared decisions regarding pharmacological treatment of children with ASD.

The effect of Self-Regulation Based Cognitive Psychoeducation Program on emotion regulation and self-efficacy in children diagnosed with attention deficit hyperactivity disorder

Z. Sökmen^{1*} and S. karaca²

¹Department of Psychiatric Nursing and ²Marmara UniverDepartment of Psychiatric Nursing, Marmara University, Institute of Health Science, ISTANBUL, Türkiye

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.951

Introduction: Attention deficit hyperactivity disorder (ADHD) is a neurodevelopmental disorder with early onset (Christiansen, H., et al. CPR 2019, 1–11), which is characterized by several symptoms, including lack of attention, hyperactivity, and impulsivity that are incompatible with age and developmental level (Caye, A., et al. 2020 JAACAP, 990–997)

Objectives: This study aimed to determine the effect of Self-Regulation Based Cognitive Psychoeducation Program on emotion regulation and self-efficacy in children diagnosed with attention deficit hyperactivity disorder (ADHD) and receiving medication.

Methods: The sample of this study with control group and pre-test, post-test and follow-up randomized experimental design consisted of children followed in the child and adolescent mental health outpatient clinic of a state hospital. The data were evaluated by parametric and non-parametric analyses.

Results: A statistically significant increase was determined in the internal functional emotion regulation mean scores of children, who participated in the Self-Regulation Based Cognitive Psychoeducation Program, measured before, immediately after, and 6 months after the intervention ($p < 0.05$). A statistically significant increase was also found in their external functional emotion regulation mean scores measured before and 6 months after the intervention ($p < 0.05$). In addition, a statistically significant difference was found between their internal dysfunctional and external dysfunctional emotion regulation mean scores measured before and 6 months after the intervention; however the mean scores of those in the control group 6 months after the intervention were higher than those in the intervention group ($p < 0.05$). Furthermore, there was a statistically significant increase in their self-efficacy mean scores measured before and 6 months after the intervention ($p < 0.05$).

Conclusions: The Self-Regulation Based Cognitive Psychoeducation Program was found to be effective in increasing the levels of emotion regulation and self-efficacy in children with ADHD.

Interrelations of Intelligence and Social-Adaptive Skills in Adolescents with Multiple Developmental Disorders: A Pilot Study

E. Shvedovskii^{1,2*}, N. Maltseva³, D. Melnikova³, S. Dronova³ and A. Bitova³

¹Mental Health Research Center; ²Moscow State University of Psychology & Education and ³Regional non-profit social organization "Center for Curative Pedagogics, Moscow, Russian Federation

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.952

Introduction: The relationship between social adaptation and intelligence in adolescents with developmental disorders varies depending on various psycho-social factors. Adolescence is marked by pubertal changes in mental and physical development. Previous research has revealed a moderate correlation between intelligence and various groups of adaptive skills in adolescents with Down syndrome. However, studies involving adolescents with multiple developmental disorders are relatively scarce in the existing literature

Objectives: Determine the distribution of intelligence among adolescents with severe multiple disabilities; Identify the connection between intelligence and the level of adaptation in this group; explore the connection between intelligence and independence skills in the subjects.

Methods: The study included 11 adolescent participants enrolled in a comprehensive social skills development intervention program at the Center for Curative Pedagogics: 5 girls and 6 boys, mean age - 14,0 yrs. Age st.dev: 24,3 and 18,4. ICD-10 DS of participants were: F48.xx, F70.xx, F80.xx, F84.xx, G40.xx, G80.xx, Q74.xx, and Q90.xx. Following tools were used: Leiter-3 scales (LIQ), Vineland-3 Adaptive Behavior Scales (VSS); Perkins I.C.A.N. independence Scales (ICAN).

Results: Selected variables including were tested with the Shapiro-Wilk test. p-values of the SW test indicated that data were not distributed normally: LIQ ($w=0.953$, $p=0.685$); VSS ($w=0.964$, 0.821); ICAN ($w=0.877$; $p=0.095$).

For the identification of the connections between the intelligence (LIQ) and adaptive functioning (VSS) we used r-Spearman criteria. These parameters showed significant monotonic relationship ($r_s = 0.961$, $p<0.001$). Mean IQ level of the sample is characterized as mildly impaired (mean = 62.9). The adaptive and the independence skills level of the sample are also far below the low normative results (57.1 and 48.7 respectively). Images 1,2 and 3 shows the distribution of the data. The correlation between IQ (LIQ) and independence skills (ICAN) is not significant ($r_s = 0.671$, $p<0.024$), as well as the correlation between adaptive and independence skills ($r_s = 0.733$, $p<0.010$).

Conclusions: We made an exploratory study of the adolescent participants of the comprehensive social skills development intervention program at the Center for Curative Pedagogics. Results show that non-verbal intelligence of the participants shows strong connection to the adaptive skills, but not to the independence skills.

Sample size is very small, which is explained by the specifics of the intervention. Further research should be focused on the increasing sample and the expanding analysis parameters, such as social and family history, intervention details and the additional variables of the existing measurements.

Exploring the Impact of Wildfires on Children's Psychological Well-being: A Comprehensive Review of Recent Literature

M. K. Adu^{1*}, B. Agyapong² and V. I. O. Agyapong¹

¹Department of Psychiatry, Dalhousie University, Halifax NS and

²Department of Psychiatry, University of Alberta, Edmonton, AB, Canada

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.953

Introduction: Wildfire disasters have become increasingly rampant. There is a critical need for all to fully understand the mechanism and impact of these disasters on humans, with a special emphasis on the mental health effects they pose on the affected individuals and communities. This article specifically presents a scoping review of the psychological reactions of children and adolescents post-wildfire disaster.

Objectives: This review aims to synthesize currently available literature regarding the impact of wildfire on mental health, specifically the psychological reactions of children to wildfires.

Methods: We identified 8 research articles using 6 databases for this review. Data extraction was performed using a qualitative descriptive approach.

Results: The results identified post-traumatic stress disorder (PTSD), anxiety, depression, stress, alcohol/substance misuse, hopelessness, low resilience, reduced quality of life, and self-esteem as the psychological conditions manifesting in children and adolescents post-wildfire disaster. PTSD was the most evaluated psychological reaction in the participants (7 out of eight studies).

Conclusions: This review highlights that deleterious mental health effects, such as PTSD, depression, anxiety, and suicidality, can persist in children for years post-wildfire disaster. Factors such as gender, direct exposure to the wildfire, re-traumatization, and resilience informed or ameliorated the severity of the impact of wildfire on children and adolescents. Our findings further emphasize the need for multi-year funding and programs to support children and adolescents' mental health, including children with disabilities in the communities that have experienced wildfire disasters.

Experience in the Psychotherapeutic Treatment of Eating Disorders in Children and Adolescents: A Brief Approach and EMDR Outcomes

L. López Gómez-Miguel*, L. Herranz Núñez, L. Santolaya López, F. Benavides Rivero, A. Privado Aranda and M. González San José

Unidad de Salud Mental, Hospital Universitario de Toledo, Toledo, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.954

Introduction: This study is based on our experience at public hospitals and private clinics of Toledo and Madrid, where we have addressed the treatment of children and adolescents presenting with Eating Disorders (EDs). Our intervention focuses on the application of brief psychotherapy, with particular emphasis on the effectiveness of Eye Movement Desensitization and Reprocessing (EMDR) in these cases.

Objectives: The primary objective of this study is to determine the benefits of applying EMDR in cases of pediatric and adolescent EDs in comparison to other psychotherapeutic techniques.

Methods: Over a period of one year, brief psychotherapy sessions were conducted with children and adolescents diagnosed with EDs. An integrative approach was used, combining family systemic therapy, cognitive-behavioural therapy techniques, and brief psychodynamic approaches, along with EMDR sessions. Pre and post treatment assessments were conducted to measure changes in symptoms and patients' quality life.

Results: The results obtained reveal significant improvements in patient symptomatology, including a notable reduction in food-anxiety, dietary restriction and compensatory behaviours. Furthermore, improvements were observed in body image perception and patients' overall quality of life. Incidence of relapse cases was minimal.

Conclusions: Our experience suggests that the application of a brief psychotherapy approach, combined with EMDR sessions, can be highly effective in treating children and adolescents with EDs. Early intervention and individualized adaptation of therapies are essential for achieving positive and lasting outcomes in this patient group. These findings underscore the importance of considering integrative approaches in the care of EDs in young population.

The relation between autism and psychosis: overlapping and differing features

M. B. Ruas Resende*, F. Agostinho, R. Nogueira, F. A. Silva, R. Lousada and D. Cotovio

Psychiatry, Hospital de Loures, Lisbon, Portugal

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.955

Introduction: Autism spectrum disorders (ASD) and schizophrenia (SCZ) have a strong historic connection. At the beginning of the 20th century when referring to schizophrenic patients Eugen Bleuler used the term autism to describe the apparent withdrawal from the outside world. Other authors also emphasized the association between this two entities. In fact, only in DSM-III were these disorders placed in different diagnostic categories. Today, even though this nosological vision still prevails, a growing number of studies have shown significant overlaps between the two disorders. Patients with the diagnosis of ASD often experience psychotic symptoms and similarly schizophrenic patients have a high prevalence of autistic traits.

Objectives: To clarify the distinction between ASD and psychotic disorders, namely to help the clinical and phenomenological distinction between patients with a primary psychotic disorder versus patients with the diagnosis of an autism spectrum disorder that might also experience psychotic symptoms.

Methods: Research on UpToDate using the terms “Autism Spectrum Disorders”; “Schizophrenia” and “psychosis”.

Results: Delusional beliefs and paranoid ideation are common findings in autistic individuals in the same way that they constitute one of the main features of schizophrenia spectrum disorders. However, in ASD individuals one must be vigilant of its distinction with “childish fantasies”. Both disorders (ASD and SCZ spectrum disorders) share Theory of Mind (ToM) impairments that contribute to the development of paranoia.

Sensory anomalies are common in ASD and might be confused with hallucinations. However, anomalous perceptual experiences can and do often happen in ASD and are clinically overlapping with hallucinatory phenomena. In the case of a neurodevelopment disorder, however, they could probably be better understood as a part of it more than the signal of a co-occurring psychotic disorder. Attenuated psychotic symptoms pose an even more complex subject because of the overlap between autistic symptoms and subclinical psychotic symptoms. Another area that poses diagnostic difficulties has to do with the distinction between negative symptoms seen in schizophrenia and autistic symptoms. Lack of emotional reciprocity in ASD can be confused with “blunted” affect in schizophrenia. Other overlapping features between these two entities can be identified.

Conclusions: The diagnostic boundaries between ASD and SCZ are not always clear. Their overlapping characteristics and potential co-occurrence might pose important diagnostic challenges in clinical practice. The clinical course of both diseases frequently represents a key element for the differential diagnosis between autism and psychosis. The profound knowledge of these two entities is of extreme importance contributing to the implementation of more targeted and effective management strategies.

doi: 10.1192/j.eurpsy.2024.956

Introduction: Nowadays children and adolescents are exposed to cyber victimization. This modern form of aggressive behavior has a negative impact on the psychological of victims, self esteem, and social interaction

Objectives: To investigate the relation between cyber victimization and depression in tunisian preadolescents and adolescents

Methods: The Arabic validated version of the “cyberbullying assessment instrument” was distributed through social media groups of preadolescent and adolescents in Tunisia. The participants were also invited to answer items about social and demographic characteristics. The participation was voluntary, without confidential data.

Results: Fifty four preadolescent and adolescent aged between 9 and 16 years old have participated. The average age was 12.4 years old. 64% of participants were girls. More than 80% of children have

their own smartphone and a personal count on social media. Among those respondents, 12 (22.2%) reported being cyberbullied at least once in the year. The children most likely to be bullied were girl aged between 9 and 12 years old with a poor socioeconomic level. Low self esteem, depressive symptoms, anxiety symptoms are associated with cyber victimization.

Conclusions: The level of cyber victimization among preadolescents and adolescents is underestimated. Psychiatric disorder associated to this phenomena have to be considered in order to develop strategies and intervention to reduce the cyberbullying among vulnerable population.

Association and predictor role of MASC scores in pharmacological or psychological treatment indication in a sample of children and adolescent in Spain

C. Canga-Espina^{1,*}, C. Vidal-Androher², M. Vallejo-Valdivielso¹, C. Maestro-Martin² and A. Diez-Suarez¹

¹Child and Adolescent Psychiatry and ²Clinical Psychology, Clínica Universidad de Navarra, Pamplona, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.957

Introduction: Anxiety is one of the most common Mental Health diagnosis in underage population. We decided to study if there was any variable that would lead us to a specific treatment indication using the MASC (Multidimensional Anxiety Scale for Children).

Objectives: Prevalence of psychiatric disorders and comorbidities in an underage population.

Possible association between MASC questionnaire scores and the indication for pharmacological and/or psychological treatment.

Methods: This is a descriptive, observational, retrospective, quantitative study with data from patients between June 2016 and 2023. **Inclusion criteria:** 3-18 year-old-spanish-speakers who met criteria for a ICD-11 disorder. **Exclusion criteria:** absence of legal representatives, intellectual disability. **Variables:** Age, sex, psychiatric family history, ICD-11 diagnosis, treatment indication and MASC's subscales (physical symptoms, harm avoidance, social anxiety and separation anxiety). **Statistical analyzes** were performed with STATA-15 program, using as **independent variables** MASC questionnaire, and **dependent ones** the indication treatment and diagnosis.

Results: The sample contains 1024 patients, with a mean age of 12 (SD 4.028). **Table 1** shows that the most frequent diagnosis is ADHD, with combined presentation with a prevalence of 22.27%, followed by Anxiety Disorders, without differentiating by subtypes (17.93%). It also shows that Defiant and Oppositional Disorder is the most prevalent comorbidity (9.66%) followed by Anxiety Disorder not specified (4.99%). **Table 2** stands that there are significantly higher scores in all MASC subscales in those patients who do have prior psychiatry family history. We found in **Table 3** statistically significant differences were found between the score on the Physical Symptoms subscale based on whether the patient was undergoing previous treatment, both pharmacological (8.45 vs. 7.59) and psychological treatment (9.01 vs. 7.95) compared to those who were not (pharmacological 7.36 vs. 7.06), psychological (7.21 vs. 6.92). All these data have been adjusted.

MASC Physical symptoms	27,64		17,93 - 38,98	*	33,47		25,89	*	35,06		25,47	*
MASC Harm avoidance	62,1		55,25 - 70,13	*	62,29		62,06		65,8		63,03	
MASC Social anxiety	33,54		19,02 - 28,81	*	19,92		24,62		27,27		22,45	
MASC Separation anxiety	33,54		22,54 - 36,1	*	27,54		30,74		34,63		30,64	

Conclusions: Anxiety disorders are the most common form of Mental Disorder in young people, with a global prevalence of 6.5% (Rapee et al.2023). However, in our sample the most common one is ADHD as our center is specialized in it. We found that the most prevalent one was Oppositional Defiant Disorder, as it is the most frequent comorbidity of ADHD (Vallejo-Valdivielso et al,2019; Faraone et al,2021). The increase of one point in the Physical Anxiety subscale increases the probability of indicating pharmacological treatment, which could be explained because of how functional limitation these symptoms cause. The increase in all the subscales of the MASC implies an increase in the probability of an indication for psychological treatment as it is the gold-standard treatment for anxiety in children.

Disclosure of Interest: None Declared

EPV0194

Relationship between MASC scores and diagnosis in a sample of children and adolescents in Spain

C. Canga-Espina^{1*}, C. Vidal-Androher², A. Diez-Suarez¹, C. Maestro-Martin² and M. Vallejo-Valdivielso¹

¹Child and Adolescent Psychiatry and ²Clinical Psychology, Clínica Universidad de Navarra, Pamplona, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.958

Introduction: Anxiety is one of the most common Mental Health diagnosis in underage population. We decided to study if there was any variable that would lead us to a specific diagnosis, using the MASC questionnaire (*Multidimensional Anxiety Scale for Children*).

Objectives: 1. Describe the prevalence of the different anxiety disorders and the differences in its prevalence according to sex. 2. Examine possible differences and associations between MASC questionnaire scores and a specific anxiety diagnosis.

Methods: This is a descriptive, observational, retrospective, quantitative study with data from patients between June 2016 and 2023. **Inclusion criteria:** 3-18 year-old-spanish-speakers who met criteria for a ICD-11 disorder. **Exclusion criteria:** absence of legal representatives, intellectual disability. **Variables:** sex, ICD-11 diagnosis, MASC's subscales (Physical Symptoms, Harm Avoidance, Social Anxiety and Separation Anxiety) and CGI. **Statistical analyzes** were performed with STATA-15 program, using as independent variables MASC questionnaire and dependent one Anxiety Diagnosis.

Results: The sample contains 1024 patients. Figure 1 shows the distribution of Anxiety Disorders: Unspecified Anxiety Disorder (47%), Separation Anxiety Disorder (23%), Simple Phobias (9%) and Social Anxiety Disorder (7%). Figure 2 represents the distribution by sex, with the differences being statistically significant (p<0.05) for all anxiety disorders, meaning that girls have higher prevalence of all anxiety disorders. Figure 3 shows how age correlates significantly and directly with all the subscales, meaning the older the patients are the higher the scores. We also found that boys have lower scores and a lower percentage of alteration in all subscales. CGI scale also correlates positively with all the subscales, specially with Physical Symptoms. All these data have been adjusted.

Image:

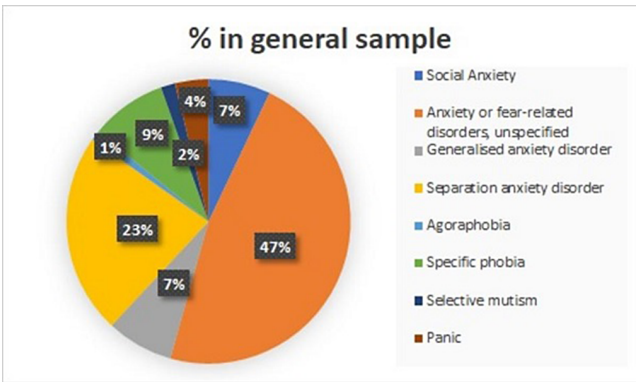

Image 2:

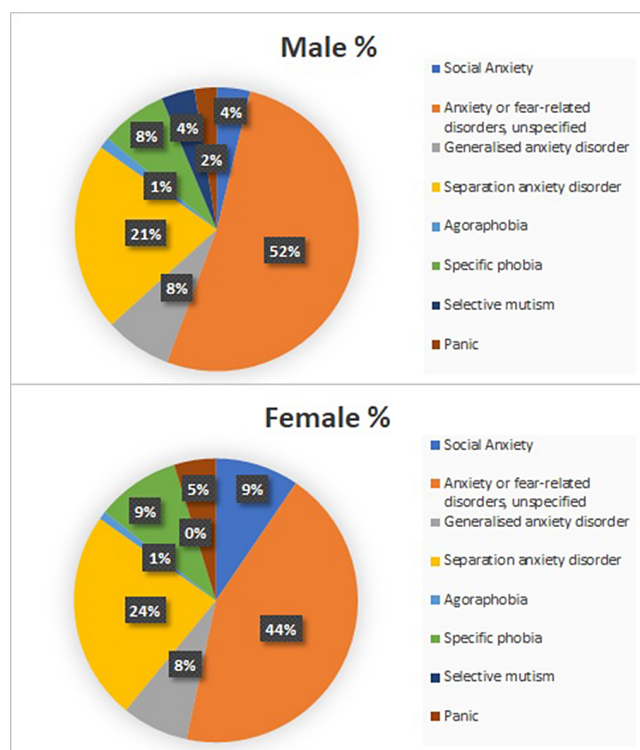

Image 3:

Q2 VS BASAL	EDAD	AFS	AEP	AS	AxS	CGI
Age	1					
Physical symptoms	0,2436	1				
Harm avoidance	0,1932	0,7351	1			
Social anxiety	0,1946	0,6911	0,7213	1		
Separation anxiety	-0,0079	0,617	0,7881	0,6661	1	
CGI	0,1818	0,1431	0,0736	0,1021	0,679	1

r = -1
r = +1

Conclusions: Anxiety disorders are the most common form of Mental Disorder in young people (global prevalence of 6.5%, Rapee et al.2023). Prevalence for specific Anxiety Disorders in underage population are less reliable, because of the unequal age of samples (Rapee et al.2023). Separation Anxiety disorder is the most prevalent among children (La Maison et al., 2018), while Social Anxiety disorder is among adolescents (Lawrence et al.2015). We did not categorized our sample, being Separation Anxiety disorder the most frequent followed by Social Anxiety. We observed a correlation between some subscales and a specific diagnosis: the risk of presenting a Social Anxiety disorder is multiplied by 1.08 for each point of increase in that subscale and the risk of presenting a Separation Anxiety disorder is multiplied by 1.05 for each increase of 1 point in Separation Anxiety subscale. However, the diagnosis of Simple Phobia decreases with the increase in scores in all subscales, maybe due to the fact that there are not many items that specifically evaluate fears.

Influence of genetic background on the clinical picture of bipolar affective disorder in a population of children and adolescents

K. Kamińska, M. Bień, K. Dąbrowska*, M. Janas-Kozik,
L. Cichoń and K. Wilczyński

Medical University of Silesia, Katowice, Poland

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.959

Introduction: Bipolar disorder in children is characterized by a different course than in adults, which is a diagnostic difficulty. DAT-1 is a dopamine transporter gene that regulates dopaminergic neurotransmission through the mechanism of active reuptake of this neurotransmitter from the synapse. Polymorphisms within the described gene can result in changes in dopamine levels, which may have implications for the development of bipolar disorder.

Objectives: The aim of the project was to analyze the relationship between single nucleotide polymorphisms (SNPs) within the dopamine transporter gene DAT-1 and the risk of development of bipolar disorder in a population of children and adolescents.

Methods: 21 healthy controls (12 females, 9 males) have been recruited into the study and 13 patients (9 girls, 4 boys) with bipolar disorder diagnosis from Department of Psychiatry and outpatient clinic, were recruited for the study group. Questionnaires such as the KSADS-PL were carried out and blood was taken for laboratory tests of four SNPs within the DAT-1 transporter. PQStat, Microsoft Excel 2013 and StatSoft STATISTICA were used to perform the statistical analysis.

Results: SNPs within the dopamine transporter gene and environmental risk factors influenced the risk of developing bipolar disorder in the population of children and adolescents.

Conclusions: The ambiguity in results emphasizes the necessity for further investigations into correlation between genetic factors in bipolar disorder etiology. Future research should involve more participants. The results of this project are likely to make a significant and valuable contribution to the current knowledge of bipolar disorder and to the development of innovative diagnostic methods, making a significant contribution to the advancement of science.

Projective technique “Bird’s Nest Drawing” in child clinical psychology

M. Zvereva^{1*}, N. Zvereva¹, A. Sergienko¹, S. Strogova¹, D. Klak¹,
E. Antonova¹ and E. Balakireva²

¹clinical psychology and ²child psychiatry, FSBSI MHRC, Moscow, Russian Federation

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.960

Introduction: The “Bird’s Nest Drawing” technique is one of expressive drawing projective techniques. In Russia it has been

used since the 2020s. We suggest the pilot version of using this projective technique in child clinical psychology. There were investigated the cognitive and emotional components of performance by children with different types of ontogenesis.

Purpose: pilot application of the technique of “Bird’s Nest Drawing” (BND) in the psychological diagnosis of children with different types of ontogenesis.

Objectives: 69 children and adolescents 6-17 years old (28 male), examined at the Mental Health Research Center. 1. hospital patients (11-16 years old, 18 persons) diagnoses F20.8, F21.4, 2) outpatient clients with psychological diagnostics (7-16 years old, 45 persons), most of them have psychiatric diagnoses and some of them came for a consultation independently of doctors (there were family and behavior problems). 3) children conceived with the help of assisted reproductive technologies (IVF) - participants in a program for studying cognitive and emotional-personal development (5-13 years old, 8 people). Control group of normal children (14 persons).

Methods: Bird’s Nest Drawing (D.Kaiser, 2003, Kuftyak, 2021) - clinical expert assessment of the drawing parameters (size, location, quality, compliance with instructions) and the emotional component (color, self-assessment of the drawing).

Results:

Table 1. Frequency of different indicators of BND in compared groups of children.

Groups	N	Central place	High Quality of drawing	Nest out of tree	birds / eggs	Different colors	Safety of nest	High Assessment by participants	High positive emotional expression Assessment by experts
Hospital patients	18 (4 m)	12	4	10	4	10**	4	13**	5**
Outpatient clients	45 (22 m)	38	13	19	17	32	10	25**	17
Children IVF	8 (2 m_)	7	2	4	3	6**	1	6	3
Normal children	14(6 m)	14	3	7	4	12**	4	13**	11**

** - significance of the differences (p≤0,05 by φ criterion).
Based on the data obtained, it can be noted that the most different between groups turned out to be an indicator for using different colors, subject's assessment his picture and emotional expression assessment of picture by experts. Other parameters are similar: please of drawing,

Discussion: We have obtained our own results about BND method in children with different type of ontogenesis. These data are similar to D.Kaiser and E.Kuftyak in opportunity of good diagnostic practice of BND method in children and adolescents with different type of ontogenesis in scientific

Conclusions: BND method is a good test for child clinical psychology as a projective one. Restrictions of this investigation - small groups, simple parameters for assessment. We plan to continue this work with more clinical (diagnosis, syndrome et cetera) and sex and age characteristics.

Disclosure of Interest: None Declared

EPV0199
Application of the identity disorder questionnaire AIDA+LoPF in adolescents with affective pathology and schizotypal disorder

M. Zvereva* and N. Zvereva
clinical psychology, FSBSI MHRC, Moscow, Russian Federation
*Corresponding author.
doi: 10.1192/j.eurpsy.2024.961

Introduction: To assess the difference in the personality functioning of adolescents with schizotypal disorder and affective disorders, we used the AIDA + LoPF questionnaires, which are well established as questionnaires for identifying identity disorders in adolescents. We hypothesized that adolescents with affective pathology are much more likely to have identity disorders than adolescents with schizotypal personality disorder. Clinical assessment of diseases was carried out by psychiatrists using ICD-10

Objectives: Adolescents with affective disorders -10 (F31), schizotypal disorder adolescents – 11 (F21). Age 12-18

Methods: AIDA+LoPF questioners by authors K. Goth & K. Schmeck, Russian version by M. Zvereva & S. Voronova & N. Zvereva

Results: The table presents statistical analysis data using the Mann-Whitney non-parametric test

Table 1. Significant scales of the AIDA questionnaire

SCALES AIDA	U-CRITERIA	P
TOTAL SCORE: IDENTITY INTEGRATION AIDA	86,000	0,02
Consolidating emotional self-experience	84,000	0,03
COHERENCE	86,500	0,02
CONSISTENCY IN SELF CONCEPTS	88,500	0,01
AUTONOMY, EGO-STRENGTH	88,000	0,02
INTEGRATING COGNITIVE SELF-EXPERIENCE	88,000	0,02

Table 2. Significant scales of the LoPF questionnaire

SCALES LOPF	U-CRITERIA	P
Identity	89,000	0,01
Coherence (Ego-strength)	88,000	0,02
SELF-DIRECTION	89,000	0,01
SELF CONGRUENCE	88,000	0,02
PURPOSEFULNESS	86,000	0,02

Conclusions: We have obtained preliminary results that show a difference between the identity disturbance of adolescents with affective pathology and those with schizotypal disorder. Adolescents with affective pathology are much more likely to have various types of identity disorders than adolescents with schizotypal disorder. To clarify this, a larger sample and a wider range of disorders are required

Disclosure of Interest: None Declared

Melatonin and self harm behavior in youth, beyond the sleep impact

N. Kouki*, A. Maamri, N. kouki, F. Ghrissi, A. Hajri and H. zalila

Outpatient psychiatry department, razi, manouba, Tunisia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.962

Introduction: Sleep disorders in youth are associated to psychiatric disorders and may lead to significant negative effects on cognitive skills, emotional regulation and behavior such as self harm.

Objectives: The aim of our study is to highlight the melatonin effects on reducing self harm behaviors in the youth.

Methods: Our work is a literature review based on the PubMed interface and adapted for 2 databases: Science Direct and Google Scholar using the following combination (self harm [MeSH terms]) AND (melatonin [MeSH terms]) AND (youth [MeSH terms]) .

Results: We initially reviewed 6 articles published between 2012 and 2022. We retained 3 articles which corresponded to the aim of our study.

Self harm behaviors were mainly described in youth during adolescence. In fact, self injurious release may be considered as way to release emotional tension and physical discomfort.

Melatonin prescribed in youth for the treatment of sleep disorders not only improved sleep ,but also mood disorders and impulsivity. Melatonin restores indirectly serotonin levels through a continuous bidirectional connexion . Therefore it is efficient on psychiatric comorbidities, especially anxiety and depression which are associated with intentional self-harm.

Conclusions: Melatonin is the most prescribed drug for sleep disturbances in children and adolescents, its impact covers a large spectrum of disturbances including the self harm behaviors.

Gender diversity and autism spectrum disorder in child and youth population

P. R. Rodríguez*, M. M. Grimal, E. E. M. Castellano,

F. A. R. Batista and N. M. Pérez

Psychiatry, Hospital Universitario de Gran Canaria Doctor Negrín, Las Palmas de Gran Canaria, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.963

Introduction: Interest in the co-occurrence of gender dysphoria and autism spectrum disorder has gained prominence in recent years. Gender dysphoria refers to the distress experienced when there is an incongruence between gender identity and sex assigned at birth. On the other hand, autism spectrum disorder is characterized by difficulties in communication and social interaction, as well as restrictive and repetitive patterns of behavior.

Objectives: The aim of this paper is to review the current available literature in order to expand our knowledge about gender identity and dysphoria in the population with autism spectrum disorder.

Methods: A qualitative review was conducted over the last 20 years, using the Medline database through PubMed. Combinations of MeSH terms related to gender identity and people with autism spectrum disorder were used, selecting those studies in English, French or Spanish that met the objectives of the review, excluding references in other languages. The scientific evidence obtained was analyzed and synthesized.

Results: The development of gender identity of people with autism spectrum disorder can be a complex process. Comparing the general population with the population with autism spectrum disorder, a higher prevalence of gender dysphoria has been evidenced in the population with autism spectrum disorder, and within this group when segmented by gender, greater in women than in men.

Conclusions: This review highlights the importance of increasing knowledge about sexuality and gender dysphoria in people with autism spectrum disorder in order to facilitate the development, understanding and acceptance of their gender identity and sexual orientation of these people.

EPV0203

Sensory reactivity in children and adolescents with autism

S. Perez^{1*} and I. Martin²

¹Psychiatry, Los Arcos del Mar Menor Hospital and ²psychiatry, Infante Mental Health Center, Murcia, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.964

Introduction: The gut-brain axis establishes the relationships between bacteria, neurotransmitters and psychophysiological responses associated with a neuronal and behavioral correlate in autism and different mental disorders.

In recent years, there has been an increase in studies on the implications of the gut microbiota (MI) in children with autism spectrum disorders (ASD).

Objectives: 1. To study if there is a dysbiosis or alteration of the MI can trigger the appearance of ASD symptoms.

It is considered that there is a frequent comorbidity with gastrointestinal symptoms (GS), pain and sensory reactivity in ASD, and that these are indicators of a possible alteration in the gut-brain axis.

Methods: In this sense, children with ASD have hypersensitivity to certain visual, olfactory, tactile, etc. stimuli. which makes them be more picky about food and have certain repetitive patterns of behavior, as a consequence they present gastrointestinal symptoms such as constipation and abdominal pain. Sensory reactivity can influence both feeding and sleep patterns in autism.

Results: Currently, there are measuring instruments for sensory reactivity, pain and gastro-intestinal symptoms. However, there are several limitations of these instruments and especially with sensory reactivity in autism because: (1) the items had not been developed in collaboration with interested parties (pediatricians, neuropsychologists, etc.) and (2) the lack of structural validity analysis. Thus, it appears that most validation studies do not meet the criteria of sufficient psychometric quality according to the COSMIN guidelines. Additionally, there is a lack of consensus around terminology (e.g., sensory

overreactivity, hyperreactivity, SOR, etc.) and components relevant to sensory functioning.

Conclusions: In the present work, preliminary data are presented on new measures to take into account to evaluate sensory reactivity and pain in the population with autism. This is a first step to obtain an index of the gut-brain axis for the ASD population.

Keywords: ASD, gut-brain, sensory reactivity, pain

Childhood and adolescent schizophrenia and networking

S. Perez-Sanchez^{1*} and I. Martin²

¹Psychiatry, Los Arcos del Mar Menor Hospital and ²Psychiatry, Infante-Murcia Mental Health Center, Murcia, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.965

Introduction: Reviewing the histories of patients with childhood and adolescent schizophrenia, on numerous occasions, traumatic factors with great emotional and social impact are observed, such as situations of mistreatment, abuse and emotional deprivation, where help is requested but resources are scarce and the approach is limited without work in network.

Objectives: 1. Analysis of the consultation pathways in adolescents with severe psychiatric and socio-familial symptoms and the time delay in optimal guidance. 2. Evaluate the services involved. 3. Evaluate the clinical control of treatment with aripiprazole.

Methods: Retrospective observational analysis, 5 months, of prodromal symptoms of childhood psychosis and help-seeking pathways in a 13-year-old adolescent, as well as a description of the pharmacological approach and professional teams involved.

Results: A 13-year-old adolescent who went to the emergency room with her mother for ingesting anti-cockroaches with self-inflicted intent. Reviewing his medical history, 4 serious autolytic gestures were detected in the last 2 months. Referred to Mental Health who did not attend.

On clinical examination, florid psychotic, with perplexity, self-reference, ideation of harm, language and behavioral disorganization. Auditory and kinesthetic hallucinations. A situation of neglect of the minor and abuse by the parents is detected; the risk had not been previously reported. Oral aripiprazole (up to 15 mg/day) was prescribed with good tolerance and progressive improvement in symptoms.

We worked jointly with Social Services, the Juvenile Prosecutor's Office, Education and the hospital Psychiatry unit. In some of the resources the situation was already evident, the scope of their action was limited and delaying attention for months.

Conclusions: Based on cases like this, we ask ourselves if psychiatrists are sensitized to the comorbidity of serious mental pathology and the existence of risk situations in minors and if they are oriented toward multiprofessional management. Networking provides us with an early diagnosis, improving the therapeutic approach.

Characteristics of the stressors associated with suicidal behavior in adolescence

S. Susana Perez^{1*} and I. Martin²

¹Psychiatry, Los Arcos del Mar Menor Hospital and ²Psychiatry, Infante-Murcia Mental Health Center, Murcia, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.966

Introduction: In the assessment of suicidal behavior, recent studies describe the great influence of an environmental component with adverse life events and stressors that can influence ideation and self-harm.

Objectives: -1. We propose to analyze the reasons for consultation of adolescents between 12 and 16 years old who consult for suicidal ideation/behavior. 2. Estimate the frequency of different socio-family life events.

Methods: -A retrospective review of emergency consultations in the last 4 months is performed. Sociodemographic data, vital events, reason for consultation and evolution in the following 40 days after the first consultation are collected.

Results: -Data are collected from 16 adolescents who consult due to suicidal ideation/gesture in a period of 4 months, of which 42% (7) are women and 57% (9) are men. The reasons recorded as stressful life events were: 32% unstructured family environment, 13% death of a close relative, 37% poor parental supervision, 26% end of a romantic relationship, 15% legal problems, 2% sexual or physical abuse, 68 % academic problems, 13% bullying. It was observed that in 63% of the cases they had more than one adverse experience.

Conclusions: -Different adverse life events frequently precede suicidal ideation and behavior that can be minimized or go unnoticed and undervalued. A meticulous clinical history can clarify some of the reasons that influence the hopelessness and clinical anguish that suicidal patients present. Its early detection provides the opportunity for an early and specialized approach

Disclosure of Interest: None Declared

EPV0207

General features of existential depression in youth

V. Kaleda* and U. Popovich

Mental Health Research Centre, Moscow, Russian Federation

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.967

Introduction: The axial symptom of existential depression in youth is overvalued ideas about the meaninglessness of human life, its inconsistency with a certain "spiritual self-ideal"; ideas of humiliation, insolvency, low value, imperfection of society are noted, which accompanies varying degrees of severity of suicidal thoughts. The high suicidal risk, insufficient knowledge of such conditions makes it important to study.

Objectives: Determination of the clinical and psychopathological consequences of existential depression in youth.

Methods: 53 male 16-25 years old with F31.3, F31.4, F32, F33 (ICD-10) with the existential depression were examined with clinical-psychopathological method, psychometric assessment of

depression was carried out using the HDRS scale, assessment of suicidal intentions - using the C-SSRS scale. Also were analyzed: premorbid personality structure, hereditary burden in first-degree relatives, the role of exogenous provocations. Statistical data processing was carried out using the STATISTICA software package 10.0 for WINDOWS (StatSoft, USA, was used Pearson χ^2 test, Student t-test. The critical level of statistical significance is $p \leq 0.05$. **Results:** A significant role in the manifestation of existential depression was played by exogenous provocations ($\chi^2=9.47$, $p=0.05$), especially psychotrauma: the most common were the death of a close relative or friend, unrequited love, and failure to enter the desired university. According to the premorbid personality structure schizoid (56.7%) and psychasthenic personalities (30.2%) prevailed. When assessing hereditary burden ($\chi^2=9.59$, $p=0.047$), pathocharacterological features were noted in first-degree relatives in 32.1% cases, affective disorders in 26, 4%. In terms of social and labor status ($\chi^2=9.47$, $p=0.05$), university students naturally predominated (56.6%). The average age of onset of depression was 17.8 ± 1.2 years, duration 3.7 ± 1.5 months. Non-suicidal self-harm was observed in 32.1%, especially in the initial stages of depression. Among suicidal tendencies ($\chi^2=9.58$, $p=0.048$), anti-vital thoughts (50.9%) and passive suicidal thoughts (34%) dominated; 5.7% of patients attempted suicide. On the HDRS scale, patients scored an average of 18.2 ± 1.7 points, which reflected the severity of depression; the total score on the C-SSRS scale was 2.12 ± 0.34 .

Conclusions: In the formation of existential depression, a significant role of exogenous provocations, especially psychotrauma, was discovered; a high suicidal risk was confirmed. Existential depressive states differed in duration; patients of the identified typological varieties scored high on the HDRS and C-SSRS scales. In the future, it is planned to study the follow-up group for the purpose of a detailed analysis of the dynamics of such conditions and their nosological affiliation.

Challenges Associated with the Identification of Autism Spectrum Condition Symptomatology in Girls: A Grounded Theory Lite Approach

N. Dolović

Angerona, educational and rehabilitation private practice, Čakovec, Croatia

doi: 10.1192/j.eurpsy.2024.968

Introduction: Female Autism Spectrum Conditions (FASC) often go without a proper diagnosis, receive misdiagnoses, or are diagnosed late in life compared to males. These circumstances can lead to negative consequences in their overall health, emotional well-being, educational attainment, job opportunities, and independence. There is a growing body of literature highlighting distinctions between females and males in the context of autism. Regrettably, these insights are not effectively making their way into practical applications. While shifting entrenched perspectives among practitioners is a gradual process, there is an immediate and pressing need for change in this regard. Numerous misconceptions persist regarding the presentation of FASC, hindering the recognition of its

diverse effects based on an individual's cis-gender identity or other factors.

Objectives: The purpose of this study is to identify key challenges associated with the identification of ASC symptomatology in girls, with the goal of informing future research and clinical practice.

Methods: Using constant comparative analysis applicable to grounded theory lite with an inductive approach, this study employs an interpretative research methodology with a focus on generating theory from qualitative data, albeit with certain shortcuts or less resource-intensive steps. Data were collected through interviews providing insights into their experiences, behaviors, and developmental history, observations enabling to capture real-time behavioral and communicative patterns, and notes during first and initial developmental assessment, as well as using ADOS-II with some participants (according to referrals and parents' decision), in the period of 3 years (2020-2023) from 25 girls age 18 months to 15 years and their mothers, and occasionally both parents.

Results: Preliminary findings indicate a complex interplay of behavioral, communicative, and social challenges in these girls, shedding light on potentially distinctive patterns of symptom expression in comparison to boys. Furthermore, barriers hindering parental involvement in the diagnostic process have also been identified. This study holds significant importance as it may inform future research efforts aimed at addressing these challenges that currently impede clinicians in the early identification of FASC, which manifests quite differently in girls compared to boys.

Conclusions: Taking into account certain study limitations, the significance of this research lies in its capacity to influence future research initiatives. By illuminating the obstacles that hinder clinicians in the early detection of FASC, which manifest distinctively in girls compared to boys, it emphasizes the pressing need to address these challenges. This, in turn, enhances early detection and support systems for FASC, ultimately contributing to their well-being and quality of life.

Pineal gland cyst and ADHD in a juvenile patient: a case report

A. Kovačević, N. Rančić, T. Mastelić, M. Ćurković, I. Barišić, I. Ložina, M. Rogulj, D. Lasić and T. Glavina*

Psychiatry Department, University Hospital of Split, Split, Croatia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.969

Introduction: The role of the pineal gland in psychiatric disorders is poorly investigated. There are studies, primarily on adult patients, that indicate a higher presence of pineal gland abnormalities in patients suffering from depression, schizophrenia and attention-deficit/hyperactivity disorder (ADHD). When it comes to ADHD, there is speculation about the role of melatonin and the influence of the pineal gland on the dopaminergic system. Data on the association between pineal gland cysts and ADHD in juvenile patients are particularly scarce.

Objectives: Due to all of the above, our goal is to present the case of a nine-year-old male patient who has a confirmed cyst of the pineal gland and is being treated for ADHD.

Methods: The patient was examined by a neuropsychiatrician, EEG and brain MRI were performed. He was also examined by a psychologist and by a psychiatrist. Endocrinological, hematological, rheumatological, pulmonological treatment and karyotyping were performed.

Results: MRI of the brain revealed a cyst of the pineal gland with an anteroposterior diameter of 1 cm without significant compression. The EEG was mildly slowed and paroxysmally dysrhythmic for the age, ie. paroxysms of high-voltage delta waves were described. The EEG findings after sleep deprivation were paroxysmally altered with rare focal changes in the right temporoparietal region. Through psychological analysis, it was determined that specific deficits persist in the area of verbal understanding, perceptual organization and visual processing, information processing speed, numerical reasoning, attention and short-term memory. On the level of visuomotor perception and coordination, deviations are observed by organic type. He is motorically more active, impulsive, emotionally immature, easily distractible.

Conclusions: The etiology of ADHD is poorly researched, and so is the role of the pineal gland, its cyst and melatonin. There is scant knowledge for other psychiatric disorders, but primarily from researches on adult psychiatric patients. Additional researches are definitely needed on this topic, especially in the field of child and adolescent psychiatry.

EPV0211

The biological modeling of autism spectrum disorders

A. Sidenkova*

Psychiatry, Ural State Medical University, Yekaterinburg, Russian Federation

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.970

Introduction: Autism Spectrum Disorders (ASD) are heterogeneous pathological conditions characterized by difficulties in establishing social contacts and the manifestation of repetitive behavior. An atypical trajectory of brain maturation, impaired neurogenesis, synaptogenesis, and an imbalance in the excitatory and inhibitory systems of the CNS form the morphofunctional basis of the ASD

Objectives: scientific publications

Methods: scientific analysis

Results: These pathological changes appear at different stages of brain maturation. They are the result of multifactorial environmental influences. To understand the functioning of this complexly organized system in time and space, a three-dimensional model is needed. The closest in vitro model of the human brain from early embryonic stages to aging is brain organoids. Human brain organoids are self-organizing three-dimensional cell aggregates derived from pluripotent stem cells. Organoids summarize neurogenesis, gliogenesis, synaptogenesis, cell migration and cell differentiation, gyrification of the cerebral cortex, reflect the connections of brain regions. The use of a 3D brain model makes it possible to simulate diseases, reactions to drugs in cells obtained from patients. The use of telencephalon organoids in the ASD model revealed that neuronal migration deficiency, acceleration and disruption of cell cycle synchronization, aberrant cell proliferation, abundant synaptogenesis, temporary deviations in the development of the cortex,

increased branching of neurons, unbalanced inhibitory differentiation of neurons, high activity of ion channels are the result of impaired activity FOXG1. FOXG1 is responsible for the overproduction of GABAergic neurons. The shift towards GABAergic neurons induced by FOXG1 is positively correlated with the severity of ASD symptoms and is seen as a precursor to the future of ASD

Conclusions: Thus, ASD as a socially significant disease with a heterogeneous type of inheritance, multi-link pathogenesis, realized in different periods of ontogenesis and involving different brain loci, requires special attention of researchers for the personification of diagnosis and therapy. The hiPSCs can provide insight into the cellular mechanisms underlying ASD as a neuropsychiatric disorder, providing access to the development of platforms for in vitro drug screening and patient-tailored therapy.

Borderline personality disorder in adolescents as a predictor of social anxiety

L. Baranskaya

Psychiatry, Psychotherapy and Narcology, Ural State Medical University, Yekaterinburg, Russian Federation

doi: 10.1192/j.eurpsy.2024.971

Introduction: Borderline personality disorder (BPD) is a mental disorder characterized by unstable relationships, a tendency to self-destruction, affective and behavioral dysregulation and BPD are a clinical problem

Objectives: Early detection and timely intervention for BPD is becoming a new public health priority as it helps prevent the adverse personal, social and economic consequences of the disorder. Borderline personality disorder first manifests itself, as a rule, in adolescence, so it is easy to mistake it for manifestations of "difficult age" characteristic of the period of growing up. In this sense, the typical signs of borderline personality disorder are not original: low self-esteem, emotional excitability, impulsive behavior and sudden mood swings, to one degree or another characteristic of all adolescents. An alarming exception is, perhaps, only a tendency to self-harm and, the so-called, desocialization of a teenager, the loss of social skills and connections (for example, friendships). Recently, experts have increasingly mentioned desocialization in connection with the development of Internet technologies and gadgets that replace communication in real life for many teenagers

Methods: An anonymous survey of 57 older teenagers conducted. The degree of borderline personality disorder assessed using IPDE, STAI, and CDI. Statistical processing of the results carried out in Microsoft Excel using measures of the central trend (arithmetic mean, standard deviation) and correlation analysis. The significance of the differences between the groups was determined using the Student's t-test ($p < 0.05$)

Results: On average, the level of BPD among the respondents was at a low level of 9.81 (± 4.43) points. The severity of personal anxiety was at a high level of 45.02 (± 13.25) points, situational anxiety was also at a high level of 41.14 (± 14.93). The severity of depression was above average and amounted to 55.84 (± 14.33) points

Conclusions: Teenage girls are more prone to anxiety and depression than boys are. High anxiety causes a tendency to depression,

and these two factors affect the occurrence of PRL. The average score does not affect the manifestations of anxiety, depression and the occurrence of BPD

Is body image misperception associated with sociodemographic factors and life habits? a cross-sectional study 1399 Tunisian school-adolescents

F. Mohamed¹, S. Sellami^{2*}, D. Amira¹, J. Fares³, G. Rim³ and M. Jihenne¹

¹Department of Psychiatry, Ibn el Jazzar University Hospital, Kairouan, Tunisia, Kairouan; ²Department of Psychiatry, Mohamed Taher Maamouri University Hospital, Nabeul, Tunisia, Nabeul and ³Department of Epidemiology, Farhat Hached University Hospital, Sousse, Tunisia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.972

Introduction: Understanding adolescents perceptions of their weight status and the factors influencing these perceptions is pivotal for developing targeted interventions and policies to counteract the rising obesity trends.

Objectives: This cross-sectional study aimed to determine the accuracy of weight status perceptions among Tunisian adolescents compared to objective metrics and to identify sociodemographic characteristics and life habits associated with the underestimation of weight status.

Methods: A cross-sectional, school-based study was conducted among a randomized sample of adolescents attending secondary schools in Sousse, Tunisia. A total of 1399 students participated, with anthropometric measurements taken, and a pre-tested Arabic questionnaire administered to gather sociodemographic data and perceived weight status, assessed using the Figure Rating Scale (FRS). The accuracy of perceived weight status was determined by comparing the measured weight status with participants' self-reported perceptions. We evaluated the association between body weight distortion and life habits which included regular physical activity, screen time (time spent on internet per day), number of fruits and vegetables consumed per day, and fast-food consumption.

Results: The study achieved an 86.68% response rate, with over half of the participants being female (60.5%), and the average age being 17 years. The majority of adolescents (41%) perceived themselves as having normal body weight, while 34.5% perceived themselves as underweight, 16.6% as overweight, and 7.9% as obese. However, based on BMI categories, 72.6% had a normal measured weight, 20.4% were overweight, and 6.9% were obese. A substantial proportion of participants (45.6%) underestimated their weight status, with a significant proportion being objectively overweight or obese (26%). Furthermore, we found a significant association between the perception of weight accuracy with four correlates: gender, mother educational level, regular physical activity, and the number of fruits and vegetables consumed per day.

Conclusions: The findings revealed a disparity between perceived and actual weight status among Tunisian adolescents, with a

significant underestimation of weight status, particularly among those who are overweight or obese. The results highlighted the crucial need for interventions that address weight perception inaccuracies and promote healthy weight awareness and management among adolescents in Tunisia. The study underscored the importance of further research to understand the development and progression of body weight underestimation throughout adolescence and the roles of lifestyle behaviors in shaping weight perceptions.

Watersports Inclusion Games: The Benefits for Participants and the Impact of COVID-19 on Access

M. Killalea^{1*}, A. Warraitch¹, J. Murphy² and E. Barrett³

¹School of Medicine, University College Dublin; ²Irish Sailing and ³Child and Adolescent Liaison Psychiatry, Children's University Hospital Temple Street, Dublin, Ireland

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.973

Introduction: The Watersports Inclusion Games is a free annual weekend event, where young people with a range of physical and intellectual disabilities and their families/siblings participate in various inclusive watersports activities.

Objectives: This study aims to assess the psychological benefits of watersports for young people with various physical and intellectual disabilities and investigate the extent of the impact of the COVID-19 pandemic on their access to watersports.

Methods: Following a literature review, a survey containing both quantitative and qualitative aspects was constructed using Survey-Monkey and circulated to the parents/guardians of participants three times following the event. The survey was completed anonymously on an opt-in basis and 28 responses that met our criteria for analysis were collected. Qualitative data from free-text responses were grouped under themes and quantitative data was analysed using SPSS.

Results: Despite 64% (n=18) of respondents indicating that their disability increased their vulnerability to COVID-19 in some capacity, the effect of the pandemic on accessibility was not statistically significant. This could be due to the small response number, or the everyday limitations participants faced prior to the pandemic. 92% (n=25) of participants indicated that there was great inclusion in the watersports activities and that they were "very beneficial" regarding the possibility of the whole family's participation [p=0.005]. The survey also found a statistically significant association between the event's activities being considered both "accessible" and "very beneficial" in terms of boosting self-confidence, with 57.1% of responses indicating agreement to this. (p=0.016)

Conclusions: Full-family participation and accessibility of activities were key facilitators to the enjoyment and benefit of participants. Programmes should be established that allow able-bodied siblings and young people with disabilities to participate in the same activities.

Paraphrenia – current psychopathological and diagnoses landmarks

E. Lukacs*, A. Nirestean, L. M. Grebenisan, A. Sima Comaniciu and E. G. Strete
Psychiatry, George Emil Palade University of Medicine, Pharmacy, Science, and Technology of Targu Mures, Targu Mures, Romania
*Corresponding author.
doi: 10.1192/j.eurpsy.2024.974

Introduction: Paraphrenia, classically known as a chronic delusional-hallucinatory psychosis, currently has an uncertain nosological status, not being included in DSM-5 either. It can be integrated into the group of schizophrenic and delusional psychoses, but with obvious distinctive attributes. Currently, in the context of the increase in the incidence of childhood autism, the psychopathological pictures from the spectrum of psychoses in adulthood are also diversifying. Paraphrenic clinical pictures retain their specificity regarding the subject’s functioning in life roles and the absence of cognitive impairment despite the absurdity of delusional ideas while maintaining a good insertion in reality.
Objectives: We refer to patients who can be classically classified in the diagnosis of paraphrenia, with the aim of bringing back into question the validity and authenticity of this nosological entity.
Methods: The case descriptions aim to highlight the common clinical-evolutionary attributes and the distinctive ones between paraphrenia and other schizophrenic and delusional psychoses, emphasizing the differentiations corresponding to the involvement of personality and the ability to function in life roles.
Results: It is confirmed that in the case of subjects who can be classified as paraphrenic, fundamental personality structures are preserved, a good adaptation in roles with insignificant cognitive deterioration phenomena, a well-preserved insight but with a high potential of unpredictability so characteristic of the world of psychoses.
Conclusions: We believe that paraphrenia remains a psychopathological and clinical entity within which, although opposites coexist, the reporting and adaptation to objective reality is preserved - thanks to “double accounting”. From this perspective, paraphrenia confirms its distinct nosological status.

Sex differences in diagnostic stability in first episode psychosis after 1-year follow-up

B. Jiménez-Fernández^{1*}, A. Toll-Privat^{1,2}, D. Bergé-Baquero^{2,3,4}, N. V. Motta-Rojas¹, M. Delgado-Marí¹, T. Legido-Gil^{2,3,4}, L. Martínez-Sarduni^{3,4}, T. Legido-Gil^{3,4}, J. Cuevas-Esteban¹ and A. Mané-Santacana^{3,4,5}
¹Psychiatry, Hospital Universitari Germans Trias i Pujol, Badalona; ²Centro de Investigación Biomédica en Red Salud Mental (CIBERSAM), Madrid; ³Institut de Neuropsiquiatria i Addiccions (INAD), Parc Salut Mar; ⁴Fundació Hospital del Mar Medical Research Institute (IMIM) and ⁵Centro de Investigación Biomédica en Red Salud Mental (CIBERSAM), Barcelona, Spain

*Corresponding author.
doi: 10.1192/j.eurpsy.2024.975

Introduction: Diagnostic stability is a controversial issue in first episode psychosis (FEP) due to heterogenous symptoms and unclear affective symptoms. Differencing affective and non-affective psychoses is important as treatment strategies are different. Initial affective symptomatology has low specificity for predicting the subsequent diagnosis of affective psychosis. Sex has proven to be relevant for clinical and functional outcomes but it remains unclear how sex may contribute to diagnosis switch of FEP.
Objectives: To determine the role of sex in diagnostic stability in a sample of FEP after 1-year follow-up.
Methods: Diagnoses of FEP patients from Hospital del Mar of Barcelona were assessed at baseline and 1 year after. Univariate analyses was performed for all diagnoses and dichotomic variable (affective/non-affective). Logistic regression model was performed to know which variables predict diagnosis switch.
Results: 256 patients were enrolled. No differences were found at baseline between completers and non-completers (**Table 1**). No significant differences between men and women at baseline diagnosis were found, neither all diagnoses (p=0.274) nor the dichotomic variable affective/non-affective (p=0.829) (**Table 2AB**). Significant differences were found at 1-year follow-up between men and women, for all diagnoses (p=0.043) and the dichotomic variable (p=0.039). Sex was the only variable that predicted diagnosis switch (**Figure 1**), PANSS, CDSS, YMRS, GAF and cannabis did not.

Table 1. Baseline characteristics of participants

	Completers (n=188)	Non-completers (n=68)	p
Women (n, %)	71 (37.8)	30 (44.1)	0.111
Age (M, IQR)	24 (20-28)	22 (20-28)	0.899
Cannabis use (M, IQR)	5.5 (0-18)	7 (0-21)	0.231
DUP (M, IQR)	45 (12.5-130)	36 (11.25-115.75)	0.213
PANSS (m, sd)	44.55 (10.17)	40.93 (10.42)	0.761
CDSS (M, IQR)	2 (0-7)	3 (0-5.5)	0.199
YMRS (m, sd)	19 (9.64)	17.6 (9.15)	0.845
GAF (M, IQR)	30 (25-50)	30 (25-35)	0.114

Impulsivity: A Dimensional Perspective in PD and ED. Comparison of Results in a Case-Control Study.

M. Pérez-Lombardo^{1,2,*}, Í. Alberdi-Páramo^{1,2}, W. Ayad-Ahmed^{1,2}, J. L. Carrasco-Perera^{1,2} and M. Díaz-Marsá^{1,2}
¹Psiquiatría, Hospital Clínico San Carlos and ²Psiquiatría y Medicina Legal, Universidad Complutense de Madrid, Madrid, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2024.976

Introduction: Personality Disorders (PD) - specifically Borderline Personality Disorder (BPD), and certain Eating Disorders (ED) share common clinical features. One of these features is impulsivity, studied individually in each diagnostic group, and scarcely used to encompass specific profiles of these patients. Understanding the common clinical variables of this patient population would facilitate therapeutic efforts and enable greater precision regarding the prognosis of these patients.
Objectives: This study aims to study impulsivity in a group collectively formed by BPD and ED, compared to a control group, in contrast to the individualized study approach typically conducted in the literature.

Methods: A cross-sectional descriptive study is conducted to assess impulsivity as a common diagnostic variable in a group of PD and ED in comparison with a healthy control group. The sample was collected between 2016 and 2019 at the Hospital Clínico San Carlos, totaling 108 subjects.
Results: A statistically significant difference is observed ($p<0.005$ in all scales) in total impulsivity, cognitive impulsivity, motor impulsivity, and unplanned impulsivity in the cases group comprising patients diagnosed with PD and ED, compared to the control group from the general population.
Conclusions: Impulsivity is closely related to the concept of borderline personality disorder. This analysis also includes eating disorders, with the difference from the control group still statistically significant. The presence of common clinical variables in these groups (PD and ED) may have clinical and therapeutic implications that differ from those pursued thus far. This allows moving away from the categorical model and understanding these disorders from a more enriching and advanced dimensional perspective.”

EPV0221

Non-Standard Diagnostic Assessment reliability in psychiatry: A study in a Brazilian outpatient setting using Kappa

H. Rocha Neto¹, D. Telles-Correia^{1*}, L. Koiller² and M. Cavalcanti²
¹Psiquiatria, Faculdade de Medicina de Lisboa, Lisbon, Portugal and ²Programa de Pós Graduação em Psiquiatria e Saúde Mental, Universidade Federal do Rio de Janeiro, Rio de Janeiro, Brazil
*Corresponding author.
doi: 10.1192/j.eurpsy.2024.977

Introduction: The use of Structured Diagnostic Assessments (SDAs) is a solution for unreliability in psychiatry and the gold standard for diagnosis. However, except for studies between the 50s and 70s, reliability without the use of Non-SDAs (NSDA) is seldom tested, especially in non-Western, Educated, Industrialized, Rich, and Democratic (WEIRD) countries.
Objectives: We aim to measure reliability between examiners with NSDAs for psychiatric disorders.
Methods: We compared diagnostic agreement after clinician change, in an outpatient academic setting. We used inter-rater Kappa measuring 8 diagnostic groups: Depression (DD: F32, F33), Anxiety Related Disorders (ARD: F40–F49, F50–F59), Personality Disorders (PD: F60–F69), Bipolar Disorder (BD: F30, F31, F34.0, F38.1), Organic Mental Disorders (Org: F00–F09), Neurodevelopment Disorders (ND: F70–F99) and Schizophrenia Spectrum Disorders (SE: F20–F29) (Check table 1 about diagnosis hierarchy and observed frequency in sample). Cohen’s Kappa measured agreement between groups, and Baphkar’s test assessed if any diagnostic group have a higher tendency to change after a new diagnostic assessment. This research was approved by IPUB’s ethical committee, registered under the CAAE33603220.1.0000.5263, and the UTN-U1111-1260-1212.
Results: We analyzed 739 reevaluation pairs, from 99 subjects who attended IPUB’s outpatient clinic. Overall inter-rater Kappa was moderate, and none of the groups had a different tendency to change (Check table 2 for diagnostic change distribution). Our

tests achieved the followinf results: Cohen Kappa 0.70, IC: 0.66–0.74; Weighted Kappa 0.72, IC:0.72 – 0.72; Bhapkar Test $X^2 = 5.98$, Df = 7, P-value = .55; Achieved Power (w=0.1): 0.93

Table 2 Agreement between examiners for eight diagnostic groups

	ARD	BD	DD	DRD	ND	Organic	PD	SSD
ARD	39	3	9	0	2	0	3	3
BD	1	154	7	3	2	2	4	10
DD	9	10	71	0	0	2	5	9
DRD	0	2	0	4	0	0	0	2
ND	1	2	1	0	51	1	1	6
Organic	0	1	0	0	3	20	0	5
PD	4	2	1	1	0	0	33	3
SSD	5	20	11	2	8	5	4	192

Conclusions: NSDA evaluation was moderately reliable, but the lack of some prevalent hypothesis inside the pairs raised concerns about NSDA sensitivity to some diagnoses. Diagnostic momentum bias (that is, a tendency to keep the last diagnosis observed) may have inflated the observed agreement.

Exploring the connections between psychiatric disorders and climate change

I. Marinić* and L. Mužinić Marinić

Clinic for Psychiatry, University Hospital Dubrava, Zagreb, Croatia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.978

Introduction: Considering the increased occurrence of climate changes in the world and their consequences on human health and quality of life, there is an increase in psychiatric disorders, including anxiety disorders, mood disorders, and stress related disorders caused by climate changes.

Objectives: To explore the connections between psychiatric disorders and certain types of climate change.

Methods: Data from research related to climate change and its impact on mental health are presented.

Results: Research indicates an increase in psychological disorders related to climate change from several diagnostic categories, consequently to the acute and long-term effects of climate changes, depending on the type of climate event, individual sensitivity, socioeconomic conditions, community support and assistance, and response to therapeutic interventions.

Conclusions: In addition to raising awareness of the impact of climate change on psychological health, it is important to develop strategies for providing psychological and psychiatric assistance, both immediately after a climate event and during long-term exposure to adverse climate conditions, especially for vulnerable groups.

The Psychosocial Impact of Climate Change and natural disasters

D. B. Ghosh Dastidar

Psychiatry, Calcutta National Medical College, Kol, India

doi: 10.1192/j.eurpsy.2024.979

Introduction: In this study we have studied the impacts of natural disaster yash on the development of PTSD in a rural hamlet of West Bengal.

Objectives: Correlation of natural calamity and trauma ie post traumatic stress disorder in exposed population.

Methods: Setting of the study was a relief camp operated for victims of climate change and natural disasters ie cyclone yash 2021.Tool for data collection - PCL 5 questionnaires, socio demographic pro forma, data was analyzed by using statistical SPSS.

Results: Analysis shows that there is statistical correlation between post traumatic stress disorder and subjects exposed to climate change events such as cyclone Yash.

PCL-5 cut-off score between 31-33 is indicative.

Conclusions: Our study clearly demonstrates the impact of climate change and natural disasters on the development of post traumatic stress disorder in the study group.

EPV0226

Eco-anxiety, how can the awareness on fighting global warming is becoming a mental health problem

M. Barbosa* and A. R. Fonseca

SPSM, Centro Hospitalar de Leiria, Leiria, Portugal

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.980

Introduction: Although the issue of climate change usually brings thoughts of environmental impact and physical health concerns to our consciousness, climate change also affects people’s mental health. Nowadays there is an emerging condition about climate change anxiety (CCA), defined as negative responses associated with global warming, with apprehension and stress related to the anticipation of threats to the ecosystem and our species. It may include cognitive, emotional, and behavioral responses, for example, persistent worries, psychological distress, or sleep difficulties related to long-term consequences of climate change, and can result in functional impairment.

Objectives: A literature review to analyse the evidence, to be aware of individuals overconcerned about global warming, bring awereness and promote an appropriate seek of professional help when needed

Methods: Using the Medline database through the Pubmed search engine was used, with the keywords: “climate change anxiety”, “eco-anxiety”.

Results: Despite the lack of studies, CCA affects a substantial proportion, especially the younger population, aged from 16 to 25 years old worldwide. As a result of ecoanxiety, people are becoming anxious about their future and the future of the planet

as we currently know it, the terrifying and at some extent uncertainty of it. It is documented the importance of green and blue spaces (water places) specially in urban areas for mental wellbeing – as our environment is quickly changing with the global warming, the reduction/disappearing of these areas are ongoing; besides this direct consequence, the disruption of these places results in feelings of loss due to changes to personally significant places a phenomenon known as ‘ecological grief’. Additionally, the occurrence of natural disasters like heatwaves, hurricanes, flooding, wildfire, and drought, raising concern and the socially-mediated impacts of forced migration and conflict caused by it. Self-reported presentations may include panic attacks, insomnia, obsessive thinking, and/or appetite changes caused by environmental concerns. If prolonged symptoms, depressive, anxious disease, post-traumatic stress disorder, among others can develop.

Conclusions: To reduce eco-anxiety individuals can take steps to reduce their carbon footprint, engage in activism and advocacy, bringing more awareness to the subjects and thus taking measures to mitigate the effects of climate change and protect the environment. It's equal important to consider and address the mental health impacts of climate change, this additionally includes providing adequate emotional and psychological support to those affected.

Disclosure of Interest: None Declared

EPV0227

Impact of mean monthly temperature on psychiatric admissions: data from an acute inpatient unit

N. Rizzo Pesci^{1*}, S. Peracchia¹, E. Teobaldi², G. Maina^{1,2} and G. Rosso^{1,2}

¹Department of Neurosciences “Rita Levi Montalcini”, University of Turin, Turin and ²Unit of Psychiatry, San Luigi Gonzaga University Hospital, Orbassano (TO), Italy

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.981

Introduction: Psychiatric disorders are large contributors to the global disease burden and their prevalence is increasing. Global climate is also facing changes, including a rise in temperatures. Many clinical conditions are affected by meteorological factors and there are numerous reports on the effect of climate changes on such conditions. Psychiatric disorders are also influenced by climatic factors but the literature on the effects of climate changes on mental health is limited.

Objectives: The aim of this study is to investigate the impact of rising temperatures on the risk of acute exacerbation of psychiatric disorders.

Methods: Data were collected retrospectively for a total of 139 months, *i.e.* from January 2012 to July 2023. Recordings of mean monthly temperatures were obtained from registries of the meteorological station of the Department of Physics of the University of Turin. For each of the 139 months, deviations from the average temperature of that month of any year were computed (ΔTm). Anonymised socio-demographic and clinical data on patients admitted during the observation period to the acute psychiatric unit of San Luigi Gonzaga University Hospital (Turin, Italy) were extracted from the hospital registry. Linear regression analyses were used for statistical analyses.

Results: A total of 5420 admissions to our psychiatric ward were recorded over the observation period. Monthly deviations from average temperature and monthly number of admissions were

directly correlated, with regression coefficient 1.803 ($P = 0.0048$) (Fig.1A). Linear regression analysis was performed between ΔTm and number of admissions according to diagnostic group. The regression coefficient was 0.1336 ($P=0.5334$) for admissions of patients with schizophrenia and related disorders (SCZ) (Fig.1B), 0.4575 ($P=0.0295$) for bipolar disorders (BD) (Fig.2A) and 0.3381 ($P=0.0382$) for major depressive disorder (MDD) (Fig.2B).

Image:

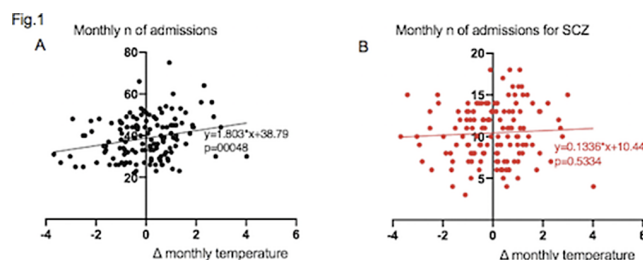

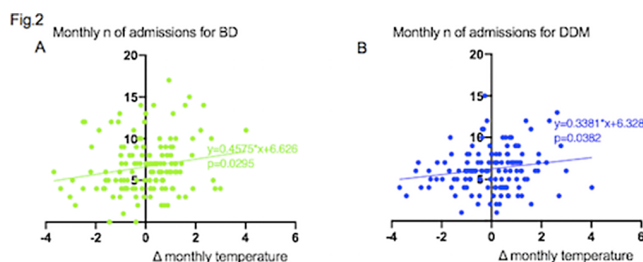

Image 2:

Conclusions: These results confirm the impact of meteorological factors on mental disorders. In particular, we observed a positive correlation between monthly temperature and the number of admissions to our acute inpatient unit. The correlation was significant when taking into consideration admissions for exacerbation of bipolar disorder and major depressive disorder, but not when considering admissions for schizophrenia. This highlights the importance of climatic factors especially in mood disorders, provides new insights into their etiopathological mechanisms and provides information that can be implemented for follow up and relapse prevention.

The role of the community in providing psychological and social support after catastrophic events

L. Mužinić Marinić* and I. Marinić

Clinic for Psychiatry, University Hospital Dubrava, Zagreb, Croatia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.982

Introduction: Natural disasters are a risk for significantly disrupting the quality of life as a result of changes in life circumstances they bring, such as endangering health, property, existential issues, and can lead to social exclusion. They can also affect mental health and increase the risk of developing psychiatric disorders.

Objectives: To show the impact of natural disasters on the psychosocial functioning of people in the affected area and the importance of adequate preparedness of the social community, including mobile teams, with an emphasis on providing somatic, psychological, and social support.

Methods: Data were collected from research on the consequences of major natural disasters and providing psychological, psychiatric and social support to the affected population.

Results: After natural disasters, there are significant changes in social functioning with the possible development of mental health problems. It is especially evident in sudden and intense catastrophic events.

Conclusions: In addition to the immediate provision of psychiatric and psychological assistance to victims, people who have experienced a catastrophic event need to be provided with immediate and continuous assistance and socioeconomic support, due to the need for better social inclusion and return to their role in the community.

Nomophobia, phubbing and social phobia in Portuguese young adults and adults

B. R. Maia^{1*} and D. Sousa²

¹Universidade Católica Portuguesa; Center for Philosophical and Humanistic Studies and ²Universidade Católica Portuguesa, Braga, Portugal

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.983

Introduction: To our knowledge there is no study exploring the interrelationship between nomophobia, phubbing and social phobia in Portuguese young adults and adults.

Objectives: To explore the nomophobia, phubbing and social phobia levels, the interrelationship between these three constructs, in a sample of Portuguese young adults and adults.

Methods: 316 subjects, with a mean age of 25.71 years old ($SD = 8.231$; range 18 - 59) fulfilled a sociodemographic questionnaire, and the Portuguese validations of the Nomophobia Questionnaire, the Phubbing Scale and the Social Interaction and Performance Anxiety and Avoidance Scale.

Results: All the subjects presented nomophobia (100%, $n = 316$), with 62% ($n = 196$) presenting a moderate risk level and 22% ($n = 69$) an higher risk level. The mean of the 'total phubbing score' was of 21.50 ($DP = 5.50$) and 'smartphone obsession' was the phubbing subscale with an higher score ($X = 12.81$, $DP = 3.50$). The mean of the total nomophobia was of 80.0 ($DP = 22.83$) and 'not being able to communicate' was the nomophobia subscale with an higher score ($X = 24.75$, $DP = 9.95$). Considering social phobia scale, the mean of the 'anxiety/distress' subscale was of 95.36 ($DP = 25.14$)

and of the 'avoidance subscale' was of 89.56 ($DP = 25.53$). Almost 22% ($n = 69$) of the subjects presented 'social anxiety' and 24% ($n = 76$) presented 'social avoidance', suggesting probable social phobia cases (higher than the proposed cut-off scores). Positive and significant correlations were found between all the nomophobia and phubbing subscales (ranging from .30** to .61**). Positive and significant correlations, mostly with low magnitude, were found between nomophobia and social phobia subscales (ranging from .03** to .22**), except for 'social avoidance' subscale, which correlation was negative (-.021*). Females presented higher levels of nomophobia ($Md = 176.28$) and phubbing ($Md = 167.22$) than males ($Md = 124.73$, $U = 7301.500$, $p < .001$; $Md = 141.93$, $U = 9475.500$, $p = .019$, respectively). Total social phobia scores and nomophobia (not being able to access information and giving up convenience subscales) were significantly higher in young adults. **Conclusions:** Nomophobia, phubbing and social phobia are significantly intercorrelated. Future longitudinal studies are needed to clarify nomophobia and phubbing etiology. The level of nomophobia (100%) found in this sample is specially worrying.

Addressing the Comorbidity Between Epilepsy and Psychiatric Disorders

A. H. I. Abu Shehab^{1*}, T. Simona², U. Ion³, D. C. Voinescu⁴, C.-F. Buci⁵ and A. Ciubară⁶

¹Psychiatry Department, "Elisabeta Doamna" Psychiatric Hospital, Galati; ²Psychiatry Department, Carol Davila University of Medicine and Pharmacy, Bucharest; ³Psychiatry Department, University of Medicine and Pharmacy of Craiova, Craiova; ⁴Rheumatology department, "Dunărea de Jos" University - Faculty of Medicine and Pharmacy, Galati; ⁵public health and management, University of Medicine, Pharmacy, Science and Technology of Târgu Mureș, Târgu Mureș and ⁶Psychiatry Department, "Dunărea de Jos" University - Faculty of Medicine and Pharmacy, Galati, Romania

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.984

Introduction: The intricate and multifaceted nature of the link between epilepsy and psychiatric diseases is evident. Patients diagnosed with epilepsy frequently exhibit concurrent psychiatric illnesses, including but not limited to depression, anxiety, psychosis, and attention-deficit disorders. Gaining a comprehensive understanding of the fundamental mechanisms and implementing efficacious ways to effectively address this co-occurring medical condition is crucial in order to achieve the most advantageous results for patients.

Objectives: The objective of this study is to examine the frequency, neurobiological bases, and consequences for treatment of psychiatric comorbidities in patients diagnosed with epilepsy. The study aims to offer a thorough understanding of the subject and promote interdisciplinary collaboration.

Methods: A systematic review of literature was conducted, focusing on clinical studies, neuroimaging findings, and neurochemical changes in patients with both epilepsy and psychiatric disorders. Additionally, best-practice recommendations for the clinical management of this patient population were identified.

Results: The results suggest that the coexistence of epilepsy and psychiatric diseases may be affected by neuroinflammation, abnormalities in neurotransmitters, and shared genetic factors. In addition, the implementation of integrated therapy techniques that include both neurological and psychological components has demonstrated encouraging findings in enhancing patient outcomes.

Conclusions: The identification and proficient management of psychiatric comorbidities in individuals with epilepsy are of utmost significance. The establishment of interdisciplinary collaboration between neurologists and psychiatrists, supported by continuous research, is necessary in order to provide comprehensive treatment and enhance the overall well-being of individuals affected by these conditions.

Impact of addictive comorbidity on bipolar disorder type I

A. Adouni*, Y. zgueb, F. ben othman, I. bouguerra and R. jomli
psychiatry department A, Razi hospital, Manouba, Tunisia
*Corresponding author.

doi: 10.1192/j.eurpsy.2024.985

Introduction: Among all mental pathologies, bipolar disorder (BD) is the one in which addictive comorbidity is most frequent. Recent studies suggest that this comorbidity has harmful consequences, threatening patients' quality of life.

Objectives: Describe addictive comorbidity and determine its prevalence in a population of patients with BD I.

Study the impact of addictive comorbidity on the evolution of BD I.

Methods: A cross-sectional, comparative study was conducted over a six-month period in the after-care unit of psychiatric wards at Razi Hospital, including patients treated for BD I according to DSM 5 criteria and stable on treatment.

The study included two phases: first, sociodemographic, clinical and therapeutic characteristics were collected using a pre-established form. The CAGE, DUDIT and MARS scales, validated in Arabic, were then administered.

Results: We included 100 patients (60 men and 40 women) with a mean age of 43.55 years.

Substance use disorder (SUD) was reported in 31% of our population; 22 alcohol users with a mean CAGE score of 1.23 (0-3), while psychoactive substance use was reported in 19 patients with a mean DUDIT score of 13.37 (0-28).

Forensic history was higher in the group of patients with comorbid SUD ($p < 0.001$). Poor compliance with treatment and irregular follow-up were also significantly more associated with addictive behavior, respectively $p = 0.008$ and $p = 0.048$.

We found no association between SUD and suicidal behavior or evolutionary symptoms of the disorder.

Conclusions: SUD are generally factors in the poor prognosis of BD. It is important to identify the determinants of this comorbidity, so that these risk factors can be appropriately targeted through appropriate therapeutic interventions and thus limit these negative consequences.

The impact of the severity of Obstructive Sleep Apnea syndrome on quality of life

A. Fki^{1*}, A. Ben lazreg², R. Bouchech³, R. Ben cheick³ and G. Sakly³

¹occupational medicine department, Sahloul university hospital;

²Faculty of Medicine and ³department of Neurophysiology, Sahloul university hospital, Sousse, Tunisia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.986

Introduction: The negative impact of obstructive sleep apnea syndrome (OSA) on the quality of life of affected individuals is one of the serious consequences of this pathology. Consideration of this quality of life as one of the therapeutic objectives is essential.

Objectives: to evaluate the impact of the severity of OSA on quality of life in affected patients

Methods: We conducted a cross-sectional study involving 40 patients diagnosed with OSA by polysomnography in the Sleep unit, department of Neurophysiology at Sahloul university hospital in Sousse, Tunisia. This study was based on a generic questionnaire (SF-12) to assess the quality of life.

Results: The mean age was 49.7 ± 7.87 years with a sex ratio of 1.10. The mean apnea-hypopnea index (AHI) was 29.72. OSA was mild, moderate and severe in 40%, 22.5% and 37.5% of cases respectively. The majority of our patients had an impaired quality of life with an average score of 42.78. There was a positive linear relationship between physical and mental components of the SF-12 and AHI ($p = 0.026$ and $p = 0.019$ respectively). Mental component of the SF-12 was significantly associated with treatment with CPAP (continuous positive airway pressure) ($p = 0.014$).

Conclusions: Our study has shown that the severity of OSA has an impact on different domains of quality of life. The management of this disease should not be limited to controlling the disease but should aim for overall patient satisfaction.

EPV0236

Thyroid dysfunction: an unlikely culprit behind psychotic symptoms

A. S. Pires*, M. Pires, I. F. Vaz, S. Mouta, B. Jesus, J. C. Mendes, S. Castro and D. Cruz e Sousa

Department of Psychiatry and Mental Health, Local Health Unit, Guarda, Portugal

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.987

Introduction: A number of studies have demonstrated that hyperthyroidism increases the prevalence of psychiatric disorders and the likelihood of depressive symptoms, anxiety and hypomania. Apathetic hyperthyroidism is a syndrome, which presents with symptoms of depression, apathy, somnolence or pseudodementia in the absence of the usual symptoms and signs of hyperthyroidism. This condition is more common in the elderly although it has also been described in young adults and adolescents.

In the majority of cases, treatment of hyperthyroidism results in an improvement in neuropsychiatric manifestations in parallel with

an improvement of psychical (somatic?) symptoms and psychotropic medication is deemed unnecessary.

Approximately one-third of patients with Graves' hyperthyroidism are prescribed psychotropic drugs. Sometimes to treat mental symptoms like psychosis or severe agitation, sometimes to treat mental symptoms remaining after amelioration of hyperthyroidism, and sometimes when the diagnosis of Graves' hyperthyroidism has been missed and the patient is treated as having a primary psychiatric disorder.

Objectives: To present a case of a patient with neuropsychiatric symptoms caused by thyroid dysfunction.

Methods: Case presentation and non-systematic review of existing literature on Pubmed using the following keywords: hyperthyroidism, psychiatric disorders, psychiatric symptoms, depression, psychosis.

Results: We report the case of a 21-year-old female without history of psychiatric illness who presented to the emergency department with somnolence, apathy, cognitive impairment (answering "I don't know" to most questions), poverty of speech, abulia, perplexity and delusional belief of ruin, in addition to physical symptoms namely alopecia and weight loss. According to her father, she was very active and dynamic person until two days prior, when he started noticing growing apathy, leading to job absenteeism. Urine analysis for elicit drugs was negative.

Investigation for organic disease was undertaken and the blood analysis revealed overt hyperthyroidism.

She was initially treated with aripiprazol. After thyroid dysfunction was identified, she was evaluated by an endocrinologist and started treatment with tiamazol and propranolol, presenting gradual remission of the psychiatric changes. Aripiprazole was discontinued and she was reevaluated in psychiatry consultation after about a month, with complete remission of psychiatric manifestations and normalized thyroid function.

Conclusions: Neuropsychiatric manifestations of thyroid dysfunction are often misdiagnosed as a primary psychiatric disorder. It is necessary to optimize the medical management of these patients in whom the psychiatric symptoms masks a curable organic cause.

Substance use, anxiety and depression among Tunisian college students

E. Bergaoui*, A. Bouallagui, M. Moalla, M. Zrelli, G. Amri and R. Ghachem

Psychiatry B, Razi hospital, Manouba, Tunisia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.988

Introduction: Substance use and mental health symptoms are frequent among college students worldwide.

Objectives: This study examined the prevalence of substance use, anxiety and depression among college students and their associated factors.

Methods: A total of 115 college students aged between 19 and 30 years from different universities completed a self-reported online survey during March 2023. The questionnaire included items on demographic information, substance use and the Hospital Anxiety and Depression scale.

Results: Women represented 70% of our population. The average age was 25.1 ± 3.5 years.

Twenty-nine (25,2%) were smokers, thirty-three students (28,7%) consumed alcohol and nine students (7,8%) used cannabis. Five students used ecstasy. Four students used LSD. Three students used cocaine.

Average HADS anxiety score was 7.96 ± 4.26 . Twenty-one students (18,3%) had mild anxiety symptoms. Thirty-three students (28,7%) had moderate to severe anxiety symptoms.

Average HADS depression score was 8.59 ± 4 . Thirty-one students (27%) had mild depressive symptoms. Forty-one (35,7%) had moderate to severe symptoms of depression.

Smoking was unrelated to gender, age, field of studies, economic or social status, family or personal history. It was related to drinking and doing other activities or hanging out with friends ($p < 0.001$). Drinking alcohol was related to the field and year of study, age, hanging out with friends and other substance use ($p < 0.001$). Using cannabis was related to psychiatric family history ($p < 0.05$). Using one substance was related to using other substances ($p < 0.05$). Anxiety was related to gender ($p < 0.001$). Depression levels were related to socio-economic status ($p = 0.041$). Poly-use was more frequent among older students ($p = 0.003$) and medical students ($p = 0.031$). Substance use was unrelated to anxiety and depression levels.

Conclusions: Tunisian universities should consider detecting students with substance and mental health problems and offer them support and treatment if needed.

EPV0239

Epilepsy and psychiatric pathologies: A study of a case series

E. Smaoui*, M. Bouhamed, D. Mnif, F. Cherif, I. Feki and J. Masmoudi

Psychiatry department, CHU Hédi Chaker, Sfax, Tunisia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.989

Introduction: Psychiatric pathologies are more common in people with epilepsy than in the general population and have a negative impact on the quality of life of these patients.

Objectives: The objective of this work is to illustrate, through a series of cases, the complex relationship between epilepsy and psychiatric pathologies.

Methods: We report the cases of four patients with different psychiatric pathologies associated with epilepsy admitted to the psychiatry department of Hedi Chaker Sfax. We collected the clinical characteristics of these patients based on their medical files.

Results: The patients were aged 64, 45, 38 and 26 respectively. The first patient had a late-onset vascular epilepsy following the psychiatric pathology onset by 20 years. In the remaining cases epilepsy onset preceded the psychiatric pathology by 6, 3 and 1 year respectively. The aetiology of epilepsy was juvenile myoclonic epilepsy, and idiopathic in 2 cases. The psychiatric pathologies were schizophrenia, obsessive compulsive disorder with schizoid personality, schizoaffective disorder in the bipolar type and mild intellectual

disability with histrionic personality, respectively. Familial history of psychiatric disorders was found 2 patients and of epilepsy in one.

Conclusions: Epilepsy and psychosis have a complex and bidirectional relation. Not only are patients with epilepsy at a greater risk of developing a psychotic disorder, but patients with a primary psychotic disorder are also at greater risk of developing epilepsy. The fact that the association between these pathologies is more frequent than expected should prompt more in-depth studies concerning the underlying etiopathogenic mechanisms to improve their management.

Disclosure of Interest: None Declared

Depression, Ulcers and Confusion – A Clinical Case of Behçet's Disease with Psychiatric Presentation

F. M. H. Agostinho*, M. B. Resende, M. J. Amaral, R. Nogueira, V. P. Falcão and D. Cotovio

Psychiatry, Hospital Beatriz Angelo, Lisbon, Portugal

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.990

Introduction: Behçet's disease, a rare autoimmune disorder, can present a challenging diagnostic puzzle, particularly when neuropsychiatric symptoms take the forefront. In this case study, we delve into the diagnostic process of a 43-year-old patient without prior psychiatric history, who initially presented with depressive and catatonic symptoms. The trajectory from psychiatric admission to a final diagnosis of Behçet's disease with neuropsychiatric involvement underscores the importance of interdisciplinary collaboration and the consideration of rare diseases in psychiatric assessment. Clinical remission was achieved with immunosuppressive therapy.

Objectives: Presentation of a clinical case of Behçet's disease with neuropsychiatric manifestations.

Methods: Review of the patient's clinical data in SOARIAN platform and research on UptoDate and Pubmed using the terms "Catatonia," "Behçet disease," "Neuro-Behçet," and "Psychiatry."

Results: We present a clinical case of a 43-year-old patient, originally from India, not fluent in Portuguese or English, with no prior psychiatric history, who presented to the emergency department exhibiting mutism and was admitted to the psychiatry department with the diagnostic hypothesis of depressive episode with psychotic and catatonic symptoms. During hospitalization, severe vitamin deficiencies, gastrointestinal symptoms (vomiting, abdominal pain, and hematochezia), and gynecological symptoms (dyspareunia and vaginal discharge) were observed. From a psychiatric perspective, in addition to depressive and psychotic symptoms, atypical symptomatology incongruent with the initial diagnosis was identified, raising suspicion of an "organic" disease. There was an atypical fluctuation in symptoms, with periods of severe behavioral disorganization interspersed with periods of apathy and psychomotor retardation, significant alterations in attention and memory, and executive deficits. Additionally, there was a poor response to psychiatric medication and electroconvulsive therapy. A colonoscopy revealed ulcers at the ileocecal valve, and gynecological lesions suggestive of a vasculitic process were observed. Autoimmunity testing showed positivity for HLA B51/52. Given the

neuropsychiatric, gastrointestinal, and gynecological manifestations, along with suggestive autoimmunity, the diagnosis of Behçet's Disease with neurological involvement was established. Clinical remission was achieved only with immunosuppressive therapy. The case is enriched by the complex diagnostic journey, multiple complications encountered (including valproic acid-induced encephalopathy), and the challenges faced in treating neuropsychiatric manifestations.

Conclusions: This clinical case exemplifies the challenges in diagnosing a systemic disease with primary psychiatric presentation, as well as the therapeutic success resulting from multidisciplinary collaboration in a public hospital.

EPV0241

Comorbidity of mental disorders in synthetic cannabinoids abuse: clinical dynamics, behavior, adaptation

G. Selivanov^{1,2,3,4*} and N. Bokhan^{1,5}

¹Mental Health Research Institute, Tomsk; ²Saint Petersburg University of State Fire Service of Emercom of Russia; ³Psychiatric Hospital of St. Nicholas the Wonderworker; ⁴Rehabilitation Treatment Center "Child Psychiatry, St. Petersburg and ⁵Siberian State Medical University, Tomsk, Russian Federation

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.991

Introduction: The study of the phenomenon of deformation of mental disorders, clinical dynamics, behaviors, and adaptations in case of abuse of synthetic cannabinoids is of relevance.

Objectives: To study the phenomenon of deformation of mental disorders, clinical dynamics, behaviors, and adaptations in case of abuse of synthetic cannabinoids

Methods: Catamnestic, clinical-psychopathological methods (PANS, SANS, CGI, MMPI, CGI, STAI, LSI, TPA, ICD-10), statistical (Python 3.11.0).

Results: 291 men (age from 18 to 35 years) were examined: 240 - F12.2xx, of which 98 - F60.xx-F62.xx, 142 - F20.xx and 51 - F20.xx without substance abuse. The study took place from 2018 to 2023 based on psychiatric institutions of the Russia, Tomsk region, St. Petersburg, Noyabrsk and Nizhnevartovsk.

Conclusions: The phenomenon of abuse of synthetic cannabinoids is a factor in the deformation of mental disorders. Persistent exogenous visual and delusional disorders contribute to the symptoms of exacerbations of schizophrenia; schizophrenic symptoms are included in psychotic episodes in personality disorders. In remission of schizophrenia, there is a quasi-adaptation from socio-professional environments, mostly addictive and criminalized, a pronounced smoothing of emotional impoverishment, a stigmatizing symptom is mainly a volitional defect, as well as frequent rehospitalizations not indirectly related to drugs. In remissions of drug use in patients with personality disorder, persistent schizophrenia of behavior. In patients with schizophrenia and patients with personality disorders, there is a distortion of behavior with a predominance in patterns of inclinations to delict, nonconformity, isolation in an addictive environment, suspiciousness. Drug abuse may initiate auto-aggression predominantly in

individuals with personality disorders and to a lesser extent in patients with schizophrenia. True suicides in drug users include only episodes with depressive symptoms.

Anxiety disorder and depressive disorders in teens

I. Belabbes

arazi hospital, sale, Morocco
doi: 10.1192/j.eurpsy.2024.992

Introduction: Anxiety and mood disorders are frequent causes of consultation in child psychiatry. In pediatrics, they can be the cause of life-threatening or psychological complications, such as suicidal ideation, anxiety attacks, scarification or suicide attempts.

Objectives: Discuss the clinical and therapeutic features of anxiety-depressive syndromes.

Methods: We shed light on anxiety-depressive syndromes through the study of complex clinical cases encountered in child psychiatric hospitalization.

Results: We report a case series of 10 patients, the majority of whom were female. The age range was 12 to 17 years. Clinical features included emotional manifestations such as sadness, tantrums and anxiety, as well as cognitive symptoms such as memory and concentration problems, with dark or suicidal ideation, and occasional endangerment behaviors such as scarification or suicide attempts.

Treatments range from psychosocial interventions, including therapeutic mediation, psychotherapy and social support, to pharmacological treatment with antidepressants, hypnotics, neuroleptics and, rarely, mood regulators.

Conclusions: The frequency and severity of anxiety-depressive syndromes in the absence of adequate care underlines the importance of screening, early diagnosis and treatment of children with these disorders.

EPV0244

Adult Attention-Deficit/Hyperactivity Disorder and Borderline Personality Disorder: diagnostic and management challenges

M. Barbosa* and A. R. Fonseca

SPSM, Centro Hospitalar de Leiria, Leiria, Portugal
*Corresponding author.

doi: 10.1192/j.eurpsy.2024.993

Introduction: Borderline Personality Disorder (BPD) and Attention-Deficit/Hyperactivity Disorder (ADHD), relatively common psychiatric pathologies (5% and 1-2% respectively), share several characteristics, specially impulsivity and emotional dysregulation. With different therapeutic approaches, it is therefore important to distinguish the entities for a correct approach to the patient. Clinical evidence has also demonstrated high comorbidity between two entities, and therefore this recognition is of equal relevance.

Objectives: Analyze the clinical evidence, in order to better understand the dynamics between the two pathologies as comorbid or differential diagnosis, for an appropriate approach to the patient.

Methods: Authors used the Medline database through the Pubmed search engine, with the keywords: "PBP", "PHDA".

Results: These two pathologies share impulsive and spontaneous actions with poor thinking about the consequences; nonetheless, ADHD individuals tend to show this impulsivity by being more impatiente when they have to wait, talking over other people, interrupting others; on the contrary, in BPD impulsivity can be showed more as self-harm behaviors.

As for the emotional dysregulation, that both entities share, in the comorbid case it is known that it is the most severe form. This characteristic is part of the central characteristics of BPD where these individuals experience intense and unstable emotions. They have difficulty regulating their emotions which can lead to rapid changes in mood, and they report feelings of emotional emptiness and difficulty in establishing stable relationships. As for ADHD individuals, despite present, it's not a core symptom, as they have more control over their emotions, and have more adaptative cognitive strategies. Attention deficit can be a core symptom of a subtype of ADHD and has not yet been reported in patients with PBP, except in comorbid situations. According to studies, 30-60% of patients with PBP report and score on attention deficit scales. Truth is both entities have intellectual disfunctionalities.

Results of genetic studies are very inconsistent, however epigenetic research and reseach focusing on hypothetized vulnerability genes or sites have been promising.

Conclusions: A complete clinical history is particularly important in these cases and sometimes difficult, as so, clinicians should be aware to prevent misdiagnosis and provide the best care for both disorders and the comorbidity. Given that treatment differs between both pathologies, psychotherapy in BPD, and the multi-modal approach in ADHD, it is imperative to distinguish the two entities. In comorbid cases, a combination of the two therapies has demonstrated effectiveness but much more studies are needed.

"Unraveling the Diagnostic Dilemma: Unusual Presentation of Huntington's Disease with Predominant Psychiatric Symptoms and Late-Onset Motor Manifestations"

M. I. M. M. N. Ibrahim* and M. Iderapalli

Essex Partnership University NHS Foundation Trust, Basildon, United Kingdom

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.994

Introduction: Huntington's Disease is a neurodegenerative disease inherited in an autosomal dominant fashion. The underlying genetic defect is unstable CAG trinucleotide repeat expansion with a repeat length longer than 36 resulting in pathological aggregation of abnormal protein causing cell death.

The clinical symptoms encompass 3 main domains-motor, cognitive and psychiatric. The psychiatric symptoms often in atypical form appear decades before other symptoms causing significant impact on patient's functioning and quality of life.

Here, we discuss an unusual presentation of Huntington's Disease causing diagnostic dilemma.

Objectives: Case report discussing the unusual presentation of Huntington's Disease.

Methods: Case: Mr X is a 61 year old Caucasian male. He had an uneventful birth and early childhood attaining milestones appropriately. He experienced childhood adversity in the form of sexual abuse between ages 2-14 years. His mental health difficulties started following sexual abuse when he attempted to end his life by hanging and overdosing at age 15. He got married twice, both of which broke down. There is a history of significant alcohol abuse between ages 40-50. Following this, he had a myocardial infarction and a stroke requiring stenting.

He presented to Psychiatric Outpatient Services in 2011 with auditory hallucinations, social anxiety with panic attacks, OCD type rituals, claustrophobia and feeling hot all the time. He was started on an antipsychotic medication for psychosis, but clinically deteriorated. He started having anger outbursts, marching on the spot, and head banging. He was diagnosed with Huntington's Chorea in 2021 after he had developed chorea. He currently has low mood and is head banging for hours.

Results: Psychiatric symptoms in HD can span a variety of domains but most common are symptoms of frontal lobe dysfunction-disinhibition, poor attention, irritability, impulsivity and personality change. Apathy, emotional blandness and social withdrawal are also prominent features.

Mr X had strong family history of Paranoid Schizophrenia (aunt and cousin). There was no family history of HD. His mental health problems started early in life with DSH, Depression and Harmful use of Alcohol. He presented predominantly with psychotic symptoms like auditory hallucinations, social anxiety, paranoia. Motor symptoms started late which he incorporated into voluntary movements like head banging which made it difficult to differentiate from deliberate self harm.

Conclusions: Psychiatric symptoms constitute the core of HD. Studies have shown that though depression and personality change are typical of HD, there are number of other psychiatric symptoms that can impair quality of life. Early diagnosis and treatment of these symptoms will help patients and families to cope better with severe symptoms of this progressive disease.

EPV0246

Concurrent Gender Dysphoria/Incongruence and Autism Spectrum Disorder, a literature review

N. Clementi^{1,2,*}

¹General Adult Psychiatry/ Gender Identity Clinic, Royal Cornhill Hospital, NHS Grampian and ²University of Aberdeen, School of Medicine, Aberdeen, United Kingdom

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.995

Introduction: Several studies have found that ASD (Autism Spectrum Disorder) and GD (Gender Dysphoria by DSM-V)/GI (Gender Incongruence by ICD-11) tend to co-occur, and in recent years the interest and publications on this comorbidity has increased rapidly.

Objectives: To review the prevalence of ASD in individual with a diagnosis of GD/GI.

To better tailor and improve care offered in the National Health Service (NHS) Gender Identity Clinics (GICs) throughout the UK.

Methods: Systematic literature review was conducted via Pub Med, MEDLINE and PsycINFO by the author, for all English-language articles published between 2018 and 2023, containing keywords as ASD, GD (Gender Dysphoria), GI (Gender Incongruence), transgender, autistic traits, autism, gender diversity, gender variance.

Results: Rate of people with ASD appear to be higher in people accessing Gender Identity Clinics (GICs) than in the general population. Results from this literature review show increased prevalence of GD and GI in ASD population.

Conclusions: This comorbidity has highlighted the importance of better tailor transgender healthcare services for people with neurodevelopmental conditions and neurodiversity, to avoid delay in ASD individuals accessing care and gender affirming medical treatments. Services should strive to provide an effective and equitable service. It is also important to better identify potential barriers for ASD people in accessing gender care. Literature also shows the people with ASD have more difficulties in communicating and describing their gender narrative and to express their wishes for gender treatments. Symptoms including problems in communications and social skills, obsession and rigidity can also impact their assessment of GD/GI in gender identity services. Some studies showed that for individuals who have concurrent ASD and GD/GI, assessment in GICs may be extended to better review their wishes for gender identity and for gender affirming treatment. Further research is needed to better investigate and understand factors explaining the relationship between ASD and gender diversity. There is still limited research in the real life experiences of gender diverse and autistic people. There is also a need to improve Gender reassignment protocol nationally to better care for individual with ASD and GD/GI throughout GICs in the UK.

Osmotic demyelination syndrome (ODS), and psychiatric manifestations

P. Argitis^{1*}, A. Karampas², M. Peyioti¹, A. Goudeli¹, S. Karavia¹ and Z. Chavias¹

¹Psychiatric, General Hospital of Corfu, Corfu and ²Psychiatric, General Hospital of Ioannina, Ioannina, Greece

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.996

Introduction: Hyponatremia can be potentially fatal if it is not corrected immediately. The rapid correction of chronic hyponatremia can cause demyelinating brain lesions.

Objectives: A fifty-six year old female was brought to the emergency department of the psychiatric clinic by her daughter, with incomprehensible speech and psychomotor agitation. She was diagnosed several years ago with bipolar disorder, with valproic acid and quetiapine being her current medication. She has been living alone, in a small suburban city. Approximately twenty four hours

before her admission to the hospital she visited her daughter, which aligns with the onset of symptoms.

Methods: After both the brain CT scan and the lab results came back normal, the patient was admitted to the psychiatric clinic of the General Hospital of Corfu. On the fourth day of the patient's hospitalization - when both her speech and the psychomotor agitation showed signs of improvement- we were informed that three days before her admission to the clinic she visited the emergency department of another hospital where she was treated for hyponatremia. The patient's hyponatremia was corrected over the span of twelve hours by 35 mEq.

Results: After receiving this information, we ordered a brain MRI scan which revealed a central pontine myelinolysis. The result can explain the clinical symptoms that our patient showcased before her admission and could have been caused by the rapid correction of hyponatremia.

Conclusions: The patient's speech was fully restored after four weeks and there were no symptoms consistent with any psycho emotional disorder.

Disclosure of Interest: None Declared

EPV0248

QTc prolongation in patients hospitalized in enclosed psychiatric facilities in Corfu

P. Argitis^{1*}, A. Karampas², M. Peyioti¹, S. Karavia¹ and Z. Chavarras¹

¹Psychiatric, General Hospital of Corfu, Corfu and ²Psychiatric, General Hospital of Ioannina, Ioannina, Greece

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.997

Introduction: An undeniably significant amount of psychotropic medication can evidently affect the corrected QT (QTc) interval, which puts patients' lives at risk. More specifically, certain antipsychotic medication can increase the risk of QTc prolongation and by extension the risk of a potentially fatal arrhythmia or sudden cardiac death.

Objectives: Electrocardiograms (ECG) were contacted in one hundred and four (104) chronic patients, with psychosis, through out their hospitalization in several enclosed psychiatric facilities in Corfu. Almost the entirety of the patients along side their antipsychotic medication were also taking various other medication for their individual pathological issues. We observed any changes that might have occurred on the ECG in comparison with each patient's medication and it's potential effect on the QTc.

Methods: The measurements of the QT interval were made manually in lead V5 and the mathematical conversion was contacted using the Hodges correction formula.

Results: At least one ECG (n = 104) was performed. Among them 29,8% (n=31) had ECG abnormalities, including 13,5% (n=13) with a prolonged Qtc ($481.2 \pm 26,8$ ms). Covariates significantly associated with the QTc were gender (+17.2 ms if female, $p < 0.0001$) and age (+0.4 ms/year, $p = 0.0001$).

Conclusions: The QTc prolongation that was evident in a notable number of patients, emphasizes the importance of QTc monitoring in patients who are taking anti-psychotic medication. QTc prolongation risk factors should be assessed before the administration or prescription of any anti-psychotic medication.

Persistent Adult-Onset Attention-Deficit/Hyperactivity Disorder (ADHD) Manifesting as Occupational Impairment: Highlighting the Therapeutic Potency of Methylphenidate

P. S. Gopan

Psychiatry, Surabhi medical college, Siddipet, India

doi: 10.1192/j.eurpsy.2024.998

Introduction: This case study emphasizes the significance of considering unrecognized adult-onset ADHD, particularly in patients with chronic forgetfulness and occupational inefficiencies refractory to standard treatment options. The case outlined involves a 33-year-old male with enduring cognitive impairments, leading to Extreme Anxiety Disorder with detrimental consequences on his professional progression and personal well-being.

Objectives: This necessitates the need for advanced research initiatives and broader awareness programs to facilitate improved diagnostic accuracy and optimization of therapeutic outcomes. Emphasizing ADHD as a potential cause of such symptomatology in adults and integrating effective treatment options can potentially pave the way to personalized therapeutic protocols.

Methods: The patient was approached via meticulous reconsideration of previous unsuccessful treatment paradigms that primarily included antidepressants and anxiolytics, which yielded cyclical patterns of negligible amelioration, compounded by intermittent emergence of suicidal ideation. Given the limited response, a differential diagnosis of Adult-Onset ADHD was entertained.

Results: The therapeutic intervention involving Methylphenidate administration led to a remarkable enhancement in the patient's mental health and occupational efficiency. Progress was also evidenced in the patient's improved confidence and self-esteem, with critical implications for his professional and personal life dynamics.

Conclusions: This case study underscores the transformative potential of precise ADHD management in adults with chronic cognitive impairments. Further research studies involving larger cohorts are warranted to enhance the understanding of adult ADHD, its prevalence, and therapeutic strategies, which could serve as key elements in improving the overall quality of life for these patients.

The difficulties of Adult ADHD management within a Community Mental Health Team

S. Haugh* and H. Belay

Department of Psychiatry, Connolly hospital, Dublin, Ireland

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.999

Introduction: ADHD is a neurodevelopmental disorder characterised by: inattention, hyperactivity and impulsivity. Diagnosis of ADHD in adults is complex, owing to the need for retrospective evidence that symptoms began in childhood as well as the high rates of comorbid mental health conditions. There are no public specialized clinics for adults with ADHD in Ireland. In their absence, referrals are sent to general adult psychiatry.

Objectives: An audit of standards of care received by patients with ADHD against those set by the NICE guidelines.

Methods: Care received pre and 8 weeks post MDT (multi-disciplinary team) educational session. Inclusion criteria: existing adult community mental health team (CMHT) patients with a diagnosis of ADHD. Recommendations as per NICE guideline used for assessment: Specialist MDT team input, OT/ Psychology input, MDT review of reports, Specialist consultant with training in diagnosis and treatment, Diagnosis based on structured assessment e.g. DIVA, Detailed psychiatric assessment, Physical health monitoring before commencing treatment (e.g. ECG), Ongoing physical health monitoring (BP, HR, weight), Patient regularly attending follow up

Results: There were 7 patients with diagnosed ADHD attending the CMHT, 4 male, 3 female aged 19-42yo. 4 patients were diagnosed privately (average age at diagnosis 31yrs). 2 were diagnosed by CAMHS. And 1 was diagnosed by primary care psychology (age 27). 8 weeks following MDT meeting; 2 patients had been commenced on ADHD medication. Those on the wait list for OT/ psychology remained on the wait list.

Conclusions: ADHD is a specialised area which requires a specialist MDT led by a consultant with expertise in diagnosis and treatment. As evidenced by this audit, despite the best efforts of adult psychiatric services, teams are not sufficiently resourced to meet the needs of adults with ADHD and fall short of the expected standards of care.

'Comorbidity, Co-Pathology and Confusion': The Critical Importance of the ADHD - Anxiety Disorders Relationship

S. Anand^{1*}, S. Kapoor² and I. Arora³

¹Department of Psychiatry and Behavioral Sciences, George Washington University, Washington, DC, United States; ²Medical School (MD graduate of 2023), Windsor University School of Medicine, Cayon, Saint Kitts and Nevis and ³AMWA Nationals Student Division, Medical University of the Americas, Nevis, West Indies, Barbados

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1000

Introduction: Given the widespread prevalence of ADHD and Anxiety Disorders, and their obvious impact on mood, cognitions, individual productivity, interpersonal relationships and self-esteem, accurate diagnosis and treatment of these disorders should rightly be considered paramount. ADHD shares several co-morbidities (including and especially the anxiety disorders). With the decades-long rise in the number of stimulant prescriptions, the increasing number of self-report measures, and 'confusing' DSM-5 criteria, concerns remain as to how accurately ADHD and/or

anxiety disorders are actually being diagnosed and treated, especially when comorbid with one another.

This presentation seeks to highlight the downstream consequences of overdiagnosis, underdiagnosis and missed diagnoses when it comes to both Anxiety disorders and ADHD. Its overarching aim is to offer clinicians a 'roadmap' through the ADHD and Anxiety Disorders diagnostic and treatment 'maze'. A pragmatic, guided evaluation of symptoms and functionality is outlined, striving for improved clinical understanding of how ADHD and Anxiety Disorders (when co-morbid) actually affect each other and whether they are, in fact, related disorders.

Objectives: Participants will be expected to have a more solid understanding of:

The extent and ramifications of underdiagnosis, missed diagnoses and overdiagnosis with respect to Anxiety Disorders and ADHD, as result of current DSM-5 diagnostic criteria, common clinical pitfalls and assumptions, as well as clinician biases.

How ADHD and Anxiety disorders can affect the presentation and prognosis of the corresponding comorbid disorder.

How clinicians should approach these two disorders (whether comorbid or not) in order to facilitate effective individualized treatment.

The hypotheses and evidence that ADHD and anxiety are different or that they are related subtypes of the same endophenotype.

The circuitry of, and inputs to, the Prefrontal Cortex and how this can be usefully applied in clinical practice.

Methods:

1. Literature Review of electronic research databases to include: PubMed, Google Scholar, and PSYCHINFO
2. Review of statistics of prevalence, incidence of the above two disorders, and number/type of prescriptions for ADHD and anxiety worldwide derived from the above as well as the CDC and NIMH
3. Review of existing North American, European and Australasian treatment guidelines as well as expert consensus recommendations for ADHD, Anxiety Disorders, as well as both disorders when comorbid with one another.

Results: To be provided by the presenters via Powerpoint slides at the open panel discussion

Conclusions: To be provided and discussed at the open panel discussion

Disclosure of Interest: None Declared

Suicidal behaviors in mental illness: A case-control study. Suicidal behaviors in mental illness: A case-control study

A. Boumnijel, S. Rouached, S. Boudriga*, M. Lagha, W. Homri, I. Ben Rhomdhane and R. Labbane

Department of Psychiatry C, Razi Hospital, Mannouba, Tunisia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1001

Introduction: The assessment of suicide risk remains a critical concern, especially within the psychiatric community. Mental health professionals continually work to identify and support

individuals at risk, emphasizing the need for ongoing research and training in this area.

Objectives: The objectives of our study were to understand the characteristics of patients hospitalized after a suicide attempt (SA), analyze the characteristics of these attempts, identify risk factors associated with suicidal behaviors, and determine predictors for recurring suicidal behavior.

Methods: The study's methodology was retrospective, descriptive, and comparative. It was conducted with 277 patients hospitalized in the psychiatric department "C" of Razi Psychiatric Hospital in Manouba. The sample consists of 72 individuals who attempted suicide, divided into two groups: first-time attempters and recurrent patients, and 205 controls hospitalized for other reasons during the same period.

Results: Results showed a significant increase in the frequency of hospitalizations for SA, rising from 0.7% to 2.25% of the total admissions between 2018 and 2022. Those who attempted suicide were on average 32.5 years old, predominantly female, urban residents, with a moderate socioeconomic status, secondary or higher education, unemployed, unmarried, childless, and lacking strong family support.

The study identified several risk factors associated with suicide attempts, including risky behaviors, previous life events, type II bipolar disorders, personality disorders, the number of psychiatric hospitalizations, and the quality of follow-up. However, schizophrenia was negatively correlated with SA.

Suicidal recurrence was observed in 65.5% of attempters and was linked to personal psychiatric follow-up history, mood disorders, personality disorders, the presence of stress factors, and caustic substance ingestion.

Conclusions: In conclusion, the study underscores the importance of assessing suicide risk among individuals with mental disorders to implement appropriate prevention strategies.

Alcohol-Induced Psychosis: Beyond Korsakoff. Case report and Literature Review

Á. De Vicente Blanco*, B. Orgaz Álvarez, P. Ibáñez Mendoza, M. Velasco Santos and J. Garde González

Hospital Universitario La Paz, Madrid, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1002

Introduction: Chronic consumption of alcohol has clear deleterious effects on the nervous system. Among its less-recognized consequences are subacute and chronic alcohol-induced psychotic disorders. Lasègue, Garnier, Magnan, and Michaux provided exhaustive clinical descriptions of different presentations of *subacute alcoholic delusional disorder*, while Kraepelin, Allamagny, and Neveu defined the characteristics of *chronic alcoholic hallucinatory psychosis*. Both conditions are characterized by the occurrence of hallucinations and vivid dream-like content in their delusions, along with potential emotional detachment from the symptoms. Presently, both conditions are categorized under the generic term 'Alcohol-Induced Psychotic Disorder,' with limited available scientific literature.

Objectives: Our goal is to bring attention to the existence of subacute and chronic alcohol-induced psychosis in individuals with long-term alcohol users.

Methods: Case report using clinical records and a non-systematic literature review.

Results: A 63-year-old male, with a forty-year history of chronic alcoholism and no other prior mental health issues, was admitted in the emergency department. He conveyed vague delusional notions regarding his roommate and described vivid morning dreams in which he tried to communicate but couldn't speak. This led him to believe his roommate harboured harmful intentions. Additionally, he mentioned that for the past two months, he had developed a telepathic connection with his sister and his deceased mother, with whom he felt he communicated without speaking. He described feeling strangeness and anxiety concerning these experiences, which he firmly believed to be undeniably real. He reported being able to hear the voices of his mother and sister. He also described short-term memory problems dating back two years. He denied any other psychopathology and exhibited probable ideational and emotional impoverishment secondary to chronic alcohol consumption. Confirmation of the patient's account was provided by his family members. The prescribed treatment included antipsychotic medication and a recommendation for alcohol abstinence.

Conclusions: Descriptions of chronic and subacute alcohol-induced psychoses are found in early psychiatric textbooks but have been omitted from contemporary classifications. While their incidence is low among chronic alcohol users, they represent a severe clinical entity. These disorders are usually distinguished by the presence of delusions and vivid hallucinations characterized by dream-like content. This distinct symptomatology aids in the accurate differentiation from other psychotic disorders and clinicians should be aware of their existence.

Disclosure of Interest: None Declared

Unraveling the Enigma: Huntington's Disease Masquerading as Treatment-Resistant Psychosis - A Case Study

A.-G. Zanfir^{1,2*}, D. C. Pacale¹, C. Moraru¹, I.-S. Zamfir¹ and G. Marian¹

¹Prof. Dr. Alexandru Obregia Clinical Psychiatry Hospital and ²Faculty of Psychology and Educational Sciences, University of Bucharest, Bucharest, Romania

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1003

Introduction: This unusual case report unfolds a complex and emblematic scenario involving the diagnosis and management of a 46-year-old patient with treatment-resistant psychiatric symptoms, eventually revealing a significant association with Huntington's Disease (HD). The initial presentation at Obregia Hospital featured early signs of psychosis, such as mood swings, social withdrawal, and mild cognitive impairment. Despite predominant treatment with atypical antipsychotics, significant improvements remained elusive.

Objectives: Our primary objectives were to document the intricate diagnostic journey, the challenges faced in managing the patient's

psychiatric symptoms, and the eventual revelation of an underlying neurological disorder, Huntington's Disease. We aimed to emphasize the importance of a multidisciplinary approach to such complex cases.

Methods: The patient's clinical course was closely monitored, and the Positive and Negative Syndrome Scale (PANSS) was used to assess the severity of symptoms upon admission. The patient's severe psychotic state led to involuntary hospitalization. Clinical observations pointing to an underlying neurological disorder prompted a neurology consultation and further investigations, including brain CT and MRI scans, but also genetic testing.

Results: The CT scan revealed potential Huntington's Disease evolution, while genetic testing confirmed the presence of the specific HTT mutation. Brain MRI with contrast substance highlighted characteristic Huntington's Disease changes, such as cortical atrophy, necrosis, and substantial loss of brain tissue, particularly in the basal ganglia, cortical regions, and thalamic nuclei. The patient was hospitalized for nearly seven weeks, during which various psychiatric medications were trialed with limited success. However, a gradual increase of Trihexyphenidyl dosage, as well as a wash-up with saline solution and vitamin supplements (B1, B6, and C), was initiated. Subsequently, the introduction of oral haloperidol in gradually increasing doses led to significant improvements in psychiatric symptoms, dyskinesia, and overall functionality.

Conclusions: This complex case underscores the paramount importance of a multidisciplinary approach in diagnosing and managing patients with Huntington's Disease and concurrent psychiatric symptoms. The revelation of a confirmed Huntington's Disease diagnosis also necessitated genetic testing for the patient's two adult children, with the son testing positive. This case illustrates the challenges of adapting treatment strategies continuously in such multifaceted scenarios and highlights the compelling need for a collaborative and integrative approach.

Implementing policies and predictive stochastic models to restrict borderline personality disorder's access to restricted medications: comorbidity with factitious disorder, functional neurological disorder and medically unexplained symptoms

C. G. Lazzari

Community Mental Health, UK NHS, BRIGHTON, United Kingdom
doi: 10.1192/j.eurpsy.2024.1004

Introduction: We are facing increased access to hospital beds and increased use of restricted medications by people with borderline personality disorder (BPD). Our former research shows BPD comorbidity with factitious conditions, functional neurological disorder and medically unexplained symptoms. We also registered that persons with BPD might craft or exaggerate symptoms to access restricted medications. In the worst cases, they might share these medications (benzodiazepines, hypnotics, and anxiolytics) with street values for profit or other recreational purposes.

Objectives: To generate forecasting models and preventive policies to deal with BPD factitious disorders and improve the effectiveness of the UK National Healthcare Service (NHS) in reducing unnecessary admissions to general and psychiatric hospitals. More selective policies will capture and discourage BPD's feigning and exaggerating symptoms for accessing restricted medications.

Methods: The underlying analysis framework is stochastic forecasting. We used current knowledge and data to complete systematic future predictions extracted from recent trends. A logical-mathematical model generated the required expressions. We identify four major model components to be introduced in the model: BPD (A), factitious disorders (B), prescribing restricted medications (C), antisocial behaviours (D), and access to hospital beds (E).

Results: The Boolean expression becomes [A then B then C then D then E], or $[A \Rightarrow (B \Rightarrow (C \Rightarrow (D \Rightarrow E)))]$ with a truth density of 96.875% (Figure 1).

Conclusions: BPD should alert healthcare of the risks of symptom exaggeration and factitious mental diseases. These conditions are used to access often restricted medications, such as benzodiazepines, sleep tablets, and anxiolytics, for personal and communal use. Street sharing of these last increases local criminality. In worst cases, a hospital bed is granted without preventive triage. The risk is the indoor access to these medications. We advocate policies for the discontinuation of community prescription of these drugs.

Prevalence of psychiatric disorders in patients with craniofacial malformations - a statistical analysis

G. Pereira Bernd¹, V. Dall Agnol Bouvier¹, T. Brusa da Costa Linn¹, I. Cho de Almeida¹, B. de Oliveira de Marchi¹, L. Guinter Muccillo^{2*}, C. G. Menezes Chaves Barcellos², C. Paz Portinho¹ and M. V. Martins Collares¹

¹Universidade Federal do Rio Grande do Sul, Porto Alegre and ²Feevale, Novo Hamburgo, Brazil

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1005

Introduction: Craniofacial malformations have long been associated with a heightened risk of psychiatric disorders. Understanding this link is crucial, as it can inform early intervention and support for affected individuals, enhancing their overall well-being. Research in this area aims to shed light on the prevalence and nature of these disorders within the craniofacial population, ultimately improving healthcare and quality of life for affected individuals.

Objectives: This study aims to establish a comprehensive understanding of the relationship between craniofacial malformations and psychiatric disorders. Specifically, our objectives include: assessing prevalence, identifying risk factors, evaluating impact and informing clinical practice. This research aims to improve the holistic care and mental well-being of individuals with craniofacial malformations, contributing to a more comprehensive approach in the field of psychiatry.

Methods: This cross-sectional study was conducted at a prominent referral hospital named Hospital de Clínicas de Porto Alegre during the month of August 2023.

Participant Selection: Patients with craniofacial malformations of all ages and both genders.

Data Collection: We conducted structured interviews with participants to gather demographic information, medical history, and details of their craniofacial conditions.

Medical Records Review: Medical records were reviewed to corroborate craniofacial diagnoses and identify any comorbid conditions.

Statistical Analysis: Data were analyzed using appropriate statistical techniques to assess the association between craniofacial malformations and psychiatric disorders.

Ethical Considerations: The study adhered to all ethical guidelines, with informed consent obtained from participants or their legal guardians. Ethical approval was obtained from the hospital's Institutional Review Board.

Data Handling: Confidentiality and data security were ensured throughout the study, with all data anonymized to protect participant privacy.

Results: In our study, we assessed 132 different patients, comprising 62 females and 70 males. The youngest patient was 2 months old, while the oldest was 56 years old. The mean age of the patients was 16.22 years, with a median of 9 years, a harmonic mean of 18 years, and a standard deviation of 15.23 years.

Among the patients, 24 exhibited psychiatric disorders, evenly split between 12 males and 12 females. Their average age was 16.21 years, with a median of 10 years, a harmonic mean of 6.13, and a standard deviation of 14.57. The youngest patient with evidence of a psychiatric disorder was 2 years old.

Image:

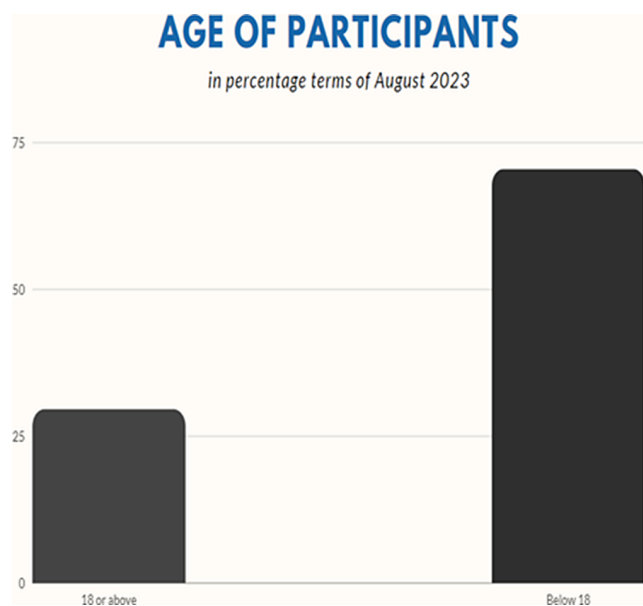

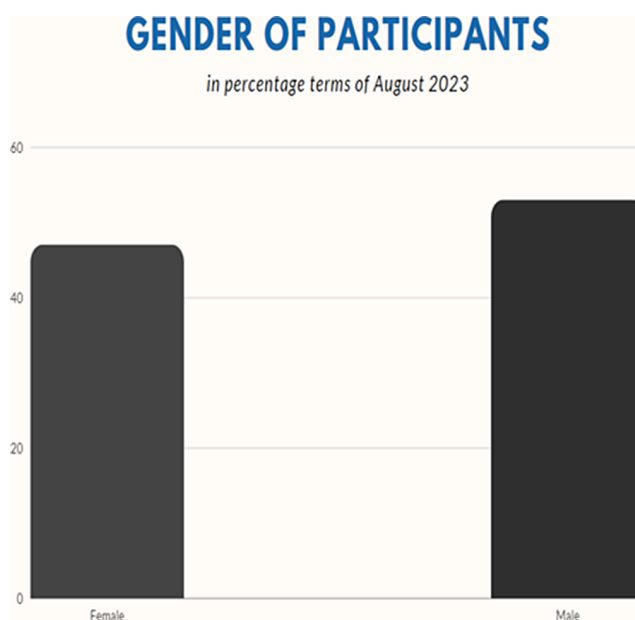

Image 2:

Conclusions: Our study underscores the prevalence of psychiatric disorders among craniofacial patients, which seems to be greater than the general population, emphasizing the need for integrated care that considers both medical and psychological aspects, thus enhancing the overall well-being of these individuals.

EPV0259

Prevalence of Low Self-Esteem Among Patients Treated in the Craniofacial Surgery Department of an international Reference Hospital

G. Pereira Bernd¹, V. Dall Agnol Bouvier¹, T. Brusa da Costa Linn¹, I. Cho de Almeida¹, B. de Oliveira de Marchi¹, L. Guinter Muccillo^{2*}, C. G. Menezes Chaves Barcellos², C. Paz Portinho¹, M. V. Martins Collares¹ and R. Ribas Leite³

¹Universidade Federal do Rio Grande do Sul, Porto Alegre; ²Feevale, Novo Hamburgo and ³Pontifícia Universidade Católica do Rio Grande do Sul, Porto Alegre, Brazil

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1006

Introduction: Craniofacial surgery is a specialized field that addresses congenital and acquired deformities of the head and face. While the physical outcomes of craniofacial surgery are well-documented, less attention has been given to the psychological well-being of adult patients. This abstract aims to explore self-esteem issues among adult patients treated at the Craniofacial Surgery Sector of HCPA (Hospital de Clínicas de Porto Alegre), where a substantial proportion of adult patients have reported self-esteem problems.

Objectives:

1. To assess the prevalence of self-esteem issues among adult patients (≥ 18 years old) attending the HCPA Craniofacial Surgery Sector.
2. To examine potential contributing factors to self-esteem problems in this specific patient population.
3. To evaluate the impact of self-esteem on the mental health and psychosocial functioning of adult craniofacial surgery patients.
4. To propose recommendations for psychosocial support and intervention strategies tailored to the needs of adult patients in this context.

Methods: This cross-sectional study involved 132 adult patients who had undergone or were scheduled for craniofacial surgery at HCPA. Participants reported self-esteem issues in their talk with the hospital's physicians, and their medical records were reviewed to collect demographic and clinical data. Additionally, participants provided information about their mental health status and psychosocial functioning.

Results: Among the 39 adult patients included in the study, 37 (94.9%) reported experiencing self-esteem issues, such as lack of confidence or feeling unattractive. The most commonly reported contributing factors were visible facial differences, social interactions, and prior surgical experiences. Patients with lower self-esteem had a higher likelihood of reporting symptoms of depression and anxiety and reported lower overall psychosocial functioning compared to those with higher self-esteem.

Conclusions: This reveals a strikingly high prevalence of self-esteem issues among adult patients attending the Craniofacial Surgery Sector at HCPA. These findings underscore the importance of recognizing and addressing the psychological well-being of adult craniofacial surgery patients. Comprehensive psychosocial support, including counseling, peer support, and interventions to enhance self-esteem, should be integrated into the care of these patients. By addressing self-esteem concerns, healthcare providers can improve the mental health and overall quality of life of adult craniofacial surgery patients.

EPV0260

Prevalence of psychiatric and cognitive disorders in patients with Pierre-Robin sequence - a statistical analysis

G. Pereira Bernd¹, V. Dall Agnol Bouvier¹, T. Brusa da Costa Linn¹, I. Cho de Almeida¹, B. de Oliveira de Marchi¹, L. Guinter Muccillo^{2*}, C. G. Menezes Chaves Barcellos², C. Paz Portinho¹ and M. V. Martins Collares¹

¹Universidade Federal do Rio Grande do Sul, Porto Alegre and

²Feevale, Novo Hamburgo, Brazil

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1007

Introduction: The Pierre-Robin sequence (PRS), characterized by micrognathia, glossoptosis, and cleft palate, has long been a subject of clinical interest. Recent research suggests a potential association between PRS and cognitive or psychiatric disorders. This study explores this intriguing connection, shedding light on

the complex interplay between craniofacial anomalies and mental health.

Objectives: This study aims to establish a comprehensive understanding of the relationship between Pierre-Robin Sequence and psychiatric disorders. Specifically, our objectives include: assessing prevalence, evaluating impact and informing clinical practice. This research aims to improve the holistic care and mental well-being of individuals with craniofacial malformations, contributing to a more comprehensive approach in the field of psychiatry.

Methods: This cross-sectional study was conducted at a prominent referral hospital named Hospital de Clínicas de Porto Alegre, an international reference in Pierre-Robin Sequence, during the month of August 2023.

Participant Selection: Patients with PRS. Inclusion criteria encompassed individuals of all ages and both genders.

Data Collection: Trained medical personnel conducted structured interviews with participants to gather demographic information, medical history, and details of their craniofacial conditions.

Medical Records Review: Medical records were reviewed to corroborate craniofacial diagnoses and identify any comorbid conditions.

Statistical Analysis: Data were analyzed using appropriate statistical techniques to assess the association between PRS and psychiatric disorders.

Ethical Considerations: The study adhered to all ethical guidelines, with informed consent obtained from participants or their legal guardians. Ethical approval was obtained from the hospital's Institutional Review Board.

Data Handling: Confidentiality and data security were ensured throughout the study, with all data anonymized to protect participant privacy.

Results: In our study, we assessed 28 different patients with Pierre-Robin Sequence, comprising 13 females and 15 males. The youngest patient was 2 months old, while the oldest was 22 years old. The mean age of the patients was 4.75 years, with a median of 3 years and a standard deviation of 5.36 years.

Among the patients, 6 exhibited psychiatric disorders, split between 4 males and 2 females. Their average age was 10 years, with a median of 9 years and a standard deviation of 4.2. The youngest patient with evidence of a psychiatric disorder was 5 years old.

Conclusions: This study underscores a concerning reality within the Pierre-Robin population, pointing to a high prevalence of psychiatric disorders. These findings highlight the urgent need for integrated care, emphasizing the importance of early psychiatric assessment and tailored interventions to enhance the overall well-being of individuals facing the challenges of PRS.

Disclosure of Interest: None Declared

Prevalence of skin disorders among psychiatric inpatients

M. Turki, W. Abid, O. Khardani, A. Mellouli, M. A. Megdiche*, N. Halouani, S. Ellouze and J. Aloulou

psychiatry B department, Hedi Chaker university hospital, sfax, Tunisia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1008

Introduction: The interface between dermatology and psychiatry is complex and of clinical importance. Skin disorders in psychiatric inpatients are common, serious and under diagnosed.

Objectives: The aim of our study was to assess the prevalence and profile of several skin diseases observed in psychiatric inpatients.

Methods: We conducted a cross-sectional study in the period from October 13, 2023 to October 20, 2023, among psychiatric male inpatients, hospitalized in psychiatry B department of the Hedi Chaker University Hospital (Sfax, Tunisia). We collected socio-demographic and clinical data using a pre-established form.

Results: Over a period of a week, 35 patients were included in our study. The mean age of patients was 39.97 years. Among them, 80% were single and 14.3% were married. Addictive behaviors were reported in 74.3% of cases. The level of hygiene was good in 74.3% of patients. The three most common psychiatric diagnoses were schizophrenia (31.4%), followed by bipolar disorder (28.6%) and schizoaffective disorder (25.7%). We recorded 13 cases of skin diseases (37.2% of patients). Dermatological lesions were dominated by traumatic origin in 14.3% of cases. They were of infectious origin in 11.4% of cases, immunoallergic in 8.6% and parasitic in 2.9%.

Conclusions: The prevalence of skin diseases is high in psychiatric inpatients, for whom proper skin care is necessary to improve their quality of life.

Symptoms of anxiety and depression among osteoporotic women

A. Feki¹, I. Sellami^{2,3*}, B. Trabelsi⁴, Z. Gassara¹, S. Ben Djemaa¹, A. Abbes², M. Ezzeddine¹, M. H. Kallel¹, H. Fourati¹, R. Akrou¹, Y. Mejdoub⁴ and S. Baklouti¹

¹Rheumatology; ²Occupational medicine, Hedi Chaker Hospital; ³Medicine University and ⁴Preventive medicine, Hedi Chaker Hospital, Sfax, Tunisia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1009

Introduction: Osteoporosis (OP) prevalence is on the rise as a result of an ageing population and lifestyle factors such as inactivity. Previous research has reported OP in individuals with depressive symptoms. Furthermore, OP has been shown to be a risk factor for anxiety.

Objectives: In this study, we aimed to describe anxiety and depression symptoms among osteoporotic women in a university hospital in Tunisia.

Methods: A cross-sectional study was conducted between January and June 2023 in a university hospital in Tunisia. Women with postmenopausal OP in the rheumatology department were interviewed. A hospital anxiety and depressive scale was used to describe anxiety and depression symptoms among patients. It consists of seven items for depression (HADS-D) and seven items for anxiety (HADS-A). For each component a score ≤ 7 indicated the absence of symptomatology.

Results: Seventy-two women diagnosed with post-menopausal OP participated in the study. The mean age was 72.5 (± 1.08). The median duration of menopause was 23 years (IIQ = [10.5-28.5]).

All patients were receiving bisphosphonates. Fifty-eight women (80.5%) were identified with depressive symptoms. The median depression score was 17.5 (IIQ = [9-19]). Physical activity was significantly and inversely associated with the presence of depressive symptoms ($r = -0.36$; $p = 10^{-3}$). Those who were overweight or even obese had significantly more depressive symptoms than those who were not overweight (94%, 57%, $p = 0.001$).

The median score of anxiety was 16 (IIQ = [9-17]). Sixty-three patients (87.5%) were identified with anxiety symptoms. Physical activity was significantly and inversely associated with the presence of anxiety symptoms ($r = -0.489$; $p = 10^{-3}$). Women who had bone fractures were significantly more anxious than those without a history of bone fractures (100%, 63%, $p < 10^{-3}$). Patients who were overweight were significantly more anxious than those with normal weight (96%, 57%, $p < 10^{-3}$).

Conclusions: Physical activity and obesity were associated with depression and anxiety among osteoporotic patients. These data are consistent with previous findings. That's why, promoting physical activity and weight loss is essential to preventing mental disorders among osteoporotic women.

Anxiety in patients with ankylosing spondylitis in southern-Tunisia: Level and associated factors

A. Feki¹, I. Sellami^{2,3*}, N. Ketata⁴, M. Baklouti⁴, Z. Gassara¹, S. Ben Djemaa¹, S. Ben Djemaa¹, M. Ezzeddine¹, M. H. Kallel¹, H. Fourati¹, R. Akrou¹, Y. Mejdoub⁴ and S. Baklouti¹

¹Rheumatology; ²Occupational medicine, Hedi Chaker Hospital; ³Medicine university and ⁴Preventive medicine, Hedi Chaker Hospital, Sfax, Tunisia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1010

Introduction: Ankylosing spondylitis (AS) is the second most common rheumatic disease after rheumatoid arthritis. The significant functional impact of this chronic disease can affect patients' mental health.

Objectives: The aim of this study was to determine the prevalence of anxiety in subjects with AS in Southern-Tunisia and to identify its associated factors.

Methods: It was a retrospective study conducted in 2021 over a period of 5 years on patients with AS consulting the rheumatology department at the Hedi Chaker University Hospital in Sfax, Southern-Tunisia. The "Anxiety and Depression scale" was used to screen for anxiety. A score ≥ 11 defined confirmed anxiety symptoms.

Results: Of the 62 patients, 35 were male (56.5%), giving a male to female ratio of 1.3. Twenty-seven patients (43.5%) were aged between 35 and 50 years. The level of education was primary in 19 cases (30.6%) and university in 15 cases (24.2%). A family history of chronic disease was present in 32 cases (51.6%). Severe fatigue was noted among 27 patients (43.5%). Quality of life was poor in 39 patients (62.9%). The mean anxiety score was 11.35 ± 4.6 . Thirty-four subjects (54.8%) had confirmed anxiety symptoms and 19 (30.5%) had borderline symptoms. Confirmed anxiety was significantly associated with the educational level ($p = 0.03$) (illiterate:

87.5%, primary: 68.4%, secondary: 35% and university: 46.7%). Similarly, having a family history of chronic disease (OR=3.3; $p=0.02$), suffering from severe fatigue (OR=36, $p<0.01$), having associated depression (HAD score ≥ 11) (OR=19.5; $p<0.001$) and having poor quality of life [Ankylosing spondylitis quality of life questionnaire (Asqol) Score ≥ 13] (OR=15.8; $p<0.001$) were statistically associated with higher prevalence of confirmed anxiety symptoms.

Conclusions: It was found that patients treated for AS frequently suffer from psychological co-morbidities, particularly anxiety, which can lead to a further deterioration in their quality of life and even their withdrawal from active life. Thus, anxiety should not be ignored when treating these patients.

Postictal psychosis : Case Report and Literature Review

S. Ajmi*, M. Bouhamed, K. Makni, S. Hentati, I. Feki, R. Sallemi and J. Masmoudi

Psychiatry A, Hedi Chaker University Hospital, Sfax, Tunisia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1011

Introduction: The prevalence of psychosis in patients with epilepsy is estimated approximately 7.8%. However, postictal psychosis appears to be much less common, with a prevalence of 2% in epilepsy. Postictal psychosis is defined as psychotic episodes starting within less than one week after an epileptic seizure.

Objectives: Our aim was to study the clinical characteristics and the therapeutic options through a case report and a review of the literature.

Methods: Case report and unsystematic literature review were obtained by searching the Pubmed.gov database. Thirty-six articles were identified through searches of this database and thirty-five articles were included in the selection of in-text articles integral

Results: A 32-year-old men patient, without a personal or family history of psychiatric illness, was admitted to a psychiatric unit for a psychotic episode which has started three days before, mystical delusions, irritability, disorganized behavior, and aggressiveness, that had emerged shortly after a cluster of generalized tonic-clonic GTC seizures. Additionally, divided attention and memory deficits were noticed during psychiatric hospitalization.

Past medical history was relevant for epilepsy since he was 20 years olds. He did not regularly attend follow-up neurology appointments and had poor adherence to antiepileptic treatment. Last tomography images, a day before the hospitalization in psychiatry, had documented hypodense lesions in the periventricular white matter and subcortical semi-oval center distributed bilaterally and symmetrically suggestive of leukopathy. During the hospitalization, biochemical screening, renal and thyroid function were normal, serologies for B and C hepatitis were negative.

Psychotic symptoms subsided in the first 36 hours after admission upon treatment with Risperidone 4 mg/day, carbamazepine 600 mg/day, and 150 mg phenobarbital.

Conclusions: From our research, we can deduce that although these syndromes are widely recognized, standard diagnostic manuals fail to acknowledge them, resulting in a noticeable lack of

attention in the literature. Therefore, it is crucial for physicians to carefully examine patients with known risk factors for the symptoms of postictal psychosis.

Post-Ictal Mania: A Case Report with Literature Review

W. Haouari*, S. Omri, A. Labyadh, R. Feki, I. Gassara, N. Smaoui, J. Ben Thabet, M. B. Maalej, M. Maalej, N. Charfi and L. Zouari

Psychiatry C, Hedi Chaker university Hospital, Sfax, Tunisia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1012

Introduction: While postictal mania is a well-recognized clinical condition, it has received less research attention compared to other postictal manifestations.

Objectives: Drawing upon an analysis of a case report that underscores the clinical and therapeutic challenges associated with comorbid epilepsy and mania, a literature review was carried out to investigate the connection between these two disorders.

Methods: We illustrate a case of comorbidity between mania and epilepsy and provide a concise review of the literature summarizing the key characteristics of this association.

Results: This case pertains to Mr. M, a 44-year-old male with a history of frontal epilepsy characterized by secondary partial generalization, which was partially controlled with sodium valproate. He was admitted to our service due to acute agitation following a loss of consciousness lasting a few minutes.

Upon admission, the patient exhibited symptoms of mental confusion. A neurological examination did not uncover any abnormalities. Brain computed tomography revealed mild frontal atrophy. Video electroencephalography conducted during the interictal period and outside the episodes of confusion did not reveal any abnormalities. The patient was restarted on sodium valproate (20 mg/kg/day) and clonazepam (2 mg/day). Following a lucid interval of ten days, the patient started to manifest psychiatric symptoms, which included irritability, hostility towards his spouse, increased talkativeness, thought pressure, and an unusual sense of familiarity, raising suspicion of post-ictal mania.

Conclusions: Based on this clinical case and the existing scientific literature, post-ictal mania occupies a distinct position among the mental disorders observed in the post-ictal period. Therefore, clinicians must be aware of these conditions to facilitate accurate diagnosis and appropriate management.

Association between G6PD deficiency and schizophrenia A case report

B. Abassi^{1*}, F. Fekih-Romdhane¹, F. Baccar¹, M. Cheour¹, R. Damak¹ and S. Ellini¹

¹Ibn Omrane, Razi Hospital, Mannouba, Tunisia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1013

Introduction: G6PD is essential for the production of NADPH, which is a cofactor for many enzymes involved in antioxidant defense and neurotransmitter synthesis. A deficiency in this enzyme could lead to increased oxidative stress, impaired neurotransmitter and immune function. The latter have been implicated in the pathophysiology of schizophrenia.

Objectives: The present case is presented to underscore the infrequent and uncharacteristic manifestation of this condition, in the context of clinical symptoms and the trajectory of evolution of schizophrenia when associated with G6PD Deficiency. Moreover, it sheds light on the challenges clinicians encounter in the management of such cases.

Methods: A case report of a patient who was admitted to the Psychiatry Department ("Ibn Omrane") of Razi Hospital".

Results: Mr. M.T is a 26 year-old unmarried man. He comes from a non-consanguineous marriage and has an educational level of a bachelor's degree plus three additional years of study. He has a significant family medical history. His maternal uncle is under treatment for a chronic psychotic disorder. He has a personal history of G6PD deficiency and no specific habits to note. At the age of 24, he insidiously developed anxiety with incoherent statements of persecution accompanied by behavioral manifestations leading to mistrust and social isolation. He discontinued his studies for a year and began verbalizing suicidal thoughts accompanied by self-harm behaviors.

The family sought help from a psychiatrist who prescribed 5 mg of olanzapine, which was covertly administered to the patient.

At the age of 28, after a suicide attempt, he was involuntarily admitted to Razi Hospital. The clinical presentation was dominated by disorganization, with a partial response to treatment.

Conclusions: More research is needed to confirm the association between G6PD deficiency and schizophrenia and to determine the underlying mechanisms. Larger studies with well-defined populations and methodologies are needed. It is also important to study the interaction between G6PD deficiency and other genetic and environmental factors that contribute to schizophrenia.

Spiritual awakening. Substance abuse, dual pathology

M. J. Gordillo Montaña^{1*}, L. Rodriguez Rodriguez¹, C. Pérez Aparicio¹ and S. V. Boned Torres¹

¹Hospital Can Misses, Eivissa, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1014

Introduction: Kambó is considered an "ancestral medicine" by the indigenous tribes of the western region of the Amazon.

Objectives: Through this clinical case, the aim is to present the particularities of the symptoms and management of patients with consumption of not so common substances, such as Kambo or salvia divinorum, as well as the evolution that will occur in a patient with a previous diagnosis of a Depressive Episode.

Methods: We present the case of a 23-year-old male, Gestalt therapy student. History of tobacco, THC, and recent use of salvia divinorum and Kambo. He began follow-up by psychiatry in a private setting three years ago due to a severe depressive episode,

having required treatment with antidepressants, antipsychotics and benzodiazepines, and having been triggered by a serious assault. The episode is resolved and follow-up is discontinued. Family history of depressive syndrome and suicide.

He resumed contact through the Emergency Department, requiring hospital admission due to symptoms compatible with a manic episode with psychotic symptoms. It begins with behavioral alterations and global insomnia that are related to the consumption of some substance, initially unknown to them, making the skin lesions they presented suspect the consumption of kambo.

Results: We assess the risk of consuming these substances, which are sometimes used as alternative therapies, and especially in this type of patient, who is more vulnerable and perhaps seeks a way out of the problems they present.

Conclusions: In our case, it triggered a manic episode with psychotic symptoms, which consisted of delusional ideation of mystical content accompanied by auditory hallucinations. The episode took about a month to subside, despite treatment. Subsequently, there have been more episodes with similar characteristics, and they have not been associated with the consumption of kambó, but have been linked to the consumption of "natural medicinal substances."

Atypical psychosis in a patient with intracranial hypertension: clinical case and review

B. Lázaro Alonso

Psychiatry and Mental Health, Hospital Universitario Ramón y Cajal, Madrid, Spain

doi: 10.1192/j.eurpsy.2024.1015

Introduction: Several neurologic conditions can produce or mimic psychotic symptoms. It is important to make an exhaustive differential diagnosis between a psychiatric manifestation of an underlying neurological condition and a primary psychiatric one. We explore through the present clinical case of a young woman admitted to neurology the relationship between intracranial hypertension and a case of atypical psychosis that resolved itself with the treatment of the intracranial hypertension, without the need for anti-psychotic medication.

Objectives: To explore through the presented clinical case and the concerning literature the concept and management of psychotic-like symptoms in patients with intracranial hypertension.

Methods: We present a clinical case and a review of the existing literature concerning atypical psychosis or psychosis-like symptoms in cases of intracranial hypertension.

Results: We report the case of a 24 year old woman with no relevant medical history hospitalised in the neurology unit due to suspected encephalitis. Native to New Zealand, she is brought from the airport due to behavioural alterations. During the last few days before admission she had presented with incoherent speech, derailment, religious and persecutory delusions, and erotomania towards her cousin. She described feelings of strangeness with her surroundings and of time moving at a different speed than usual, either faster or slower. She also had a headache and visual alterations, as well as

memory errors concerning recent events, clouding of consciousness and inattention.

No fever or other relevant physical symptoms. A lumbar puncture is done, which shows an opening pressure of 37mmHg but no other anomalies. Body CT scan shows no relevant findings. Empirical treatment with dexamethasone is initiated for suspected encephalitis, progressively reducing the dosage until suspension in the following days. During her stay at the hospital she is assessed by ophthalmology, which finds no abnormalities in the eye fundus examination, and psychiatry. A second evacuating lumbar puncture is done to reduce intracranial hypertension. No antipsychotic treatment is initiated: the symptomatology remitted with the lowering of intracranial pressure. At time of discharge, the patient remained asymptomatic without treatment and was able to return home to continue outpatient neurologic study of the etiology of the intracranial hypertension.

Finally, we conduct a review of the existing literature concerning psychotic and psychosis-like symptoms in patients with intracranial hypertension, to explore the diagnostic and management options of this rare finding.

Conclusions: Our findings point to the existing relationship between intracranial hypertension and psychosis-like symptoms. Further studies on pathogenic mechanisms and therapeutic management are required.

EPV0275

Hepatic encephalopathy in cirrhosis and alcohol dependence: complex clinical challenges and multidisciplinary management

C. Alario-Ruiz*, B. Arribas-Simon, P. Martinez.Gimeno, M. Calvo-Valcarcel and O. Martin-Santiago

Hospital Clinico Universitario, Valladolid, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1016

Introduction: Liver cirrhosis, a chronic liver disease, can be closely linked to chronic alcohol abuse, posing a significant medical challenge. Hepatic encephalopathy (HE), a neuropsychiatric condition resulting from liver dysfunction, commonly occurs in cirrhotic patients due to the accumulation of neurotoxic substances like ammonia and manganese in the body. Managing cirrhosis and alcohol addiction is crucial to enhancing the quality of life for these patients, as HE can manifest in various ways and with varying degrees of severity.

Objectives: To emphasize the importance of recognizing and treating hepatic encephalopathy as a potential complication of liver cirrhosis and sedatives during alcohol withdrawal.

Methods: We compiled clinical data, medical history, neuroimaging tests, and therapeutic interventions applied.

Results: A 55-year-old man with a complex medical history, including Child-B liver cirrhosis, portal hypertension, hypertension, diabetes mellitus, and chronic alcohol abuse with numerous prior hospitalizations for acute pancreatitis and severe head trauma related to alcohol consumption, presented to the emergency department with symptoms of alcohol withdrawal and suicidal thoughts, leading to lorazepam administration and a

recommendation for admission to a specialized Therapeutic Community. After 72 hours, he developed hepatic encephalopathy with symptoms such as confusion, sleep disturbance, sweet-smelling breath, abnormal hand movements, conjunctival icterus, and urinary difficulties.

An EEG revealed a globally attenuated and disorganized bioelectrical activity with triphasic waves. The magnetic resonance imaging showed signs of hepato-cerebral degeneration, including T1-weighted hyperintensity in the lentiform and mesencephalic nuclei due to manganese deposition. Treatment was adjusted to reduce sedative use, and therapy with Rifaximin and Lactulose was initiated to control blood ammonia levels. After a week, the patient exhibited significant neurological improvement, underscoring the importance of appropriate management in patients with hepatic encephalopathy related to liver cirrhosis and chronic alcohol abuse.

Conclusions: This case underscores the complexity of HE in patients with liver cirrhosis and alcohol dependence. HE can present in various ways, from subtle symptoms to severe episodes of confusion and coma. Findings on EEG, such as triphasic waves, are characteristic of HE and reflect brain dysfunction. Furthermore, manganese accumulation in the brain, as evidenced by magnetic resonance imaging, may contribute to neurological symptoms in cirrhotic patients. In this context, the early recognition and multidisciplinary treatment are emphasized to improve the quality of life and prevent the progression of this neuropsychiatric complication. EEG and magnetic resonance imaging findings play an essential role in the evaluation of these patients.

Management of Acute Organic Change of Character cases by Liaison Psychiatry Unit

E. Cesari*, H. Álvarez, H. Andreu, L. Bueno, O. De Juan, J. I. Mena, I. Ochandiano, L. Olivier, S. Salmerón and L. Pintor²

Department of Psychiatry and Psychology, Institute of Neuroscience, Hospital Clinic de Barcelona and ²Department of Psychiatry and Psychology, Head of Liaison Psychiatry Unit, Hospital Clinic de Barcelona, Barcelona, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1017

Introduction: The Acute Organic Change of Character (AOCC) is an organic mental disorder subtype in which perception, thought, mood and personality impairment predominate. It consists in a change in the individual's general behaviour or attitude, which is shown to be closely associated with or caused by an underlying organic process, and which is rapidly resolved when the organic noxious agent is eliminated (Pintor et al. Journal of Psychiatry and Psychiatric Disorders 4 (2020): 354-358).

Objectives: To describe the importance of taking AOCC diagnosis into consideration and the role of liaison psychiatrists in AOCC management by presenting two AOCC cases admitted to the Hospital Clinic of Barcelona.

Methods: We retrospectively reviewed two AOCC cases in patients followed by our hospital's liaison psychiatry unit during the summer of 2023. We also searched for previous case reports of AOCC using a PubMed query.

Results: Case 1: A 50-year-old male who suffered a polytrauma with diffuse axonal injury (DAI). His relatives and the referring medical team observed a change in his behaviour consisting in irritability, suspicion, hostility and impatience. No cognitive impairment nor fluctuation in the described symptoms were observed. At the time of discharge character changes were still present due to DAI slow and unpredictable clinical course. Symptomatic treatment with risperidone 6mg/day and quetiapine 100mg/day was administered achieving a satisfactory clinical response.

Case 2: A 47-year-old woman with type 2 diabetes who suffered an infectious cellulitis that spread causing sepsis. The patient began to appear disruptive with verbose and tangential speech during her admission. No cognitive impairment nor fluctuation in the described symptoms were observed. Symptomatic treatment with risperidone 10mg/day and olanzapine 5mg/day was administered achieving a satisfactory clinical response. At the time of discharge character changes described before were almost resolved.

Conclusions: The clinical presentation of both cases suggested organic mental disorders in which a change in general behaviour predominates. Liaison psychiatrists play a key role in AOCC management by recognizing the clinical pattern, helping if needed with psychopharmacological treatment and ensuring a good understanding of the disorder both by the referring medical team and the patient's relatives. To our knowledge, it would be of great importance to achieve a better understanding of this clinical condition which to date we consider to be underdiagnosed.

Disclosure of Interest: None Declared

EPV0277

Unraveling a Psychiatric Puzzle: Corticosteroid-Induced Psychosis in Addison's Disease. A case report

F. Mayor Sanabria*, M. Fernández Fariña, M. E. Expósito Durán, C. E. Regueiro Martín-Albo, C. Arroyo Del Val, M. Paz Otero and Í. Alberdi Páramo

Instituto de Psiquiatría y Salud Mental, Hospital Clínico San Carlos, Madrid, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1018

Introduction: The spectrum of neuropsychiatric adverse effects of corticosteroids ranges from unspecific symptoms to structured psychotic or affective episodes. We present the case of a 30-year-old woman admitted to our hospital due to behavioral alterations, coinciding with the initiation of treatment with corticosteroid boluses as part of a chemotherapy regimen for gastric adenocarcinoma. She had a previous diagnose of Addison's disease, undergoing treatment with supplemental corticosteroids.

Objectives:

- 1) To describe the clinical particularities of this case, focusing on the psychopathological aspects and their correlation with the corticoid treatment.
- 2) To review the available literature regarding the clinical characteristics and management of corticosteroid-induced psychosis, with special interest in patients with adrenal insufficiency that require long term steroid supplementation.

Methods: A review of the patient's clinical history and complementary tests were carried out. Likewise, we reviewed the available literature in relation to the clinical presentation of corticosteroid-induced psychosis and its pharmacological management.

Results: The patient was admitted to our hospital due to acute behavioural alterations, which temporally coincided with the 4th cycle of FOLFOX chemotherapy and corticosteroid boluses. She presented with incoherent speech, with *non sequitur* answers and glossolalia, as well as dysphoric affect and purposeless behavior. She presented a favorable clinical course after the initiation of treatment with antipsychotics and temporary suspension of corticosteroid treatment.

Manic symptoms are the most common presentation of "corticosteroid-induced psychosis", with the key characteristic being the temporal association with the corticosteroids administration. Although the discontinuation of steroids generally results in a sudden decrease in symptoms, additional treatment with antipsychotics such as haloperidol or olanzapine might be required for a symptomatic control. In patients with adrenal insufficiency, long-term treatment with lithium or anti-seizure treatments are effective strategies in relapse prevention when a higher steroid dose is required.

Conclusions:

- Corticosteroid-induced psychosis is a well described clinical phenomenon, that usually presents with manic symptoms rather than psychotic experiences.
- Progressive discontinuation of corticosteroid treatment usually results in complete cessation of symptoms, but additional psychopharmacological treatment might be required, especially in patients with adrenal insufficiency undergoing long-term corticosteroid treatment.
- This case outlines the psychopathological richness in the presentation of corticosteroid-induced psychosis, and illustrates the challenges in the pharmacological management in patients with adrenal insufficiency.

Development and Validation of the Isotretinoin Hesitancy Scale

E. Agaoglu¹, I. G. Yilmaz-Karaman^{2*}, C. Yastibas-Kacar³, H. Kaya-Erdogan¹, T. Mutlu¹ and E. Acer¹

¹Dermatology; ²Psychiatry, Eskişehir Osmangazi University, Eskişehir and ³Psychology, Adana Alparslan Türkeş Science and Technology University, Adana, Türkiye

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1019

Introduction: Isotretinoin is an effective treatment for acne vulgaris; however, many patients experience anxiety while deciding to get it. Isotretinoin, indeed, has significant adverse effects. On the other hand, effective treatment of acne vulgaris may reduce dermatological and psychiatric complications.

Objectives: The present study aims to develop and validate the Isotretinoin Hesitancy Scale to measure the patients' drawbacks to the treatment.

Methods: The specialists, including dermatologists and mental health professionals, determined an item pool of 30 items. Before the data collection, all items were checked by the researchers in terms of clarity and acceptability. Thus, the eight items were removed from the questionnaire due to having similar meanings, measuring the facts about treatments that are not the study's objective, and containing unclear statements. The final version of the questionnaire, which consists of 22 items, was applied to the participants.

Results: One hundred patients with acne vulgaris were recruited. Among the participants, 72% were women, and the mean age was 22.72. Most patients' acne severity was group 2 (40%) and group 3 (36%). Three items were removed because of having low item-total score correlations. Five items were removed in factor analysis because of low factor loading or cross-loading. Exploratory factor analysis results of the scale are presented in Table 1.

Table 1. Exploratory Factor Analysis Results of the Scale

	Factor 1 (min-max)	Factor 2 (min-max)	Factor 3 (min-max)
Isotretinoin treatment can lead to dryness of lips, nose, and eyes.	0.516-0.842		
Isotretinoin treatment may have many side effects.			
Isotretinoin treatment may cause damage to the liver.			
Side effects of isotretinoin treatment may affect my daily life.			
Isotretinoin treatment may cause depression.			
Isotretinoin treatment may cause elevation of cholesterol level.			
Isotretinoin treatment may cause infertility in men.		0.425-0.945	
Isotretinoin treatment may cause infertility in women.			
Isotretinoin treatment may prevent height gain.			
In case of pregnancy, isotretinoin treatment may cause congenital defects in the baby.			
I'm afraid of using isotretinoin for a long period.			0.569-0.890
I stop the isotretinoin treatment as soon as possible.			
I will wait as long as I can before using isotretinoin treatment.			
I need more reassurance about isotretinoin treatment.			

The Cronbach alpha score of the final form of the scale was found to be .81, the internal consistency of the first factor (hesitancy related to reversible adverse effects) was calculated as .79, the second factor (hesitancy related to irreversible adverse effects) was calculated as .78, and the final factor (isotretinoin-related anxiety) was found to be .72.

Conclusions: The Isotretinoin Hesitancy Scale is valid and reliable among patients with acne vulgaris.

Disclosure of Interest: None Declared

Brief Psychotherapeutic and Psychopharmacological Interventions as Facilitators of Bariatric Surgery Success in Patients on the Anxious-Impulsive Spectrum: A Pilot Study

Í. Alberdi-Páramo^{1,2*}, M. Navas Tejedor³, M. Paz Otero¹, J. Sánchez- Rodríguez¹ and D. Gimeno Álvarez¹

¹Hospital Clínico San Carlos; ²Universidad Complutense and ³Psiquiatría, Hospital Clínico San Carlos, Madrid, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1020

Introduction: Patients undergoing bariatric surgery often present with impulsive behavior and symptoms of anxiety. In this context, brief psychotherapeutic interventions such as nutritional education, cognitive restructuring, and behavioral activation have been shown to enhance pre-surgery weight loss and improve the likelihood of successful surgical outcomes. Furthermore, anorexi- genic pharmacological treatments involving fluoxetine, bupropion, naltrexone, eslicarbazepine, zonisamide, and topira- mate have been associated with increased success rates of the bariatric intervention.

Objectives: To assess the impact of brief psychotherapeutic inter- ventions and psychopharmacological treatments on the success of bariatric surgery in anxious-impulsive patients, investigating the effectiveness of combined strategies in enhancing preoperative weight loss and surgical outcomes.

Methods: Within the framework of a third-level hospital's Bar- iatric Surgery Protocol, a total of 63 obese patients were assessed using the MINI International Neuropsychiatric Interview (MINI), Hamilton Anxiety Rating Scale (HARS), and Barratt Impulsiveness Scale (BIS-11) during the pre-surgical evaluation. Patients with Axis I pathologies were excluded, leaving a sample of 56 participants (38 females; BMI: 43.58±8.72 kg/m2; age: 48.5 ±9.7 years). Individuals displaying mild anxiety (6-14 points on HARS) and moderate/severe anxiety (>14 points on HARS) and/ or those with a BIS-11 score exceeding 32.5 were selected for combined psychotherapeutic and psychopharmacological inter- ventions.

Results: Categorized by anxiety and impulsiveness levels, the patient distribution was as follows:
Mild anxiety without impulsiveness: 19 patients
Mild anxiety with impulsiveness: 31 patients
Moderate/severe anxiety without impulsiveness: 2 patients
Moderate/severe anxiety with impulsiveness: 15 patients
This pilot study explores the potential synergy between brief psycho- therapeutic interventions and psychopharmacological approaches in enhancing the outcomes of bariatric surgery for patients within the anxious-impulsive spectrum.

Conclusions: The results shed light on the feasibility and potential benefits of a combined treatment strategy, contributing to the optimization of bariatric surgery success in this specific patient population. Further research is warranted to confirm and general- ize these findings.

EPV0280

Enhancing Physical Health in Patients with Severe Mental Disorder: Addressing Physical Multimorbidity

I. Š. Filipčić^{1*} and I. Filipčić²

¹Department of psychiatry and psychological medicine, University Hospital Zagreb and ²Psychiatric Clinica Sveti Ivan, Zagreb, Croatia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1021

Introduction: Over the last two decades, a growing volume of research has discovered a correlation between severe mental disorders (SMD) and early mortality. This is attributed to the elevated incidence of chronic physical illnesses and multimorbidity, resulting in a reduction of life expectancy by 10-20 years. Individuals with SMD exhibit lower rates of prevention, diagnosis, and treatment for medical comorbidities when contrasted with the general population (GP).

Objectives: The objective is to assess the prevalence of CPM and its impact on psychiatric treatment outcomes in individuals with SMD, and to propose preventive interventions to enhance physical health.

Methods: This nested cross-sectional study enrolled 343 SSD patients and 620 GEP.

Results: Individuals diagnosed with SMD encounter CPM earlier in life compared to the GP. Notably, individuals under 35 years old within the schizophrenia spectrum disorder have almost three times higher odds for experiencing CPM compared to their GP counterparts, a difference that is both clinically and theoretically significant. This disparity is especially pronounced among younger women, with the gap widening the younger the patient is in comparison to peers in the general population. CPM has been identified as a factor affecting the outcomes of psychiatric treatment.

Conclusions: The treatment approach for SMD should be tailored to accommodate the diverse physical multimorbidity patterns of patients. It's imperative for future research to delve into how CPM impacts the outcomes of SMD treatments. There's a pressing need for detailed treatment guidelines addressing CPM in patients with SMD.

EPV0281

A Study on Irritable Bowel Syndrome (IBS) in Mental Health Professionals and the Psychosocial Factors Affecting This

J. Hong

psychiatry, Iksan hospital, Iksan, Korea, Republic Of

doi: 10.1192/j.eurpsy.2024.1022

Introduction: The present study investigates irritable bowel syndrome in mental health professionals and the characteristics of psychosocial factors that affect this.

Objectives:

Methods: The present study selected an irritable bowel syndrome group among 291 mental health professionals based on the Rome III criteria, and investigated demographic variables. The Hospital Anxiety Depression Scale (HADS), Psychosocial Well-being Index (PWI), and Korean Occupational Stress Scale (KOSS) were used to evaluate psychosocial factors. An independent t-test and chi-square test were used to determine differences between the groups, and a

logistic regression analysis was used to determine the odds ratio (OR) of IBS based on occupational stress. SPSS 21.0 (IBM Statistical Package for the Social Sciences 21.0) was utilized for all statistics.

Results: Differences in demographic variables based on IBS group were not statistically significant. Depressive symptoms ($t = -4.767$, $p < 0.001$) and anxiety ($t = -4.068$, $p < 0.001$) were higher in the IBS group, and psychosocial well-being was lower ($t = 2.288$, $p < 0.05$). The OR of IBS based on depressive symptoms was 5.737 (95% CI = 2.24–14.69). There were significant differences in occupational stress based on IBS within the subordinate domains of physical environment ($t = -3.160$, $p < 0.01$), job demand ($t = -3.273$, $p < 0.01$), interpersonal conflict ($t = -2.295$, $p < 0.05$), job security ($t = -3.005$, $p < 0.01$), and lack of reward ($t = -2.046$, $p < 0.05$). The OR of IBS based on the subordinate domains of occupational stress was 3.708 (95% CI = 1.20–11.41) in physical environment, and 3.759 (95% CI = 1.33–10.56) in job demand.

Conclusions: The results of the present study verify that psychosocial factors in mental health professionals have a close correlation with IBS. Accordingly, improvements in both IBS symptoms and quality of life should occur through proactive intervention in these variables.

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1023

Introduction: Exercise and other lifestyles are key treatment strategies to improve diabetes outcome, prevent cardiovascular risk and may also result in further results in quality of life and emotional symptoms.

Objectives: To evaluate the effectiveness of an exercise intervention program for people with diabetes or cardiovascular risk.

To evaluate the influence of previous mental health and quality of life status in the results.

Methods: 61 people with a type 2 diabetes or cardiovascular risk factors were recruited from health primary health centers in

Ponferrada (EL Bierzo), including patients from the mental health association. After informed consent they were included in a 20 week, twice a week supervised walking training program to improve exercise and other lifestyles. A poster used for advertisement of the activity ("the way/walk to change diabetes") is displayed in image 1). Baseline and after 20 weeks BMI and Waist perimeter were assessed, quality of life was evaluated with EQ-5D-5L and WHO-5 scales and the weekly steps walked were recorded previously and after the intervention with the subject usual mobile device. Differences in the variables were compared with Paired Ts and repeated ANCOVAs measures adjusted by gender, age and initial steps.

Results: 46 subjects (75.4%) completed more than 90% of the sessions and 3 more 70-90%. The 19.7% that did not complete had worse scores in SF-12 Role Physical ($t:2.261$, $p=0.041$) and Role Emotional ($t:2.048$, $p=0.045$) and Mental Component Summary ($t:2.313$; $p=0.036$) and WHO5 Total Score ($t:2.101$; $p=0.040$) at Baseline. Main reasons for dropout (Image 2) were health related problems (50%) and adherence to exercise and motivation problems (31.25%).

Those who completed the training improve number of weekly steps (baseline: 42022.92 ± 18836.35 , final: 66448.06 ± 28914.58 ; $t:5.038$; $p<0.001$), BMI (29.45 ± 4.66 to 28.25 ± 4.09 kg/m²; $t:5.629$; $p<0.001$), waist (from 107.34 ± 9.98 to 102.88 ± 9.79 cm; $t:6.840$; $p<0.001$) and the EoQ-5D-EL VAS (from 72.88 to 82.42 ; $t:6.122$; $p<0.001$, image 3). The increase in the steps correlated directly with the improvement in the EoQ VAS ($r:0.308$; $p=0.033$).

Image:

Image 1. Poster used to advertise the activity in the health centers

Image 2:

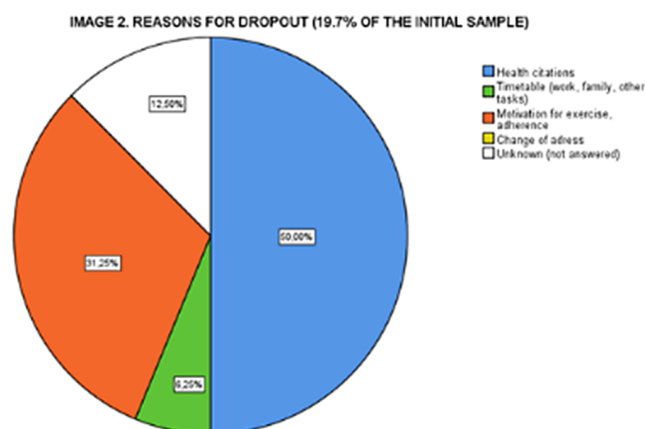

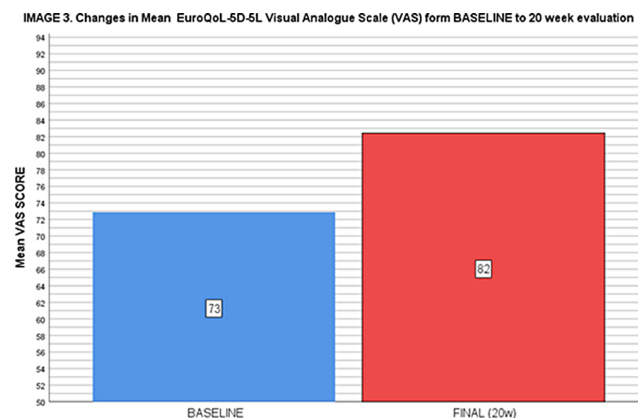

Image 3:

Conclusions: Exercise and lifestyle supervised intervention programs appear to be useful to improve physical health, wellbeing, emotional symptoms and quality of life in people with diabetes and cardiovascular risk.

Factors associated to higher dropout rates were previous limited quality of life scores and mental health worse status. These could be related with limited motivation and adherence to the program and may be of interest to develop specific strategies for these high-risk groups.

Studies focused on the long-term effect of the program are warranted.

Self-perceived health of patients hospitalized due to non-psychiatric conditions: associations with psychiatric comorbidities and substance use

M. Pons-Cabrera^{1*}, E. Caballería-Lamora¹, L. Navarro-Cortés¹, M. Balcells-Oliveró¹, L. Pintor-Pérez² and H. López-Pelayo¹

¹Health and Addictions Research Group (Grup de Recerca Emergent, 2021 SGR 01158, AGAUR). IDIBAPS. Addictions Unit. Psychiatry and Psychology Service. ICN and ²Consultation-Liaison Psychiatry Unit. Psychiatry and Psychology Service. ICN, Hospital Clínic de Barcelona, Barcelona, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1024

Introduction: Self-perceived health (SPH) is an epidemiologically used variable, recognized as a subjective yet predictive indicator of mortality (Bopp *et al.* Plos One 2012; 7:e30795) SPH, among other subjective indicators, such as quality of life, contributes to understanding an individual's overall experience and well-being. While health information, including medical diagnoses given by physicians, forms a substantial part of an individual's subjective health (Falconer & Quesnel-Vallée, 2017; 190 227-236) the World Health Organization (WHO, 2014) defines health not only by the absence of somatic diseases but also encompasses components of social and mental well-being.

Objectives: This study aims to explore factors associated with a poorer level of self-perceived health in inpatients due to non-psychiatric conditions with a focus on mental health and substance use-related factors.

Methods: We recruited 800 patients during their hospital stay for various pathologies in cardiology, pneumology, internal medicine, and gastroenterology units. Self-reported sociodemographic variables and well-being-related variables, such as SPH, were collected during admission. The MINI Neuropsychiatric Interview was administered to screen for psychiatric conditions, the ASSIST scale assessed the risk related to the use of various substances. Data on the frequency and quantity of substance use, in the three months prior to admission, were also recorded by timeline follow-back. Information on the severity of somatic comorbidity was gathered using the Charlson Comorbidity Index. Non-parametric tests compared SPH in different groups, and variables showing significant differences were included in a multivariate linear regression analysis. This study obtained approval from the ethics committee.

Results: Significant and clinically relevant differences were found in the SPH of patients with anxiety disorders, depressive disorders, and bipolar disorders. These patients reported lower SPH than those without these comorbidities. Patients scoring medium or high risk on the ASSIST scale for tobacco, alcohol, and cannabis also demonstrated lower SPH compared to those with low-risk scores. In the multivariate analysis, accounting for confounding factors, including comorbidity severity, patients with depressive disorders maintained statistically significant lower levels of SPH ($\beta = -13.391$, $p < 0.001$), as did those with bipolar disorders ($\beta = -6.096$, $p = 0.019$).

Conclusions: Patients with anxiety, depressive, or bipolar disorders, as well as those with higher-risk use of tobacco, alcohol, and cannabis, exhibited lower SPH. After adjusting for other relevant factors, such as diagnosed somatic pathology, patients with affective disorders continued to score lower in SPH levels. Proper attention and management of psychiatric comorbidities and substance use are crucial in medical hospital settings.

Psychosocial interventions for cardiac surgery patients: context of interdisciplinary interaction

O. Nikolaeva^{1,2}, V. Babokin^{2,3}, N. Trofimov^{2,3} and M. Alhasan^{4*}

¹Department of Hospital Therapy, Ulianov Chuvash State University; ²Chuvash Republic Cardiology Clinic; ³Department of Surgical Diseases and ⁴Medical Faculty, Ulianov Chuvash State University, Cheboksary, Russian Federation

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1025

Introduction: Multi-staged and personalized in nature, psychosocial interventions for cardiac surgery patients explain the necessity of relying on the potential of interdisciplinary interaction

Objectives: To present the review of the model of interdisciplinary interaction of experts and institutions in the course of psychosocial interventions for cardiac surgery patients, which is currently used in the Chuvash Republic.

Methods: This model involves the experts and institutions of the regional healthcare system, the regional system of social care, the regional and federal system of education, non-governmental medical and health resort institutions, and private practitioners.

Results: In the center of this model is the Regional Cardiology Center, which interacts with the Psychotherapeutic Center and the Republican Mental Hospital's Helpline. It also involves the town hospitals and the central district hospitals, non-governmental clinics and private practitioners. The process of rehabilitation and follow-up care continues in the regional health resorts. The social service centers provide additional support. The institute of chief experts of the regional Health Care Ministry, which includes a psychiatrist, cardiologist, psychotherapist, and psychologist, oversees the overall activity. The clinic faculty professors and associate professors are involved in the development of the programs.

Conclusions: The practical results of using the regional model of interdisciplinary interaction enhance the potential of psychosocial interventions for cardiac surgery patients.

The psychological profile of patients with hypertension and its role in patients' self-care

T. Stamoulis^{1*}, E. Dragioti¹, M. Gouva¹ and M. Kourakos¹

¹Research Laboratory Psychology of Patients, Families and Health Professionals, Department of Nursing, School of Health Sciences, University of Ioannina, Ioannina, Greece

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1026

Introduction: Hypertension is a major risk factor for premature death, cardiovascular disease, and stroke worldwide. However, due to the chronic nature of hypertension, patients are at an increased risk of developing mental and emotional disorders, which can affect their adherence to self-care.

Objectives: To conduct a systematic review to investigate the psychological profile, psychological characteristics, and personality traits of hypertensive patients and their role in self-care adherence.

Methods: A thorough and comprehensive literature search was conducted to identify relevant studies for this review. PubMed, Scopus, and APA PsycInfo databases were searched from their inception until March 7th, 2023. The protocol for this review will be registered in the International Prospective Register of Systematic Review (PROSPERO) in the future.

Results: After applying inclusion and exclusion criteria and removing duplicate results, 55 articles were selected, the majority of which were grouped into three main categories based on psychological profiles for accurate analysis and comparison.

Conclusions: This systematic review contributes to the investigation of the relationship between psychological profiles and self-care in hypertensive patients. Despite the prevailing controversy in the literature, a greater proportion of studies indicate that depression, anxiety, low quality of life, type D personality and neurotic personality have a negative impact on self-care in hypertension.

Neuropsychiatric Manifestations of Tuberous Sclerosis in a young adult male in a Psychiatry Hospital in Botswana: a case report

W. T. Chabalala^{1,2*}, K. Bojosi^{1,2}, T. Maphane^{1,2} and A. Olashore^{1,2}

¹Department of Psychiatry, University of Botswana and ²Department of Psychiatry, Sbrana Psychiatry Hospital, Gaborone, Botswana

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1027

Introduction: Tuberous sclerosis complex (TSC) is a disorder that affects multiple systems and was first described in 1880. Its symptoms include seizures, intellectual disability, and adenoma sebaceum. TSC is caused by mutations in the TSC1 and TSC2 genes and is inherited in an autosomal dominant manner.

Objectives: This report highlights a case of a patient with an unusual psychological presentation evaluated in a psychiatric hospital.

Methods: The patient presented with psychotic features and abnormal behavior. A physical examination showed neurocutaneous lesions. After assessment a diagnosis of Tuberous sclerosis complex was confirmed through MRI Brain and genetic testing. Some of his relatives also showed similar neuropsychiatric symptoms.

Results: Tuberous sclerosis complex is diagnosed based on TSC Clinical Consensus Group guidelines of 2012. Our patient fulfilled 4 of the major criteria and genetic testing also yielded a pathogenic variant. A TAND checklist (TSC-Associated Neuropsychiatric Disorders) is used to guide clinicians on areas to prioritize when managing TSC patients.

Image:

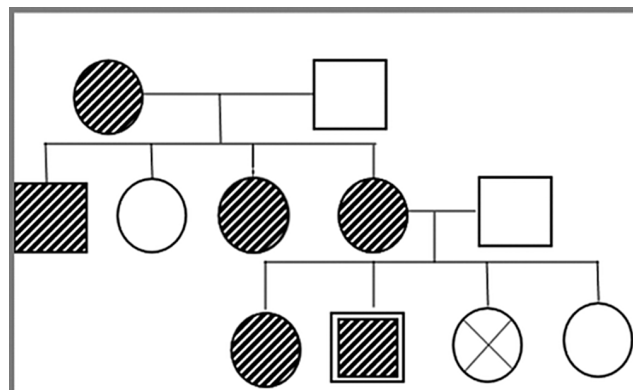

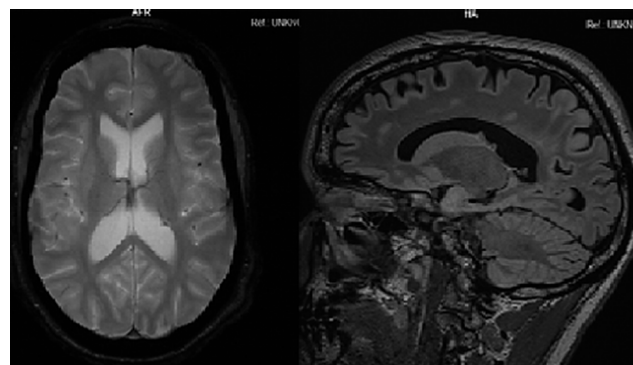

Image 2:

Image 3:

Conclusions: Given that psychiatry may be the first contact for TSC patients, especially in low-resource settings. Patients referred to psychiatry, therefore, need to be thoroughly examined to exclude neuropsychiatric disorders, and a multidisciplinary team approach is vital in investigating and managing these cases.

Elevated Soluble ST2 Blood Levels in Patients with Depression and Comorbid Heart Failure: A Correlative Study

A. K. Sikora* and S. Fedorov

Ivano-Frankivsk National Medical University, Ivano-Frankivsk, Ukraine

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1028

Introduction: Depressive disorders frequently coexist with chronic medical conditions like heart failure (HF), significantly impacting patients' overall health and quality of life. This study aims to explore the correlation between soluble ST2 molecule levels and the presence of depressive disorders in patients with heart failure.

Objectives: A total of 200 patients, all diagnosed with heart failure, were included in this study. Among them, 30 patients were mentally healthy, and the remaining 170 exhibited medium-level depressive disorders. Blood samples were collected and analyzed for soluble ST2 levels to assess the potential correlation between depressive disorders and soluble ST2 levels in patients with heart failure.

Methods: A total of 200 patients, all diagnosed with heart failure, were included in this study. Among them, 30 patients were mentally healthy, and the remaining 170 exhibited medium-level depressive disorders. Blood samples were collected and analyzed for soluble ST2 levels to assess the potential correlation between depressive disorders and soluble ST2 levels in patients with heart failure.

Results: The study demonstrated a statistically significant finding, indicating that the levels of soluble ST2 were 1.6 times higher in patients with depression and comorbid heart failure compared to mentally healthy individuals with heart failure.

Conclusions: This study elucidates a statistically significant correlation between medium-level depressive disorders and elevated soluble ST2 levels in patients with coexisting heart failure, shedding light on the potential role of soluble ST2 as a biomarker in identifying and managing depressive disorders in heart failure patients. The observed 1.6-fold increase in soluble ST2 levels in heart failure patients with depression emphasizes the importance of mental health assessment and intervention in individuals with chronic medical conditions, particularly heart failure, to enhance overall care and outcomes.

Intractable Singultus: Causes, diagnosis and treatment. A case report

C. Díaz Mayoral^{1*}, E. Arroyo Sánchez¹, A. Martínez Pillado² and P. Setién Preciados¹

¹Psiquiatría, Hospital Universitario Príncipe de Asturias and

²Psiquiatría, Hospital Universitario Rey Juan Carlos, Madrid, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1029

Introduction: Hiccups are involuntary, spasmodic contractions of the diaphragm and intercostal muscles that cause inspiration and are interrupted by closure of the glottis. Most sources define the term "persistent hiccups" as lasting more than 2 days and "intractable" as lasting more than 1 month. Both are most likely associated with a pathologic process. "Intractable hiccups" should lead to investigation of organic pathology. If it does not improve, it can interfere with the patient's ability to eat, socialize and sleep, leading to a significant worsening of quality of life. "Intractable hiccups" are more frequent in men (91%), over 50 years of age. Women suffer from psychogenic hiccups more frequently than men. Anxiety or stress can trigger hiccups. Multiple neurotransmitters are involved.

Objectives: We present a theoretical review on the topic.

Methods: A bibliographic review on the topic.

Results: In recent years, new trials and case series have been published, and regulatory agencies have issued new recommendations on the use of pharmacologic agents for this indication. The literature has described the efficacy of several pharmacologic agents in the empiric treatment of persistent and intractable hiccups. Most of these target dopaminergic and GABAergic receptors.

Based on limited efficacy and safety data, Baclofen and Gabapentin can be considered as first-line treatment for intractable and persistent hiccups, as they suggest efficacy and are less likely to cause long-term side effects than standard neuroleptic agents. Dopamine blocking agents such as Metoclopramide, Chlorpromazine, and Haloperidol, could be used as second line. In one study, withdrawal of Benzodiazepines or addition of Pregabalin was found to help reduce hiccups.

The patient we consulted came for persistent hiccups or singultus of 2 years of evolution. Organic pathology was ruled out. She related the onset of the symptoms to different stressors that had caused her anxiety. We administered Escitalopram and Gabapentin and indicated withdrawal of Bromazepam, which she started taking months ago. In follow-up appointments she reported a decrease in the intensity and frequency of the symptoms, with a notable improvement in her quality of life.

Conclusions: Considering all available evidence, a treatment algorithm with Baclofen is recommended as first-line therapy for persistent and intractable hiccups. Gabapentin may also be safe and effective in the long-term treatment of this condition, especially for patients with CNS disease. Metoclopramide is no longer recommended for long-term treatment of hiccups. Clinical experience also supports the use of Chlorpromazine and other neuroleptics for acute, but not long-term, treatment. Going forward, large multicenter studies will be needed to create an adequate evidence base for the treatment of persistent and intractable hiccups. Until then, guidelines will continue to be based on unreliable data and clinical experience.

Psychiatric disorder in prolonged post-concussive syndrom : clinical assessment, physiopathology and management review of the literature

I. Bouguerra*, A. Touiti, A. Hajri, A. Maamri and H. Zalila

Outpatient and Emergency Psychiatric Department, Razi Hospital, Manouba, Tunisia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1030

Introduction: According to the American Psychiatric Association's Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition (DSM-5), post concussive syndrome (PCS) is given a diagnosis of either major or mild neurocognitive disorder (NCD) due to traumatic brain injury TBI. However Persistent post-concussion symptoms (PPCS) are more complex, and typically involve multidisciplinary assessment and management. The symptoms are varied, non-specific and the therapeutic process is defiant for psychiatrist.

Objectives: To investigate the semiology of persistent post-concussion syndrome (PPCS) and the therapeutic challenges it poses.

Methods: A literature review was made on Pubmed, Google Scholar and Cochrane library using keywords: "post-concussive syndrome", "psychiatric disorder", "depression", "post-traumatic stress disorder", "treatment", "physiopathology".

Results: The physiopathology of persistent PCS is controversy. The Symptoms are due to the Concept of "Symptom Generators" which results from the alterations in neurophysiology and neuropathology secondary to the injury, and pre- or post-injury psychological factors physiological concussion. The Global cerebral metabolic disturbance, the autonomic nervous system dysfunction and the cerebral blood flow dysregulation induce biochemical cascade, excitotoxic reaction and immunotoxicity.

Clinical diagnoses associated with PPCS are: Major depressive disorder, Post traumatic stress disorder, Anxiety disorder, Substance abuse disorder, Psychotic disorder and Antisocial personality disorder. For the non pharmacological management: A systematically early information and a graded physical exercise in addition to other treatment are essential.

Antidepressant, benzodiazepine and mood-stabilizer are the most recommended treatments for psychiatric symptoms. Atypical neuroleptics are indicated in delirant disorder, behavior disorder and antisocial personality disorder. Some studies suggest the methylphenidate and biperiden to treat several cognitive impairment and severe behavior disorder.

Conclusions: (PPCS) is far from being a subjective complaint by patients. It is a complex clinical entity that groups symptoms that overlap with other psychiatric diagnoses, such as depression, post-traumatic stress disorder, and mood disorders. Early neuropsychiatric assessment and personalized pharmacological and psychotherapeutic treatment are essential factors in the prognosis of the disease.

Late-onset mania as a manifestation of neurosyphilis: A Case Report

A. Labyadh*, S. Omri, W. Haouari, I. Gassara, R. Feki, N. Smaoui, L. Zouari, J. Ben thabet, M. Maalej, N. Charfi and M. Maalej Bouali

psychiatry C department, hedi cheker hospital, Sfax, Tunisia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1031

Introduction: The evaluation of manic behavior with later onset is crucial, as various organic factors such as medications, infections, metabolic disturbances, tumors, and epilepsy can serve as potential etiological causes. While not universally observed, most studies indicate a connection between late-onset mania and neurological disorders like neurosyphilis.

Objectives: Our study aims to investigate the relationship between late-onset mania and neurosyphilis.

Methods: In this paper, we present a case of neurosyphilis presenting exclusively with symptoms of mania.

Results: A 72-year-old Tunisian woman with no prior medical or psychiatric history was referred to the psychiatric emergency room due to alterations in her mental state and behavior over the past ten days. During the psychiatric assessment, she displayed increased motor activity, fluctuating emotions, and rapid flow of ideas. The general physical examination yielded no notable findings. The serum Venereal Disease Research Laboratory (VDRL) test returned a strongly positive result (+++), and the TPHA examination confirmed a positive result at a titer of 1/60. In the serologic analysis of cerebrospinal fluid, VDRL was also positive, thereby confirming the diagnosis of neurosyphilis (NS). The diagnosis of mania secondary to a medical condition was established. The patient was treated with ceftriaxone and antimanic medications, resulting in a significant improvement in her psychiatric symptoms within a few days.

Conclusions: This case underscores the importance of conducting serologic testing for syphilis in patients who present with manic symptoms, experience a late-onset mental disorder, and have no prior history or family history of affective disorders.

Psychological meanings reported by patients with Graves' Disease in hyperthyroidism but without ophthalmopathy about their quotidian life: A qualitative study conducted in a Brazilian university specialized outpatient service

L. S. Valladão*, F. S. Silva, C. F. Casagrande, L. M. Guerra, D. E. Zantut-Wittmann and E. R. Turato

Lab of Clinical-Qualitative Research, State University of Campinas, Campinas, Brazil

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1032

Introduction: To handle well clinical treatments, it is crucial to know the expectations of patients who seek help. We need to ask ourselves: how do patients interpret subjectively their diagnosis,

treatments, and self-care? Medical Psychology brings us theories for this understanding. Grave's Disease is an autoimmune disorder, a form of hyperthyroidism with a goitre, affecting also the eyes and the skin, as well as emotional manifestations. Weight loss, sometimes psychologically welcome, although due to a disease, can mean a psychoanalytic secondary gain. So, the medicine that leads to clinical improvement can be taken with ambivalence and bad adherence to treatment. It is important to differentiate between disease, a scientific entity explained by the clinical professional, and illness as a patient's subjective perception of an un-health.

Objectives: To understand psychodynamically the fantasies, desires, and views related to Graves' Disease as reported by patients in hyperthyroidism but without ophthalmopathy interviewed at an endocrinology-specialized outpatient clinic. (in the EPA-2023, it was presented the qualitative results of a sample in hyperthyroidism, with ophthalmopathy, studied at the same service).

Methods: Clinical-Qualitative Method designed by Turato. Data collected through Semi-Directed Interviews with Open-ended Questions in-Depth; and Field Notes, transcript fully. Treated by the Seven Steps of Clinical-Qualitative Content Analysis of Faria-Schützer, using psychodynamic concepts from Balintian Medical Psychology. Although we have extracted categories that permit us interesting discussions, we intend to close the sample (through the information saturation criterion by Fontanella) when we obtain other categories. The interviewer, a male psychologist, is the first author. The findings are validated by peer-reviewers of the Lab of Clinical Qualitative Research of the State University of Campinas.

Results: Three categories were chosen for this presentation: 1) "An atomic bomb in my life": How drastic changes of a hormonal disease re-symbolize the patient's life; 2) "I didn't think the thyroid did that much": the disease seen as a metaphor in a psychological blaming language to own disease and to himself as a sick person. 3) "I have so much medicine!": a mode of referring to treatment that would justify an undisciplined use of medications.

Conclusions: Our findings can help clinical professionals to have a better understanding of some psychological meanings which have sense in the patients' conscience, often not verbalized clearly in the conversation, and so to handle better the patients and relatives. In this way, it can reduce the patient's resistance to recommended treatment, as well as encourage the clinical team to construct empathy with them.

A Study of Dry Mouth and Gastrointestinal Disorders in Patients Taking Antidepressant

S.-Y. Lee^{1*} and H.-J. Lee²

¹Psychiatry, Wonkwang University Hospital and ²Public Health, Wonkwang University Graduate School, Iksan, Korea, Republic Of

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1033

Introduction: Dry mouth is a subjective symptom of the feeling of dehydration inside of the mouth and is closely linked to reduced salivary secretion. The occurrence of dry mouth and GI disorders due to antidepressants greatly affects the course of the mental disorder and medication compliance, but it has barely ever been studied.

Objectives: The purpose of this study was to identify the characteristics of dry mouth and gastrointestinal (GI) disorders in antidepressant patients.

Methods: The study included 103 antidepressant-taking patients. Antidepressants were classified according to their mode of action. The GI disorders were investigated using the medical records of the patients. The Patient Health Questionnaire-15 and a questionnaire for assessing dry mouth symptoms were used in this study. The questionnaire for the evaluation of dry mouth symptoms, a visual analog scale (VAS)-based instrument, developed and evaluated for reliability by Lee et al. was used to assess dry mouth. In the questionnaire, 6 VAS items were assessed for the extent of dry mouth (0-100 points): 1) dry mouth at night or when waking up in the morning, 2) dry mouth during the day, 3) dry mouth when eating, 4) difficulty in swallowing, 5) subjective evaluation of the volume of saliva in the mouth, and 6) overall discomfort in daily life. Additionally, four items examined behaviors due to dry mouth (1-5 points): 1) frequency of waking up from sleep due to dry mouth, 2) frequency of preparing drinking water before going to bed, 3) frequency of drinking water when eating solid foods, and 4) frequency of eating hard candies or chewing gums to help dry mouth.

Results: The score for "overall discomfort due to dry mouth in daily life" (31.72 ± 33.82), "dry mouth at night or in the morning" (47.86 ± 35.87), and "dry mouth during the day" (39.83 ± 31.67) were slightly higher than "discomfort in chewing or swallowing foods". According to somatization severity, the mean values were 116.36 ± 113.34 in the mild, 213.18 ± 136.98 in the moderate, and 277.59 ± 201.44 in the severe, the between-group difference was significant ($F=10.294$, $p<0.001$). According to the class of antidepressants, the mean score was 180.00 ± 147.5 for vortioxetine, 194.25 ± 169.33 for selective serotonin reuptake inhibitors (SSRIs), 223.61 ± 156.70 for serotonin and norepinephrine reuptake inhibitors (SNRIs), 75.00 ± 57.00 for norepinephrine dopamine reuptake inhibitors (NDRIs), 201.67 ± 174.66 for Nasser, and 116.67 ± 132.03 for agomelatine. A total of 67 (65.0%) patients had at least one GI disorder.

Conclusions: The study findings are expected to help increase medication compliance in antidepressant patients by better controlling the side effects experienced by the patients.

Disclosure of Interest: None Declared

EPV0298

Personalization of therapy of psychopathological complications of cardiac surgery in artificial circulation conditions

M. Markova^{1*}, D. Mankovsky² and T. Abdriakhimova³

¹Kharkiv National Medical University, Kharkiv; ²SI "Heart Institute of the Ministry of Health of Ukraine" and ³Bogomolets National Medical University, Kyiv, Ukraine

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1034

Introduction: The study of the clinical and phenomenological features of psychopathological complications of cardiac surgery (CS) in artificial circulation conditions (ACC), the development of modern approaches to early diagnosis and prognosis of

psychopathology is an effective way to solve this problem has valid medical and social significance.

Objectives: To increase the effectiveness of prevention of psychopathological disorders in cardiosurgical interventions based on personalization of their correction.

Methods: The examination included the use of socio-demographic, instrumental, biochemical, clinical-psychopathological, psychometric, and statistical methods.

Results: The study sample consisted of 700 patients who were treated by CS in ACC at the SI “Heart Institute of the MH of Ukraine”.

It was found out that the most common complication is postsurgeon cognitive dysfunction (PCD) (72.0% of patients), postsurgeon encephalopathy (PE) (31.0%) is less common, and cerebral infarction (CI) is the least common (12.2%).

It was revealed that the core psychopathological symptoms associated with CS are cognitive disorders (72.0% of the examined) and affective symptoms, represented by depressive (38.1%) and anxiety (33.9%) manifestations of mild and moderate expressiveness, and auxiliary constructs – dysomnic (29.7%), asthenic (17.9%) and somatovegetative (9.0%) disorders. The highest prevalence of psychopathological symptoms was found in patients with CI, somewhat less in patients with PE, and the lowest in patients with PCD. Signs of mild depressive disorder were found in patients who underwent CS in ACC, elevated levels of adynamic depression indicators, depression with fear and agitated depression, as well as increased levels of anxiety: the average level of anxiety, mental and somatic anxiety. The indicators of expressiveness of depression and anxiety in patients with CI turned out to be the highest, in patients with PE – lower, and in patients with PCD – the lowest. We proposed a mathematical model for predicting the development of psychosocial maladjustment (PM) in patients who have undergone CS in ACC. It is based on a comprehensive assessment of three key vectors that can have a mutually potentiating pathogenetically related effect on the course of the formation of PM: surgical, neurological, and psychopathological. A complex of diagnostic, corrective and preventive measures for each of the risk groups has been developed.

Conclusions: Verification of the proposed model on a representative sample of patients confirmed its high predictive ability and reliability in use.

Predictors for Burnout Among Healthcare Workers in a Post -Covid Era

L. Lim^{1*}, G. Heng², L. Loh², Y. H. Chan³, L. Eng², C. Chan⁴ and J. Fam²

¹Psychiatry; ²Department of Psychiatry, Singapore General Hospital; ³Biostatistics Unit, National University of Singapore, Yong Loo Lin School of Medicine and ⁴Duke- NUS Medical School, Singapore, Singapore

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1035

Introduction: We aimed to study predictive factors for burnout (BO) among healthcare workers in a tertiary hospital in Singapore.

Objectives: We hypothesized that burnout would be associated with singles, females, and foreign born staff recently moved into this country, unaccompanied by family members.

We further hypothesised that BO would be associated with those scoring less on resilience. Recognising that social support mitigated against stress and burnout, we hypothesized that those who perceived less support would be more prone to BO.

Methods: The study questionnaire was sent via corporate email to all staff with email access. We stressed that data would be fully anonymised. No financial rewards were given for participation which was carried out on a voluntary basis.

The following instruments were used, viz. F-SozU K-6, a brief form of the perceived social support questionnaire; Connor Davidson Resilience Scale; Oldenburg Burnout Inventory; Patient Health Questionnaire-4 item; Demand Control Support Questionnaire and Leisure Time Satisfaction Scale. Ethics approval for the study was sought from the SingHealth Centralised Institutional Review Board, which granted exemption of participant consent.

Analyses were performed using Stata version 17.0 (StataCorp. 2021), with statistical significance set as 2-sided 5% ($p < 0.05$). The reliability and internal consistency of the scales used were assessed using Cronbach Alphas and Confirmatory Factor Analysis (CFA).

Results: Neither males nor females were more at risk for BO. And contrary to what we hypothesised those who recently moved to this nation were not at greater risk for BO ($p > 0.05$). Multivariate analyses showed that younger workers displayed higher burnout scores ($p < 0.001$). The psychological demand sub-score was positively associated with burnout [0.61 (95% CI 0.45 to 0.77), $p < 0.001$]. Conversely, decision latitude [-0.33 (95% CI -0.44 to -0.21), $p < 0.001$] and support [-0.47 (95% CI -0.60 to -0.35), $p < 0.001$] were negatively associated with BO.

Those who experienced anxiety or depressive symptoms were respectively more likely to experience burnout [0.30 (95% CI 0.02 to 0.58), $p = 0.035$ and 0.72 (95% CI 0.41 to 1.02), $p < 0.001$], with a clear association between higher PHQ-4 scores and risk for burnout ($r = 0.619$).

Moreover, satisfaction with utilisation of leisure time was inversely related to BO [-0.55 (95% CI -0.68 to -0.41; $p < 0.001$)]. We could not find any association between number of years worked, profession, marital status and perceived social support and BO, on multivariate analysis ($p > 0.05$).

Conclusions: Stress reduction interventions should be made available for all staff, especially addressing those at highest risk for burnout.

The COVID-19 pandemic as a traumatic experience in the general population

T. Mastelić¹, V. Višić², T. Borovina Marasović¹, N. Rančić¹, D. Vukorepa¹, M. Milanović¹, Ž. Kralj¹, E. Burilović¹, M. Pernat¹, K. Glavičić², M. Baković², A. Sabljarić², S. Kozina³, D. Lasić¹, M. Mavar² and T. Glavina^{1*}

¹Psychiatry Department, University Hospital of Split, Split; ²Psychiatric Hospital Ugljan, Ugljan and ³Psychological medicine, School of Medicine Split, Split, Croatia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1036

Introduction: The COVID-19 pandemic has significantly affected everyday life in most countries of the world. Researches conducted in 2020 showed that COVID-19 was a traumatic experience for 18-60% of respondents in the general population, depending on the country where the research is conducted. Researches for later periods are rare, although we can expect significant changes. We found only one study from 2023 on this topic, although not on the general population.

Objectives: That is why we were interested in what the situation is like after 3 years of the pandemic, when we have been living without non-pharmacological anti-pandemic measures for almost a year.

Methods: The research was conducted at the beginning of 2023. 48 respondents who were not treated psychiatrically or are medical workers were surveyed, because it was shown that these groups were exposed to a greater risk of impaired mental health during the COVID-19 pandemic. To assess the level of traumatic experience, i.e. the risk of developing PTSD as a consequence of the COVID-19 pandemic, we used the Impact of Event Scale With Modifications for COVID-19 (IES-COVID19). A score on that scale of 27 to 34 indicates a clinically significant level of trauma, i.e. there is a 75% chance of developing PTSD. A result of 35 and above suggests that it is necessary to seek professional help.

Results: Our research included 19 (39.6%) men and 29 (60.4%) women. The average age of the respondents is 60.4 years. 29 (60.4%) respondents know that they have recovered from COVID-19. 2 (4.2%) subjects were treated in the hospital due to COVID-19. 8 (16.7%) respondents have a traumatic experience of the COVID-19 pandemic. 5 (10.4%) respondents are in the category of clinically significant level of trauma, while 3 (6.3%) respondents are in the category that should seek professional help. The group traumatized by COVID-19 does not have significantly more respondents who recovered from COVID-19 ($p=0.510$) nor does it differ in terms of gender representation ($p=0.984$).

Conclusions: At the beginning of the COVID-19 pandemic, there were discussions about whether it can even be classified as a traumatic experience and whether we can talk about PTSD as a consequence of the pandemic. With this time lag, it seems that in part of the population we are finding PTSD symptoms that are a consequence of the pandemic, but to a lesser extent than research at the beginning of the pandemic suggested. Certainly, additional research is needed on this topic. Also, it is necessary to examine risk factors for possible prevention, as well as therapeutic possibilities.

Contagion beyond the virus: A case obsessive-compulsive disorder centered on Covid-19

A. S. Pires*, M. Pires, J. Nunes, I. F. Vaz, S. Mouta, B. Jesus, D. Cruz e Sousa and D. Figueiredo

Department of Psychiatry and Mental Health, Local Health Unit, Guarda, Portugal

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1037

Introduction: The Covid-19 pandemic has generated an unprecedented impact on multiple levels (health, occupational, economic,

and social) which affected the general population and has been an enormous stress factor for individuals with obsessive-compulsive disorder (OCD), particularly for those with contamination symptoms. Many patients, as well as healthy individuals, experienced new obsessive-compulsive-like symptoms centered on COVID-19 during the pandemic. However, data on this population are still scarce.

Objectives: To present a case exemplifying the association between the Covid-19 pandemic and the onset of OCD.

Methods: Case presentation and non-systematic review of existing literature on Pubmed using the keywords: Covid-19, OCD, pandemic, depression.

Results: We report a case of a 30-year-old female who presented to the emergency department due to depressive mood and suicidal ideation associated with exacerbation of OCD symptoms, namely intense fear of being infected with Covid-19. These symptoms led to avoidance of touching objects, surfaces or even herself in addition to frequent and long rituals of hand-washing and showers. She was asymptomatic prior to being infected with Covid-19, when she started developing obsessive ideas of contamination. She sought psychiatric support and was medicated with fluoxetine, olanzapine and clonazepam. Due to insufficient symptom control, she was admitted to the psychiatry ward, where treatment was initiated with aripiprazol and fluvoxamine. After dose titration, gradual remission of OCD symptomatology and depressive mood was observed.

Conclusions: The present case illustrates the correlation between Covid-19 and the onset of OCD symptomatology. Existing studies demonstrate that the pandemic worsened the landscape of symptoms of OCD, both in diagnosed patients as well as in previously healthy individuals. However literature is still limited thus, multi-national and cross-cultural, longitudinal studies are warranted to gain further insights on this topic.

Online T group experiences during COVID-19 pandemic

G. Arbanas¹, A. Botica^{2*}, H. Goršić³, M. Baković⁴, M. Bagarić⁵ and I. Barun³

¹department of forensics, University Psychiatric Hospital Vrapče, Zagreb; ²Department of psychiatry, University Hospital of Split, Split; ³University Psychiatric Hospital "Sveti Ivan", Zagreb; ⁴Ugljan, Psychiatry Hospital, Zadar and ⁵University Psychiatric Hospital Vrapče, Zagreb, Croatia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1038

Introduction: Online group therapy has become more popular in the past few years. But as a result of the COVID-19-caused pandemic, it developed suddenly. Due to the conventional face-to-face format no longer being possible and the need for psychotherapists to conduct psychotherapy online, the pandemic has had significant effects on group psychotherapy and the interactions between group therapy members. While therapists are becoming accustomed to the modern form of psychotherapy, its efficacy is being questioned due to technical issues, the problem of the therapeutic alliance, the environment, the ability to read nonverbal signals, breaking group

norms, etc. Since the pandemic did not abate, as a part of specialist education training groups were also held online.

Objectives: The pandemic changed the basic settings of our Group-Analytic Training Group, forcing us to switch to online sessions. This study aimed to find personal experiences that varied throughout online and face-to-face meetings.

Methods: Seven out of the twelve participants accepted to take part in the group therapy/training after it was recommended by the group leader that they write a paper. After 30 sessions, the group turned from face-to-face to online group therapy, and the members were asked how they felt about the difference between the two types of therapy. A questionnaire was produced by the group's leader and a number of other participants, who then forwarded it through email to every group member.

Results: Everyone who participated thought that because one can more quickly pick up on non-verbal signs in a face-to-face scenario, it was simpler to notice feedback from the other group members. Most participant comments focused on the leader's role. The majority of members claimed that taking part in the experiential group had benefited both their personal and professional lives. However they thought the in-person setting was better since it was more interesting and complex.

Conclusions: Since there were no other options during the epidemic, group therapy has moved to virtual environments, although there are still a lot of problems to this method. The formation of group cohesion becomes difficult by the absence of group members' physical presence and by the inability to completely understand nonverbal communication.

Relationship between changing cognitive domains and atypical antipsychotic treatment in bipolar disorders: a three-year observational study in a psychiatric rehabilitation center during COVID-19 pandemic

F. Franza¹, B. Solomita¹ and A. Franza^{2*}

¹"Villa dei Pini" Clinic, Psychiatric Rehabilitation Centre, Avellino and

²Neamente Study Center, Napoli - Avellino, Italy

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1039

Introduction: Bipolar Disorders have been consistently associated with cognitive dysfunction across a broad range of cognitive domains (patients, who usually took psychiatric drugs, sometimes presented changes of cognitive disorders). Many studies have focused on improving the illness severity of patients with MDD or BD by combining mood-stabilizing drugs with atypical antipsychotics (AA). However, the results are contradictory and have not confirmed the certain superiority of AA to other therapeutic strategies. Among these, the cognitive remedy has demonstrated important effectiveness on cognitive variations in this group of patients.

Objectives: In our study, we tried to evaluate some changes in cognitive function in patients with BD treated with antipsychotics related to critical problems with typical cognitive tests.

Methods: In our observational study, we recruited forty-three inpatients (20 females, 23 males) affected by Bipolar Disorder

(DSM-5 criteria; particularly 78.5% affected by BD-I), in a psychiatric rehabilitation center. All patients were included in the ordinary rehabilitation treatment. All patients were treated with mood stabilizers (lithium n. 14; valproate n. 29), and at least one AA. The AAs have been the following: quetiapine, aripiprazole, and olanzapine (authorized in Italy)(Table 1). The observation period lasted three years, during three significant waves of the COVID-19 pandemic.

All patients at baseline (T0) (March-April 2020), T1 (Maj-June 2021), T2 (April-Maj 2022), and T3 (April – June 2023) were administered the following rating scales: BPRS, YMRS, GAF, and HAM-D

The data were statistically analyzed with the EZAnalyze 3.0 software for the Excel platform.

Results: In Table 2 and Graphic the results obtained with the rating scales and statistical analysis are shown. In BRPS the data shows a statistically significant reduction in the total score in all periods analyzed. Similar results were found in the GAF and YRMS scales. However, with the HAM-D Scale, there was evidence of an increase in T2, although the differences were not statistically demonstrated. The differences in mean scores are more evident for quetiapine and olanzapine.

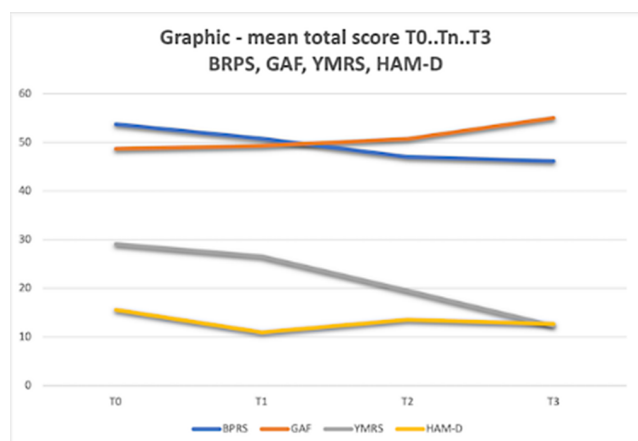

Image:

Table 1 - Epidemiological data and Drugs			
	Number	Age (mean YRS ±SD)	
Total	43	41,88	13,10
Felames	20	41,95	13,13
Males	32	41,83	13,36
mean daily dosage (mg)			
Aripiprazole	11	12.82	
Olanzapine	12	17.34	
Quetiapine	20	564.55	
Lithium	13	321.59	
Valproate	20	923.54	

Image 2:

Table 2 – EZAnalyze rating scales						
	BPRS T0	BPRS T1	BPRS T2	BPRS T3	P	Eta Squared
Mean:	53.744	50.791	47.000	46.163	0.000	0.368
Std. Dev:	10.050	9.244	7.792	9.131		
Comparison	Mean Difference	T-Value	P - Unadjusted	P - Bonferroni	Eta Squared	
BPRS T0 vs T3	7.581	6.294	0.000	0.000	0.480	
	GAF T0	GAF T1	GAF T2	GAF T3	P	Eta Squared
Mean:	48.698	49.302	50.721	55.023	0.000	0.347
Std. Dev:	7.984	6.951	6.526	7.751		
Comparison	Mean Difference	T-Value	P - Unadjusted	P - Bonferroni	Eta Squared	
GAF T0 vs T3	6.326	5.440	0.000	0.000	0.408	
	YMRS T0	YMRS T1	YMRS T2	YMRS T3	P	Eta Squared
Mean:	29.118	26.559	19.500	12.324	0.000	0.640
Std. Dev:	5.564	7.033	8.232	7.413		
Comparison	Mean Difference	T-Value	P - Unadjusted	P - Bonferroni	Eta Squared	
T0 and T3	16.794	10.490	0.000	0.000	0.764	
	HAM-D T0	HAM-D T1	HAM-D T2	HAM-D T3	P	Eta Squared
Mean:	15.559	10.971	13.559	12.706	0.113	0.058
Std. Dev:	10.437	7.461	8.718	8.909		

The ANOVA results indicate that none of the repeated measures differed significantly

Image 3:

Conclusions: Our observational study showed that the atypical antipsychotics used in our work allowed a significant improvement of the symptoms in BD. However, the pandemic waves have no correlation with the treatment performed. New studies are necessary to highlight the relationship of the pharmacological treatment of BD with the progress of the COVID-19 pandemic.

Persistent COVID an differential diagnosis with depression symptoms

B. Arribas Simon^{1*}, M. J. Mateos-Sexmero¹, O. Martin-Santiago¹, P. Andres-Olivera², B. Rodriguez-Rodriguez², P. Martinez-Gimeno¹, N. Navarro-Barriga³, T. Jimenez-Aparicio¹ and M. Andreo-Vidal¹

¹Psychiatry, Hospital Clinico Universitario, Valladolid; ²Psychiatry, Complejo Asistencial Universitario, Salamanca and ³Hospital Clinico Universitario, Valladolid, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1040

Introduction: We present the case of a 48-year-old woman, a nurse, referred from the Internal Medicine department for evaluation of depressive symptoms and accompanying somatic presentation following COVID-19. The aim is to highlight a recently emerging condition that we are increasingly encountering in our clinics, which can complicate the diagnosis of an underlying affective disorder

Objectives: Diagnosed with COVID-19, confirmed by a positive PCR test, 6 months ago following an infection in the workplace. The clinical picture consisted of mild symptoms, with a ten-day course and apparent resolution at the time of hospitalization. She returned to her work activities and gradually began to report fluctuating symptoms, including headaches, mild shortness of breath, fatigue, as well as a tingling sensation in the upper extremities, especially in the hands. Additionally, she described feelings of restlessness,

depressive mood, and intense fatigue. In additional tests: (CT-Scan) there are signs of mild bilateral lower lung fibrosis.

Methods: Treatment with Duloxetine was initiated for a case of depressive symptoms with accompanying physical symptoms. The differential diagnosis considered Major Depressive Disorder, Single Episode, and Adjustment Disorder with Depressed Mood.”

Results: We are facing a clear case of depressive clinic that may have endogenous features, if we adhere to criteria such as those in the DSM-5, as it would meet the criteria for Major Depressive Disorder, Single Episode. However, we have a clearly identified trigger, so we also need to perform a differential diagnosis, primarily with Adjustment Disorder with Depressed Mood: here, the symptoms appear within 3 months following the stressful agent (in this case, SARS-CoV-2 infection). Unlike Major Depressive Episode, once the agent has ceased, the symptoms do not persist beyond 6 months (which we do not know because the physical symptoms causing disability have not disappeared). In addition to purely psychiatric diagnoses that we are accustomed to, we must consider a new diagnostic entity that is becoming more prevalent as the pandemic progresses, namely “long-covid” or persistent COVID. These are generally middle-aged women who, several months after infection, continue to manifest a multifactorial complex of symptoms. These symptoms persist over time, not only the classical ones but also many others that can appear during the ongoing course of the disease.

Conclusions: Beyond the purely psychiatric diagnoses we are accustomed to, we must also consider a new diagnostic entity that is becoming more prevalent as the pandemic continues to advance: Persistent COVID or ‘long-COVID.’ Generally, this condition affects middle-aged women who, several months after contracting the virus, continue to exhibit a multifactorial complex of symptoms. The most common symptoms include fatigue/asthenia (95.91%); general discomfort (95.47%); headaches (86.53%); and low mood (86.21%)

Insomnia and pain in COVID-19 survivors: a cohort Tunisian study

T. Mariem¹, B. Nadia^{1*}, B. A. Houada², M. Islem¹, H. Najla¹, M. Sameh³, K. Samy³, E. Sahar¹ and A. Jihen¹

¹Psychiatry “B”; ²Preventive medicine and hospital hygiene and ³Pneumology, Hedi Chaker university hospital, Sfax, Tunisia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1041

Introduction: The SARS-COV-2 infection emerging in 2019 caused over 600 million infected people worldwide leading to an explosion of multiple physical and mental health problems. In this study we brought the light to the persistent troubles in sleep and pain among the survivors of the pandemic.

Objectives: We aimed to assess the prevalence of insomnia and the severity of pain among covid-19 survivors, and to seek an association between the two disorders.

Methods: We conducted a prospective cohort study including 121 Tunisian COVID-19 inpatients who had been discharged alive from hospital. Each enrolled patient was asked about the period before the hospital stay, and the 6-9 month-period after hospital

discharge, using the *visual analog scale* (VAS) to assess pain, *insomnia severity index* (ISI) to evaluate insomnia severity and the *mMRC* (modified British Medical Research Council) to estimate dyspnea.

Results: The median age of participants was 59 years. Among them, 51.2% were females.

Our findings showed a significant increase in VAS score after COVID infection (1 [IQR (1-2)] vs 3 [1-6]; $p < 0.001$) as well as with the ISI score (1 [IQR (1-1)] vs 5 [IQR (1-9)]; $p < 0.0001$). The prevalence of insomnia and pain in long haulers was 30.56% and 26.4% respectively.

We found a significant correlation between insomnia and pain ($p < 0.0001$, $r = 0.398$). We also found a significant association between dyspnea and insomnia ($p < 0.0001$) and between dyspnea and pain ($p = 0.001$). The age of the patients was correlated with insomnia ($p = 0.028$) and with dyspnea ($p = 0.007$) but not with pain. Female gender was associated with developing insomnia ($p < 0.0001$) and with pain ($p = 0.001$) but not with dyspnea.

Conclusions: Screening for persistent symptoms after the pandemic is important to help the survivors getting a better recovery in the long term.

Influencing factors of presenteeism among Portuguese workers in a private social solidarity institution in the aftermath of COVID-19

C. Laranjeira^{1,2*} and A. C. Maurício^{1,3}

¹School of Health Sciences; ²ciTechCare, Polytechnic University of Leiria, Leiria and ³Santa Casa da Misericórdia de Porto de Mós, Porto de Mós, Portugal

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1042

Introduction: In ordinary circumstances, the employed individuals demonstrate significant levels of psychological distress and presenteeism, a situation that has been further intensified by the COVID-19 epidemic. Furthermore, a limited number of studies have examined the phenomenon of presenteeism in the context of the COVID-19 pandemic, therefore necessitating the undertaking of the present study.

Objectives: The goal of this study was to investigate the levels of presenteeism and its related characteristics, as well as job satisfaction and psychological distress, among a sample of employees employed at a Private Social Solidarity Institution (IPSS) in Portugal.

Methods: A cross-sectional survey was undertaken in 2022 to observe personnel from an IPSS located in the central area of Portugal. The research had a sample size of 71 workers who were provided with a signed authorization. The survey was designed to gather both general and professional information from participants. Additionally, it included the Stanford Presenteeism Scale (SPS-6), the Job Satisfaction Questionnaire (S20/23), and the Kessler Psychological Distress Scale (K10) as measurement tools.

Results: The occurrence of presenteeism was seen in 32 employees, accounting for 45.1% of the sample, whereas illness absence was reported by 38 workers, representing 54.3% of the sample. The majority of the individual assessments for S20/23 demonstrated a

higher degree of satisfaction (mean ≥ 4.5 points.), with the exception of the salary-related issue, which elicited a higher level of discontent (mean = 3.36 ± 1.9 pts.). Approximately 50.7% of the individuals had a high or very high susceptibility to experiencing or developing a mental condition. The correlation matrix revealed a statistically significant moderate positive association between presenteeism and work satisfaction, as well as a statistically significant moderate negative link between presenteeism and psychological distress ($p < 0.01$). The associated factors of presenteeism were found to be marital status, quality of sleep, illness absenteeism, health perception, and psychological distress. The combined effect of these predictors was shown to account for 35.8% of the variance in presenteeism.

Conclusions: It is expected that the outcomes of our research will stimulate more investigations into the tangible implications of presenteeism in promoting improved health and well-being within the workplace.

Screening the dysfunctional grief and its associated factors due to a death from covid-19 in Tunisia

F. Askri*, M. Dhemaïd, K. Mahfoudh, S. Jedda, U. Ouali and A. Aïssa

PSYCHIATRY A, RAZI HOSPITAL, Manouba, Tunisia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1043

Introduction: In Tunisia, the 2019 corona virus pandemic was a challenging health situation, with more than 28 000 confirmed deaths in May 2022. The pandemic was responsible for people losing their beloved ones in a sudden and brutal ways. Even though the numbers of bereaved people had been escalating, little attention was paid toward their mental health. Grief is a normal response to losing someone close. However, recent studies have shown that the covid-19 grief is more severe than other causes of grief. It not only causes a negative impact on the bereaved life aspects but also creates severe consequences in the society. Screening a possible dysfunctional grief is a major need to prevent serious outcomes.

Objectives: To identify the prevalence of covid-19 dysfunctional grief and find out the possible associated risk factors to it.

Methods: A cross sectional online survey designed using Google Forms and distributed on social media platforms (Facebook, Instagram, WhatsApp) was conducted from 16 February 2022 to 05 May 2022. The participants provided information related to socio-demographic data. Covid-19 grief scale was assessed using the pandemic grief scale, which was translated into Arabic but not validated.

Results: A sample of 106 participants were recruited to this study. The sample was composed of Approximately 72% female and 28 % males, most of them were aged between 26 and 35 years old (37.7%) . Overall, individuals who lost a loved one more than 06 months period were more frequent (81%). 91.7 % of the sample scored above the cut score of 7 on the PGS.

Covid-19 grief was higher among those who sought psychological help ($p = 0.02$). In this sample, there was no associated risk factors between different socio-demographic characteristics and

dysfunctional grief, as well as no correlation were found between period of time since the loss and dysfunctional grief ($\rho = 0.186$, $p = 0.56$).

Conclusions: Although our study did not find a significant high prevalence of dysfunctional grief giving the small number of participants. More studies and screening must be conducted to identify those at risk of developing dysfunctional grief to prevent the serious individual and general outcomes.

EPV0311

The impact of Covid-19 on the Mental Health of the Portuguese Population

I. Santos* and B. Saraiva

Psychology, Psicobodycare, Porto, Portugal

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1044

Introduction: Covid-19 does not only have repercussions on the physical level, representing a new way of life, both individually and in society. The pandemic results in invisible consequences for the population's mental health.

Objectives: This study aimed to explore the consequences of Covid-19 on mental health in Portugal with a view to understanding and promoting the well-being and happiness of the Portuguese.

Methods: The study included 105 young people and adults, aged between 18 and 59 years ($M = 21.81$, $SD = 5.34$), with 43.3% males and 52.7% females. A sociodemographic questionnaire was applied to all participants, as well as the Échelle de Mesure des Manifestations du Bien-Être Psychologique (ÈMMBEP; Massé et al., 1998 - Portuguese translation by Monteiro, Tavares & Pereira, 2012) which translates into a response scale 5-point Likert type, with five subscales, including happiness. In addition, a semistructured interview with data collection instruments was administered.

Results: The results obtained demonstrate the negative impact of Covid-19 on the level of well-being, regardless of the participant's gender or age.

Conclusions: The data presented point to the need to sensitize individuals to the risk of the pandemic in terms of mental health, thus increasing society's awareness of the psychological effects of this new global disease. Therefore, coping mechanisms are essential to promote well-being and successfully overcome the pandemic.

Post-traumatic stress disorder in adolescents during the Covid-19 pandemic: a cross-sectional study of 326 cases

K. Mayssa*, B. Jaweher, K. Ali, B. T. Donia, H. Imen, A. Hela, K. Khaoula and M. Yourr

Department of Child Psychiatry, University Hospital of Hedi Chaker, Sfax, Tunisia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1045

Introduction: Since December 2019, the coronavirus pandemic has led to the deaths of almost 4.37 million people worldwide and 21,905 people in Tunisia. Containment measures, stress due to fear of infection by the virus and death are likely to be traumatic events, particularly in adolescents, and may lead to the development of symptoms of post-traumatic stress disorder (PTSD).

Objectives: To determine the prevalence of PTSD in a population of adolescents during the COVID-19 pandemic and to identify the factors associated with it.

Methods: This study was a cross-sectional among a representative sample of students enrolled in secondary schools, in the region of Hama- Gabes. We used a pre-established information sheet comprising 27 questions exploring sociodemographic and family data and specific data relating to the COVID-19 pandemic. The Arabic version of The Child PTSD Symptom Scale (CPSS) was used to screen for PTSD symptoms.

Results: 326 adolescents were collected which the mean age was 16.6 years (14 to 18 years). The family environment was conflictual in 11.9% of cases. Among the adolescents, 5.5% had a history of somatic pathology. A history of psychiatric pathology was noted in 0.6%, dominated by depression. Personal infection by Covid-19 was noted in 4% of adolescents. A family member was affected in 27.3% of cases. Adolescents were exposed to the death of a close relative in 22.4% of cases. PTSD was diagnosed (according to the CPSS) in 37.4% of cases, with mild severity in 6.5%, moderate in 0.6%, moderately severe in 8%, severe in 5.2% and extremely severe in 17.2%. The analytical study showed that PTSD was correlated with a conflictual family environment ($p=0.017$), personal infection by COVID ($P=0.003$), infection of a close relative by COVID ($P<0.001$) and the death of a close relative by COVID ($p<0.001$).

Conclusions: According to our study, the frequency of post-traumatic stress disorder among adolescents during the COVID-19 pandemic was high, underlining the need to screen at-risk populations for populations for early intervention.

Disclosure of Interest: None Declared

Resilience among Tunisian adolescents during the COVID19 pandemic: about 326 cases

K. Mayssa*, B. Jaweher, K. Ali, K. Khaoula, B. T. Donia, H. Imen, A. Hela and M. Yourr

Department of Child Psychiatry, University Hospital of Hedi Chaker, Sfax, Tunisia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1046

Introduction: The COVID-19 pandemic has caused psychological distress in all the communities and through all ages. Some people seemed to be less affected and to be resilient because of a dynamic interaction between individual, relational and environmental factors.

Objectives: We aim on this present study to evaluate the resilience and factors associated with it among a representative sample of Tunisian adolescents during the COVID19 pandemic.

Methods: We conducted a cross sectional, descriptive and analytic study among Tunisian adolescents enrolled in secondary schools, in

the Hamma region of the city of Gabes during the period extending from 5 March to 26 May 2021. Students were asked to complete a pre-established questionnaire, which contains questions about socio demographic features, medical history and knowledge about the pandemic of covid-19. The Child and Youth Resilience Measure (CYRM-28) was used to evaluate the global resilience and resources contributing to it. The CYRM-28 contains three resources including individual, relationship with primary caregivers and contextual factors. Higher scores reflect higher levels of factors associated with resilience.

Results: A total of 326 adolescents aged between 14 and 18 years old participated on this study (mean age 16.65 years 1). There were 92 boys and 234 girls. In our sample, 4% of adolescents were infected by the Covid-19. The infection of a family member by this virus was noted in 27.3 % of cases. Adolescents were exposed to the death of a family member by Covid-19 in 22.4% of cases. The Global CYRM28 score was 105 ± 22.39 . We found that adolescents who had loosen a family member because of the COVID infection, were less resilient than others (100 vs 107; $p=0.023$). Adolescents with a moderate to low socioeconomic level were less resilient especially with regard to contextual resilience (35, 57 vs 37, 83; $p=0.019$). On the other hand, adolescents keeping means of leisure during this epidemic were significantly more resilient especially in the personal resources ($p=0.024$).

Conclusions: Our findings conclude to some individual, relational and contextual factors that contribute or alters the process of resilience. Recognizing the strengths and capacities of adolescents would allow the development of programs and resources that can help these young people develop resilience skills.

doi: 10.1192/j.eurpsy.2024.1047

Introduction: The coronavirus pandemic has led to sudden changes in the lives of people around the world. The health threat, earthquakes and epidemiological measures caused certain psychological reactions in everyone. Psychiatric patients are particularly vulnerable to stress, so we were interested in how the changes at the beginning of the pandemic affected their psychological functioning. **Objectives:** To check changes in some areas of psychological functioning of outpatient psychiatric patients after the “lockdown” in 2020 and to examine their connection with some sociodemographic and treatment variables.

Methods: Patients of the University Psychiatric Hospital Sveti Ivan filled out a survey questionnaire designed for the purpose of

research, which consisted of sociodemographic data and items examining different areas of psychological functioning, when they arrived for an outpatient check-up.

Results: Variables were formed that examine: changes in unpleasant emotions, lack of support, lack of social interaction, changes in performing daily duties, changes in self-help behaviors and health concerns. Statistical analysis showed a significant increase in all variables, with the largest occurring in lack of social interaction, health concerns, and unpleasant emotions. The predictors of changes in psychological functioning were female gender, younger age in combination with cohabitation with parents, and the number of hospitalizations.

Conclusions: After the “lockdown” in 2020, psychiatric patients report a deterioration in psychological functioning.

doi: 10.1192/j.eurpsy.2024.1048

Introduction: Psychotic patients are a vulnerable population from a social and health point of view. The SARS Cov-2 pandemic affected millions of people around the world, however, its effects on psychotic patients in Avilés Spain, have not been analyzed.

Objectives: The objective of this study was to determine and compare the mortality of patients with psychosis due to SARS Cov-2 in Avilés, Spain with others regions and countries in the European Union. Determine the influence of social condition and antipsychotic treatment on the condition of these patients.

Methods: This is a descriptive, observational study, in which patients diagnosed with psychosis in the period 2020-2021 who contracted SARS Cov-2 infection in Avilés, Spain, were studied to determine those who died from this cause. The influence of social status and antipsychotic medication, as well as sociodemographic factors (age, sex, marital status) were analyzed and compared with other regions and countries of the European Union.

Results: Despite the high mortality rate in patients with psychosis, during the years of the pandemic SARS Cov-2 played an important role given the vulnerability of these patients.

Conclusions: The negative effects and deaths during the COVID-19 pandemic were at the time a major problem for public health worldwide. This study concluded that the morbidity and mortality of psychotic patients who contracted COVID-19 was lower than the rest of the population.

The emergence of new obsessions and compulsions after COVID-19: a case report

M. Abdelkefi*, R. Feki, I. Gassara, N. Smaoui, S. Omri, N. Charfi, L. Zouari, J. Ben thabet, M. Maalej bouali and M. Maalej

Psychiatry C department, Hedi Chaker university hospital, sfax, Tunisia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1049

Introduction: The coronavirus pandemic has affected mental health since its outbreak in 2019 and several studies have revealed that obsessive-compulsive disorder (OCD) patients were adversely affected.

Objectives: The aim of our present report is to study the impact of the coronavirus infection on OCD.

Methods: We illustrate a case of new emerging obsessions and compulsions after a COVID-19 infection in a patient consulting at the Psychiatry C department of the Hedi Chaker University Hospital.

Results: Mr. HB first presented in our outpatient unit of the Psychiatry C department at the age of 32. His medical history was unremarkable except for a COVID-19 infection in June 2022 that did not cause any organic complications. His family history was negative without neurological and psychiatric diseases. Further history revealed that OCD symptoms already started before his infection with COVID-19. At that time, he suffered from compulsions with the urge to constantly wash his hands and check rituals, but his symptoms were not severe enough to make him seek a psychiatric consult or treatment. However, since July 2022, soon after his infection with COVID-19, he suffered from new obsessions and compulsions, he would spend hours calculating all the numbers he sees and counting the number of letters in the words he came across. Non-surprisingly, OCD symptoms caused relevant problems in social life, and at work, he had difficulties concentrating and working. Due to his symptoms, he had neglected hobbies, avoided social contact, spent less time with his family, and even had suicidal thoughts. Therefore, pharmacotherapy with clomipramine was initiated with a maximal dose of 150 mg/d. Because of adverse events and lack of efficacy, he stopped medication and decided to consult our department to seek a different treatment. Therefore, sertraline was started at the dose of 50 mg/d along with psychotherapy.

Conclusions: People with OCD are likely to be more susceptible to the mental health impact of COVID-19. Responses to the pandemic are not only associated with an increase in all Obsessive-Compulsive (OC) symptoms and their severity but also the emergence of new types of obsessions and compulsions. Consequently, therapists should consider the effects of the pandemic on all OC symptom dimensions and adjust their treatment plans accordingly.

Psychopharmacological factor in the course of COVID-19 among psychiatric inpatients

M. Sorokin¹, A. Shabelnik¹, M. Bocharova^{1,2*}, N. Lutova¹, O. Limankin^{3,4}, L. Azarova³ and N. Neznanov^{1,5}

¹V.M.Bekhterev National Medical Research Centre for Psychiatry and Neurology, St. Petersburg, Russian Federation; ²King's College London, London, United Kingdom; ³St. Petersburg Psychiatric Hospital No. 1 named after P.P. Kashchenko; ⁴North-Western State Medical University named after I.I. Mechnikov and ⁵FSBEI HE I.P. Pavlov SPbSMU MOH Russia, St. Petersburg, Russian Federation

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1050

Introduction: It is known that many psychopharmacological drugs have anti-inflammatory, as well as antibacterial and antiviral effects.

Objectives: To investigate the association between the severity and duration criteria of COVID-19 with psychopharmacotherapy in double-diagnosed patients.

Methods: A total of 169 case histories from a specialized infectious psychiatric department (May 2020 to January 2021) were evaluated. Progression indicators of severe and mild COVID-19, along with the duration of persistent SARS-CoV-2 viral shedding, were assessed in correlation with the administration of antidepressants, antipsychotics, and acid sphingomyelinase inhibitors (FIASMA-active drugs).

Results: The use of any psychotropic agents was associated with a 0.9% increase in the risk of severe course of COVID-19 for each unit increase in the systemic inflammation index PLR, specifically in patients with intellectual disability (ICD-10 codes F70-79), when compared to patients with schizophrenia (ICD-10 codes F20-29): $R^2_{McF}=0.138$; $AIC=181$; $\chi^2=25.8$; $df=9$; $p=0.002$. High PLR values and the use of FIASMA-active drugs were associated with prolonged COVID-19 duration, while antidepressant therapy and elevated C-reactive protein levels were associated with a reduced predicted duration of viral shedding in 13.8% of variance: $R^2=0.0864$; $AIC=1299$; $F=5.2(3)$, $p=0.002$. Including the nosology of psychiatric disorders in the regression model increased the proportion of explained variance to 22.8%.

Conclusions: Thymoanaleptic therapy for individuals with psychiatric disorders may act as a protective factor against COVID-19. There is no evidence suggesting adverse effects of antipsychotics on the severity and duration of COVID-19. Further research is necessary to investigate the effects of FIASMA-active psychopharmacological agents within nosologically homogeneous groups.

The factor structure the PHQ-9 in Russian patients recovered from COVID-19

M. Zinchuk^{1*}, G. Kustov¹, S. Popova¹, A. Razmakhnin¹, D. Zhuravlev¹, R. Akzhigitov¹ and A. Guekht^{1,2}

¹Moscow Research and Clinical Centre for Neuropsychiatry and ²Pirogov Russian National Research Medical University, Moscow, Russian Federation

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1051

Introduction: The nine-item Patient Health Questionnaire-9 (PHQ-9) is the first choice for screening for depression in primary care and other medical settings. The PHQ-9 has been shown to be a reliable and valid measure of depression symptoms, but there is disagreement among researchers about the factor structure of this questionnaire. Recent systematic reviews have found four different factor models of the PHQ-9, with one- and two-factor models being the most common. This discrepancy may be due to linguistic, cultural and clinical differences between the populations studied. The factor structure of the Russian version of the PHQ-9 during the COVID-19 pandemic has not been examined in any study to date.

Objectives: The aim of our study was to determine the factorial structure and internal consistency of the Russian version of the PHQ-9 in COVID-19 survivors.

Methods: Fourteen thousand 725 (female - 11479 (78.0%), age - 18-79 years (M - 47.09, SD - 12.70) participants completed an online survey including the PHQ-9 and an ad hoc questionnaire focusing on sociodemographic and COVID-related characteristics. McDonald's omega coefficient was estimated to determine the internal consistency of the questionnaire. Exploratory structural equation modelling (ESEM) with weighted least squares mean and variance adjusted estimator and geomin rotation was performed in Mplus 7.

Results: ESEM provided evidence for a three-factor structure of the PHQ-9, representing affective (items 2, 6, 9), anergic (items 1, 3) and somatic (items 3, 5, 7, 8) dimensions of depression. These factors fit the data well (CFI - 0.998; TLI - 0.994; RMSEA (95% CI) - 0.028 (0.024 - 0.032)), better than a single factor (CFI - 0.955; TLI - 0.940; RMSEA (95% CI) - 0.089 (0.087 - 0.092)) and two-factor (CFI - 0.985; TLI - 0.971; RMSEA (95% CI) - 0.062 (0.059 - 0.065)). The McDonald's omega was 0.82.

Conclusions: Our study revealed a three-factor structure of the Russian version of the PHQ-9 in COVID-19 survivors. COVID-19. A high internal consistency of the Russian version of the instrument was confirmed.

Investigation of the factor structure of GAD-7 in Moscow residents exposed to SARS-CoV2

M. Zinchuk^{1*}, G. Kustov¹, V. Nadezhda¹, A. Razmakhnin¹, D. Zhuravlev¹, R. Akzhigitov¹ and A. Guekht^{1,2}

¹Moscow Research and Clinical Centre for Neuropsychiatry and ²Pirogov Russian National Research Medical University, Moscow, Russian Federation

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1052

Introduction: Rates of anxiety in the general population increased significantly during the COVID-19 pandemic. Several studies have shown that people exposed to SARS-CoV2 are at increased risk for both exacerbation and de novo development of anxiety disorders. Therefore, screening for anxiety disorders in this at-risk population is essential. In pre-pandemic studies, the 7-item Generalized Anxiety Disorder Questionnaire (GAD-7) was one of the most commonly used self-report instruments. Its validity has been demonstrated in several studies. However, there is no agreement among researchers about its underlying internal structure. Both

one-factor and two-factor solutions have been reported. This discrepancy may be due to linguistic, cultural, and clinical differences between the populations studied. To our knowledge, no studies have been conducted to investigate the factor structure of the GAD-7 in the Russian-speaking community sample and the psychometric properties of this questionnaire in SARS-CoV2 exposed individuals.

Objectives: The aim of the study was to determine the factorial structure and internal consistency of the Russian version of the GAD-7 in a large sample of Moscow residents exposed to SARS-CoV2.

Methods: Fourteen thousand 725 (male - 11479 (78.0%), age - 18-79 years (M - 47.09, SD - 12.70) Moscow residents exposed to SARS-CoV2 completed an online survey including the GAD-7 and an ad hoc questionnaire focusing on socio-demographic characteristics. McDonald's Omega was used to assess internal consistency. Exploratory structural equation modelling (ESEM) with weighted least squares means and variance adjusted estimator and geomin rotation was used to assess the factor structure of the Russian version of the GAD-7.

Results: The McDonald's Omega of the Russian version of the GAD-7 was 0.85, indicating a good internal consistency of the questionnaire. ESEM provided evidence for a one-factor solution that fits the data well (CFI - 0.996; TLI - 0.995; RMSEA (95% CI) - 0.041 (0.037 - 0.045)).

Conclusions: In Russian people exposed to SARS-CoV2, the GAD-7 showed good internal consistency. Our results are consistent with those of previous studies that reported a single-factor solution for the questionnaire.

Coping strategies facing Covid-19, perceived social support, and trait anxiety among Tunisian caregivers

N. Smaoui^{1*}, B. Jallouli^{1,2}, I. Gassara¹, R. Feki¹, S. Omri^{1,3}, M. Bou Ali Maalej¹, N. Charfi¹, J. Ben Thabet¹, L. Zouari¹ and M. Maalej¹

¹Psychiatry C department, Hedi Chaker university hospital; ²Faculty of Medicine, Sfax and ³University of Sfax, SFAX, Tunisia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1053

Introduction: Caregivers in the Sfax region, Tunisia, having been at the forefront in the face of the Covid-19 pandemic, were therefore faced with intense stress. It seemed useful and interesting to us to study their adaptation strategies during this period of pandemic.

Objectives: The aims of our study were to identify the coping strategies used by Tunisian Healthcare workers (HCW) during the Covid-19 pandemic and to study the links of the different coping strategies with perceived social support and trait anxiety.

Methods: A cross-sectional, descriptive, and analytical study conducted among 254 Tunisian HCW working at the Habib Bourguiba and Hedi Chaker university hospitals in Sfax, during period from January 2021 to April 2021. the questionnaire used included an information sheet and three scales; "Social support questionnaire 6" (SSQ-6), "State Trait Inventory Anxiety Form Y2" (STAI-Y2), and "Ways of Coping Checklist" (WCC).

Results: Using the WCC scale, the strategy most used by participants was the problem-focused one ($M = 2.98 \pm 0.53$), followed by the emotion-focused strategy ($M = 2.65 \pm 0.58$), and that centered on the search for social support ($M = 2.64 \pm 0.59$). Using the SSQ-6, the mean score for the availability of perceived social support was equal to 8.91 ± 4.59 and the score mean perceived satisfaction was equal to 28.63 ± 5.84 . The prevalence of trait anxiety was 50%, according to the STAI-Y2. Statistical tests showed that problem-focused coping was the strategy most adopted by non-anxious participants. They also showed that the higher the availability of perceived social support, the more the social support-seeking coping strategy was chosen, and the higher the perceived satisfaction with perceived social support, the less the emotion-focused strategy was chosen.

Conclusions: It seems necessary to propose a learning program for coping strategies to counter the potential emergence of ineffective strategies and to reinforce the use of effective strategies, in order to improve or maintain optimal well-being of health personnel.

Psychiatric disorders in patients after hospitalization for COVID-19: Frequency, coping behaviours and associated factors

N. Sghaier^{1*}, H. Ben Garouia¹, H. Khiari¹, W. Belaguide¹, J. Mannai¹ and H. Bellali²

¹Psychiatry Departement, Ibn Jazzar Hospital, Kairouan and ²Preventive and Community Departement, Habib Thameur Hospital, Tunis, Tunisia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1054

Introduction: The COVID-19 pandemic caused an unprecedented major health crisis. Current data suggest that psychiatric sequelae may persist for a long time in survivors after infection.

Objectives: The objectives of our study were to determine the frequency of anxiety, depression, sleep disorders, and posttraumatic stress disorder in patients after hospitalization for COVID-19 infection, and to investigate factors associated with their occurrence as well as to identify coping behaviors in these patients.

Methods: This was a descriptive cross-sectional study conducted at Ibn Jazzar Kairouan Hospital between September and December 2021 among patients who consulted three months after their hospitalizations for COVID-19 infection. The assessment of the different psychiatric disorders was performed using the validated Arabic versions of the Hospital Anxiety and Depression Scale, Post-traumatic Stress Disorder Checklist for DSM-5 and the Pittsburgh Sleep Quality Index. Coping behaviors were studied using the Brief-COPE scale.

Results: Our work included 104 patients. The median age was 55.5 years [IQR:47-64]. The gender ratio M/F was 1.12. Anxiety and depressive symptoms were found in 26.9% and 25% of cases, respectively. The frequency of post-traumatic stress disorder was 22.1% and that of sleep disorders was 41.3%. Problem-solving strategies were the most widely adopted, followed by emotion-focused strategies. Younger age, female gender, persistence of a physical symptom, impairment of daily activity, and stigma were factors independently associated with psychological distress. No association was found between the intensive care unit stay and psychiatric disorders. Problem-focused and emotion-focused

coping were negatively correlated with the different psychological outcomes studied.

Conclusions: Psychological distress in COVID-19 survivors persists beyond the acute phase and results from an intricacy of several factors. This highlights the importance of regular psychiatric follow-up after hospitalization in order to identify and treat, as early as possible, psychiatric disorders.

Impact of COVID-19 on community mental health care referrals

T. C. Gomes

Psychiatry, Tallaght university hospital, Dublin, Ireland

doi: 10.1192/j.eurpsy.2024.1055

Introduction: As the global community grapples with the aftermath of the COVID-19 pandemic, its reverberations extend beyond the realm of physical health, significantly impacting mental health care systems. This article delves into the multifaceted effects of COVID-19 on community mental health care referrals, scrutinizing the challenges, adaptations, and potential innovations that have emerged in the wake of this unprecedented crisis. By examining the nuanced interplay between the pandemic and mental health care access, we seek to shed light on crucial considerations for the future of community mental health services in a post-pandemic landscape.

Objectives: To understand impact of Covid 19 pandemic on number of referrals received by a specific community mental health service.

Methods: We analysed number of referrals to a specific community mental health services since July 2019 until July 2022.

Results: During the period assessed we noticed a significant decrease to number of new referrals to a specific community mental health service with onset of covid 19 pandemic. We also noticed a progressive increase to the number of referrals in the first six months of July 2022.

Conclusions: The COVID-19 pandemic has had a significant impact on attendance to healthcare appointments, leading to decreased attendance, shift to telemedicine, delays in care, increased no-shows, and rescheduling of appointments. The pandemic has also highlighted the importance of being prepared for and able to adapt to changes in the healthcare landscape.

The fundamental beliefs held by individuals living with HIV and university students during the challenges posed by the second wave of the COVID-19 pandemic in Russia

V. V. Titova*, V. I. Rozhdestvenskiy, I. A. Gorkovaya, D. O. Ivanov and Y. S. Aleksandrovich

Department of Psychosomatics and Psychotherapy, Saint Petersburg State Pediatric Medical University, Saint Petersburg, Russian Federation

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1056

Introduction: Baseline beliefs, as conceptualized by R. Janoff-Bulman in her cognitive theory of mental trauma, represent an inherent internal framework that shapes how individuals perceive and assess traumatic events. It is widely acknowledged that the pandemic has had a profound impact on the global economy and the living conditions of individuals. Consequently, it is reasonable to assume that during a pandemic, one's ability to adapt to these altered circumstances is influenced by their foundational beliefs. Consequently, exploring these fundamental beliefs in two at-risk groups, namely university students and individuals with confirmed HIV, becomes a subject of significant interest.

Objectives: This study aims to examine the fundamental beliefs of patients with HIV and university students in the context of the second wave of the new coronavirus pandemic in Russia.

Methods: Data collection took place from January to July 2021 using a custom-developed Google form. The study involved 35 Russian university students majoring in humanities and 59 HIV-positive patients. We employed the WAS-37 methodology, adapted for use in Russia, to assess their baseline beliefs.

Results: We found that on the scales "Fairness" ($M = 21.00 \pm 3.73$ - students, $M = 20.53 \pm 4.63$ - patients, $p = 0.616$), "Luck" ($M = 31.74 \pm 5.06$ vs $M = 29.59 \pm 7.33$, $p = 0.129$) and "Control beliefs" ($M = 26.66 \pm 4.80$ vs $M = 27.12 \pm 4.42$, $p = 0.636$) students did not differ from patients. Scores on the Environment Benevolence scale were higher in students ($M = 35.46 \pm 7.33$ vs $M = 30.50 \pm 7.09$, $p = 0.002$) and on the Self Image scale were higher in HIV patients ($M = 26.63 \pm 6.97$ vs $M = 30.03 \pm 5.41$, $p = 0.010$).

Conclusions: During the latter stages of the COVID-19 pandemic in Russia, individuals living with HIV, when compared to students, tended to perceive the world around them as being more perilous and unfriendly, while simultaneously viewing themselves as possessing greater integrity. From our perspective, this latter observation could be interpreted as a means of self-defence against the perceived hostility of the external world. In such pandemic circumstances, it may be advisable to consider the use of supportive psychotherapy for individuals living with HIV.

Disclosure of Interest: None Declared

EPV0326

The quality of life for students pursuing humanities disciplines and individuals living with HIV during the second wave of the COVID-19 pandemic in Russia

V. V. Titova*, V. I. Rozhdestvenskiy, I. A. Gorkovaya,
D. O. Ivanov and Y. S. Aleksandrovich

Department of Psychosomatics and Psychotherapy, Saint Petersburg State Pediatric Medical University, Saint Petersburg, Russian Federation

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1057

Introduction: The COVID-19 pandemic has had a significant impact on people's lives, affecting various aspects of society and potentially altering the quality of life of certain groups. The World Health Organisation defines quality of life as an individual's physical, psychological, emotional, and social health as perceived by themselves in relation to society. It appears that the pandemic disproportionately affected the most susceptible societal segments, comprising university students who encountered significant stress

due to the shift to remote learning, and individuals living with HIV who faced difficulties in accessing medical assistance.

Objectives: The study aimed to investigate the quality of life of students studying the humanities disciplines and HIV patients during the second wave of the COVID-19 pandemic in Russia.

Methods: Data collection was conducted from January to July 2021, using a Google form developed by the researchers. The study included 35 students from Russian universities studying humanities specialities and 59 HIV-positive patients. To check the quality of life, we used the WHOQOL-BREF questionnaire, adapted for use in Russia.

Results: We found that on the domains "physical and psychological well-being" ($M = 20.26 \pm 3.89$ - students, $M = 21.43 \pm 3.62$ - patients, $p = 0.144$) and "self-image" ($M = 19.11 \pm 3.53$ vs $M = 19.52 \pm 2.92$, $p = 0.553$) respondents from the two groups did not differ from each other. The domain "microsocial support" was more pronounced in students than patients ($M = 10.71 \pm 2.48$ vs $M = 9.17 \pm 2.96$, $p = 0.011$). A similar situation was observed in "social well-being" ($M = 27.23 \pm 4.33$ vs $M = 24.97 \pm 5.24$, $p = 0.034$).

Conclusions: During the second wave of the COVID-19 pandemic in Russia, individuals living with HIV experienced a lower quality of life compared to students in humanities disciplines. Individuals living with HIV reported lower satisfaction with their relationships within their immediate environment, including family and friends, as well as their overall social well-being, encompassing factors like safety, material wealth, access to medical care, and transportation. In these pandemic conditions, it became evident that individuals with HIV required more extensive social support measures than students.

EPV0327

The connection between professional burnout of medical workers and the specific working conditions during the COVID-19 pandemic in Russia

E. V. Deshchenko^{1*}, J. E. Koniukhovskaia², O. B. Stepanova¹,
I. M. Shishkova³, E. I. Pervichko¹, O. V. Mitina¹ and
E. A. Dorokhov¹

¹Lomonosov Moscow State University; ²Higher School of Economics, Moscow and ³Ryazan State Medical University, Ryazan, Russian Federation

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1058

Introduction: The COVID-19 pandemic has certainly become a stressful event for medical workers, so the aim of this research was to study the pandemic-specific working conditions that may be associated with the professional burnout of medical workers in Russia.

Objectives: To study the pandemic-specific working conditions that may be associated with the professional burnout of medical workers in Russia.

Methods: The Maslach Burnout Inventory (MBI) was used to measure the level of professional burnout. It was filled out by medical workers from January 2021 to November 2022.

The sample consisted of 314 medical workers (57 men and 255 women), whose average age was 36.97 ± 11.93 . According to the level

of education, the sample included specialists with secondary general education (4.14%), with secondary special education (19.4%), with incomplete higher education (11.46%), with higher education (59.87%) and PhD (5.1%). 35 people (11%) of the surveyed medical workers worked in the red zone.

Results: Working in the red zone is significantly associated with Emotional Exhaustion ($p=0.002$) and Depersonalization ($p=0.002$), but not with a Reduction in Professionalism.

The working conditions of medical workers who were significantly associated simultaneously with Emotional Exhaustion, Depersonalization and Reduction of professionalism (respectively): (1) Lack of confidence in support from the health system and the state in case of illness ($r=0.170$, $p=0.002$; $r=0.202$, $p=0.000$; $r=-0.171$, $p=0.002$); (2) Inability to meet the usual personal needs (daily routine, nutrition, communication with loved ones) as employment increases at work ($r=0.200$, $p=0.000$; $r=0.154$, $p=0.006$; $r=-0.186$, $p=0.001$); (3) Lack of confidence in their own professional competence in the fight against COVID-19 due to lack of knowledge about COVID-19 ($r=0.202$, $p=0.000$; $r=0.148$, $p=0.009$; $r=-0.211$, $p=0.000$); (4) Lack of confidence in their own effectiveness in the fight against COVID-19 due to the increase in the volume of work and the expansion of the scope of professional responsibilities ($r=0.234$, $p=0.000$; $r=0.152$, $p=0.007$; $r=-0.177$, $p=0.002$); (5) Lack of access to up-to-date information about COVID-19 ($r=0.190$, $p=0.001$; $r=0.158$, $p=0.005$; $r=-0.140$, $p=0.013$).

The Emotional Exhaustion scale is also associated with the fear of getting infected and getting sick with COVID-19 ($r=0.125$; $p=0.026$), as well as the lack of quick access to testing when COVID-19 symptoms appear ($r=0.169$; $p=0.003$).

Conclusions: Thus, not only work in the red zone, but also many specific working conditions during the COVID-19 pandemic can become a provocation factor for the deterioration of the emotional state of medical workers.

Introduction: Many medical workers suffered from severe professional burnout while working in the conditions of the COVID-19 pandemic, but few of them had the opportunity to find psychological help.

Objectives: The aim of the research was to study the relationship between emotional burnout and self-help strategies in medical professionals during the pandemic.

Methods: The Maslach Burnout Inventory (MBI) was used to measure the level of professional burnout. It was filled out by medical workers from January 2021 to November 2022.

The sample consisted of 314 medical workers (57 men and 255 women), whose average age was 36.97 ± 11.93 . According to the level of education, the sample included specialists with secondary general education (4.14%), with secondary special education (19.4%), with incomplete higher education (11.46%), with higher education (59.87%) and PhD (5.1%). 35 people (11%) of the surveyed medical workers worked in the red zone.

Results: When medical workers experience severe Emotional Exhaustion and Depersonalization, they often try to help themselves by drinking alcohol ($r=0.156$; $p=0.005$; $r=0.184$; $p=0.001$), eating ($r=0.227$; $p=0.000$; $r=0.151$; $p=0.007$), taking medications ($r=0.204$; $p=0.000$; $r=0.212$; $p=0.005$), solitude ($r=0.204$; $p=0.000$; $r=0.133$; $p=0.019$), watching TV series ($r=0.173$; $p=0.002$; $r=0.146$; $p=0.01$). With an increase in the Reduction of professional skills, medical workers also eat more ($r=-0.148$; $p=0.009$) and try to learn something new, engage in self-development ($r=-0.137$; $p=0.015$). It is important to note that the desire to seek psychological help is associated only with Emotional Exhaustion ($r=0.121$, $p=0.032$), that is, he/she may be aware at an early stage of professional burnout, when the symptoms of depersonalization and reduction of professional skills have not yet occurred.

Conclusions: Thus, all the considered self-help methods are already used with pronounced symptoms of professional burnout, but do not lead to its pronounced decrease. It is important to note that seeking psychological help is possible with awareness of emotional exhaustion, but not with depersonalization and reduction of professional skills.

Comparison of perceptions about COVID-19 disease in patients and in medical professionals during the pandemic

E. V. Deshchenko^{1*}, J. E. Koniukhovskaia², O. B. Stepanova¹, I. M. Shishkova³, E. I. Pervichko¹, O. V. Mitina¹ and V. F. Petrenko¹

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1060

Introduction: The COVID-19 pandemic poses a serious threat to mental well-being both for patients who have suffered from coronavirus disease and for medical workers of this period. The difference in perceptions about COVID-19 in patients and those who care for them reflects the peculiarities of assessing the coronavirus pandemic and their own coping capabilities.

Objectives: The aim of the research was to compare the perceptions about COVID-19 in patients and medical professionals during the pandemic.

Methods: A Short questionnaire of Disease Perception (E. Broad-bent) was used to study patients' perceptions about COVID-19

disease. The same questionnaire was modified for the perceptions about the COVID-19 pandemic to study the peculiarities of the perceptions about COVID-19 by medical professionals.

The study was conducted from January 2021 to November 2022. The sample consisted of 314 medical workers (57 men and 255 women), whose average age was 36.97 ± 11.93 , and 390 patients (64 men and 326 women), whose average age was 28.58 ± 10.74 . 35 people (11%) of the surveyed medical workers worked in the red zone.

Results: Medical professionals and patients tend to assess the impact of the pandemic on life in the same way. However, according to medical professionals, the COVID-19 pandemic will last longer than according to patients (4.93 ± 2.81 vs 3.18 ± 2.29 , $p=0.000$). Doctors assess their ability to control the pandemic significantly worse than patients assess their disease as a result of coronavirus infection (2.82 ± 2.28 vs 5.30 ± 2.88 , $p=0.000$). Medical workers have a worse assessment of the effectiveness of the measures taken to combat the pandemic (4.75 ± 2.63 vs 5.50 ± 2.67 , $p=0.000$). Doctors are less likely to find symptoms of coronavirus (2.88 ± 2.32 vs 4.98 ± 2.75 , $p=0.000$) and less concerned about the spread of COVID-19 (3.75 ± 2.55 vs 4.20 ± 2.63 , $p=0.023$). Whereas patients have a worse understanding of what COVID-19 is (6.32 ± 2.87 vs 5.52 ± 2.83 , $p=0.000$), and they believe that COVID-19 affects their emotional state to a greater extent than doctors did (3.60 ± 2.66 vs 4.39 ± 2.90 , $p=0.000$).

Conclusions: Thus, the specifics of the perceptions about COVID-19 may largely depend on whether a person is faced with a coronavirus in the role of a patient or a medical worker. The emotional state of patients is more affected by the pandemic combined with a worse understanding of COVID-19, while medical workers feel less control and tend to regard the measures taken to combat the pandemic as less effective.

The connection between personal factors and burnout among medical workers during the COVID-19 pandemic

E. V. Deshchenko^{1*}, J. E. Koniukhovskaia², O. B. Stepanova¹, I. M. Shishkova³, E. I. Pervichko¹, O. V. Mitina¹ and E. R. Semenova¹

¹Lomonosov Moscow State University; ²Higher School of Economics, Moscow and ³Ryazan State Medical University, Ryazan, Russian Federation

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1061

Introduction: Work in the severe conditions of the pandemic has become a risk factor for the deterioration of the medical workers' psychological state, which together can lead to professional burnout and, as a consequence, to professional mistakes (Pervichko, Konyukhovskaya, 2020).

Objectives: The aim of the research was to study the connection between personal factors of medical workers and professional burnout during the COVID-19 pandemic.

Methods: The degree of professional burnout was assessed using Maslach Burnout Inventory (MBI) (Maslach, 2000; Vodopianova, Starchenkova, 2008), HEXACO Personality Inventory (short version) was used to study personality traits (Ashton, Lee, 2007; Egorova, et al., 2019).

The study was conducted from May 2020 to October 2022. The sample consisted of 197 medical workers (32 men and 165 women), whose average age was 38.85 ± 12.05 .

Results: Honesty as a personality trait is negatively significantly associated with emotional exhaustion ($r=-0.268$, $p=0.000$), depersonalization ($r=-0.323$, $p=0.000$) and positively associated with a smaller reduction in professionalism ($r=0.290$, $p=0.000$). Emotionality in medical workers is positively significantly associated with emotional exhaustion ($r=0.358$, $p=0.000$) and depersonalization ($r=0.243$, $p=0.001$) and with a greater reduction in professionalism ($r=-0.380$, $p=0.000$). Extroversion is negatively associated with emotional exhaustion ($r=-0.478$, $p=0.000$) and depersonalization ($r=-0.376$, $p=0.000$) and positively associated with a smaller reduction in professional achievements ($r=0.566$, $p=0.000$). Benevolence and conscientiousness reveal negative associations with depersonalization ($r=-0.248$, $p=0.001$; $r=-0.180$, $p=0.012$) and positive associations with a smaller reduction in professionalism ($r=0.190$, $p=0.008$; $r=0.301$, $p=0.000$).

Conclusions: Thus, the state of emotional exhaustion during burnout is associated with greater emotionality, less honesty and extroversion. Whereas depersonalization and a greater negative assessment of one's own professional competence and productivity is associated with less honesty, more emotionality, less extroversion, benevolence and conscientiousness.

EPV0331

The connection between the experience of the disease and perceptions about COVID-19 in patients

E. V. Deshchenko^{1*}, J. E. Koniukhovskaia², O. B. Stepanova¹, I. M. Shishkova³, E. I. Pervichko¹, O. V. Mitina¹ and E. R. Semenova¹

¹Lomonosov Moscow State University; ²Higher School of Economics, Moscow and ³Ryazan State Medical University, Ryazan, Russian Federation

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1062

Introduction: Since the COVID-19 pandemic has had a serious impact on the psychological state of the population, the individual experience of COVID-19 disease may affect the content of perceptions about coronavirus in those who have been ill with it.

Objectives: The aim of the research was to study the connection between patients' experience of the disease and their perceptions about COVID-19.

Methods: A Short questionnaire of Disease Perception (E. Broad-bent) was used to study patients' perceptions about COVID-19 disease. The wording "disease" was replaced with "COVID-19 disease".

The study was conducted from January 2021 to November 2022. The sample consisted of 390 patients (64 men and 326 women), whose average age was 28.58 ± 10.74 .

Results: The subjective assessment of the duration of COVID-19 disease and its impact on the patient's life is higher if the patient is still sick with COVID-19 ($r=0.340$, $p=0.008$; $r=0.312$, $p=0.000$), in a more severe form ($r=0.341$, $p=0.000$; $r=0.298$, $p=0.000$), less satisfied with the attitude of medical workers during illness ($r=0.151$, $p=0.003$; $r=0.143$, $p=0.005$), more afraid for the health of their loved ones ($r=-0.194$, $p=0.000$; $r=-0.181$, $p=0.000$). At the same time, greater concern about COVID-19 and a greater assessment of its impact on the emotional state is associated with patients' fear for the health of loved ones ($r=-0.267$, $p=0.000$; $r=-0.242$, $p=0.000$) and more severe course of the disease ($r=0.107$, $p=0.035$; $r=0.126$, $p=0.013$). Less sense of control in a COVID-19 disease situation is associated with a more severe course of the disease and greater fear for the health of loved ones ($r=-0.174$, $p=0.001$; $r=0.154$, $p=0.002$).

Conclusions: Thus, whether the patient has recovered after COVID-19 or not yet, how severe this disease was, how satisfied he was with the attitude of medical workers towards him during the illness and how much he fears for the health of loved ones during the pandemic, is related to such perceptions about COVID-19 disease as an assessment of the disease duration, its impact on life, emotional state, concern about one's own illness and understanding of its nature.

The Impact of the COVID 19 Pandemic on Psychiatric Hospitalizations in a Portuguese Department: A Retrospective Observational Study

J. R. Freitas*, C. P. Desport, D. O. Martins, M. Santos and C. Fonseca

Psiquiatria, Centro Hospitalar e Universitário de Santo António, Porto, Portugal

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1063

Introduction: The World Health Organization declared the coronavirus outbreak a pandemic on March 11th 2020. Since then, the containment measures were leading to increasing mental health problems in the general population and worsening of some pre-existing psychiatric conditions. To our knowledge, there are few studies characterizing the impact of the COVID-19 pandemic on psychiatric hospitalizations across the world.

Objectives: We aimed to compare the number and characteristics of the hospitalizations in the mental health department of a Portuguese psychiatric hospital from March 2nd 2019 to October 31st 2019 with those that occurred in the same period in 2020.

Methods: We conducted a retrospective observational study including all patients admitted to hospital during these periods ($n=805$). Sociodemographic data, clinical characteristics and information about the context of hospitalization were collected. Statistical analysis was performed using t Student Test, Mann-Whitney and Chi-square.

Results: In the pandemic period there was a marked reduction in the number of psychiatric hospitalizations. There was a statistically significant difference in the median length of stay and in the percentage of involuntary hospitalizations between the two periods. In 2019, the most frequent International Classification of Diseases (10th Revision) diagnostic categories were F30-F39 (mood disorders) and in 2020 were F20-F29 (schizophrenia, schizotypal and delusional disorders).

Conclusions: The reorganization of services and the decrease in admissions through the emergency department may explain these results.

Enduring the unseen burden: a qualitative analysis on long-term emotional impact of COVID-19 on long-term care workers

L. Gonzalez-Spinoglio^{1*}, A. Monistrol-Mula¹, C. Vindrola-Padros², S. Aguilar-Ortiz¹, B. Carreras³, J. M. Haro¹ and M. Felez-Nobrega¹

¹Research and Development Unit, Parc Sanitari Sant Joan de Déu, Institut Sant Joan de Déu, Sant Boi de Llobregat, Spain; ²Department of Targeted Intervention, University College London, London, United Kingdom and ³Department of Psychiatry and Psychology, Institute of Neuroscience, Hospital Clínic, Barcelona, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1064

Introduction: Long-term care facilities, such as nursing homes and other assisted living facilities, have been hit particularly hard by the COVID-19. The overall pandemic created an enormous pressure on long-term care workers (LTCWs), making them particularly vulnerable to mental disorders. However, most of the existing evidence regarding the well-being of care professionals has predominantly focused on frontline healthcare workers.

Objectives: This study aimed to identify long-term psychological needs of LTCWs derived from the COVID-19 pandemic, as part of a project that is developing an intervention to reduce psychological distress in this population group.

Methods: We performed a qualitative study with a rapid research approach. Participants were recruited from long-term care facilities located in Catalonia, Spain. Between April and September 2022, we conducted semi-structured interviews inquiring about the most psychologically challenging stages of the pandemic, perceived emotions during those stages, main determinants of those emotions, and their emotional state at the time of the interview. We used a qualitative content analysis method with an inductive-deductive approach.

Results: Thirty LTCWs participated in the study. Mean age was 44 ($SD=11.4$), 87% were females and one third were from foreign nationalities. The period of the pandemic with highest mental health burden was the outbreak, with almost every worker having experienced some form of emotional distress. Emotional distress persisted over time in more than half of participants, with fatigue and nervousness being the main emotions expressed at the time of the interview. High workload, feeling that pandemic times are not over and poor working conditions that have remained since then,

have been the most frequently expressed determinants of such emotions.

Conclusions: Long after the pandemic outbreak, emotional distress is still relevant. The persistent burden of psychological distress points to a need for institutions to take action to improve working conditions and promote employees' wellbeing.

Impact of the Second Wave of the COVID-19 Pandemic on the Quality of Life and Emotional Well-being of Students studying humanities disciplines in Russia

V. I. Rozhdestvenskiy*, V. V. Titova, I. A. Gorkovaya,
D. O. Ivanov and Y. S. Aleksandrovich

Department of Psychosomatics and Psychotherapy, Saint Petersburg State Pediatric Medical University, Saint Petersburg, Russian Federation

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1065

Introduction: The second wave of the COVID-19 pandemic had a significant impact on the quality of life and emotional well-being of the Russian population, with increased emotional disorders such as depression and anxiety. This study focuses on the specific context of Russian university students studying humanities disciplines, who had to adapt to remote learning and self-education during the pandemic.

Objectives: This study aimed to assess the quality of life and measure the levels of depression, anxiety, and stress among Russian humanities students. Additionally, it examined the correlations between quality of life and emotional disorders.

Methods: Data collection was conducted between January and April 2021 using a customized Google form. The study included 35 students from Russian universities. Quality of life was assessed using the WHOQOL-BREF questionnaire, and levels of depression, anxiety, and stress were determined using the DASS-21 methodology, both adapted for use in Russia.

Results: The mean values for the quality of life domains were as follows: "physical and psychological well-being" ($M = 20.65 \pm 3.85$), "self-image" ($M = 19.21 \pm 3.54$), "microsocial support" ($M = 10.39 \pm 2.36$), and "social well-being" ($M = 27.93 \pm 4.15$). Notably, 54% of respondents exhibited no symptoms of depression, 66% showed no signs of anxiety, and 69% reported no stress. Correlation analysis revealed that there was no statistically significant relationship between stress and quality of life, and social well-being did not correlate with emotional disturbances.

Conclusions: During the second wave of the COVID-19 pandemic, the majority of Russian humanities students did not experience clinical manifestations of depression, anxiety, or stress. To improve their emotional well-being, students should prioritize their physical and psychological health, self-perception, self-esteem, and relationships with their immediate social circles, particularly their families. In this pandemic context, broader social factors such as recreational opportunities took a back seat in students' priorities.

EPV0336

Fundamental beliefs, as well as levels of depression, anxiety, and stress experienced by Russian students during the second wave of the COVID-19 pandemic

V. I. Rozhdestvenskiy*, V. V. Titova, I. A. Gorkovaya,
D. O. Ivanov and Y. S. Aleksandrovich

Department of Psychosomatics and Psychotherapy, Saint Petersburg State Pediatric Medical University, Saint Petersburg, Russian Federation

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1066

Introduction: A pandemic caused by a novel coronavirus is an immensely traumatic event. Researches indicate that such events significantly impact various aspects of individuals, including their physical, emotional, cognitive, behavioural, and social functions, affecting different components of their personality structure. However, the experience of trauma itself is influenced by implicit internal structures known as underlying beliefs. Consequently, emotional responses to traumatic events may be interconnected with these core beliefs.

Objectives: This study aimed to explore fundamental beliefs among Russian university students and analyze their associations with emotional reactions such as depression, anxiety, and stress.

Methods: Data collection took place from January to April 2021 using a custom-designed Google form. The study involved 35 Russian university students. We employed the WAS-37 methodology to investigate fundamental beliefs and the DASS-21 methodology to assess the levels of depression, anxiety, and stress. Both questionnaires were adapted for use in Russia.

Results: We found that the mean values of the "Benevolence of the surrounding world" ($M = 35.5 \pm 7.3$) and "Luck" ($M = 31.7 \pm 5.1$) scales are higher than the normative mean values for the Russian population. In contrast, the mean values of the "Fairness" ($M = 21.0 \pm 3.7$), "Self-image" ($M = 26.6 \pm 7.0$) and "Beliefs about control" ($M = 26.6 \pm 4.8$) scales are generally not different from the normative values. Depression has negative correlations with Self-image ($r_s = -0.590$, $p < 0.01$) and Beliefs about control ($r_s = -0.509$, $p < 0.01$). No statistically significant correlations of anxiety and stress with baseline beliefs were obtained.

Conclusions: During the second wave of the pandemic, Russian university students tend to view the world around them as less perilous than the broader population does, and they perceive themselves as more fortunate. Depressive feelings among students are linked to their lower beliefs in the value and importance of their self, as well as their perception that the world around them is not sufficiently controllable.

EPV0337

Variations in self-regulation of behaviour among different groups of the Russian population during the second wave of the COVID-19 pandemic

V. I. Rozhdestvenskiy*, V. V. Titova, I. A. Gorkovaya,
D. O. Ivanov and Y. S. Aleksandrovich

Department of Psychosomatics and Psychotherapy, Saint Petersburg State Pediatric Medical University, Saint Petersburg, Russian Federation

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1067

Introduction: During a pandemic, the population is required to adapt effectively to drastically altered environmental conditions to avoid the development of psychiatric disorders or other maladaptive responses. This adaptation is closely linked to an individual's ability to regulate their behaviour effectively and to develop traits such as pliability and autonomy.

Objectives: The research aims to investigate individual self-regulation among students studying humanities disciplines and individuals living with HIV during the second wave of the COVID-19 pandemic in Russia.

Methods: Data collection took place from January to July 2021 using a custom-designed Google form. The study involved 35 university students in Russia specializing in humanities and 59 individuals living with HIV. To assess the development of individual self-regulation and determine its specific profile, we utilized the "Behavioural Self-Regulation Style" questionnaire developed by V. I. Morosanova.

Results: We found that 43% of students have an average level of self-regulation, 37% - high and 20% - low. Among people living with HIV the distribution is similar: 53 % have an average level of self-regulation, 37 % - high and 10 % - low. The analysis of average results of the scales did not reveal statistically significant differences among the groups of respondents. The average profiles have no pronounced peaks and look as follows: planning ($M = 5.77 \pm 2.16$ - students, $M = 6.24 \pm 1.90$ - patients, $p > 0.05$), modelling ($M = 5.26 \pm 1.80$ vs $M = 5.69 \pm 1.90$, $p > 0.05$), programming ($M = 6.00 \pm 1.50$ vs $M = 5.93 \pm 1.66$, $p > 0.05$), performance evaluation ($M = 6.26 \pm 1.42$ vs $M = 5.78 \pm 1.60$, $p > 0.05$), pliability ($M = 6.17 \pm 1.87$ vs $M = 6.58 \pm 1.90$, $p > 0.05$) and autonomy ($M = 5.00 \pm 2.33$ vs $M = 5.56 \pm 2.08$, $p > 0.05$) were almost at the same level in both the student and patient groups.

Conclusions: During the second wave of the COVID-19 pandemic in Russia, there were no significant distinctions observed in the self-regulation behaviour styles between students and individuals living with HIV. The majority of participants from these chosen groups demonstrated a similar average level of effectiveness in self-regulating their behaviour, as well as comparable degrees of pliability and autonomy development.

The Parent Attitudes about Childhood Vaccination against COVID-19 in Tunisia

I. Bouguerra*, A. Touiti, W. Askri, S. Hlayem and A. Bouden

Child and adolescent psychiatry, Razi Hospital, Manouba, Tunisia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1068

Introduction: The vaccination of children and adolescents against covid 19 is an ongoing debate. While in some countries the program of vaccination of children under 12 years old is already implemented, in others the balance of risk and benefits is a dilemma. Parents' perception and decision about covid vaccination is an important parameter to consider.

Objectives: The aim of this study is to evaluate the parents' attitude about childhood vaccination against Covid 19 in Tunisia.

Methods: The "vaccine hesitancy scale (VHS) adopted from WHO's Strategic Advisory Group of Immunization" with 8 items translated in tunisian dialect and an additional ten survey item about the Characteristics of parents and their vaccination status against Covid 19. The survey is distributed on social media groups of parents of tunisian children and adolescents.

Results: Thirty parents have answered the survey. More than 80% of the participants were female with an average age of 38 years old. Among 30 participants 24 were vaccinated against covid 19 at least for once, but only one of them 10% decided to vaccinate their children against covid 19, while 3% are indecisive about the subject. Although 97 % of the children and adolescents have already been vaccinated completely according to the national vaccination program. The most common reasons for the refusal were. Parents consider that routine childhood vaccines are safe, necessary and useful more than covid vaccine. Some parents reported that their children have been infected by the virus so they have doubts about the usefulness of the vaccination.

Conclusions: A year after the pandemic, covid 19 contamination and vaccination against the virus are still an issue. With the emergence of new variants, the decline in protective measures, vaccination against covid is in the process of integrating routine programs. But the lack of information on the effectiveness of the vaccine and the adverse effects are a source of hesitation and refusal for parents. A large-scale national study is necessary before.

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1069

Introduction: The COVID-19 pandemic was originally of a magnitude exceeding that of previous epidemics, placing a heavy burden on healthcare systems in general and healthcare professionals in particular.

Objectives: To assess the prevalence of depressive and anxiety symptoms among healthcare professionals at Farhat Hached Hospital in Sousse during the COVID-19 pandemic and to identify associated risk factors.

Methods: This is a descriptive cross-sectional study conducted among healthcare professionals practicing in the Farhat Hached Hospital of Sousse, which took place during the period extending between August and November 2021. The 9-item Patient Health Questionnaire (PHQ-9), the 7-item Generalized Anxiety Disorder (GAD-7), were used to assess depression and anxiety respectively.

Results: Our study included 326 healthcare professionals from the Farhat Hached University Hospital. The mean age of our population was 36.38 ± 10.19 years, with a clear female predominance of 81.3%. The prevalences of depression and anxiety were 46% and 35.3% respectively. Female gender and being a paramedical staff were risk factors for depressive and anxiety symptoms. On the other hand, professional seniority of over 5 years was statistically significantly associated with anxiety. Sporting activity was inversely associated with depressive and anxiety symptoms.

The multi-variate analytical study revealed that the practice of leisure activities other than sport was a protective factor against the occurrence of depressive symptomatology in healthcare professionals, while current smoking and the practice of a sporting activity were inversely associated with the occurrence of anxious symptomatology.

Conclusions: These findings underline the need for specific prevention strategies to reduce these symptoms and help healthcare professionals maintain their mental health. This will help to guarantee the quality and efficiency of work in the medical environment, to better control the pandemic.

Hematological impact of COVID-19 mRNA vaccination in patients treated with Clozapine

A. Touiti^{1,2*}, I. Yaich^{1,2}, C. Ben Said^{1,2} and N. Bram^{1,2}

¹Forensic Psychiatry Departement, Razi Hospital, La Manouba and
²Faculty of Medecine of Tunis, Tunis El Manar University, Tunis, Tunisia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1070

Introduction: Clozapine is an atypical antipsychotic that is primarily prescribed for treatment-resistant schizophrenia. Despite its proven efficacy, the prescription of clozapine is sometimes limited by its hematologic side effects, including agranulocytosis. During the SARS-CoV-2 pandemic, schizophrenia is recognized as a risk factor for developing severe forms of the infection. Early and complete vaccination of patients has been recommended. However, there is limited data on the effect of the vaccine on the risk of hematologic abnormalities in patients treated with clozapine.

Objectives: To study the hematologic effect of the mRNA vaccine against COVID-19 in a population of patients with treatment-resistant schizophrenia treated with clozapine.

Methods: Twenty-five patients hospitalized for schizophrenia at the forensic psychiatry department of Razi Hospital in Manouba, Tunisia, were included. Eighteen patients were treated with clozapine, and seven patients were treated with other antipsychotics. Consent from patients and/or their relatives was obtained before vaccination. The results of complete blood counts performed as part of the therapeutic protocol were compared between the two groups before and after administration of the vaccine.

Results: No patient experienced agranulocytosis induced by clozapine after vaccination against COVID-19. Blood cells counts, red blood cells counts, and platelets were within the normal ranges. However, a decrease in the number of WBCs, neutrophils, and lymphocytes was observed in patients treated with clozapine without significant difference compared to the patients treated with other neuroleptics, but there was no severe neutropenia or need to stop treatment.

Conclusions: The prescription of clozapine, the introduction protocol, and treatment administration have been greatly influenced by the COVID-19 pandemic due to the hepatotoxic risk of the drug. Vaccination is essential to prevent severe forms of the infection, especially in at-risk populations such as patients treated for schizophrenia. The potentiation of hematologic side effects induced by clozapine by the vaccine is not documented. The COVID-19 mRNA vaccine is safe even with clozapine

doi: 10.1192/j.eurpsy.2024.1071

Introduction: Patients with mental illness, particularly those with treatment-resistant schizophrenia, are at increased risk of severe COVID-19. The protective effect of vaccination against severe disease has been demonstrated, and vaccination of vulnerable individuals was a priority during the vaccination campaign. However, the effect of vaccination on the psychiatric symptoms of the disease is not well understood.

Objectives: To investigate the impact of COVID-19 vaccination on psychiatric symptoms and somatic symptoms in patients hospitalized for treatment-resistant schizophrenia.

Methods: Thirty patients hospitalized for treatment-resistant schizophrenia with a history of medico-legal acts were admitted to the forensic psychiatry department at Razi Hospital in Manouba, Tunisia. The consent of patients and/or their relatives was obtained before vaccination, and potential side effects were explained to patients and their families. A neuropsychiatric assessment and clinical examination of patients were performed by their referring psychiatrist before vaccination and one month after.

Results: The patients were all male, with a mean age of 42.3 years. No patient had an allergic reaction to the vaccine. No patient was infected with the virus one month after vaccination. On the clinical level, 30% of patients had general symptoms such as fatigue and

myalgia, which improved spontaneously within a few days. On the psychiatric level, exacerbation of positive symptoms such as hallucinations and delusions was found in 26% of patients. No increase in the frequency of agitation episodes or risk of hetero-aggressive behavior was reported. Sleep disturbances such as difficulty falling asleep and fragmented sleep were reported. The most common functional complaints reported by patients were palpitations, which were a source of somatic concern.

Conclusions: Several side effects of the vaccine have been documented and are taken into account in the daily practice of practitioners, but psychiatric effects are poorly reported and are sometimes attributed to the underlying disease. A complete examination, objective assessment, and regular follow-up are necessary to identify symptoms early and prevent relapses. Because of the small size of the sample, results could not be generalized. Further studies on a larger scale should be conducted.

doi: 10.1192/j.eurpsy.2024.1072

Introduction: The coronavirus infection emerging in 2019 caused a plethora of physical and mental health problems around the world. Recent studies showed a persistent psychological distress even after few months of the infection.

Objectives: To determine the prevalence of depressive symptoms, insomnia and dyspnea among covid-19 survivors.

Methods: We conducted a prospective cohort study including 121 Tunisian COVID-19 inpatients who had been discharged alive from hospital. Each enrolled patient was asked about the period before the hospital stay, and the 6-9 month-period after hospital discharge. Patient Health Questionnaire-9 (PHQ-9) was used to assess depressive symptoms. We assessed *insomnia via the insomnia severity index (ISI)* and *dyspnea through the mMRC* (modified British Medical Research Council).

Results: The median age of participants was 59 years. The prevalence of depressive symptoms and insomnia increased significantly after the pandemic (5.7% vs 57.9%, $p=0.038$, $r=0.189$; and 4.9% vs 26.4%; $p<0.0001$, $r=0.349$ respectively). Younger patients presented more depressive symptoms ($p<0.0001$). females were more likely to suffer from depressive symptoms ($p<0.0001$). Dyspnea was more prevalent among survivors with depressive symptoms ($p=0.001$). Patients with depressive symptoms exhibited more insomnia ($p<0.0001$).

Conclusions: The pandemic of covid19 emerged a wide range of physical and mental health problems with complex physiopathology. The early detection of these disorders improves the quality of life of these patients.

doi: 10.1192/j.eurpsy.2024.1073

Introduction: The global COVID-19 pandemic and subsequent lockdowns have significantly impacted global wellbeing and highlighted the close link between mental and physical health. Social isolation and quarantine have proven to be major stressors, leading to emotional distress and unpredictable psychological consequences.

Objectives: We explored the pandemic's impact on individuals' physical and mental health and social relationships.

Methods: We conducted a cross-sectional study using a questionnaire which included among other socio-demographic questions, the Fear of COVID-19 Scale, the World Health Organization Quality-of-Life Scale (WHOQOL-BREF) and the Toronto Empathy Questionnaire (TEQ).

Results: A total of 511 adults (55.1% males) participated in this study. Participants reported increased social media use (more than 4-5 times/week) during the lockdown, which was associated with increased fear of COVID-19 and negative effects on mental and physical health, and social relationships ($p<0.01$). Conversely, non-work-related outings (once a week) were associated with lower fear ($p<0.01$) and better well-being ($p<0.05$). Higher fear, particularly for loved ones, was associated with negative effects. The level of physical health was moderate to high, with varying levels of satisfaction in different areas. Empathy correlated with increased fear ($p<0.01$) and reduced mobility ($p<0.05$).

Conclusions: The COVID-19 pandemic and lockdowns significantly affected physical and mental health, highlighting the importance of tailoring interventions for vulnerable populations and promoting adaptive coping strategies in times of crisis.

doi: 10.1192/j.eurpsy.2024.1074

Introduction: Children, who are particularly vulnerable in emergency situations, need tailored mental health strategies.

Objectives: We investigated the impact of the COVID-19 pandemic on anger and life satisfaction in children.

Methods: September 2021, we conducted a cross-sectional study in Preveza, Greece, interviewing 91 students aged 10-12 years from four elementary schools. The survey included socio-demographic questions, the Anger Expression Scale for Children (AESC), and the Satisfaction with Life Scale (SWLS). AESC scores range from 6 to 30 indicating anger severity, while SWLS scores between 5-9 signify extreme dissatisfaction and 31-35 extreme satisfaction.

Results: Significant correlations were found between the number of siblings (p 0.004), duration of electronic play (p 0.005), and duration of sleep (p 0.014) with life satisfaction. Children without siblings, with limited play consumption, and early bedtimes had lower life satisfaction. The presence of a television in their room (p 0.027) and daily use of television and social media (p 0.007) correlated with anger management and behavior. Social media/TV use was associated with better anger management.

Conclusions: Despite the pandemic lasting almost two years, children's anger levels in Preveza remained stable, possibly due to outdoor activities and online interactions. These findings provide insights for policy makers, healthcare professionals, and parents seeking to improve anger management of children.

Atypical case of anterograde amnesia after cerebral infarction and anti-NMDA encephalitis post Covid 19 infection: A complex clinical case

M. Gebele

Subacute psychiatry unit, Hospital Gintermuiza, Jelgava, Latvia
doi: 10.1192/j.eurpsy.2024.1075

Introduction: Only a few cases of primary anterograde amnesia with confabulation after severe complex brain damage have been described in the literature.

Objectives: To describe a case of anterograde amnesia with confabulation in a patient with severe and extensive brain damage.

Methods: case report

Results: Case presentation: A 48-year-old male patient with a medical history of diabetes mellitus type II, hypertension, presented to a psychiatric clinic for the first time. He was admitted to the hospital due to the manifestation of disruptive aggressive behaviour, aimless wandering, and excessive, impulsive expenditure of financial resources. At the time of hospitalization and during the hospital stay, the patient exhibited a state of elevated mood and anterograde amnesia compounded by the presence of prominent confabulation, easily irritable mood with a tendency to conflict. No physical limitations.

Background: The patient is an active long-distance driver for 15 years. A year before hospitalization in psychiatric clinic, he was travelling to Moscow, he had episode of headache and unconsciousness after which hospitalization. Diagnosed with multiple infarcts of embolic origin in the right frontal lobes, both cortical and subcortical, on the right side at the level of the uncus, in the medial anterior parts of the right occipital lobe, on the left side in the insula and at the level of the capsula externa, in the anterior basal part of the left temporal lobe. After hemodynamic stabilization, he was repatriated to Latvia. Stationary positive SARS-CoV-2 PCR, O2 support therapy required.

The patient develops auditory and visual hallucinations, which do not correct on antipsychotic therapy. Lumbar puncture was performed, which showed positive anti-NMDA antibodies, magnetic resonance - autoimmune limbic encephalitis with damage to the gyrus cinguli of the insula cortex of both temporal lobes and the right subfrontal part with spread throughout the right temporal lobe, bilaterally in the mediobasal structures of the temporal lobes and the right thalamus with progressive changes. The patient receives immunomodulatory therapy, plasma exchange and immune globulin. Hallucinations decrease on the background of therapy. At discharge - moderate ataxia in the legs, disorientation in time, severe short-term memory disorders.

The patient in his mind lives like nothing has happened and the same life continues.

Image:

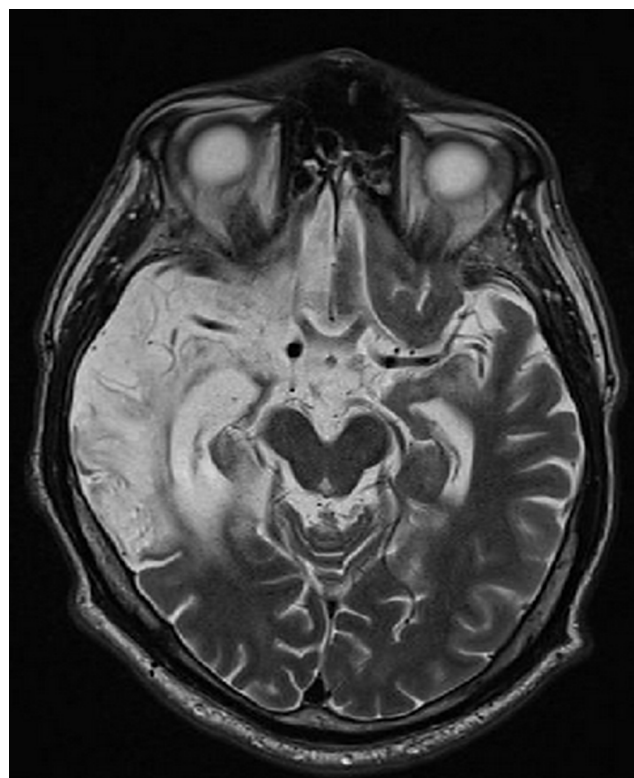

Image 2:

Conclusions: The long-term prognosis for the patient remains uncertain, given the multifaceted nature of the condition and the extent of brain damage. Continuous monitoring, rehabilitation, and ongoing support will be essential to assess cognitive recovery and improve the patient's quality of life.

Mental well-being of Tunisian COVID-19 survivors: a cohort study

M. Turki¹, N. Bouattour^{1*}, H. Ben Ayed², S. Ellouze¹, R. Jbir¹, S. Msaad³, S. Kammoun³, N. Halouani¹ and J. Aloulou¹

¹Psychiatry "B" department; ²Preventive medicine and hospital hygiene and ³Pneumology department, Hedi Chaker university hospital, Sfax, Tunisia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1076

Introduction: COVID-19 affected humankind worldwide in different aspects of life. Survivors still report the effects of the pandemic on daily life, physical health, and mental health.

Objectives: To assess effects of the pandemic on the mood and the quality of life of the survivors.

Methods: We conducted a prospective cohort study including 121 Tunisian COVID-19 inpatients who had been discharged alive from hospital. Each enrolled patient was asked about the period before the hospital stay, and the 6-9 month-period after hospital discharge, using several scales: the validated Arabic version of

"Patient Health Questionnaire" (PHQ-9) to screen for depressive symptoms, and "EuroQol five-dimension three-level" (EQ-5D-3L) to assess the quality of life.

Results: The median age of participants was 59 years, with extreme values ranging from 18 to 80. Among them, 51.2% were females. As compared with baseline status of patients, the depressive dimension assessed through PHQ was significantly impaired (7.05 vs 1.12; $p < 0.001$). The different dimensions of the EQ-5D-3L showed significant deterioration in mean scores (mobility: 1.09 vs 1.31, $p < 0.001$; selfcare: 1 vs 1.11, $p = 0.001$; daily activities: 1.09 vs 1.49, $p < 0.001$; pain and disturbance: 1.17 vs 1.49, $p < 0.0005$ and anxiety and depression: 1.07 vs 1.57, $p < 0.001$). Depressive symptoms were 10 times more frequent in post-COVID (57.9% vs 5.7%). The post-COVID PHQ-9 score was correlated with the post-COVID EQ-5D-3L score ($p = 0.033$).

Conclusions: This study points out the long-term impact of the COVID infection. Therefore, the clinician should screen for possible psychological distress even after resolution of the disease, in order to guarantee a better quality of life.

Quality of sleep among trainee doctors at the Charles Nicolle Hospital after vaccination against COVID19

Z. Athimni, G. Bahri, M. Mersni, I. Youssef, D. Brahim, H. Ben Said, N. Mechergui, N. Ladhari and K. Imene*

Department of Occupational Pathology and Fitness for Work - Charles Nicolle Hospital, Tunis, Tunisia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1077

Introduction: Sleep quality depends on several factors such as smoking, physical activity, diet, and certain pathologies, namely obstructive sleep apnoea syndrome. Indeed, following their vaccination against COVID19, several medical trainees complained about a deterioration of their sleep quality.

Objectives: To evaluate the quality of sleep of medical trainees who work at Charles Nicolle Hospital and who were vaccinated against SARS-COV2.

Methods: We conducted a descriptive cross-sectional study among medical trainees at Charles Nicolle Hospital who were vaccinated against COVID-19 during the period from March 2020 to August 2022. Sleep quality was evaluated by the Pittsburgh Sleep Quality Index (PSQI) questionnaire. Trainees were contacted during the period August 2022 to September 2022.

Results: Sixty-nine medical trainees, vaccinated against Covid19 joined our study. Forty-nine of them had a significant sleep disturbance: Pittsburgh Sleep Quality Index (PSQI) greater than five. The average age was 29.39 ± 3.04 years with a female majority (73.5%). No psychiatric history was found. The most affected category of trainees were residents (71.4%). Forty-three of them were inoculated with the messenger RNA vaccine and 4 with inactivated vaccine. Twenty-one patients vaccinated with the messenger RNA vaccine received two doses, seventeen received three doses and only one received a single dose. Sleep latency was high in 20,4% of cases. A sleep duration of less than five hours per night was found in 18,4% of the cases. Six participants reported using a sleep aid three to four times a week.

Conclusions: Our study revealed a significant sleep disturbance in medical trainees at Charles Nicolle Hospital. This could be due to the SARS-CoV2 vaccination but can also be explained by the night shifts and the stress to which they are exposed, especially during this pandemic period.

Peculiarities of the first time diagnosed mental disorders formation in after the coronavirus disease COVID-19

N. O. Maruta*, V. Y. Fedchenko, T. V. Panko and I. O. Yavdak
Borderline psychiatry, "Institute of Neurology, Psychiatry and Narcology of the NAMS of Ukraine" SI, Kharkiv, Ukraine

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1078

Introduction: The world community is only at the beginning of awareness of the peculiarities of the formation, course and outcome of the psychopathological consequences of the impact of the SARS-CoV-2 pandemic.

Objectives: To investigate the clinical and anamnestic features and their influence on the formation of psychopathological consequences in patients with first diagnosed mental disorders who have experienced COVID-19 and were exposed to the stressors of the SARS-CoV-2 pandemic.

Methods: 97 patients with first diagnosed mental disorders who have experienced COVID-19 and were exposed to the stressors of the SARS-CoV-2 pandemic were examined (F 32.0-32.2 – 34 patients, F 40-45 – 32 patients, F 06.3-06.6 – 31 patients). Clinical-psychopathological, clinical-anamnestic methods, including information about the experienced coronavirus disease COVID-19, the impact of the stressors of the SARS-CoV-2 pandemic, and methods of statistical analysis were applied.

Results: The conducted research made it possible to identify the phenomenological structure of mental disorders that develop after the coronavirus disease COVID-19. This structure includes depressive disorders (35.05%), neurotic, stress-related and somatoform disorders (32.99%), as well as mental disorders of organic genesis (31.96%). An important result of the study was the determination of the heterogeneity of mental pathology in the context of the influence of stressogenic factors of the pandemic and other psychogenies. In this aspect, all mental and behavioral disorders must be divided into 3 variants of pathology, which differ in the mechanisms of formation: caused by the pathoplastic factors of COVID-19 and the patient's personal reactions to the disease; related to the psychogenic effects of the stressors of the SARS-CoV-2 pandemic; with a combined mechanism of influence of pathoplastic and psychogenic factors. Certain diagnostic and phenomenological regularities characteristic of each of the options are defined. The influence of pathoplastic factors and personal reactions to the disease is associated with the formation of depressive disorders. Pandemic stressors most often cause the development of neurotic, stress-related and somatoform disorders. Under the influence of combined factors, disorders of organic genesis are formed to a greater extent. The initial manifestations of pathology also differ with different formation mechanisms: when pathoplastic factors predominate, asthenia, depression and sleep disturbances prevail; with leading psychogenic influences – anxiety and tension; when the above factors are combined – asthenia, stress and cognitive disorders.

Conclusions: The significance of the obtained data lies in the possibility of studying the role of the psychopathological consequences of COVID-19 in the genesis of mental disorders.

The impact of the COVID-19 pandemic on the mental health of nursing professionals in the state of São Paulo

M. C. V. R. De Oliveira^{1*}, E. Ribeiro dos Santos² and E. C. Araujo³

¹Medical College, UNOESTE, PRESIDENTE PRUDENTE; ²Regional Nursing Council of the State of São Paulo Brazil, COREN-SP and ³CORENSP, SÃO PAULO, Brazil

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1079

Introduction: This is a descriptive cross-sectional clinical study with professionals from the Nursing Team (Nursing Assistant, Nursing Technician and Nurse).

Objectives: To assess the psychological impact of the Covid-19 pandemic on nursing staff professionals.

Methods: A descriptive, quantitative, cross-sectional study will be applied to a structured interview aimed at collecting sociodemographic and occupational data, Mental Health Scales evaluating professional exhaustion - Oldenburg Burnout Inventory and Beck's Anxiety Rating Scale to assess the state of anxiety.

Results: About 13,587 nursing professionals were interviewed, including nurses, technicians and nursing assistants. They were evidenced through the behavior indexes related to insomnia, the desire to cry and appetite variation may be related to the long working hours, the fear of contamination and the consequent absence from work, as well as the fear of getting sick may be related to the fact that the professional stops being a caregiver and starts to be cared for.

Conclusions: the study denotes the importance and need for interventions to promote and prevent mental well-being in health professionals exposed to COVID-19, these need to be implemented immediately, for nursing professionals, as they are on the front line, demanding attention Special. In this sense, the Nursing Council of the State of São Paulo created and implemented some bills such as the Obligation of Rest Rooms in Health Units, the Cuidando de Quem Cuida Program and the Yellow September Campaign in Allusion to actions for Nursing professionals for the prevention and promotion in mental health category.

Coping self-efficacy and personal growth in the situation of the COVID-19 threat

O. G. Kvasova^{1*}, E. A. Karacheva^{1,1}, P. I. Prichkodko¹, M. S. Magomed-Eminov² and O. O. Savina¹

¹Psychological Helping and resocialization Department and ²Head of the Psychological Helping and resocialization Department, Moscow State University after M.V.Lomonosov, Moscow, Russian Federation

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1080

Introduction: In studies of the socio-psychological consequences of the COVID-19 pandemic, models focused on the negative aspects of stressors, dysfunctions, anxiety. We present the attempt to expand the context and include in the field positive personal resources for psychological well-being and even post traumatic personality growth after disasters. Sometimes separation from family and friends, lack of medicines and medical resources, loss of income, social isolation to humanity, do not automatically assume that a person is capable and responsible for effectively coping with life difficulties.

Objectives: 397 (students and patients of clinic average age 26, 2/3 are female

Methods: Peritraumatic Distress Index (CPDI) (Feng, 2020); Impact of Event Scale (Horowitz, 1979), Coping Self-efficacy Scale (Chespeu et al, 2006); Posttraumatic Growth Inventory (Tedeschi & Calhoun, 1996), MMI (Nuttin, 1986) – adapted by M. Magomed-Eminov.

Results: Significant negative correlation between coping self-efficacy and intensity of the impact of stressful events (IES) ($r_s = -0.140$, $p < 0.05$) was predictable.

CPDI and PTG showed significant correlation (Pearson's $r = 0.23$, $p < 0.01$) between Peritraumatic Distress Index and Post-Traumatic Growth indicators only in the group of respondents who have had COVID-19. The data is confirmed by the content analysis of incomplete sentences of the subjects of COVID group. The correlation between these indicators in the Non-Covid group was insignificant.

Moreover additional information we got from narratives of infected patients: the data has been split into 3 groups of narratives in the context of cultural-historical activity theory which shows the triadic outcome of survivor after trauma : a) suffering, b) adaptation, coping, resilience, c) personal growth.

Conclusions: To interpret the data the authors propose the meaning-activity approach and personality work with negative life experience (Magomed-Eminov, 1998, 2007, 2009, 2021). Authors suggest that further research on the positive consequences of stressful events beside coping styles and mechanisms that would expand the repertoire of tools predicted the ability of a modern person to cope with adversity and use experience for deeper involvement of human resources with the help of personality work with personal experience.

Confirmatory factor analysis and measurement invariance of the Depression, Anxiety, and Stress Scale (DASS-21) among Pakistani young adults

S. M. A. Kazmi¹ and C. A. Lewis^{2*}

¹Higher Education Department, Punjab, Pakistan and ²Psychology, Leeds Trinity University, Leeds, United Kingdom

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1081

Introduction: The Depression, Anxiety and Stress Scale (DASS-21) is recognized as being a widely used measure for the assessment of negative emotional states. While the DASS-21 has been widely used for assessing mental health in Pakistan, limited research has been done regarding its factor structure and measurement invariance.

Objectives: To assess the factor structure and measurement invariance of the DASS-21 among young adults in Pakistan.

Methods: A large sample of 1361 Pakistani young adults had completed the scale during the current study comprising 666 males and 695 females with a mean age of 24.51 years.

Results: Excellent internal consistency reliability was found for the overall DASS-21 and its three subscales (depression, anxiety and stress) ranging from $r = .86$ to $.71$ (Cronbach alpha). Moreover, the three subscales were strongly and significantly associated with one another. Additionally, the results showed a good fit of the three-factor model and the one-factor model of the DASS-21 aimed at assessing gender psychological distress. Strong measurement invariance was found regarding gender therefore showing that the DASS-21 is understood and interpreted similarly by males and females. However, little evidence was found regarding the three subscales (depression, anxiety and stress) for the measurement of three distinct constructs.

Conclusions: These findings confirm the utility of the DASS-21 for measuring mental health in Pakistan among young adults.

EPV0353

Somatic Representation of Emotional Problems among Native Kyrgyz Speakers

E. Molchanova

Psychology, American University of Central Asia, Bishkek, Kyrgyzstan
doi: 10.1192/j.eurpsy.2024.1082

Introduction: The somatization problem has been one of the most acute in mental health for half a century (Kirmayer, L., 2000). Patients with somatic complaints turn to specialists in various fields but rarely to psychologists and psychiatrists, although the connection between bodily suffering and psychological difficulties sometimes lies on the surface (Molchanova E., 2016). In the last twenty years, the mechanisms of somatization have been considered by several disciplines, one of which is cultural psychiatry, which has become relevant. Unfortunately, most of the research focuses on the cultural characteristics of migrants living in the United States (Groleau, D. and Kirmayer, L. 2004). There needs to be more research on the cultural features of somatization in Kyrgyz culture.

Objectives: The goal of the study is to discover the distinctive features of the process of somatization in Kyrgyz culture

The objectives are:

To create a vocabulary of somatic phrases and idioms used to represent somatic problems to find the most commonly used somatic idioms for emotional complaints by native speakers of the Kyrgyz language.

To describe the mechanism of transformation of the emotional symptom into a specifically located and presented somatic complaint.

Methods: The research used a mixed, qualitative, and quantitative design.

The first stage is qualitative, including ten semi-structured interviews with linguists, culturologists, historians, and specialists in folk art.

The second stage included four focus groups (12 people in each group) with a follow-up analysis. The recruitment of respondents was carried out through social networks, announcements, and the snowball method.

The third stage was quantitative. With the help of the dictionary compiled at the first stage, 250 participants ranked the frequency of somatic idioms, which were used to express the emotional problems

Results: There have been found more than 200 somatic idioms, which are used to present emotional problems. The most frequent ones describe the heart, liver, and joints. Heart metaphors are associated with despair and anxiety, joints - with depression, and liver metaphors - with some personality characteristics, such as conformity and kindness. The created map of somatic representation of emotional problems shows the most frequent localization of somatic symptoms in disorders featuring somatic symptoms in native Kyrgyz speakers.

Conclusions: There is a culturally shaped specifics of somatic representations of emotional problems among native Kyrgyz speakers. More research needs to be conducted to interpret the nature of people's emotional problems represented by somatic symptoms.

Applications of art therapy/occupational therapy in neuropsychic disorders: raw art objectives: stimulation, creativity, catharsis, socialization

E. Chirila

Centrul comunitar județean, Complex de servicii sociale comunitare pentru copii și adulți, Direcției Generale de Asistență Socială și Protecția Copilului Cluj, Cluj-Napoca, Romania
doi: 10.1192/j.eurpsy.2024.1083

Introduction: Art therapy, occupational and play therapy support the idea that man becomes what he is through activity. We accept man in his totality, we oppose the rigid boundaries between “sick” and “healthy”, there is no contradiction between these states, but only an unbroken chain of neighboring nuances, of gradual differences of human life.

Objectives: Therapies based on the visual arts are also used in the discharge of repressed experiences, called in psychoanalytic terms “catharsis”, with the aim of preventing or remedying dysfunctions, facilitating maximum adaptability of the beneficiary, regardless of the degree of handicap. The activities of occupational therapy and ergotherapy has and productive objectives, in accordance with the outstanding, hidden skills, correlated with the current demands on the labor market. Art forms called: “Raw Art” can be practiced.

Methods: Traditional crafts and visual arts are reinvented as therapeutic methods. We use pottery and sculptural artistic ceramics with elements from the history of archaic arts connected with contemporary visual arts (pictures, sculpture, graphics, mixed arts and multimedia)

Results: The creative process and symbolic communication, associated with narration and imitation, develop new ways of communication, new ways of self-expression, new ways of seeing things. Throughout this process, people are more productive, more efficient, focused, calm and self-satisfied. (2014- Emilia Chirilă The role of art therapy in self-knowledge, self-esteem and interpersonal relationships in children with emotional disorders”- THE SECOND WORLD CONGRESS ON RESILIENCE: FROM PERSON TO SOCIETY may 8-10 Timisoara Romania 1139-1145 editors: M Tomita, S.Cace – MEDIUMOND- INTERNATIONAL PROCEEDINGS copyright 2014 by MEDIMOND srl 40065 Piamond (Bologna) Italy -Printed May 2014 by Editografica.Bologna Italy - ISBN 978-88-7587)

Image:

Image 2:

Image 3:

Conclusions: People who do not have a sufficiently developed vocabulary to be able to express themselves feel very good practicing art as a natural means of communication. Discovering the skills of the beneficiary, through the artistic product and the awareness of emotions and feelings open up ways to a more effective non-verbal communication.

Cultural Diversity and Mental Health Care: A Case Study

M. R. Soares*, M. P. Cameira, P. Abreu and M. Pereira

Lisbon Psychiatric Hospital Centre, Lisbon, Portugal

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1084

Introduction: In today's world of global migration and cultural diversity, mental health care grapples with persistent challenges. Despite efforts to promote cultural competency and person-centred approaches, it's vital to delve into the issues surrounding cultural differences and linguistic diversity in mental health care. This exploration highlights the complexities where culture, language, and healthcare intersect (Brisset et al., 2014; Desai et al., 2021).

Objectives: Our aim is to analyse cultural and linguistic barriers in mental health care for migrants and assess their impact on access and quality of care.

Methods: Literature review, drawing from sources such as PubMed, ResearchGate, and Google Scholar. This review will be framed around the case of a 34-year-old man from Bangladesh, who has been residing in Lisbon for a year. His clinical presentation includes depressive symptoms, disorganized behaviour, and psychotic manifestations, such as persecutory delusions. He does not speak Portuguese or English, thereby limiting his access to essential mental health treatment services. Through this review, we intend to elucidate the intricate dynamics surrounding cultural and linguistic barriers in mental health care.

Results: Migrants from diverse backgrounds face many challenges, including the loss of homes, livelihoods, and family, often leading to mental health issues like depression, anxiety, and post-traumatic stress disorder. Two primary challenges include adapting to a new life and experiencing discrimination and marginalization (Amri et al., 2013; Satinsky et al., 2019). Social stigma and mistrust hinder access to mental health services. Limited culturally competent services widen the gap between mental health needs and help-seeking attitudes. Language barriers significantly contribute to disparities in access to services (Amri et al., 2013). Additionally, mental health care providers' organizational culture often prioritizes 'ideal' patients who are native speakers, favouring individual-oriented treatment over community-focused care (Desai et al., 2021).

To address these barriers effectively, it is crucial to employ specific strategies. The Multi-Phase Model of Psychotherapy, Social Justice, and Human Rights (MPM) equips mental health counsellors to better serve immigrant communities while addressing social stigma. This comprehensive framework comprises five phases of intervention: psychoeducation, culturally responsive service delivery, cultural orientation, collaboration with local healers, and connecting patients to essential resources (Amri et al., 2013). Additionally, practitioners should receive training in effective collaboration with interpreters to provide multilingual healthcare (Brisset et al., 2014).

Conclusions: Addressing cultural and linguistic barriers in mental health care is vital. The Multi-Phase Model of Psychotherapy offers a promising approach, while collaboration with interpreters remains essential.

Dissociative Identity Disorder from a Palestinian Perspective: A Case Report

N. Marzouqa* and S. Saadeh

Psychiatry, Dr Kamal Psychiatric Hospital, Bethlehem, Palestinian, State of

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1085

Introduction: Dissociative Identity Disorder (DID) is the presence of two or more distinct personality states within an individual. It is a rare dissociative disorder where usually self-non-integration arises as a response to significant stress. As is the case for many other psychiatric disorders, the diagnosis and management of DID is highly dependent on cultural variables and contexts.

Objectives: To present a case of DID in Palestine in which the diagnosis was dependent on noticing minor changes in the patient's dialect at different times. To highlight the importance of understanding each patient's environment, values, and culture when assessing DID to avoid under- or over-diagnoses.

Methods: A case report in which we present a case of a 17-year-old Palestinian girl who suffered from three months of general fatigue, restlessness, poor coordination, and peripheral numbness. She was seen by several doctors who excluded organic causes and several spiritual healers without benefit. This caused severe deterioration of social and academic functioning. The family noticed a change in her articulation and memory issues, so they presented her to a psychiatrist. Data was collected by interviewing the patient and her family weekly for a month. The psychiatrist noted that the patient has subtle differences in accent, and directed the family to record any change in tone of voice or articulation. The patient was found to have three different accents on top of her native one, representing a total of four personalities with no memory integrity among them. She was started on Escitalopram (gradually increased) and Alprazolam (gradually decreased).

Results: The psychiatrist detected the theme of being "stuck" throughout the personalities, each in its own way, according to the context of their roots. It was revealed that the patient is engaged to a man she doesn't approve of and has "no way out" due to the social and familial significance of this relationship. Family counseling and trauma-informed psychoeducation were done, where the patient's choice was reaffirmed. This led to significant improvement in terms of mood, identity integration, and social functioning with complete resolution of split personalities in just short of one-and-a-half months.

Conclusions: This case report asserts the importance of cultural understanding and sensitivity when assessing psychiatric patients. Symptoms, triggers, psychotherapy, and psychoeducation have a universal baseline, yet are highly culturally-dependent. Through this case study, we emphasize the importance of translating universal criteria into context-specific practices.

Exploring the legacy of Ibn Imrân's Treatise on melancholia in contemporary psychiatry

S. Boudriga*, M. Lagha, M. Methni, Y. Ben Youssef,
I. Ben Romdhane, W. Homri and R. Labbane

Psychiatry C, Razi Hospital, Manouba, Tunisia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1086

Introduction: Melancholia is a concept deeply intertwined with the history of mood disorders in psychiatry. Ishâq Ibn Imrân, a prominent Arab-Muslim physician of the 12th century, contributed significantly to the understanding of melancholia in his era, its. His treatise is the oldest surviving work entirely dedicated to melancholia, making it a pivotal milestone in the history of psychiatry. It is noteworthy that Ibn Imrân's work has often been overlooked in Western psychiatry. This oversight highlights the enduring relevance of his insights within the context of modern psychiatry.

Objectives: The objective of this study is to assess the clinical and therapeutic aspects delineated by Ibn Imrân in his treatise on melancholia for their contemporary accuracy and relevance within the field of modern psychiatry.

Methods: The review method for the Ishâq Ibn Imrân treatise involves a detailed analysis of the original Arabic text and its French translation by Adel Omrani and Radhi Jazi from the Tunisian Academy of Sciences, Letters, and Arts Beit el Hekma. This includes studying the content, structure, and historical context, as well as comparing the Arabic and French versions for accuracy.

Results: The treatise is divided into two parts to clinical examination and treatment. While some of the terminology may differ from contemporary classifications, the core observations resonate with modern psychiatric knowledge. The clinical form is described as sadness, loss of pleasure, social withdrawal, dark thoughts, and loss of interest, along with somatic manifestations: sleep disturbances such as onset insomnia or hypersomnia, as well as weight loss. Additionally, perceptual disturbances, including elementary visual hallucinations (black silhouettes), are mentioned. Regarding etiologies, perinatal factors are mentioned in the treatise ("mood of the uterus"), along with six postnatal acquired causes that must be balanced in an individual: movement and rest, sleep and wakefulness, food and drink, depletion and retention, ambient air and location and psychological torment. A seasonal pattern is described, with an association between melancholia and autumn. Several clinical forms are described, with the most prominent being catatonia compared to epilepsy, in its two agitated and inhibited forms. The second part of his treatise is dedicated to treatment, focusing on individualized approaches such as talk therapy, music therapy, and dietary interventions. Ibn Imrân also describes mental strategies to correct false beliefs. For the pharmacological treatment, specific herbs have been used via oral, nasal, or intra-rectal.

Conclusions: In conclusion, Ishâq Ibn Imrân's treatise on melancholia represents a timeless cornerstone in the history of psychiatry. This historical treasure serves as a reminder of the enduring quest to understand and alleviate the complexities of mental health.

Grief in modern multicultural Europe – a way out of "disenfranchisement"

Z. Correia De Sá*, B. Castro Sousa and J. Ramos

Department of Psychiatry and Mental Health, Centro Hospitalar
Universitário da Cova da Beira, Covilhã, Portugal

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1087

Introduction: The recent addition to both ICD-11 and DSM-V of "Prolonged Grief Disorder" "PGD" raises questions regarding the complexity of the clinical manifestations and the nuances of "normal/abnormal" grief. The lack of consensus in diagnosing emphasizes grief as a non-homogeneous process highly dependent on cultural nuances and the proportion of losses.

Objectives: Provide an open discourse on (PGD) emphasizing its multicultural aspects in the diagnosis, and debate whether it reinforces mental health stigma by "pathologizing" grief in today's multicultural society.

Methods: Non-systematic review of literature using key words "Grief", "Prolonged Grief Disorder", "Multicultural aspects of Grief", "Major Depressive Disorder" and "Disenfranchised Grief", on the platforms PubMed, Medline, Google Scholar, "European Commission", "International Migration Outlook 2022" and "Pordata".

Results: Literature has not clearly provided a universal definition of grief, grief processes or the threshold of abnormality. Grief lasting longer than expected is often equated to Major Depressive Episodes, given symptomatic similarities. Migration, war and the pandemic have played a significant role in how people currently grieve. Evidence showed that in 2021 alone there was a 22% increase in the permanent immigrant population. Moreover, the top five nationalities applying for first time asylum in the EU (2022) were: Syrian, Afghan, Venezuelan, Turkish, Colombian, and as of September 2022, 5 million Ukrainian refugees were registered. These figures are not neglectable and show the multiculturalism of today's EU population. However, the development of transcultural psychometric tools assessing grief has not been uniform, lacking consistency in validating various transcultural factors. On the other hand, actively diagnosing "Prolonged Grief Disorder" has shown helpful to clinicians in recognizing the debilitating effects of some pernicious grief responses and quickly providing the necessary help.

Conclusions: Diagnosing "PGD" might lead to "psychiatrization" and "medicalization" of normative emotional processes, given different cultural backgrounds, especially due to the absence of universally applicable tools validating transcultural factors. Consequently, an inadequate consideration of context leaves patients feeling invalidated, non-supported and disenfranchised. A culturally sensitive approach is crucial, focusing on individual differences for effective grief intervention and support.

The psychosocial well-being of an individual is a driver for illegal immigration: a clinical case study

I. Bouguerra^{1,2*}, A. Touiti^{1,2}, A. Hajri^{1,2}, A. Maamri^{1,2} and H. Zalila^{1,2}
¹Outpatient Psychiatric and emergency Department, Razi Hospital, Manouba and ²Faculty of Medicine, Tunis El Manar University, Tunis, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2024.1088

Introduction: The European Border and Coast Guard Agency (Frontex) detected 330,000 irregular border crossings last year. Tunisian nationals are among the top three nationalities reported. While there are many reasons for illegal immigration,the social driver is one of the most important to study.
Objectives: To highlight the role of the social environment in promoting illegal immigration and its impact on the psychosocial well-being of individuals in Tunisia through a clinical case study.
Methods: we reported the clinical case of a 32 years old tunisian patient who was diagnosed with severe major depressive disorder and post traumatic stress disorder after an illigale immigration to Europe.
Results: A 32-year-old Tunisian man from Tataouine,a region in southern Tunisia,was the subject of this case study.He was the youngest of four siblings,had a secondary education,and worked as a shepherd.His socio-economic status was moderate,unstable and seasonal.He had already attempted to immigrate to Italy twice illegally,by sea,but had been deported both times.The patient sought consultation for depressive symptoms.In January 2023,he made a third attempt to immigrate to Europe,this time by plane.He traveled with two of his cousins,aged 18 and 20,and paid 22,000 Tunisian dinars for the trip.Both cousins died during the journey,one from hypothermia and the other from police pursuit. The patient was deported again and was diagnosed with post-traumatic stress disorder (PTSD) and a major depressive episode.

Hamilton Depression scale	PTSD checklist scale	Rosemberg self esteem scale
22 severe depression	66 sup 44	Poor self esteem 21

Tataouine is konwn as “little Paris” a region in the south-east which,according to the National Institute of Statistics,had 71 emigrants/1000 inhabitants or 7.1% of the population.Where the soci-ety promotes youth immigration through societal values.
Conclusions: The social environment in Tataouine,which has a high rate of emigration,promotes the idea that immigration is a way to achieve social status and economic security. This can lead to young people feeling pressured to immigrate, even if they are not prepared for the risks involved.

“They say I’m crazy, but I’ve lived through hell.”

N. Molina Pérez*, J. Pereira López, M. I. Santana Ortiz, P. Rivero Rodríguez, A. R. N. Del Rosario, M. M. Grimal and V. Acosta Pérez
Psiquiatría, Hospital Universitario de Gran Canaria Doctor Negrín, Las Palmas de Gran Canaria, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2024.1089

Introduction: Migration has been present in the evolution of human beings throughout history. Economic inequalities give rise to a permanent flow of people trying to improve their lives. In addition, there are people who are forced to seek asylum or refuge due to wars or political violence. Therefore, the migratory flow, gives rise to a clinical scenario in which, the arrival of immigrant people demands an adaptation of the psychiatric paradigm.
Objectives: The objective of this paper is to review the international scientific literature published on the impact of the migration process on mental health.
Methods: We propose a review of the international scientific literature published in recent years on psychiatry and migration. We present the case of a 27-year-old male, diagnosed with paranoid schizophrenia, who arrived in the Canary Islands after a 2-year migration process from his country of origin (Senegal).
Results: The limits between normality and pathology of certain types of behavior vary from one culture to another. In the case of a patient with a mental disorder who has undergone a migration process, an approach based on the cultural formulation of the case should be made, taking into account the process of adaptation to the culture of the host country, as well as the impact of the culture of origin on the patient’s interpretation of his or her psychopathology.
Conclusions: Culture can influence the acceptance or rejection of a diagnosis and treatment, affecting the course of the disease and recovery. Therefore, understanding the cultural context in which the disease is experienced is essential for a good diagnostic evaluation and effective clinical management.

Urdu Translation and Validation of the Penn Inventory of Scrupulosity-Revised

S. Ghayas¹, S. Noureen¹ and C. A. Lewis^{2*}¹Psychology, University of Saragoda, Saragoda, Pakistan and²Psychology, Leeds Trinity University, Leeds, United Kingdom

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1090

Introduction: Scrupulosity is an Obsessive Compulsive Disorder in which an individual experiences persistent doubts and fears about committing religious and moral sins. Researchers have extensively used the Penn Inventory of Scrupulosity-Revised (PIOS-R), which has been translated into various languages.

Objectives: The present study translated and validated the PIOS-R into Urdu.

Methods: The PIOS-R was translated using the forward-backwards translation method. A sample of 443 Muslim University students (male 224 and female 119) with an age range of 18 to 33 years ($M = 21.56$, $SD = 2.02$) completed the Urdu version of the PIOS-R. Cross-lingual validity was established on a further 60 participants.

Results: Confirmatory factor analysis (CFA) confirmed the two-factor structure of the Urdu version of the PIOS-R. It provided an excellent model fit to the data with chi-square 238.72, CFI = .92, GFI = .93 and RMSEA = .03. The Cronbach's alpha coefficient of total scale, Fear of God Subscale, and Fear of Sins Subscale was .84, .74, and .78 respectively were satisfactory. The convergent validity of the Urdu version of the PIOS-R was demonstrated with significant positive correlations with measures of anxiety ($r = .21$, $p < .001$) and depression ($r = .26$, $p < .001$).

Conclusions: The Urdu version of the PIOS-R is recommended for use by researchers and practitioners. The results indicated good reliability and validity information for the Urdu version of the PIOS-R, which supports the measure's utility across cultures and faiths.

Art therapy/occupational and play therapy: plastic expressiveness as a means of reducing loneliness, anxiety, sadness – research carried out during the period 2008-2022 with the theme: creation in / with elements from nature at the placement center

E. Chirila

Centru de zi de recuperare pentru copii cu autism. Centru de servicii de recuperare neuromotorie și de tip ambulatoriu pentru persoanele adulte, Direcția Generală De Asistență Socială Și Protecția Copilului Cluj, Cluj-Napoca, Romania

doi: 10.1192/j.eurpsy.2024.1091

Introduction: Occupational therapy - which also includes art therapy - is an activity/test with a purpose, it involves coordination between the sensory, motor, cognitive, and psychosocial systems of the individual. "Sciences recognize the role of observation in research... All artists who practice art therapy are based on their own artistic activity and present a common recurring feature: they are always in line with "essential pragmatism". (McNIFF, Shaun, Trust the process: an artist's guide to letting go. Creative ability. Psychological aspects. Self-actualization (Psychology). Artist-Psychology, Shambhala Publication, Boston, 1998, p. 78)

Objectives: We seek to find new development solutions through stimulation, creativity, catharsis, and socialization to be authentic, spontaneous, feel fulfilled, emotionally balanced, and transformed, with the aim of fulfilling one's social role through contact with human and environmental factors. (Emilia Chirilă, ART THERAPY IN EMOTIONAL DISORDERS OF CHILDREN AND ADOLESCENTS, printed edition 2018) ISBN 978-973-0-27683-1)

Methods: Through the graphic gesture, the child expresses various issues related to his feelings, like the search for his identity, the generated anxieties, the family and professional environment, and the situations of neglect and abuse. (MALCHIODI, Cathy A, Handbook of Art Therapy, The Guilford Press, New York and London, 2003, p. 157).

Results: The following reactions can be identified: aggression, frustration, dominance tendency, low self-esteem, fraternal rivalry, hopelessness, sadness, compensation mechanisms, self-defense, other significant psycho-traumatic aspects. The disappearance of frustrations and negative feelings due to the disinterest of parents who do not visit the beneficiaries was achieved by gaining authority over the environment and by improving pre-existing skills. emotional disorders of children and adolescents" - Journal of Neurology and Psychiatry of Children and Adolescents from Romania - 2012 - vol. 15 - no. 3- p 121-136 - ISSN (printed): 2068-8040)

Modifying Conventional Psychiatric Practice to Serve Indigenous People

L. Mehl-Madrona^{1*} and B. Mainguy²

¹Native Studies and ²Intermedia, University of Maine, Orono, United States

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1092

Introduction: Psychiatry has historically underserved Indigenous people. Earlier, cross-cultural psychiatry assumed that psychiatric disorders were universal and varied little across cultures. We must acknowledge their different views of mind and mental health.

Objectives: In our auto-ethnographic approach, we introduce or re-introduce participants to cultural beliefs, values, and methods for treating addictions, including narrative methods (storytelling), which receive greater acceptance by indigenous and marginalized peoples. Indigenous philosophy states that we see the world using the stories we have absorbed or constructed to explain our perceptions. Using substances is a story that is connected to poverty and adverse childhood events.

Methods: We create new stories to develop a sense of agency, that one's actions can make a difference in one's life. We present our experiences and findings from providing psychiatric and addiction services in rural and remote Indigenous settings in Canada (Saskatchewan and Northern Ontario) and in Maine (USA). We present data on a modified approach to psychiatric evaluations and services that emphasizes Indigenous values and begins with a life story interview that determines positive aspects of the client's history and problem areas and engages the client in therapy from the beginning of the evaluation.

Results: We will demonstrate how this process changes the process of the psychiatric interview, engages Indigenous clients, and results in better outcomes. We discuss how psychotherapy must change to engage Indigenous clients and to be effective with addictions. She will present data on this area. We present the lessons learned and the results of using this approach with a tribal population in Maine. Some key concepts include (1) reframing the person's self-story about being addicted within a threat-power-meaning network, (2) working with stories about the spirit of the addiction and the consequences of ingesting spirit-laden substances without knowing their songs and protocols, (3) constructing future-self-narratives that explore right relationships and meaningful conduct, (4) constructing stories about the intergenerational transmission of addictions and exploring the question of "whom will be the recipient of your addiction?" We understood that the client sets their goals and defines what recovery means for them, which is the heart of a harm reduction approach.

Conclusions: Indigenous cultures across the world are different but share some similarities including a highly relational approach to defining the self, a collectivist mindset in which the needs of the group can supersede the needs of the individual, a reliance upon stories for transmission of knowledge and culture, and a commitment to a biopsychosocial and spiritual approach, which is often symbolized by the metaphor of the Four Cardinal Directions.

Developing scale for affective response: anxiety, anger, depression

H. Y. Shin, D. Y. Kim and S. W. Choi*

Clinical Psychology, Duksung Women's University, Seoul, Korea, Republic Of

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1093

Introduction: People experience various negative emotions when they encounter stressful events, and these negative emotions contribute to the onset of illnesses. These emotional responses are not limited to just one; a person can experience multiple emotions at once, and the primary emotional reactions can vary depending on the severity and duration of the illness or life events. This is reason why we created a self-report scale to assess short-term emotional responses, focusing on the current emotional state experienced subjectively by patients.

Objectives: The purpose of this study was to develop an affective response scale (ARS) and examine its validity and reliability.

Methods: We established clusters of affective via a literature review and developed preliminary items based on the structure. We conducted expert content validation to converge on the final items, followed by construct validity and reliability analyses.

Results: The research findings indicate that the Affective Response Scale was composed of three main dimensions: anxiety, anger, and depression. Content validity results confirmed the validity of most items. The scale developed in this study was found to be valid in both exploratory and confirmatory factor analyses, and it was identified to be stable and consistent through the analysis of the internal reliability.

Conclusions: These results indicate that the ARS is highly reliable and valid, and that it can be utilized as an effective measure of the patient's emotion and its severity.

EPV0368

Circadian Preferences and Coping Styles to Stressful Life Events in Depression Patients

P. Güzel Özdemir*, T. Ülkevan, M. Işık and E. Sütçü

Van Yuzuncu Yıl University, Van, Türkiye

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1094

Introduction: Depressive disorder is a common public health problem that significantly impairs quality of life and has a high risk of mortality and morbidity.

Objectives: The aim of this study was to investigate circadian rhythm differences, stressful life events and coping styles in patients with depression.

Methods: The study involved 100 participants, including 50 patients with depression and 50 healthy controls, recruited from the psychiatric clinic of one-university hospital. The participants completed a sociodemographic information form, Beck Depression

Inventory (BDI), Life Events Checklist (LEC-5), Coping Inventory for Stressful Situations-Short Form (CISS-21) and Morningness-Eveningness Questionnaire (MEQ).

Results: The mean age of the patients with depression was 31.88 ± 10.6 years, and the control group was 29.84 ± 8.02 years. There were no significant relationships between the variables including gender and some other sociodemographic characteristics except education level. There were significant differences between the depression and control groups in terms of coping styles for stressful life events. Emotional coping was significantly higher in patients with depression compared to the control group, whereas task-oriented coping was significantly lower than the control group ($p < 0.05$). The majority of both depression and the control group consisted of intermediate type. Natural disasters, severe suffering, and other stressful events or experiences were more frequent stressful life events in the depression group. Task-oriented coping scores and emotional coping scores showed significant discrimination with sensitivity and specificity values.

Conclusions: Recognizing stressful life events and the coping strategies used to deal with them is important for identifying future mental problems such as depression and developing treatment and follow-up plans. Longitudinal studies are needed to fully understand how the reporting of mature and dissociative coping methods interacts with depression in recovery from traumatic events.

Mentalizing Abilities in Major Depressive Disorder and Borderline Personality Disorder: Measuring Hypermentalization and Implicit Mentalization with the Hungarian Version of the MASCD. Karakas-Török¹, E. Fábi¹, M. Szennai¹, C. Csuta¹, O. Kelemen^{2,3}, T. Tényi¹, B. Czéh^{4,5} and M. Simon^{1,5*}

¹Department of Psychiatry and Psychotherapy, Medical School, University of Pécs, Pécs; ²Albert-Szentgyörgyi Medical School, Department of Behavioral Sciences, University of Szeged, Szeged; ³Department of Psychiatry, Bács-Kiskun County Hospital, Kecskemét; ⁴Department of Laboratory Medicine, Medical School and ⁵Neurobiology of Stress Research Group, Szentágotthai János Research Centre, University of Pécs, Pécs, Hungary

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1095

Introduction: Borderline Personality Disorder (BPD) is the most common personality disorder in psychiatric care. BPD often co-occurs with Major Depressive Disorder (MDD). Both BPD and MDD are associated with various impairments of social functioning. Among these, mentalizing disturbances are the most extensively studied.

Objectives: The Movie for the Assessment of Social Cognition (MASC) is an ecologically valid video-based test, which is suitable for measuring both hypermentalization and implicit mentalization. Based on the literature, it is sensitive enough to detect mild deficits in mentalization capacities. In this study, we investigated mentalization deficits with a special focus on implicit mentalization and hypermentalization in patients with MDD and MDD+BPD with a set of well-established mentalization tests including MASC.

Methods: We examined patients with MDD (n=43) during the depressive episode. A subgroup of these patients was also diagnosed with BPD (MDD+BPD group; n=23), the other group had no comorbid personality disorder (MDD group; n=20). We assessed the patients' mentalization abilities using the Hungarian version of the Reading the Mind in the Eyes test, the Faux Pas test, and the MASC test. Additionally, symptom scales (measuring the severity of anxiety, and depression), WAIS (Wechsler Adult Intelligence Scale), the Childhood Trauma Scale, as well as scales measuring affect regulation and attachment were used during the assessment.

Results: There were no differences between the two groups in terms of age, IQ, or the severity of depression and anxiety. The MDD+BPD group exhibited significantly poorer performance in the MASC total mentalization score (MW U=118, df=1,41, $p < 0,001$), as well as in the hypermentalization score (MW U=98,5, df=1,41, $p < 0,001$). The MDD+BPD group achieved significantly lower results on the emotion recognition and mentalization measures in the RMET test ($t=2,883$, df=1,41, $p < 0,001$). The MDD+BPD group performed significantly worse on the Faux Pas test measuring mentalization (MW U=144,5, df=1,41, $p < 0,001$). In the whole sample, MASC performance correlated with overall IQ.

Conclusions: The MASC, RMET, and Faux Pas tests show a consistent trend and indicate significant differences between the mentalization abilities of MDD+BPD and MDD patients. Our findings are in line with data in the literature: BPD patients' implicit mentalization with a predominance of hypermentalization is impaired. This impairment is detectable when we compare their performance with MDD patients without BPD. In the future, a larger sample size, additional tests, and the inclusion of a control group are needed to further investigate MDD and MDD+BPD patients' mentalizing deficits. However, our results emphasize the significance of mentalization-based therapies in the therapy of patients with BPD and depression.

Depression among patients with ankylosing spondylitis in southern Tunisia: Prevalence and associated factors

A. Feki^{1*}, I. SELLAMI^{2,2}, M. Baklouti³, N. Ketata³, Z. Gassara¹, S. Ben jemaa¹, M. Ezzeddine¹, M. H. Kallel¹, H. Fourati¹, R. Akrou¹, S. Baklouti¹ and Y. Mejdoub³

¹Rheumatology; ²occupational medicine and ³Community Medicine and Epidemiology Department, Hedi chaker hospital, Sfax, Tunisia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1096

Introduction: Ankylosing spondylitis (AS) is one of the most common inflammatory rheumatisms. It is a chronic, sometimes disabling and it could cause both physical and psychological problems among patients, including depression.

Objectives: With this in mind, the objective of our work was to study the prevalence of depression among patients with AS and to determine its associated factors.

Methods: This was a retrospective descriptive and analytical study, carried out in 2021 over a period of 5 years in southern Tunisia on patients with a confirmed diagnosis of AS established in accordance with the ASAS diagnostic criteria (Assessment of Spondyloarthritis

International Society) or the modified New York criteria for AS. Depression was assessed using the *Hospital anxiety and Depression (HAD) score*. A HAD score >10 means certain depression.

Results: A total of 62 patients were included in our study. The median age was 39 years with an interquartile range (IQR) = [32-50 years]. There were 35 men (56.5%). Inflammatory back pain was noted among 51 patients (82.3%). Extraarticular manifestations were noted among 14 cases (22.6%) and were mainly ocular (11 cases; 78.4%). The diagnosis was confirmed by ASAS criteria in 55 cases (88.7%). AS was treated symptomatically in 58 cases (93.5%), specifically by basic treatment among 17 patients (27.4%) and by additional physical rehabilitation among 15 patients (24.2%). Depression was certain among 30 patients, giving a global prevalence of 48.4%. The factors statistically associated with this disease among patients with AS were having a low level of education (illiterate or primary) (Odds Ratio (OR) = 2.87; $p = 0.044$), being clinically suffering from severe fatigue (OR= 7.14; $p < 0.001$), have a poor quality of life [Ankylosing spondylitis quality of life questionnaire (Asqol) Score ≥ 13] (OR=4.52; $p = 0.007$) and have certain anxiety (HAD>10) (OR=19; $p < 0.001$).

Conclusions: In addition to its clinical impact on patients, the psychological impact of AS was considerable in terms of depression. The factors associated with it were individual, clinical, and psychological. Thus, psychological support must be coupled with AS medical management in order to prevent psychological disorders among patients, particularly depression.

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1097

Introduction: Alcohol Use Disorder (AUD) and depression are among the most prevalent mental health concerns on a global scale. The co-occurrence of alcohol use disorder (AUD) and depression has been well acknowledged, leading to intricate issues in diagnosis, treatment, and prognosis.

Objectives: This study aims to analyse the complex correlation between AUD (Alcohol Use Disorder) and depression, with a specific emphasis on examining common underlying causes, reciprocal influences, and potential implications for clinical treatment.

Methods: An exhaustive review of literature was undertaken, emphasizing epidemiological studies, neurobiological research, and the efficacy of combined treatment modalities. The review also delved into the potential role of genetics, environmental factors, and psychosocial stressors in co-occurrence.

Results: The available evidence indicates that there exists a reciprocal relationship between depression and alcohol use disorder (AUD), wherein each disease can serve as a triggering factor for the other. This interplay between depression and AUD forms a detrimental cycle that intensifies the severity of both conditions. The comorbidity of various disorders may be attributed to the presence of shared neurochemical pathways, with a particular emphasis on the serotonin system. Furthermore, the co-occurrence of both illnesses frequently leads to heightened symptom severity, reduced treatment efficacy, and a higher risk of suicide.

Conclusions: The complex relationship between alcohol use disorder (AUD) and depression underscores the need for a comprehensive and integrated therapy strategy. The effective management of this comorbidity necessitates the implementation of multidisciplinary collaboration, patient education, and early intervention.

Post-psychotic depression: what are its characteristics?

A. Abdelhamid*, S. Bellafqih, F. Laboudi and A. Ouanass

Psychiatry, Ar-Razi Psychiatric Hospital, Sale, Morocco

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1098

Introduction: Depression in psychosis has been more or less neglected as a field of study, due to its vague nosographic framework. Some studies have nevertheless focused on certain features of depression in psychosis, such as post-psychotic depression. This is a frequent phenomenon with a nosographic and etiopathogenic complexity that can lead to confusion.

Objectives: To study the characteristics of post-psychotic depression and compare results with those in the literature.

Methods: It is a prospective, descriptive, case series study conducted at the Ar-Razi psychiatric hospital in Salé. Inclusion criteria were patients diagnosed with a brief psychotic disorder, schizophreniform disorder or schizophrenia, in remission, who met the criteria for a DSM 5 characterized depressive episode. Data are collected during the psychiatric interview with the patient, using a questionnaire.

Results: Ongoing

Conclusions: Ongoing

Disclosure of Interest: None Declared

The peak of the 'Blue Monday' depression and winter blues.

A. Botica^{1*}, M. Baković², M. Strikić³, A. Delić¹ and T. Glavina¹

¹Department of psychiatry, University Hospital of Split, Split; ²Ugljan, Psychiatric Hospital, Zadar and ³Public Health Institute of Split and Dalmatian County, split, Croatia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1099

Introduction: For many people, January is the most depressing month of the year. "Blue Monday" encompasses the generally

accepted belief that Monday is the hardest day of the week compared to Friday and Saturday, which are the most anticipated days of the week. The connection between the color blue and Monday is in the emotional stage, which is presented as emotional anger. The third Monday in January is currently known as the most depressing day of the year. Speaker Cliff Arnall was the first to declare that day in 2014. The theory says that this is the time of the year when respiratory diseases are common, the day is shorter, the weather conditions are worse, and the time when people are burdened with guilt about whether they will achieve their New Year's resolutions.

Objectives: The aim of this work was to investigate that on third Monday in January there were more suicide attempts and that there were more depressive disorders in emergency psychiatric admissions.

Methods: In the research, we included participants who were examined at the Emergency Psychiatric Admission of the Clinical Hospital Center in Split, in the period from 2019. until 2023. Inclusion criteria were respondents of both sexes, examined in the outpatient clinic on Mondays in January for five years.

Results: There were 198 of them in total. The primary outcome of the research is to determine the occurrence (incidence) of psychological deterioration in patients diagnosed with the anxiety-depressive spectrum. The secondary research outcomes are of a descriptive nature, patient follow-up, examination outcome, and psychiatric heredity.

Conclusions: For now, there are no strong scientific foundations that justify the formula of "the most depressing day" of the year, some scientists believe that it is a marketing trick to achieve higher tourist revenues. However, the post-holiday period can have an impact on individuals.

"It was all yellow" first patient with resistant depression treated with esketamina

M. J. Mateos - Sexmero, B. Arribas - Simón*,

T. Jiménez - Aparicio and Ó. Martín - Santiago

Psychiatry, Hospital Clínico Universitario de Valladolid, Valladolid, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1100

Introduction: Esketamine, an active Ketamine isomeric form that indirectly inhibits the GABAergic neuronal pathways, has been recently approved to treat severe, resistant depressive disorders. Here, we present the case of a 64 years old woman diagnosed with severe, resistant depression and an initial score of 28 points in the Hamilton Depression Rating Scale who was treated with Esketamine with excellent response and a HDRS of 8 points after 4 months.

Objectives: To expose our experience with the first patient treated with Esketamine in our Hospital.

Methods: Describing the patient's pathobiography and the different treatments lines tried in first place and exposing the experience among Ketamine treatment and the final results.

Results: We present the case of a 64 years old woman, divorced and retired, who lives with her son since the aggravation of the depressive symptomatology, with no medical nor surgical background and no history in Mental Health before her first psychiatric internment in 2020. Between February 2020 and June 2023, 5 different treatments options with supervise intake were tried, including increment of the dose, antidepressant rotation, the combination of Desvenlafaxine + Mirtazapine and adding Topiramate and Lithium, with no improvement. Among this years, 3 psychiatric internments were needed because of the depressive symptoms and 1 more hospitalization in Internal Medicine was required because of the patients severe, malnutritional state. In June 2023 and after two complete analysis, a MR and a score of 28 points in the Hamilton Depression Rating Scale treatment with Esketamine was started with no incidences. She described one dissociative episode during which she assures “she was surrounded by soft, rubbery, yellow bubbles”. After 4 months of treatment the patient has recovered her previous functional rate and has an 8 points score in the HDRS.

Conclusions: In conclusion, we can affirm that Esketamine is an effective and secure option for Resistant Depression Disorder. Nevertheless, Before considering a Depressive Episode as “resistant to treatment”, treatment adherence and other medical, surgical and psychiatric comorbidities must be studied.

Tardive Dysphoria: can antidepressants cause depression?

C. P. Desport*, D. O. Martins, J. R. Freitas, M. F. Santos and L. C. de Castro

Psychiatry, Hospital de Magalhães Lemos, Centro Hospitalar e Universitário do Porto, Porto, Portugal

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1101

Introduction: tardive dysphoria is a relatively new term used to describe the phenomenon of clinical worsening of depression after long-term antidepressant use. Most of the theories proposed to explain this talk about antidepressants tachyphylaxis that implies the loss of efficacy with its prolonged use, or even a pro-depressant effect of antidepressants when used for long periods of time.

Objectives: to explore the concept of tardive dysphoria, potential causes and clinical implications, by making a literature review on the topic. Moreover we pretend to understand the challenges in its diagnosis and treatment.

Methods: bibliographical search in PubMed database, using the key-words “long-term antidepressant”, “tardive dysphoria” and “antidepressant tachyphylaxis”, limited to works published in the last twenty years.

Results: from our search resulted 53 articles, 26 were chosen for further analysis.

Conclusions: the concept of tardive dysphoria is controversial, namely doubt persists if it constitutes a clinical entity by itself caused by long-term antidepressant use or if it simply relates to cases of treatment-resistant depression. We conclude that it is necessary further investigation in this area given the significant implications on clinical practice specifically in the psychopharmacological

treatment with antidepressants, which is very common in psychiatric and general practices, with antidepressants being used to treat many mental health conditions.

Depression in the elderly and dementia with Lewy bodies: A case report of a challenging diagnosis

E. Smaoui^{1*}, D. Mnif², N. Reguaieg², F. Guermazi², S. Sakka¹, I. Baati² and J. Masmoudi²

¹Neurology department, CHU Habib Bourguiba and ²Psychiatry department, CHU Hédi Chaker, Sfax, Tunisia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1102

Introduction: Depression and dementia with Lewy bodies (DLB) are two fairly common pathologies in the elderly which can have similar presentations or be associated and therefore pose a diagnostic challenge.

Objectives: We propose to illustrate, through our case, the diagnostic and therapeutic challenge of these two pathologies.

Methods: We present the case of Ms. S. BA aged 67, without organic or psychiatric history, admitted to the psychiatry department for massive anxiety and insomnia. The troubles date back to nineteen months when the patient isolated herself, remained bedridden, lost her appetite and no longer slept. The evolution quickly led to the appearance of an excessive agitation. The patient became distracted, talking and laughing to herself, and ran away from the house. She consulted several free-lance psychiatrists and received several antipsychotic medications without improvement. The admission interview revealed a very anxious patient with a difficult contact. Her speech was centred on well-detailed visual hallucinations with themes of death. The neurological examination was difficult at first. She was started on haloperidol and clonazepam. After 2 days, neurological examination showed a parkinsonian syndrome and a temporal disorientation. Other cognitive functions were difficult to assess. The two diagnoses evoked were DLB and a characterized depressive episode with psychotic features. Standard workup showed mild anaemia and thrombocytopenia. Brain MRI and electroencephalogram and immune tests were normal. However, PET imaging was not available in our hospital. Haloperidol was immediately stopped and the patient was treated with an anticholinergic corrector in combination with quetiapine at 200 mg. The evolution was characterized by a significant reduction in anxiety and visual hallucinations with a marked improvement of the parkinsonian syndrome. Depressive symptoms took the forefront of the clinical presentation; hence we associated sertraline with quetiapine. The subsequent evolution showed a clear improvement in the depressive symptoms with total resolution of the parkinsonian symptoms and a normal cognitive evaluation.

Results: In our case, the clinical evolution constituted a key element in the diagnostic orientation. So far, it is unlikely that our patient has DLB and the diagnosis retained was a characterized depressive episode with psychotic and melancholic features. Depression in the elderly can have atypical presentations, and raise the possibility of other differential diagnoses. Diagnostic uncertainty should not delay the implementation of treatment.

Conclusions: The choice of molecules must take into account the associated somatic symptoms for a better tolerance. In the absence of a biological or iconographic examination with good sensitivity and specificity, the therapeutic test remains the only way to decide.

EPV0382

Esketamine for resistant depression in older people with cognitive impairment: a case report

F. Mazzoni*, V. Arienti, S. C. Civardi, G. Carnevale Miacca, P. Leali, F. Santilli, A. Guffanti, N. Brondino and M. Olivola

Department of Brain and Behavioral Sciences, University of Pavia, Pavia, Italy

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1103

Introduction: Depression represents a significant challenge in terms of disability among the elderly population and its responsiveness to conventional treatment approaches tends to diminish in this population group. Esketamine has shown both effectiveness and safety in addressing treatment-resistant depression in older patients.

Objectives: Currently, there is a lack of available literature regarding the use of esketamine in the treatment of patients experiencing both cognitive decline and treatment-resistant depression (TRD). We administered esketamine to a 79-year-old patient to evaluate the effectiveness and tolerance of the medication.

Methods: We recruited a 79-year-old female referred to the outpatient clinics of Pavia suffering from TRD with current Severe Depressive Episode (scoring 42 on the MADRS) with cognitive impairment (MMSE 16/30). The patient was on a fourth-line treatment. First-line treatment was started with paroxetine 40 mg from September 2021 to May 2022, switched to sertraline 50 mg. Second-line treatment with quetiapine 150 mg from June 2022 to December 2022 failed, despite optimal compliance for both lines of treatment. Then third-line treatment with fluoxetine 20 mg, olanzapine 10 mg was initiated from December 2022 to May 2023. Study duration was 12 weeks. Anamnestic data and psychometric (MADRS, HAM-D-21, HAM-A) and cognitive (MMSE and MoCA TEST) assessment were collected from medical records at baseline (T0), one month (T1) and three months (T2) follow-ups.

Results: MADRS, HAM-A and HAM-D values decreased significantly at T1 and T2 follow-ups. T0: MADRS 42, HAM-D 33, HAM-A 54; T1: MADRS 18, HAM-D 12, HAM-A 15; T2: MADRS 4, HAM-D 5, HAM-A 10. We also observed an improvement in cognitive test: T0: MMSE 16/30, MoCA test 4/30; T1: MMSE 18/30, MoCA test 6/30; T2: MMSE 20/30, MoCA test 8/30. The patient reported one episode of hypertension treated with clonidine after two months of treatment, and mild prolonged motor slowing lasting about two hours after esketamine in the first month.

Conclusions: This case documented a successful treatment using intranasal esketamine in combination with an SSRI (Fluoxetine) for an older individual with cognitive impairment and a persistent anxiety-depressive syndrome. This approach was employed as a therapeutic intervention after multiple unsuccessful attempts with other antidepressant medications. Our findings confirmed the safety and tolerability of esketamine in an elderly female with

cognitive impairment. Although a minor improvement in cognitive abilities has been noted, secondary dysfunction attributable to vascular-based cognitive decline remained. In terms of cognitive tolerance, derivatives of ketamine could potentially serve as an alternative to electroconvulsive therapy in cases of treatment-resistant depression, potentially improving short-term cognitive outcomes.

EPV0389

The use of memantine for depressive symptomatology

J. T. Coelho*, S. Timóteo and A. S. Machado

Department of Psychiatry and Mental Health, University Hospital Center of São João, Porto, Portugal

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1104

Introduction: Depression is one of the most prevalent and incapacitating disease in current times and depressive symptoms have important global functioning implications.

The serotonergic and glutamatergic systems are involved in the pathophysiology and treatment of depression. Ketamine is an N-methyl-D-aspartic acid (NMDA) receptor antagonist that has demonstrated an important role on depressive symptoms, but its use is restricted due to its dissociative effects and other possible adverse effects.

Memantine is a noncompetitive antagonist of the NMDA receptor that modulates glutamate transmission. Memantine is used for the treatment of moderate to severe Alzheimer's disease.

Objectives: In this review, we aim to investigate, organize and synthesize the current data about the use of memantine for depressive symptoms.

Methods: Our literature research focused on some of the most significant articles published in the last decade, including meta-analysis and systematic reviews.

Results: Most of the relevant literature suggests that memantine may effectively reduce depressive symptoms in patients with mood disorders.

The literature also supports that memantine's glutamatergic mechanism of action could reduce apathy and treat depression comorbid with alcohol abuse.

Memantine affects brain-derived neurotrophic factor (BDNF) production suggesting that glutamate assumes an essential role in the pathology and etiology of depression. Also, the relationship between depression and the NMDA receptor is further supported by the fact that people with major depressive disorder demonstrate higher glutamate levels in the brain and blood.

Moreover, current studies demonstrate that treatment with memantine as adjunct to selective serotonin reuptake inhibitors (namely sertraline) manifested a favourable safety and efficacy profile in patients with major depressive disorder.

Conclusions: Memantine may have a wide therapeutic use beyond its utility in neurodegenerative diseases.

More studies should be performed, especially larger controlled studies of longer duration focusing on long-term safety and efficacy.

The Effects of a Chatbot-Based Interpretation Bias Modification on Early Adulthood Depression

J. Lee* and D. Lee

Kangwon National University, Chuncheon, Korea, Republic Of

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1105

Introduction: Depression, particularly in early adulthood, presents a significant mental health challenge with far-reaching implications. Innovative approaches to address and alleviate depressive symptoms are of paramount importance in this context. One such approach involves the utilization of technology, specifically chatbot-based programs, to target specific cognitive biases associated with depression.

Objectives: The central objective is to empirically examine whether this program can effectively influence depressive mood and negative cognition in individuals grappling with depressive symptoms.

Methods: To ascertain the program’s efficacy, participants were divided into two groups: the CBM-I group (n=20), which underwent interpretation bias modification training, and the Mood Check group(n=20), which served as a control and engaged in a simple mood-checking exercise. A battery of psychological measures was employed, including assessments of depression, interpretation bias, suicidal ideation, resilience, and attention control.

Results: Analysis results showed that the CBM-I group had a significant reduction in depression (PHQ-9, CES-D) compared to the Mood Check group in the post-measurement. Moreover, resilience (CD-RISC) and attention control (ACQ) significantly improved in the CBM-I group.

Conclusions: This research serves as a stepping stone towards a deeper understanding of how chatbot-based interventions can contribute to the management of early adulthood depression, offering new perspectives and possibilities in the realm of mental health support and treatment.

EPV0391

Obesity and depression: Review on common neurobiological mechanisms and identification of potential drug targets.

J. R. Lopez^{1,2*} and R. Zaghi-Lara³

¹Posgrado de psiquiatría, Universidad de San Carlos de Guatemala;

²President, Asociación Psiquiaátrica de Guatemala and ³CIGua, Comunidad de Investigación de Guatemala, Guatemala, Guatemala

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1106

Introduction: This review aimed to identify common pathophysiological mechanisms that exist between depression and obesity, as well as pharmacological strategies used in clinical trials and animal models. It is necessary to carry out larger studies that integrate the multiple neurobiological processes of these phenomena and the search for therapeutic targets that affect these pathways.

Objectives: Conduct a literature review on the common neurobiological aspects that exist between depression and obesity. Compare pharmacological and therapeutic strategies in the management of depressive patients by means of common neurobiological mechanisms.

Methods: We used the Pubmed search engine to search for the keywords: ((depression and obesity) OR (common pathways for depression and obesity) OR (therapeutic targets for depression and obesity) OR (neurobiology of depression and obesity) OR (treatments for depression and obesity))Once the predefined screening was carried out, 68 studies were identified. 54 articles were left for review and analysis. At the end of the review, 25 studies were discarded, including 29 studies with relevance to the objectives described in the study. These articles were selected when they provided information with adequate, concrete and specific reasoning towards the scientific and methodological elements of the review.

Results:

Table 1: Findings related to the NEGR1 gene and its involvement in processes associated with alterations associated with depression and obesity.

Table 2: Findings of inflammation associated with depression and obesity in clinical trials and animal models.

Image:

AUTHORS	STUDY SUBJECTS	FINDS
Lee et al. (2012)	Mouse deficient NEGR1 constitutive line and mutagenic ENU line with loss-of-function mutation (Negr1-187N)	Expression analyses confirmed the brain-specific distribution of NEGR1, strong expression in the hypothalamus. In vitro assays demonstrated NEGR1 promoted cell adhesion and neurite growth of hypothalamic neurons.
Carboni et al. (2020)	FSL Rats	Antidepressant treatments were able to influence the Negr1-Fgfr2 pathway and support the hypothesis that Negr1-mediated modulation of neuronal plasticity is activated by antidepressant treatment.

Image 2:

AUTHORS	OBJECTIVE OF THE STUDY	SUBJECT STUDIO	FINDS
Visser et al. (1999)	Assessment of overweight and obesity associated with low-grade systemic inflammation as measured by C-reactive protein level	16,616 non-pregnant men and women aged 17 years or older.	Elevated CRP level of 0.22 mg/dL or higher and a clinically elevated stricter CRP level of more than 1.00 mg/dL. A higher BMI is associated with higher concentrations of CRP, suggesting a state of low-grade systemic inflammation in overweight and obese individuals.
Capuron et al. (2008)	Relationship between MS and depressive symptoms in a population of 323 male twins, using the Beck Depression Inventory (BDI) and analyzing plasma CRP and IL-6 levels	323 male twins, with and without MS and free of symptomatic cardiovascular disease, drawn from the Vietnam Era Twin Registry.	MS is associated with a higher depressive symptomatology characterized mainly by neurovegetative traits. Inflammation is a determinant of depressive symptoms in people with MS.
You et al. (2011)	Detecting depression-like behavior in a rat animal model induced swelling in the spleen and brain by CMS	Wistar Rats	High expression of pro-inflammatory cytokines IL-1 β , TNF- α and IL-6, and low expression of anti-inflammatory cytokines TGF- β and IL-10. Decreased BDNF mRNA in hippocampus and hypothalamus of stressed rats.
Soto et al. (2018)	To evaluate behaviors and insulin action in the brains of diet-induced obesity (OID) mice with and without antibiotic treatment.	Male mice C57BL/6J.	OID mice exhibit insulin resistance in the brain, depression-like behaviors, and anxiety, and these improve with antibiotic treatment.

Conclusions: Alterations in the NEGR1 gene, inflammatory markers, HPA axis and microbiota demonstrate multiple pathophysiological mechanisms in the clinical pictures associated with obesity and depression.

Infliximab, pioglitazone, ondansentron, BVT.2733 and palmitoyl-ethanolamide showed anti-inflammatory regulatory effects with reduction in depressive symptoms and multiple anti-inflammatory markers.

Animal models for obesity and depression present ample and reliable evidence regarding the use of drugs that direct their

therapeutic profile towards the pathophysiological mechanisms involved in pathologies involving depressive and metabolic disorders.

Effects of light therapy in the anxious-depressive clinic

M. T. Gonzalez Salvador^{1*}, R. Gutierrez-Labrador²,
M. I. C. Gómez-Ulla¹ and A. I. de la Puente¹

¹Psiquiatria, Hospital Universitario Puerta de Hierro and ²Psiquiatria, Hospital Universitario Infanta Sofia, Madrid, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1107

Introduction: Major depressive disorder (MDD) is defined as a mental disorder of multifactorial etiology, which presents with mood disturbance, mainly sadness associated with loss of interest or pleasure. Light therapy (LT) is a therapeutic intervention consisting of daily exposure to a light source. This study aims to evaluate the effects of LT on anxious-depressive symptomatology and sleep in a sample of patients diagnosed with depression.

Objectives: This study aims to evaluate the effects of LT on anxious-depressive symptomatology and sleep in a sample of patients diagnosed with depression.

Methods: Prospective case-control study, in which the cases are outpatients diagnosed with MDD and the controls are healthy individuals. Both groups underwent LT sessions and were assessed by means of validated scales, anxiety and depression symptoms before and after LT sessions, as well as changes in sleep patterns through a sleep measuring device.

Results: 11 cases and 18 controls were included in the study. Of the participants, 62.1% were female and 37.9% were male. The mean age of the sample was 54.03 ± 11.55 years. There were significant case differences in the pre and post LT scores of the depression scale. There were no significant differences in the changes in superficial, deep and total sleep and in the anxiety scale scores.

Conclusions: In the sample analysed, LT has significant effects on the cases at the level of the depression scale.

Esketamine new tool for resistant depressive disorder. About a case

M. Valverde Barea*, C. Mata Castro, P. Vargas Melero and A. España Osuna

Psychiatry, H.U. Jaén, Jaén, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1108

Introduction: Depressive disorders represent the main cause of disability in the world, due to its prevalence, its impact on the patient's quality of life and its role as one of the main risk factors for suicide. Current antidepressant treatments can take weeks to take

effect and months to achieve response and remission. It is estimated that up to 30% of patients with major depressive disorder (MDD) are resistant to antidepressant treatment, in addition, approximately 30-45% of patients with depression do not achieve an adequate response to the first antidepressant treatment. According to the STAR*D study, the more lines of treatment are required, the lower remission rates are estimated, as well as higher relapse rates during the follow-up phase. With the appearance of intranasal dosage esketamine allows the release directly to the central nervous system, the mechanism of action of esketamine is based on the antagonism of the NMDA receptor, which entails the modulation of the excitatory transmission of glutamate and the release of BDNF, activating neurotrophic signaling and synaptogenesis.

Objectives: The objective is to expose the response after treatment with intranasal esketamine in a case of resistant depression.

Methods: A 55-year-old female patient, diagnosed with resistant recurrent depressive disorder. The patient had undergone treatment with different therapeutic lines with antidepressants, and potentiators with antipsychotics, observing little response in the current episode, for which reason we evaluated the indication of intranasal Esketamine. Scales: MADRS (Montgomery Asberg Depression rating scale) =37, Hamilton Depression Scale=25, PHQ-9=20, indicating severe depression.

Results: After starting treatment with intranasal esketamine, an early response was observed. After the first month of treatment, mild depression was scored at MADRS=10 and moderate depression at Hamilton=14, PHQ-9=12, and at week 14 of treatment, it was scored mild depression in both MADRS and Hamilton. Intranasal 56mg esketamine plus 20mg escitalopram, 30mg mirtazapine and 5mg aripiprazole.

Conclusions: Intranasal esketamine offers a rapid reduction in depressive symptoms maintained over time, reducing the risk of relapse and with a favorable tolerability profile, so its use in depression resistant to treatment presents a great advance.

EPV0397

Cold water swimming as an add-on treatment for depression: a feasibility study

P. Hjorth^{1*} and M. R. V. Rasmussen²

¹Psychiatry, Psychiatric Department, Vejle. Mental Health Services, Region of Southern Denmark, University Hospital of Southern Denmark. Institute of Regional Health research, University of Southern Denmark, Odense, Denmark and ²Psychiatry, Vejle Psychiatric hospital, Vejle, Denmark

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1109

Introduction: In Denmark, 14% of patients with depression develops treatment resistant depression (TRD) after the first hospital contact. Explanations for TRD include lack of clinical effect of pharmacological treatment and reluctance to treatment due to price, discomfort, and unacceptable side effects. Cold water swimming (CWS) describes swimming outdoors during the winter season in cold to ice-cold water on a regular basis. Many winter swimmers believe that exposure to cold water is beneficial for their health. However, evidence of health effects

have been anecdotal or based on results from small sample-size studies. The available studies report that winter swimming abolishes general tiredness, boosts self-esteem and improves mood and/or general well-being.

Objectives: Aims To test if it is possible for patients with depression to participate in two weekly sessions of CWS and to measure the effects of CWS on general well-being and depression.

Methods: All psychiatric in- and outpatients from the department of psychiatry at Little Belt Hospital, Vejle with a diagnosis of depression were eligible for inclusion. CWS-sessions included a dip in an inlet - and a short swim for a few minutes – depending on individual preferences.

Results: The average water temperature was 7.5 grades C. The lowest water temperature was 2.0 grades C. 13 patients were participating in CWS sessions. One of the patients participated in 40 CWS sessions and the average number of CWS session was 14.5 (sd: 11.2). The participating patients were on average overweight, and they had mild to severe sleep problems with an average score of 10.1 (sd: 3.7) on Pittsburgh Sleep Quality index. Patients with regular CWS have a wellscore of 39.2 and at the end of the swimming season, their score has increased to 54.0. Sleep: At index for regular swimmers, the score was 10.4 and at the end of season it had decreased to 8.0 while the patients' not regular swimming had an unchanged score of 11.3. After each CWS sessions, a cheerful and uplifted atmosphere spread among the participants and the conversation afterwards was often characterized by this.

Conclusions: The nurses had an important task and function in guidance to the participating patients due to the patients' symptoms from depression. It was surprisingly easy to get all the patients to swim in the cold water. Due to the design and small numbers of participants in this feasibility study, it is not possible to draw any statistically significant results. Nevertheless, we can conclude that it is possible to use CWS as a treatment opportunity for some patients with depression. The research group members are convinced that for some patients it will be an important part of recovery from depression. Further studies with control group and a statistical satisfying larger group of participants will probably generate more knowledge's on these issues.

Disclosure of Interest: None Declared

EPV0398

The risk for inflammatory joint disease in patients with severe or treatment-resistant depression: population-based cohort study in Sweden

P. Brenner^{1*}, J. Askling¹, D. Hägg¹, L. Brandt¹, P. Stang² and J. Reutfors¹

¹Karolinska Institutet, Stockholm, Sweden and ²Janssen Research and Development, (retired), Titusville NJ, United States

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1110

Introduction: Inflammatory joint diseases (IJD), including rheumatoid arthritis (RA), psoriatic arthritis (PsA), ankylosing

spondylitis/spondyloarthropathies (AS), and juvenile idiopathic arthritis (JIA), are more common in patients with depression. However, it remains unclear whether the strength of this association varies with the severity or level of treatment resistance of the depressive episode.

Objectives: To assess the risk for IJD in patients with severe depression and TRD compared to population comparators and patients with non-severe and non-treatment resistant depression.

Methods: We conducted parallel cohort studies among 600,404 patients with a depressive episode identified in Swedish nationwide administrative registers. The prospective risk for IJD, both overall and per IJD condition, in patients with depression of any severity was compared to matched population comparators. Additionally, we assessed the same associations comparing patients with depression to those with severe or treatment-resistant depression. Analyses were adjusted for comorbidities and sociodemographic covariates.

Results: Overall, patients with depression were at increased risk for later IJD compared to population comparators (adjusted hazard ratio (aHR) for any IJD 1.34 [95% CI 1.30-1.39]; RA 1.27 [1.15-1.41]; PsA 1.45 [1.29-1.63]; AS 1.32 [1.15-1.52]). The associations were not significantly different for patients with severe depression or TRD.

Conclusions: Patients with severe and treatment resistant depression are at higher risk for inflammatory joint disease than population comparators. This association does not seem to be stronger than for patients with non-severe or non-resistant depression. Severity and treatment resistance of a depressive episode as identified in register data may not be valid depressive phenotypes for predicting risk for inflammatory joint disease.

The preponderance of major depressive disorder among women of reproductive age and the clinical utility of sertraline

A. Fagiolini¹, M. P. Mariano², E. Biesheuvel³ and P. Purushottamahanti^{4*}

¹Department of Molecular Medicine, University of Siena School of Medicine, Siena, Italy; ²Department of Psychiatry, University of the East Ramon Magsaysay Memorial Medical Center, Quezon City, Philippines; ³Global Clinical Operations, Viatris Inc, Amstelveen, Netherlands and ⁴Global Medical Affairs, Viatris Inc, Bangalore, India

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1111

Introduction: Major depressive disorder (MDD) is twice as common in women than men and is more frequently reported during their reproductive years (Shi *et al.* Front. Psychiatr 2021; 12 589687). MDD affects up to 12.7% of pregnant women and can significantly impact foetal and maternal health. Hence, clinical practice guidelines recommend focused screening and expedited management of MDD in women (Guo *et al.* Obstet. Gynecol 2018; 131(4) 671-679). Despite this, drug labelling or dosing recommendations rarely account for gender or physiological differences between sexes, even though sex steroid level variations can impact drug absorption, distribution, metabolism, and activity both pharmacokinetically and pharmacodynamically (Soldin *et al.* Clin Pharmacokinet. 2009; 48(3): 143-157). Sertraline, an SSRI approved for the treatment of MDD, is one of the safer agents which can be given to childbearing or breastfeeding women (Cuomo *et al.* Expert Opin Drug Saf 2018; 17(7) 719-725). However, studies on the efficacy of sertraline for the treatment of MDD among women of childbearing age are limited.

Objectives: This post-hoc pooled analysis evaluated the efficacy of sertraline in women with MDD, with a particular focus on women of reproductive age.

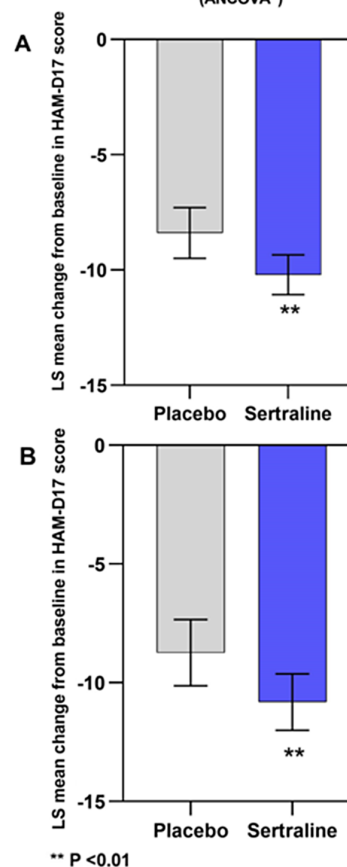

Methods: A pooled data analysis of 8 short-term clinical studies of sertraline in persons with MDD (comprising 1600 participants from North America and Europe, of whom 947 were females; with moderate to severe MDD [mean±SD baseline HAM-D17 score was 23.73±3.58 for sertraline and 23.37±3.47 for placebo]; sertraline dose, 50-200 mg) was performed. HAM-D17 total score was used to assess the efficacy of sertraline compared with placebo. The study period was 8 weeks. An MMRM method was used to analyse changes over time and ANCOVA to evaluate the change from baseline at week 8 with LOCF employed to manage missing data.

Results: The analysis set consisted of 947 women (sertraline, 612; placebo, 335). The change from baseline in HAM-D17 total score was significantly higher for sertraline than for placebo at the end of 8 weeks (LS mean difference, 95% CI: -1.81 [-3.01, -0.62], $p=0.0029$, Figure 1A). This change from baseline was statistically significant starting from week 2 and increased over time (Week 2-8; Figure 2A).

The analysis set for women of child-bearing age consisted of 572 participants aged 18-44 (sertraline, 359; placebo, 213) from 7 clinical studies. The change from baseline in HAM-D17 total score was significantly higher for sertraline than for placebo at the end of 8 weeks (LS mean difference, 95% CI: -2.08 [-3.52, -0.64], $p=0.0047$, Figure 1B). This change from baseline was statistically significant starting from week 2 (Figure 2B).

Image:

Figure 1. Least square mean (95% CI) change from baseline at end of 8 weeks (ANCOVA[#])

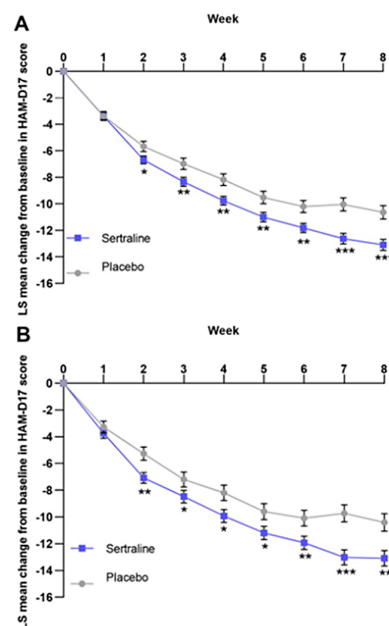

** $P < 0.01$

HAM-D17 total score change from baseline in A. all age groups B. women of childbearing age (18-44 years)
Analysis of covariance

Image 2:

Figure 2. Least square mean (95% CI) changes from baseline over time (1-8 weeks, MMRM[#])

* $P < 0.05$; ** $P < 0.01$; *** $P < 0.0001$

HAM-D17 total score change from baseline in A. all age groups B. women of childbearing age (18-44 years)

Mixed Model Repeated Measures

Conclusions: Significant improvement in HAM-D17 scores was observed in the analysis, suggesting that sertraline is efficacious in treating women with MDD, including those in the childbearing age.

Antidepressants and suicide risk in children and adolescents

S. Riam*, N. Baabouchi, H. kisra and F. laajili

Arrazi University Psychiatric Hospital, Rabat Faculty of Medicine and Pharmacy Mohammed V University, RABAT, Morocco

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1112

Introduction: In recent years, the prescription of antidepressants for children has faced significant scrutiny due to studies suggesting an elevated risk of suicide among those treated with these medications. The primary objective of this study is to examine the causal connection between antidepressant use and suicidal behavior in children and adolescents.

Objectives: In this article, we will examine the current research on this topic and discuss the current status of practical guidelines and recommendations for prescribing antidepressants to children and adolescents.

Methods: We conducted a literature review using the Google Scholar database, employing keywords such as antidepressants, suicide, children, and adolescents.

Results: The literature yielded conflicting data. While it has been established that SSRIs moderately elevate the risk of suicide ideation and attempts, with venlafaxine, paroxetine, and sertraline showing a higher risk compared to other SSRIs like fluoxetine and citalopram, several studies indicate that their use is linked to a noteworthy reduction in suicide rates among children and adolescents.

Conclusions: The existence of a definitive causal relationship between antidepressants and suicidality in children and adolescents is currently uncertain, and the underlying mechanisms remain inadequately understood.

Assessing the relationships between emotion regulation, depression, anxiety, and stress symptoms in a Tunisian University Setting

S. Boudriga*, M. Lagha, M. Methni, Y. Ben youssef, I. Ben romdhane, W. Homri and R. Labbane

Psychiatry C, Razi Hospital, Manouba, Tunisia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1113

Introduction: Difficulties in emotion regulation are known to be associated with various mental health problems, particularly depression, and anxiety.

Objectives: This study aimed to explore the relationship between emotion regulation, depression, anxiety, and stress symptoms in a Tunisian university setting.

Methods: A cross-sectional, descriptive, and analytical study was conducted among Tunisian students from August to September 2023. Data were collected through an anonymous online questionnaire, assessing sociodemographic characteristics, the Arabic version of the difficulties in emotion regulation scale short form (DRES-SF), and the depression, anxiety, and stress scale (DASS-21).

Results: A sample of 307 university students were enrolled. The sex ratio (M/F) was 0.28. In the assessment of emotional regulation difficulties, participants reported a mean total score of 42.47 ± 12.68 . The mean score of stress was 18.2 ± 11.36 , reflecting a mild severity. Participants with higher stress levels have more difficulties in emotional regulation ($r=0.658$, $p=0.00$). Participants with depressive symptoms showed a higher DRES-SF total score ($r=0.629$, $p=0.00$). Participants had a mean anxiety score of 15.6 ± 10.57 , reflecting a severe severity. A significant correlation between total DRES-SF score and anxiety ($r=0.606$, $p=0.00$).

Conclusions: Our study concluded significant positive correlations between depressive symptoms, anxiety, and stress symptoms with emotion regulation difficulties.

Adaptation and analysis of the Hungarian version of the Snaith-Hamilton Pleasure Scale

V. Koumou¹*, B. K. Nagy¹, B. Kabella¹, A. Feher², L. Pogany¹ and J. Lazary¹

¹National Institute of Mental Health, Neurology and Neurosurgery and

²Semmelweis University, Budapest, Hungary

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1114

Introduction: Anhedonia (loss of ability of experience pleasure) is a transdiagnostic symptom which is presented as a prominent complain in several psychiatric disorders, such as depressive

disorders, schizophrenia, bipolar disorder, addictive disorders, certain personality disorders etc. Specific instruments for assessment of anhedonia have been published in the international literature but their Hungarian versions are not available so far, however, the prevalence of affective disorders and suicide are also high in Hungary. The Snaith-Hamilton Pleasure Scale (SHAPS) is an instrument developed in 1995 (Snaith et al. *Br J Psychiatry* 1995;167:99-103) which purposely has been constructed with items that can be easily translated into other languages.

Objectives: The aim of our study was to translate the 14 items into Hungarian and analyse its reliability and sensitivity in a Hungarian sample consists of patients and control persons. Further aim was to explore the differences of anhedonia profiles among diagnostic categories and subgroup of major disorders.

Methods: We recruited 170 subjects (101 controls and 59 patients; 78 men and 82 women; mean age=37,9±6,1y) into our study. Among the patients there were 27 subjects with major depressive disorder (MDD), 10 subjects with bipolar disorder (BD), 9 patients with schizophrenia (SCZ), 6 patients with addictive disorder (AD) and 7 patients with anxiety disorder (ANX)±. We created two major subgroups from the different diagnostic categories: affective and psychotic subgroups to compare the anhedonic profiles. Differences of mean values between case and control, men and women and subgroups were analysed by t-tests and diagnostic categories by ANOVA tests performing in SPSS 20.0 software.

Results: Among the MDD, the BD, the SCZ, the AD and the ANX groups, patients with MDD produced the highest score (6.9±3.5; 3.9±2.4; 5.9±3.9; 2.8±2.7; 2.3±1.8, respectively), while controls prohibited 1.6±1.3. The case group scored significantly higher on the SHAPS than the control group (5.3±3.6 vs. 1.6±1.3; $p=0.0001$). The means of SHAPS did not differ significantly between the affective subgroup and the psychotic subgroup (6.0±3.7 vs. 4.8±3.2; $p=0.24$). Among the subgroup of women, the age was significantly associated with the SHAPS score ($p=0.04$), however, this association has been not detected in men.

Conclusions: The Hungarian version of the SHAPS detected marked difference between cases and controls with good reliability and sensitivity. The instrument can be useful in daily clinical routine because subjects could fill it easily and quickly. In case of patients with pronounced anhedonia, treatments with specifically targeting anhedonia can be preferred (e.g. rTMS as it was demonstrated in our earlier publications, see Lazary et al. *Sci Rep* 2021;11:8867; Elemery et al. *Front Psychiatry* 2022, 13:806731). This study was supported by the grant EFOP 5.6.2.

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1115

Introduction: Dysfunctional changes in the glutamatergic system play an important role in the pathophysiology of depression. Glutamate regulates various neuronal function, such as nerve migration, excitability, plasticity, as well as long-term potentiation and long-term synaptic depression. Failures in this process might cause emotional/cognitive changes associated with stress-induced depressive symptoms, a part of our current understanding of the pathophysiology of depression. These changes might be related to deviations in biochemical blood parameters, but also to volatile organic compounds (VOCs) measured in breath.

Objectives: 1) To replicate our previous finding that concentration of volatile organic compounds in expiratory breath gas and metabolites derived from MR spectroscopy distinguish unmedicated depressed patients from healthy participants, (2) to determine whether the amount of these VOCs is associated with severity of depression and anxiety, and (3) to correlate breath-VOC-content with glutamatergic neurotransmission and energy metabolism derived from MR spectroscopy.

Methods: 25 antidepressant-free patients with major depression according to DSM V (18-65 years of age) are recruited from our out- and inpatient clinics. The controls will consist of 25 healthy age- and sex-matched participants. Breath gas analyses will be carried out at awakening, and 30 and 60 minutes thereafter, and at 5pm using PTR-TOF-MS with direct on time measurement through a special sampler. A 7 Tesla Siemens Terra MRI scanner will be used to undertake spectroscopic measurements. Concentrations of glutamate and β -hydroxybutyrate levels in the pregenual and dorsal anterior cingulate gyrus will subsequently be assessed.

Results: Statistical analysis for differences between groups corrected for multiple measurements will be carried out. Concentration of VOCs will be correlated with brain metabolism and severity of symptoms.

Conclusions: VOCs in breath are proposed to be an efficient and non-invasive marker for depression-related biochemical changes related to disease severity, and eventually useful for personalized treatment planning.

Effects of a Cognitive Bias Modification Training on Resting State EEG Microstates in Patients with MDD and Healthy Controls

J. Kesik^{1*}, Z. Kratochwil², D. Keskin-Gökcilli¹, B. Müller² and T. Frodl¹

¹Department of Psychiatry, Psychotherapy and Psychosomatics, RWTH Aachen University, Aachen and ²Department of Psychiatry and Psychotherapy, LVR-University Hospital Essen, Duisburg-Essen, Germany

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1116

Introduction: Major Depressive Disorder (MDD) is associated with a high burden of disease and notable economic costs. Standard treatments (e.g. medication or cognitive therapy) have been shown to be effective, but some patients remain unresponsive. With the knowledge that MDD patients have been shown to display an attentional cognitive bias towards negative stimuli,

Cognitive Bias Modification (CBM)-training to focus attention on positive information is thought to improve emotional processing and depressive symptoms. Some studies imply reduced duration and occurrence of microstate D in MDD compared to healthy controls. However, the effect of CBM on microstates is still unclear.

Objectives: (1) To replicate previous findings that duration and occurrence of microstate D is reduced in patients with MDD compared to healthy controls in an independent sample and (2) to investigate the effect of an active CBM-training versus a control-training on microstates and its association with symptom improvements.

Methods: Thirty patients receiving outpatient treatment with MDD according to DSM V (aged 18-60) will be recruited in Essen and Aachen. The control group will consist of 30 healthy age- and sex-matched participants. Psychological testing will be administered and all participants will be randomized to either an active or a control training. During the next visit, resting state EEG and a GoNoGo Task with positive, neutral and negative pictures will be measured. The participants will take a tablet home to undergo 10 sessions of CBM within 14 days. The training will be consisted of a dot-probe-task. In the active condition the probe will be more likely to appear behind a positive versus a neutral picture, while appearing randomly in the control condition. After 14 days, a second EEG will be recorded.

Results: Differences in duration and occurrence of microstate D between patients and healthy controls will be analyzed by conducting ANCOVAs with age and sex as covariates. ANCOVAs for repeated measurements will be calculated to study effects of time (pre- vs. post-training) and group (patients vs. healthy controls in active training; patients in active vs. patients in control-training), on duration and occurrence of microstate D.

Conclusions: CBM-training is proposed to be an effective treatment option for MDD patients, reflected in a reduced topographical bias of microstate D in EEG.

Larks under pressure: The genetic background of the morning chronotype may contribute to depression in interaction with stress

M. Csikos¹, S. Krause¹, Z. Gal^{1,2}, G. Bagdy^{1,2}, G. Juhasz^{1,2}, X. Gonda^{1,2,3*} and D. Torok^{1,2}

¹Department of Pharmacodynamics; ²NAP3.0-SE Neuropsychopharmacology Research Group, Hungarian Brain Research Program and ³Department of Psychiatry and Psychotherapy, Semmelweis University, Budapest, Hungary

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1117

Introduction: Depression is a highly prevalent, multifactorial, complex disorder, its etiology is assumed to involve both genetic and environmental factors. Genetic factors, including biological clock genes such as *CLOCK* and *SIRT1*, have been linked to depression, particularly its symptom related sleep disturbances. Environmental factors also play a crucial role in the background of depression, particularly in interaction with genetic factors. Known

environmental stress factors include stress caused negative life events or childhood adversities.

Objectives: This study aims to delve into the chronotype-specific impacts of genes previously correlated with circadian functionality on the pathomechanism of depression in interaction with environmental stress factors.

Methods: A genome-wide association study on the 'morning chronotype' phenotype was conducted with Plink2, utilizing data from the UK Biobank discovery sample (N = 139135). Using LDpred2we derived a polygenic risk score (PRS) for the NewMood Hungarian dataset (N = 1820). We performed pathway-specific analyses including genes implicated within the genetic pathway, drawing on prior research findings. Specifically, we selected the top genes (with a false discovery rate-corrected p-value < 0.05) from the "responders vs. non-responders" analysis conducted by Jerome C. Foo et al. Transl Psychiatry 2019; 9 343). We performed a main effect analysis investigating the pathway specific PRS's effect on BSI depression scores and interaction analyses using life course (number of negative life events in the past life) and recent (number of negative life events in the past year) stress scores to investigate how the interaction term predicts depression in our target sample.

Results: Our primary analysis revealed a nominally significant protective effect (beta = -20.90938, p = 0.070218). Subsequently, in the context of our interaction analysis, we identified significant risk associations, both with lifetime stress (beta = 13.7416, p = 0.0171) and recent stress (beta = 24.6034, p = 0.0038)

Conclusions: Our study unveiled a protective role in our primary analysis, juxtaposed with risk associations in our interaction analyses. This intriguing dichotomy underscores that this genetic pathway, associated with circadian dysregulation, exerts a protective influence in association with the morning chronotype. However, it transitions into a predisposing factor for depression when influenced by environmental stress factors.

Considering these findings, our study substantiates the hypothesis that both circadian genes and chronotype contribute to the pathogenesis and clinical manifestation of depression. Additionally, it underscores the pivotal role of stress as a contributing factor in the intricate pathogenesis of depression.

Depression: Biological Non-Pharmacological Interventions. A Review.

F. A. Rodríguez Batista^{1*}, S. Trufero Miguel², R. Bordón Guerra¹ and A. R. Neyra del Rosario¹

¹Department of Psychiatry, Doctor Negrín University Hospital of Gran Canaria and ²Department of Psychiatry, Insular University Hospital of Gran Canaria, Las Palmas de Gran Canaria, The Canary Islands, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1118

Introduction: Major depressive disorder stands as one of the most significant mental health issues in the general population. It impacts the patients' quality of life and increases both morbidity and mortality. Response and tolerability to available

pharmacological treatments are often inefficient, sometimes requiring extended periods to achieve acceptable remission through combinations or augmentations. Non-pharmacological approaches constitute an element in the therapeutic options for this mental disorder. In recent years, there has been a growing interest in non-pharmacological biological treatment interventions. Among the principal ones are Electroconvulsive Therapy (ECT), Transcranial Magnetic Stimulation (TMS), Deep Brain Stimulation (DBS), and Vagus Nerve Stimulation (VNS).

Objectives: The aim of this paper is to review the current available literature to expand our knowledge about biological non-pharmacological treatment in depression, particularly ECT, TMS, DBS, and VNS.

Methods: A qualitative review was conducted over the last 5 years, using the Medline database through PubMed. We selected studies in English or Spanish that met the objectives of the review, excluding references in other languages. The scientific evidence obtained was analyzed and synthesized.

Results: There is growing evidence in this area. TMS, whose place in clinical guidelines remains unclear, is a less available treatment but might be considered in patients with moderate to severe depression who cannot receive pharmacological treatment. DBS, which shows good results in treatment-resistant major depressive disorder, achieves response rates greater than 50%. VNS has accumulated studies since its approval for treatment-resistant depression, showing some latency of response but demonstrating improvement persistence for at least two years, although some studies have not clearly shown a benefit. We also found studies demonstrating the effectiveness and favorable cost-benefit balance of ECT.

Conclusions: This review highlights the importance of increasing knowledge in these types of treatments. They have shown significant progress in recent years. We have a better understanding and use of the technique of ECT, while newer options have gained evidence in effectiveness over these years, with improvements facilitating their use in patients with treatment-resistant depression.

Neurocognitive Targets for Psychological Assistance in Patients with the Anhedonia Phenomenon within the Framework of Affective Pathology

A. Barkhatova* and M. Popov

Department of endogenous mental disorders and affective states, Mental health research center, Moscow, Russian Federation

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1119

Introduction: Anhedonia is a transdiagnostic psychopathological phenomenon that is considered a key feature for several disorders, primarily affective spectrum disorders. It exhibits a significant association with social and occupational maladjustment, reduced quality of life, and increased suicidal risk among psychiatric patients.

Objectives: The aim of this study is to identify recommendations for psychotherapeutic assistance for patients with affective spectrum disorders.

Methods: A total of 26 patients with affective spectrum disorders (ICD-10 code - F33, F31) and the phenomenon of anhedonia were examined. We utilized neuropsychological methods aimed at investigating a wide range of cognitive functions (Dynamic praxis; Color interference test; Arithmetic Tasks; Number of skips and impulsive errors; Reverse and straight rows; Verbal fluency; Design fluency; Rey-Osteritz figure) and psychometric methods designed to diagnose various types of anhedonia (consummatory (TEPS), anticipatory (TEPS), social (RSAS), and physical (PAS)).

Results: Among patients with depression, the consummatory type of anhedonia was the most pronounced. A relationship was found between anticipatory anhedonia and phonetic verbal fluency ($r = 0.487$; $p < 0.01$). Additionally, there were correlations between immediate (consummatory) pleasure experience and Rey figure errors ($r = -0.349$; $p < 0.05$). Social anhedonia was associated with phonetic verbal fluency productivity ($r = -0.509$; $p < 0.01$) and performance in visual fluency productivity ($r = -0.473$; $p < 0.01$).

Conclusions: The obtained results allow us to hypothesize that anhedonia is associated with difficulties both in evaluating and imagining possible positive stimuli, which leads to a lack of emotional response to the current stimulus. Thus, the availability of current pleasure may be linked to memory accessibility and regulatory function. When these domains are weakened, the respondent loses the ability to associate the current stimulus with positive past experiences, making it challenging to generate an emotional response in the current stimulus situation and disrupting the anticipation of pleasure. Based on the results, we propose the effective use of behavioral activation and work on the actualization of past experiences. Behavioral activation can be implemented by gradually introducing behaviors associated with past pleasures into the patient's life, followed by cognitive restructuring aimed at focusing the emotional response on past and current stimuli. In addition to this, from a neurocognitive perspective, an additional element of therapy could involve training various types of cognitive functions, with an emphasis on the auditory modality.

EPV0410

Sexual dysfunction, depression, and the impact of antidepressants

T. Jupe*, I. Giannopoulos and A. Roumpou

Psychiatric Hospital of Attica, Athens, Greece

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1120

Introduction: Sexual dysfunction is a common side effect of antidepressants and can have significant impact on the person's quality of life, relationships, mental health, and recovery. The reported incidence of sexual dysfunction associated with antidepressant medication varies considerably between studies, making it difficult to estimate the exact incidence or prevalence.

Objectives: The focus of this e-poster is to explore the incidence, pathophysiology, and treatment of depression disorder and antidepressant iatrogenic sexual dysfunction.

Methods: A bibliographical review was performed using PubMed platform. All relevant articles were found using the keywords: depression, sexual dysfunction, antidepressant.

Results: Sexual dysfunction is a common symptom of depression. Although decreased libido is most often reported, difficulties with arousal, resulting in vaginal dryness in women and erectile dysfunction in men, and absent or delayed orgasm are also prevalent. Sexual dysfunction is also a frequent adverse effect of treatment with most antidepressants and is one of the predominant reasons for premature drug discontinuation. Selective serotonin reuptake inhibitors are the most widely prescribed antidepressants and have significant effects on arousal and orgasm compared with antidepressants that target norepinephrine, dopamine, and melatonin systems. The availability of an antidepressant that does not cause or exacerbate sexual dysfunction represents an advance in pharmacotherapy for mood disorders and should reduce treatment noncompliance and decrease the need for switching antidepressants.

Conclusions: The sexual problems reported range from decreased sexual desire, decreased sexual excitement, diminished or delayed orgasm, to erection or delayed ejaculation problems. There are a number of case reports of sexual side effects, such as priapism, painful ejaculation, penile anesthesia, loss of sensation in the vagina and nipples, persistent genital arousal and nonpuerperal lactation in women.

Psychotic Depression, Mannerisms and Alzheimer's Disease: a case report

A. Izquierdo De La Puente^{1*}, P. del Sol Calderón¹ and R. Fernandez Fernandez²

¹Psychiatry, Hospital Universitario Puerta de Hierro de Majadahonda, Majadahonda and ²Psychiatry, Hospital Universitario Infanta Cristina, Parla, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1121

Introduction: We present the case of a 56-year-old patient with two depressive episodes with psychotic symptomatology in a period of three years, who began with mania and developed Alzheimer's disease.

Objectives: The case is presented with the aim of providing a brief review of psychiatric symptomatology as a prodrome of Alzheimer's disease.

Methods: A 56-year-old patient, with no psychiatric antecedents of interest, who presented a depressive episode with psychotic symptoms, requiring admission to a short hospitalisation unit, as well as antidepressant treatment with sertraline at 200mg daily and olanzapine 20mg. He remained stable for two years and was able to withdraw treatment progressively. However, after remaining euthymic without pharmacological treatment for six months, he had another episode with psychotic symptoms. In this last episode, he did not require hospital admission, but he did require a change in

antidepressant treatment, given that he did not tolerate treatment with sertraline. Treatment was therefore started with duloxetine 120mg, aripiprazole 20mg and as no clear improvement was observed, months later it was decided to use lamotrigine 100mg as a stabiliser.

Results: In this last episode, despite the significant affective improvement and maintaining psychopathological stability, without presenting psychotic symptoms, the patient presented marked dysfunction in day-to-day life due to a striking attention deficit, lack of concentration and reduced short-term memory. At the same time, he also exhibits mannerisms which are observed in the consultation room, in the form of repetitive hand movements.

For these reasons, it was decided to request MRI and SPECT, obtaining results compatible with possible incipient cognitive deterioration.

Conclusions: It seems that up to 40% of patients with dementia have depressive symptoms. It seems that depression at an advanced age may in fact be a prodromal symptom of dementia.

EPV0416

Esketamine in resistant depression: a case report

L. Carrión Expósito¹, G. Chauca Chauca^{1*}, R. Galán Armenteros¹ and M. Rodríguez López²

¹Psiquiatra and ²Enfermera, Córdoba, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1122

Introduction: Major depressive disorder is a common psychiatric condition affecting around 264 million people worldwide (WHO: Depression Fact Sheet. [Apr;2021]). Despite pharmacological advances, many patients still do not respond to antidepressant treatment or do so partially.

It is estimated that only 50-70% of patients respond to the initial antidepressant treatment according to the STAR-D study. 15% percent of cases do not respond significantly to various pharmacological and psychotherapeutic attempts (Rush AJ et. STAR-D report. *Am J Psychiatry*). The current consensus places resistant depression for a practical approach in one that has been treated with two different antidepressant strategies in adequate doses and time and has not been remitted (Souery D et al, Treatment-resistant depression. *J Clin Psychiatry* 2006). We present a clinical case of a patient with Major Depressive Disorder, resistant to several therapeutic lines, in which intranasal esketamine was initiated.

Objectives: The main objective is to report the result of treatment with esketamine in a clinical case.

Methods: This work analyzes the clinical evolution and response of a 62-year-old patient after initiating intranasal esketamine.

This is a patient with a single depressive episode, with no personal psychiatric history of interest that, after exhausting several options of pharmacological and non-pharmacological treatment.

Regulated psychotherapy based on cognitive behavioral therapy was carried out along with different pharmacological strategies according to the recommendations of the main clinical guidelines: antidepressant dose increase, antidepressant change, combination of several antidepressants and potentiation with another drug. We

measured clinical changes with MADRS Scale (Montgomery-Asberg Depression Rating Scale) at different times.

Results: From the fifth administration of esketamine the patient presented a clear improvement. At three months, the score on the MADRS scale improved markedly and at 6 months, the patient reported euthymia.

Score MADRS:

- Basal 46
- 3 Months 14
- 6 Months 1

As for the adverse effects, the patient presented in all administrations very mild dizziness.

Conclusions: The use of esketamine is a new therapeutic approach, being fast, safe and well tolerated in patients with depression who do not respond to other treatments (Sapkota A et al. Efficacy and Safety of Intranasal Esketamine in Treatment-Resistant Depression in Adults: A Systematic Review. *Cureus*.2021 Aug 21;13(8)). In our patient has proven to be effective and fast.

doi: 10.1192/j.eurpsy.2024.1123

Introduction: Chronic exposure to damaging noise can lead to hearing loss. People suffering from hearing problems find it increasingly difficult to communicate and become withdrawn. This lack of contact can lead to the onset of anxiodepressive disorders.

Objectives: To study the epidemiological and clinical particularities of hearing loss in patients with psychoaffective disorders.

To study the impact of this association on the medical aptitude for work.

Methods: Retrospective descriptive study of depressive patients with hearing loss who consulted the Occupational Medicine Department at Charles Nicolle Hospital over a six-year period from January 2016 to November 2022.

Results: Out of 150 patients with hearing loss who consulted our service, 10 patients had an axio-dépressive disorder. Seven were men and three were women. The mean age was 43 ± 5 years and the mean job seniority was 11 years [3-20]. They belonged to the telecommunications (n=6), industry (n=2), printing (n=1), and transport sectors (n=1). The job positions were: teleconsultant (n=6), operator machine (n=3) and driver (n=1). The symptoms presented by the patients were hearing loss (n=4), otalgia (n=1), dizziness (n=1), tinnitus (n=1). The average time to onset of symptoms was 13 ± 8 years [1-35]. The hearing deficits presented by the

patients were: sensorineural hearing loss (n=7), mixed hearing loss (n=1) and conductive hearing loss (n=2). The mean of Hearing loss were 34 ± 9 dB in the right ear and 34 ± 6 dB in the left ear. A declaration of the deafness as an occupational disease was indicated in two of the cases. The univariate statistical study showed that anxiety-depressive disorders were associated with tinnitus ($p=0,036$, OR=4,2[0,99-17,659]) and the position of teleconsultant ($p=0,009$, OR=5,622[1,338-23,627]). Eviction from exposition to noise was indicated in seven cases.

Conclusions: According to our study, hearing loss in patients with anxiodepressive disorders is associated with tinnitus and teleconsultant job position. Early screening of people at risk is recommended.

Attachment disturbance in women with depressive spectrum disorder, its connection with hostility

S. N. Enikolopov¹, O. U. Vorontsova¹, T. I. Medvedeva¹, O. M. Boyko^{1*} and I. V. Oleichik²

¹Clinical psychology and ²Department of endogenous mental disorders and affective states, Federal State Budgetary Scientific Institution "Mental Health Research Center", Moscow, Russian Federation

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1124

Introduction: The results of the study of psychological factors of hostility in depression are presented. The topicality of the study is due to hostility considered, on the one hand, as a property of depression, and on the other hand, as a risk factor, associated with the likelihood of auto-aggressive behavior.

Objectives: The aim of the study was to analyze the relationship between hostility and attachment disorders in endogenous depression.

Methods: The study involved 49 patients with depressive disorder (mean age $19,8 \pm 4,5$). All patients were assessed using the Hamilton Depression Rating Scale (HDRS-17 mean $21,03 \pm 6,02$). All completed the following methods: Revised Experiences in Close Relationships (ECR-R); Symptom Check List-90-Revised (SCL-90R); Aggression Questionnaire by Buss and Perry (BPAQ); I-structural test by G. Ammon (ISTA). According to the "depression" parameter of the SCL-90R, the group was divided into subgroups with high and medium severity of depression. Analysis of variance (ANOVA) or Mann-Whitney test were. Correlation analysis (Spearman) and stepwise multiple regression analysis were also used.

Results: At high levels of depression, the indicators of "hostility", "destructive" and "deficit aggression" are statistically significantly higher. The severity of depression significantly correlates with the severity of "anxiety" in attachment (close relationships), as well as with pathological "narcissism", "destructive external self-delimitation", "deficient internal self-delimitation".

For the measure of depression, regression analysis showed that the regression model explained more than 76% of the variance, with the measures of "interpersonal sensitivity", "deficit narcissism", and "avoidance" in attachment making significant contributions. For the "hostility" the regression model explains about 62% of the

variance, while a significant contribution is made, as in the analysis of “depression”, by the indicators of “interpersonal sensitivity” and “avoidance”, however, unlike “depression”, the contribution of the “destructive narcissism” is noted in contrast to the “deficit narcissism”.

Conclusions: With severe depressive symptoms, indicators of hostility are increased. Hostility in depression is associated with factors caused by a violation of early interpersonal relationships (anxious attachment), which causes increased sensitivity in relations with others, “building a barrier” between oneself and the external environment perceived as hostile in the narcissistic pathology, problems in emotional regulation. One of the targets of psychotherapeutic work may be the ambivalence between desire for symbiotic dependence and the experienced hostility.

Clinical and psychometric characteristics of depression in the elderly

R. Albu-Kalinovic^{1*}, M.-A. Pop¹, N.-S. Oana¹, B. Adela¹, V. Gabriela-Ionela² and E. Virgil-Radu¹

¹UMFVBT and ²SCJUPBT, Timisoara, Romania

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1125

Introduction: Depression in the elderly represents a multifaceted and critical area of study within the realm of geriatric mental health. As the global population continues to age, the prevalence and impact of depression among older adults have garnered increased attention from researchers and clinicians.

Objectives: This abstract delves into the comprehensive exploration of the clinical and psychometric characteristics of depression in the elderly population. This study aims to contribute to a deeper understanding of depression's manifestation in the third age, providing invaluable insights that can inform tailored interventions, improve diagnostic accuracy, and enhance the overall quality of life for older adults.

Methods: A cross-sectional study was conducted that gathered 80 patients. Their common characteristics were the signing of the consent, their admission to the Psychiatry Clinic in Timișoara and their main diagnosis with one of the ICD-10 codes F32.x, F33.x or F06.8.

This selection resulted in three groups: patients younger than 65 years old, patients older than 65 years in whom depression began before this age, and patients older than 65 years in whom depression began after 65 years of age. Anamnestic data, paraclinical, socio-demographic data, psychometric scales that measured the level of depression as well as personality scales were collected. The data that was obtained was compared and examined to find significant correlations between the 3 batches.

Results: The results show that there are no significant differences between patients with depression from rural or urban areas, showing the universality of the occurrence of this disorder among the population, regardless their environment. Depression in the third age is most often found in the elderly who have only finished secondary school, education levels playing a role in depression prevalence suggest the significance of socio-economic factors,

warranting targeted outreach and education efforts in vulnerable populations. Correlations were also found between the level of depression and certain blood parameters. The integration of these findings for an understanding of the etiology of depression can pave the way for new therapeutic approaches. Certain personality traits were correlated more with certain items on the scales that evaluated depression, thus in those with a neurotic personality it is very strongly correlated with the appearance of guilt as a symptom, agreeableness with psychomotor slowness, paranoid with insomnia, and anankastic and dependent personalities were correlated much more with social isolation.

Conclusions: By recognizing the distinct clinical features and implications of depression in older adults, we can pave the way for improved mental health care and better quality of life for this growing population. This study reinforces the importance of continuous research and collaboration in the field of geriatric mental health.

Depression, anxiety and stress among flight crews in Tunisia

Z. Athimni¹, I. Jammeli², A. Chouchane¹, I. Kacem^{1*}, A. Aloui¹, M. Bouhoula¹, A. Gaddour², M. Maoua¹, A. Brahem¹, H. Kalbousi¹, O. El Maael¹ and S. Chatti¹

¹Occupational Medicine and Professional Pathologies Department, Farhat Hached Teaching Hospital, Avenue Ibn El Jazzar, Sousse, 4000, Tunisia, Sousse and ²Occupational Medicine Department- Ibn El Jazzar Hospital, Kairouan, Tunisia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1126

Introduction: The mental health of flight crews is of paramount importance. Due to the demanding nature of their work, crew members are subject to various stress factors such as irregular working hours, time differences, operational demands and high passenger safety responsibilities.

Objectives: We aimed to evaluate the mental health of Tunisian flight crews working for a private airline.

Methods: This is an exhaustive cross-sectional study which included all flight crews working for a private airline in Tunisia who consulted the occupational medicine and pathology department at the Farhad Hached University Hospital in Sousse as part of their periodic check-up. Data collection was based on a pre-established questionnaire which included socio-demographic data, lifestyle habits and professional data. The DASS21 questionnaire was used to assess depression, anxiety and stress.

Results: Our study included 160 participants. The median age was 42 years with a female predominance. More than half were smokers (58.8%). Alcohol was consumed by 41.3% of flight crews. The vast majority drank coffee (84.4%). With regard to professional data, 71.3% were flight attendants. The median length of service was 15 years. The majority of participants had operated a medium-haul flight (< 5 hours) during the last month (65%). The majority of participants (85.6%) had a normal depression score. Almost a third of the participants (28.5%) had anxiety scores ranging from mild to moderate. One participant had extremely severe anxiety scores. The majority of flight crews

had a normal stress score (90%). After multivariate analysis, unmarried marital status, working more than 2 days a week and stress were factors independently associated with anxiety.

Conclusions: Work-related psychosocial risks can have a major impact on workers' mental health. It is therefore essential to take these risks into account and put in place preventive measures to protect workers' mental health and promote their well-being at work.

Emotional reactivity to daily events in adolescents with clinical depression and subthreshold depression: an experience sampling study

T. C.-Y. Liu^{1*}, N. T.-K. Kwok², P. W.-L. Leung², S. F. Hung³, S. M. S. Chan³, S. L. Ma³, S. W. H. Chau³, W. H. Wong³ and S. H.-W. So²

¹The Chinese University of Hong Kong, Hong Kong, Hong Kong;

²Department of Psychology and ³Department of Psychiatry, The Chinese University of Hong Kong, Hong Kong, Hong Kong

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1127

Introduction: Adolescents with depression have distinct affective reactions to daily events, but current research is controversial. The emotional context insensitivity theory suggests blunted reactivity in depression, whereas the hypotheses of negative potentiation and mood brightening effect suggest otherwise. While nonlinear associations between depression severity and affective reactivity have been observed, studies with a separate subclinical group remain rare. Subthreshold depression (SD), defined by two to four symptoms lasting for two weeks or more, provides a dimensional view to the underpinnings of affective reactivity. In this study, we compared positive affect (PA) and negative affect (NA) reactivity to positive and negative daily events (uplifts and stress) among adolescents with Major Depressive Disorder (MDD), SD and healthy controls (HC) using experience sampling methods (ESM).

Objectives: We hypothesized a stepped difference in affective reactivity along the depression spectrum: the MDD group will have the strongest reactivity of PA and NA to uplifts and stress, followed by SD and HC.

Methods: Three groups (MDD, SD, and HC) of adolescents were recruited from an epidemiologic sample entitled 'Hong Kong Child and Adolescent Psychiatric Epidemiologic Survey: Age 6 to 17'. Group status was determined by the Diagnostic Interview Schedule for Children Version 5. They completed an experience sampling diary on smartphone for 14 consecutive days, with 5-10 entries per day. Momentary levels of PA (happy, relaxed, contented), NA (irritated, low, nervous), uplifts and stress experienced before the entry were measured on a 1-7 Likert scale.

Results: The sample consisted of 19 adolescents with MDD, 30 with SD, and 59 HC. The M:F ratio was 17:19. The age range was 12-18 with a mean of 14.8. The overall ESM completion rate was 46%. The MDD group had the highest levels of stress and NA, and the lowest levels of uplifts and PA, followed by the SD and HC groups respectively ($p < 0.01$). Across groups, levels of PA were positively

associated with uplifts and negatively associated with stress, whereas levels of NA were positively associated with stress and negatively associated with uplifts. The Group x Uplift interaction effect on PA was significant, with greater PA reactivity in SD ($p < 0.01$) and MDD ($p = 0.07$) when compared with HC. The Group x Uplift interaction effect on NA was significant, with greater NA reactivity in SD than HC ($p < 0.01$). The Group x Stress interaction effect on PA was significant, with greater PA reactivity in SD than HC ($p < 0.01$) and MDD ($p < 0.01$). The Group x Stress interaction effect with NA is non-significant.

Conclusions: Contrary to our hypothesis, adolescents with SD experienced strongest PA and NA reactivity in uplifts and PA reactivity in stress. It provides evidence towards a nonlinear relationship between severity of depression and affective reactivity.

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1128

Introduction: Intranasal esketamine has recently been approved for the treatment of treatment-resistant depression in adults, with different studies showing its efficacy and tolerability. However, the real-world tolerability of this treatment is still unclear.

Objectives: Evaluate the tolerability of intranasal esketamine in a case series of 15 patients.

Methods: Our case series includes 15 patients, who received treatment with intranasal esketamine during 2022-2023. In order to evaluate the tolerability of intranasal esketamine, patients were asked to complete the TSQM and a side effect questionnaire on different moments of the treatment (one week, six weeks and six months after the beginning of the treatment).

Results: The most common adverse effects were dissociation, dizziness, and somnolence, which resolved within the hours following the administration. All of them were mild or moderate in severity, having a minor impact on the patient, so none of the patients discontinued the treatment due to adverse effects. Other adverse effects noticed were: transitory increment of blood pressure in several patients, and worsening of obsessions in a patient with previous obsessive-compulsive symptoms.

Conclusions: Our data suggests that intranasal esketamine is well tolerated, with transient and mild adverse effects. In all cases the risk-benefit ratio must be evaluated, but until more studies are done, it seems to be a safe treatment for treatment-resistant depression.

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1129

Introduction: Depression is a widespread problem that affects individuals of all ages. This study looks at the use of omega-3 polyunsaturated fatty acids (PUFAs) as an additional therapy for depression in people of different ages. Depression has an impact on everyone, from youth to the elderly, causing therapeutic concerns such as treatment resistance and recurrence. Omega-3 PUFAs, which may be found in fish and flaxseed, are important because of their impact on neurochemistry, inflammation, and neuroprotection. While pharmacotherapy, including antidepressants, has proven beneficial for many, the likelihood of remission and recurrence remains substantial. In recent years, there has been a growing interest in the potential role of omega-3 polyunsaturated fatty acids (n-3 PUFAs) in mitigating depressive symptoms. The primary constituents of n-3 PUFAs are eicosapentaenoic acid (EPA) and docosahexaenoic acid (DHA). Understanding the potential of omega-3 PUFAs across the lifespan can help address the multifaceted challenges posed by depression and improve mental health outcomes for diverse age groups.

Objectives: This review aims to assess the role of omega-3 fatty acids in depression treatment across different age groups: children and adolescents, adults (18–60), and the elderly (60+). It investigates the effectiveness and potential differences in omega-3 supplementation among these age cohorts.

Methods: A comprehensive literature search was conducted from 2003 to 2023 using PubMed, Google Scholar, and EMBASE, using specific keywords. Studies with inadequate age group information or Omega-3 intervention were excluded.

Results: In children and adolescents, several studies indicate a positive association between omega-3 supplementation and improved depressive symptoms. In adults, results are mixed, with some studies showing benefits while others do not. In the elderly, omega-3 PUFAs appear to have a more consistent positive effect on depression. In contrast, a consistent positive association was observed in the geriatric population, suggesting that Omega-3 PUFAs may hold particular promise in the treatment of depression among older adults. However, variations in methodology, dosage, and study populations contribute to these mixed findings.

Conclusions: Omega-3 PUFAs show promise as an adjunct therapy for depression across different age groups. Further research with standardized methodologies and larger sample sizes is needed to clarify their role and establish optimal dosage guidelines.

Omega-3 PUFAs should be considered as a potential complement to conventional depression treatments, emphasizing the need for personalized approaches in depression management.

EPV0425

Clinical Benefits, efficacy and tolerability of slowly titrated vortioxetine oral drops solution

A. Fagiolini*, A. Cuomo, G. Barillà, M. Cattolico, D. Koukouna, E. Mariani, S. Pardossi, C. Pierini, M. Pinzi and G. Piumini

Molecular Medicine, University of Siena, Siena, Italy

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1130

Introduction: Vortioxetine is mainly prescribed as oral tablets, usually starting at 5-10 mg per day, and is well tolerated by most patients. However, some patients may experience side effects, the most common of which is nausea, which occurs in 20.9-31.2% of people treated with doses of 5-20 mg/day (Baldwin et al, J Psychopharmacol. 2016;30:242-52). In some countries, vortioxetine is also available as an oral solution (1 drop = 1 mg), which allows a very slow titration schedule that may improve tolerability.

Objectives: To evaluate whether vortioxetine oral drop solution, started with 1-2 drops (1-2 mg per day) and increased by 1-2 drops per day to 10-20 drops (10-20 mg), is associated with better tolerability and a lower risk of nausea than that observed with oral tablets started with 5-10 mg per day, while maintaining efficacy. To provide pilot data for the design of a multicentre, prospective study.

Methods: Retrospective, single-centre, observational study. Participants were 58 consecutive patients (mean age 45 + 17 years, 55.2% female) treated with vortioxetine for a depressive episode. Vortioxetine was initiated and titrated up to 1 drop (1 mg) per day in 58.6% of subjects, and initiated and titrated up to 2 drops in 41.4% of subjects. Tolerability was assessed at all visits. CGI and MADRS scores were recorded at the following time points: T0-baseline, T1=week 1, T2=week 2, T3=week 4, T4=week 8). Comparisons were made using repeated measures ANOVA with Bonferroni correction.

Results: Nausea was reported by 8 subjects (13.8%) at T1, 4 subjects (6.9%) at T2, 1 subject at T3 (1.7%) and none at T4. Other adverse reactions (mainly dizziness, pruritus/itching, vomiting, diarrhoea, and xerostomia) were reported by a total of 6 subjects (10.3%) at T1, none at T2 and T3, and 1 subject (1.7%) at T4. The maximum dose administered was 20 mg in 75.9% of patients. No patients discontinued vortioxetine due to adverse events, but vortioxetine was discontinued prior to T4 (8 weeks of treatment) in 2 subjects due to lack of efficacy. The mean CGI at baseline was 4.3 ± 0.8. The mean value decreased to 3.9 ± 0.7 at week 1 and to 3.4 ± 0.6, 2.7 ± 0.6, 1.9 ± 0.5 at weeks 2, 4 and 8, respectively. All differences were statistically significant (p < 0.001) compared to baseline. Also from week 2, all scores were statistically significant compared to all previous assessments. The total MADRS score decreased from 28.3 ± 4.6 at baseline to 24.9 ± 4.2, 20.9 ± 4, 16.3 ± 3.6 and 10.9 ± 3 at weeks 2, 4 and 8, respectively. A significant decrease in MADRS total score was observed at each time point (p < 0.001) compared to baseline and previous assessments.

Conclusions: Slow titration with vortioxetine oral drop solution was associated with a very low percentage of patients reporting side effects in general, and nausea in particular, and with a relatively rapid improvement in depressive symptoms.

Disclosure of Interest: None Declared

Unipolar and Bipolar Depressed Inpatients: correlations with Vitamin D and Cognitive Symptoms

I. Bonfitto¹, G. Moniello², G. Francavilla¹, A. Bellomo³ and S. Dimalta^{1*}

¹Department of Mental Health, ASL FG, Foggia; ²Department of Geriatric Medicine and Gerontology, ASL CE, Caserta and ³Department of Clinical and Experimental Medicine, University of Foggia, Foggia, Italy

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1131

Introduction: Cognitive symptoms are the main factor of discomfort in depressed patients, persisting even during clinical remission (Conradi et al. *Psychol Med* 2011;41:1165-74) and inevitably compromising their quality of life (Fehnel et al. *CNS Spectr* 2013;25:1-10). Several studies have suggested the neuro-protective role of vitamin D, both through actions on the genome and rapid non-genomic mechanisms; so, low serum vitamin D levels are related to poorer cognitive performance (Goodwill et al. *JAGS* 2017;2:1-8), depressive disorders (Kjærgaard et al. *Psych Res* 2011;190:221-225) and suicide risk (Umhau et al. *PLoS One* 2013;8:e51543).

Objectives: to investigate relationships between serum vitamin D levels, depressive symptoms and cognitive performance in unipolar and bipolar depressed adults hospitalized for Major Depressive Episode (MDE).

Methods: 80 patients (34 M and 46 F; average age 48,96 ± 14,17 years; 40% with bipolar depression) were examined. Depression was investigated using Hamilton Rating Scale for Depression (HAM-D), while cognitive functions were explored by: Rey Auditory Verbal Learning Test (RAVLT) and Rey-Osterrieth Complex Figure (ROCF) to assess verbal and visuospatial memory, respectively; Trail Making Test (TMT) and Stroop Color and Word Test to assess attention, spatial planning and cognitive flexibility. Venous blood sampling was used to determine serum Vitamin D levels (average level 15,67 ± 8,7 ng/ml).

Results: At first, the serum level of vitamin D was found to be inversely correlated with HAM-D scores ($p=0,0079$), so that lower concentrations of vitamin D is related to greater severity of depression. In addition, there were strongly significant positive correlations between low vitamin D levels and poorer RAVLT and ROCF scores and strongly significant negative correlations between vitamin serum level and higher scores in TMT and STROOP test, so that calcidiol deficit is associated with poor cognitive performance. Similarly, patients with higher HAM-D scores were found to have a greater cognitive impairment (lower RAVLT e ROCF scores and higher TMT e STROOP scores).

Conclusions: In accordance with previous works, our study supports the close relationship between serum vitamin D levels and

depressive morbidity. During MDE hypovitaminosis D is related to worse disease indices, such as severity of affective symptoms and cognitive impairment, without substantial differences between clinical manifestations of unipolar and bipolar depression, both in terms of affective and cognitive symptoms and disease severity. Considering that cognitive deficits are truly disabling because they may resist to common antidepressant treatments and, as a result, persist during stages of clinical remission, vitamin d supplementation, by minimizing cognitive dysfunction, could be a good strategy to reduce the risk of relapses and to improve patients' functioning and quality of life.

Evaluation of User Satisfaction in a Supportive Text Message Program for Public Safety Personnel

G. Obuobi-Donkor^{1*}, R. Shalaby², B. Agyapong², R. D. L. Dias¹ and V. I. O. Agyapong^{1,2}

¹Department of Psychiatry, Dalhousie University, Halifax and

²Department of Psychiatry, University of Alberta, Edmonton, Canada

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1132

Introduction: Public safety personnel (PSP) encounter traumatic events in their workplace, elevating the likelihood of mental health issues. Delivering efficient, evidence-backed interventions, like supportive SMS text messaging programs, can significantly enhance PSPs' mental well-being, garnering high user satisfaction rates.

Objectives: This study evaluates users' satisfaction, receptiveness, and perceptions of the supportive SMS text messaging intervention (Text4PTSI).

Methods: Participants enrolled in the Text4PTSI program and received one-way cognitive behavioural-based supportive text messages for six months. They participated in a web-based survey delivered through SMS text messages at enrollment, six weeks, three months, and six months after enrollment. The participants' perceptions and receptiveness of the program were evaluated through a 5-point Likert scale. Data were represented as categorical variables, and overall satisfaction with the Text4PTSI program was assessed on a scale ranging from 0 to 100.

Results: Of the 131 Text4PTSI program subscribers, 81 participants responded to the survey, yielding 100 responses across the three follow-up time points. The average satisfaction score was 85.12 (SD 13.35). A significant portion of respondents, constituting 79%, agreed or strongly agreed that Text4PTSI helped them manage anxiety. Additionally, 72% reported relief from depressive symptoms, and 54% (54 out of 100 responses) felt less lonely. Moreover, the majority (84%) of participants expressed that Text4PTSI connected them to a support system, improving their mental well-being, felt more hopeful about managing concerns about their mental health or substance use (82%), and helped enhance their overall quality of life (77%). The data also revealed that most participants consistently read the supportive text messages (84 out of 100 responses, 84%), took time to

contemplate each message (75 out of 100 responses, 75%), and revisited the messages more than once (76 out of 100 responses, 76%).

Conclusions: PSP participating in the 6-month Text4PTSI intervention expressed significant satisfaction and gratitude in the follow-up surveys. Their positive feedback indicates a promising path towards increased service utilization, potentially enhancing its effectiveness and impact on end users.

Characterize and Address Mental health Problems in University Students (CAMPUS Study): preliminary results

M. Nosè*, G. Muriago, F. Tedeschi, G. Turrini and C. Barbui

Department of Neuroscience, Biomedicine and Movement Sciences, Section of Psychiatry, University of Verona, Verona, Italy

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1133

Introduction: The transition phase from late adolescence to early adulthood, which corresponds with the period of university life, is a time that offers important opportunities for personal growth. However, this developmental phase also concurs with the peak period of risk for the onset of mental health disorders. For this reason, the literature clearly identifies university students as a vulnerable population group for psychological distress and mental problems. Digital psychological interventions and e-mental health solutions are emerging as a promising solution for university students, particularly appealing due to their anonymity, portability and ease of access. Hence, the World Health Organisation has developed several psychosocial e-mental health tools including Doing What Matters in Times of Stress (DWM), which has been consistently shown effective in various vulnerable populations. These data provide the framework for the CAMPUS study that is intended for students attending the University of Verona.

Objectives: The main objective of this project is to adapt the WHO psychological intervention called “Doing What Matters in Times of Stress” (DWM) to this target population and to evaluate the effectiveness, feasibility, and acceptability of WHO’s DWM as a psychological strategy for effective mental health prevention and promotion, and for reducing psychological symptoms and distress in university students. Secondary objectives of the project include to evaluate the fidelity of DWM, to assess factors associated with its implementation and effectiveness and to co-create the necessary local conditions for implementation and up-scaling of DWM.

Methods: The CAMPUS study is a prospective non-randomized follow-up study. The target population is composed by university students of University of Verona, Italy. The online assessments, which are collected pre and post intervention, consist of an ad-hoc sociodemographic information page, and four self-administered questionnaires assessing psychological distress, depression and anxiety symptoms, and psychological well-being. In addition, implementation checklists will be administered to assess the acceptability, appropriateness and feasibility of the intervention.

Results: Preliminary results on a sample of 300 students attending University of Verona show that the adapted DWM intervention promote students’ psychological well-being and reduce the level of psychological distress as well as the risk for the later development of a psychopathology. Moreover we expect that future results would include data on the effectiveness, feasibility, and acceptability of the adapted DWM intervention among university students

Conclusions: These results provide valuable information for mental health promotion and support programs for university students, as well as insights into factors influencing its implementation and suggestions for future scaling of the intervention.

The population-based Tromsø 8 study and e-mental health

R. Wynn^{1,2*}, G. Bellika¹, L. G. Fernandez³ and V. T. Salcedo⁴

¹Clinical Medicine, UiT The Arctic University of Norway, Tromsø;

²Department of Education, ICT and Learning, Østfold University College, Halden, Norway; ³Clinical Medicine, University Miguel Hernandez, Alicante and ⁴ITACA, UPV, Valencia, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1134

Introduction: Ageing populations with increased needs, rising costs of traditional services, and new technologies are some factors driving the use of e-health services. A Norwegian study with data from 2015-2016 found that 13.5% had used apps, 7.3% had used social media, and 5% had used video services for health purposes. Little is known about the effects of many online health services, but in general they seem to increase knowledge and make most people feel reassured, although some users feel more anxious or confused after using such tools. Recent technological developments have resulted in new online health services, including AI-based technologies. More updated knowledge regarding the population’s use of e-health services in general and e-mental health services in particular, is needed.

Objectives: The objective here is to provide information about an upcoming large population-based epidemiological study and how it addresses e-health and e-mental health.

Methods: We introduce the upcoming 8th version of the epidemiological Tromsø Study and discuss its importance to the field of e-mental health.

Results: The Tromsø epidemiological study has since 1974 taken place in the Norwegian municipality of Tromsø. It contains information on a range of topics within health and illness, including topics from many medical specialties, psychiatry and substance use. In the upcoming 8th version of the study (2025-2026), more than 33,000 people aged above 40 will be invited to participate. The main questionnaire will include questions relating to a wide variety of topics, including on e-health use. We suspect the importance of e-health and e-mental health have increased lately, and we will examine how the use of e-health may impact mental health.

Conclusions: Community-based studies, such as the Tromsø Study, allow researchers to study associations between many different variables, including mental health and e-health. The upcoming Tromsø 8 study will enable us to study e-health use and its

relationship to mental health in a large sample representative of the Norwegian population.

E-Learning challenges and trainee teacher engagement: Lessons from the COVID-19 pandemic

Z. Boumaaize¹, A. Bouhaba^{1*}, H. Guider¹, M. A. Lafraxo¹, Y. El Madhi² and H. Hami¹

¹Laboratory of Biology and Health, Faculty of Sciences, Ibn Tofail University, Kenitra and ²Regional Center for Education and Training Professions, Rabat, Morocco

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1135

Introduction: The sudden emergence of the COVID-19 pandemic resulted in a compulsory shift to distance learning due to school closures. Consequently, all educational courses were delivered virtually. To facilitate this transition for students and educators, the Ministry of Education implemented digital learning platforms, such as Taalim.ma and TelmidTice. Furthermore, the Broadcasting and Television National Company reorganized its television channels to maintain continuity throughout the academic year. As a result, trainee teachers have effectively shifted to distance learning, using resources such as e-Takwine, MOOC classes, and digital classrooms.

Objectives: This study examines the factors that cause discomfort among trainee teachers and evaluates their influence on satisfaction with distance learning during the COVID-19 pandemic.

Methods: We conducted a descriptive study with 370 Moroccan trainee teachers, with a mean age of 28.30 ± 5.99 years. We collected data using a self-administered questionnaire that was divided into three sections. The initial section examined sociodemographic and professional factors, including gender, age, marital status, academic level, and training cycle. The subsequent section focuses on discomfort-inducing factors, including living arrangements during lockdown, digital skills, material availability, network connectivity, and training schedules. Finally, the concluding section analyzes the trainees' satisfaction and perceptions within their learning community.

Results: The study indicated that 75% of trainee teachers lived in homes with four to seven residents, leading to confined living arrangements. Furthermore, 55% of the participants did not have a designated workspace for studying, focusing, or engaging with instructors. Participants identified various obstacles to online learning, including 80% lacking digital skills, 60% having insufficient equipment, 73.33% experiencing connection and network issues, 78.33% being unfamiliar with online learning, and 68.33% facing an unsuitable training schedule. The study indicates a positive correlation between trainee satisfaction and engagement ($r = 0.422$, $p < 0.001$).

Conclusions: The COVID-19 pandemic has necessitated online education as a crucial resource for ensuring the continuity of education. This study highlights the paramount significance of developing effective e-training policies to direct novice teachers toward successful online learning by alleviating their discomfort factors.

Navigating Mental Health Support in Tunisia's Digital Age: Preferences, Challenges, and Paradoxes-An online survey

O. Chhaider¹, M. Lagha¹, A. Adouni^{2*}, I. Ben Romdhane¹, W. Homri¹ and R. Labbane¹

¹Psychiatry C and ²Razi hospital, Manouba, Tunisia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1136

Introduction: The digital age has transformed mental health support in Tunisia. This study explores how individuals seek assistance for mental health concerns online, considering their comfort levels, preferences, and decision-making factors.

Objectives: This study aims to: Investigate the comfort levels of Tunisians when discussing mental health concerns online Identify preferred online sources for mental health support Explore factors influencing the choice between online sources and mental health professionals

Methods: To unearth these insights, an exhaustive online survey was meticulously conducted. This survey was posted online on different social media platforms and cast a wide net, drawing responses from an eclectic cross-section of Tunisian society. The survey methodically gathered data on participants' demographics, their inclinations towards online avenues for seeking assistance, and the multifaceted factors that sway their choices in this digital age.

Results: Intriguingly, the results of this study illuminate several key findings:

Comfort Levels: A striking 47% of respondents expressed their unease about discussing their mental health concerns online. This statistic vividly underscores the intricate interplay between digital platforms and the persistent social stigma surrounding mental health issues.

Preferences for Online Sources: The study notably revealed that mental health apps and online counseling websites are emerging as the favored choices among those seeking support. This underscores the surging significance of digital mental health solutions tailored to individual needs.

Factors Influencing Preferences: An array of factors sways the preference for online sources. Among them, the allure of anonymity, the appeal of convenience, and the perception of limited access to in-person mental health professionals were prevalent. Additionally, financial constraints emerged as a notable consideration in the decision-making process.

Trust in Online Information: In contrast, individuals who leaned toward seeking assistance from mental health professionals stressed the pivotal importance of professional expertise, personalized guidance, and a comprehensive understanding of their concerns. Importantly, 38% expressed reservations about the reliability of online mental health information, underscoring the critical role of trust in the process.

Conclusions: This study sheds light on the nuanced process of seeking mental health assistance in the digital age. It emphasizes the need to address mental health stigma and improve online resource credibility. The findings highlight the importance of comprehensive mental health strategies that integrate digital solutions and traditional professional care, catering to diverse preferences and needs in Tunisia.

Exploring the Digital Mental Health Literacy of the Tunisian population: A Cross-sectional Online Survey

O. Chehaider¹, M. Lagha¹, A. Adouni^{2*}, I. Ben Romdhane¹, W. Homri¹ and R. Labbane¹

¹Psychiatry C and ²Razi hospital, Manouba, Tunisia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1137

Introduction: In the digital age, the landscape of mental health information dissemination and consumption in Tunisia has experienced a profound transformation. As the digital revolution continues to reshape our lives, understanding how individuals seek and interact with mental health information online has become increasingly critical.

Objectives: The primary objectives of this study are as follows:

- To comprehensively investigate the digital mental health literacy of individuals in Tunisia by administering an insightful online questionnaire.
- To delve into the multifaceted aspects of how Tunisians engage with mental health content on digital platforms, unveiling their comfort levels, preferences, and decision-making factors.

Methods: This study conducted an online survey comprising three sections. The first gathered demographic information to profile our diverse participants. The second explored internet usage patterns, unveiling their digital activities. The third delved into perceptions of mental health information on social media, revealing preferences. Our survey reached participants of various ages and locations in Tunisia.

Results: The findings of this study cast a revealing spotlight on the digital mental health landscape in Tunisia. A significant proportion of our respondents frequently engaged with various social media platforms. Notably, Instagram emerged as the favored platform for 80% of our participants, while 72% chose Facebook as their preferred digital sanctuary. Intriguingly, 57% of our respondents actively embarked on quests for mental health information on YouTube, with a distinct preference for video-based content.

In the labyrinth of online mental health information, our participants exhibited a discerning eye. They assigned paramount importance to source credentials, references to reputable sources, and unwavering adherence to established medical guidelines. However, beneath this discernment, a noteworthy 65% harbored doubts regarding the accuracy of online information, reflecting the inherent challenges and complexities of navigating the digital information ecosystem.

Furthermore, our study unearthed areas where social media platforms may still grapple with shortcomings in addressing the multifaceted needs of mental health consumers. Participants eloquently expressed concerns about the accuracy of information, the availability of reliable platforms, and the crucial need for a diverse array of perspectives in mental health content on social media.

Conclusions: This study offers key insights into Tunisia's digital mental health landscape. It highlights prevalent digital information consumption and preferences. Emphasizing the need for credible and diverse mental health information on social media is vital. This sample lays the foundation for enhancing available content, better supporting mental well-being in Tunisia.

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1138

Introduction: The concept of digital psychiatry, encompassing technologies such as mental health apps, Virtual Reality (VR), Artificial Intelligence (AI), and telepsychiatry, emerges as a potential solution to bridge the existing gaps in the mental health system of Pakistan. However, one of the major barriers to the implementation of these technologies is hesitancy to adopt digital tools by psychiatrists.

Objectives: This study aims to explore the current understanding of digital psychiatry, the barriers faced by psychiatrists in its' widespread implementation, and their willingness to adopt these services in clinical practice.

Methods: This cross-sectional study surveyed psychiatrists' knowledge, attitudes, and practices on digital psychiatry from 39 public hospitals across Pakistan using an online validated questionnaire from January to July 2023. Participants included psychiatry residents, fellows, and consultants practicing in Pakistan. Responses were analyzed with Raosoft software, Quirkos, and SPSS 26 using thematic analysis and correlation.

Results: A total of 200 participants responded to the questionnaire, primarily in the age range of 20-30 years (56%). The gender distribution was 55% male (N = 111) and 45% female (N = 89). Among the professional roles, 23% were consultants, 7% were registrars, 54% were psychiatry residents, and 17% were medical officers. Respondents came from both rural (N = 148, 74%) and urban (N = 52, 26%) practice settings. Regarding telepsychiatry, 46% strongly agreed that they are familiar with telepsychiatry, while 58% agreed that telepsychiatry can save time and money. Additionally, 22% strongly agreed that it's a viable approach for patient care. Concerning perspectives on Artificial Intelligence (AI) in digital psychiatry readiness, only 40% of participants had received AI training. However, 55% expressed interest in collaborating with international centers on AI-related projects. In terms of mental health apps, 62% of respondents reported limited familiarity with them. Nevertheless, 65% believed that these apps could potentially

save time and money for psychiatric health systems. Lastly, concerning Virtual Reality (VR) in psychiatric care, 57% of participants were familiar with VR technology, but only 43% were acquainted with its applications in psychiatry. Notably, 71% did not view VR as a viable replacement for in-person psychiatric management.

Conclusions: This is the first study conducted on understanding digital psychiatry in Pakistan's healthcare system, which revealed multiple challenges to digital health competency among psychiatrists. This emphasizes on the need for formal training and funding towards resources to overcome obstacles in utilizing mental health technologies.

Patterns of Internet Addiction in an Italian sample: 100% of the sample experience Nomophobia

F. Marcolini*, D. De Ronchi and A. R. Atti

Department of Biomedical and Neuromotor Sciences, University of Bologna, Bologna, Italy

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1139

Introduction: Internet Addiction Disorder, a concept introduced for the first time by Ivan Goldberg in 1995, is one of the most recently identified forms of addiction, but already considered a real psychosocial phenomenon, capable of having a profound impact on different aspects of social and psychological life of individuals. One of its most recently identified manifestations is Nomophobia, a neologism formed from the combination of terms such as “no mobile”, “phone” and “phobia”, which can be understood as the fear of feeling disconnected. It is today considered a situational phobia, characteristic of contemporary times. The most common symptoms include excessive cell phone use and constant anxiety at the thought of losing the internet connection. Others are, for example, “Ringxiety”, ringing anxiety, or the “phantom vibration syndrome”.

Objectives: This study aims to examine the spread of Nomophobia in the Italian population, evaluating psychopathological correlations that can explain its diffusion.

Methods: Between January and May 2023, an anonymous online questionnaire was randomly sent to the general population. Alongside with tests to evaluate psycho-social features, the instrument used to study Nomophobia was the *Nomophobia Questionnaire* (NMP-Q) (Yildirim *et al.* Comput Hum Behav. 2015; 49:130–7), in its Italian version (Adawi *et al.* JMIR MHealth UHealth. 2018;6:e24).

Results: The sample consists of 308 people (189 F, 119 M), with an average age of 32 years (*sd* 14). In our sample, 100% of the subjects tested positive for Nomophobia. Values indicating a state of severe Nomophobia are found in 12.3% of the sample (F 15.9%, M 6.7%). The young population, between 18 and 25 years old, represents 54% of the affected population, but more than 60% of severe cases (95% confidence interval 50-65%). The severe cases correlate positively ($p < 0.05$) with findings of high impulsiveness. There are no other studies that investigate the psychopathological correlates of Nomophobia among Italians.

Conclusions: Despite possible *biases*, the data obtained are an alarming sign of the spread of internet addiction that characterizes our times, of which the excessive use of cell phones in the form of

Nomophobia is an expression. Despite their now undisputed usefulness, mobile devices are capable of causing the onset of serious health problems, starting from exposure to radiation capable of causing dermatitis, tumors, and infertility. Furthermore, they dramatically interfere with driving safety, becoming a major cause of road accidents. Considering these consequences, it appears to be extremely important to characterize the phenomenon, as well as its psychosocial determinants, in order to proceed with its better definition and prevention.

Assessing empathy among caregivers: a cross-sectional study

M. Kahloul¹, I. Kacem^{2*}, A. Ghenim², A. Aloui², A. Chouchane², M. Ajmi¹, W. Naija¹, M. Maoua² and N. Mrizak²

¹Sahloul Academic Hospital, Anesthesia and Intensive Care Department and ²Occupational Medicine Department, Farhat Hached Academic hospital, Sousse, Tunisia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1140

Introduction: Empathy plays an important role in everyday human relationships. It is the ability to put oneself in the place of others, to represent what they think and feel. In healthcare settings, several studies have highlighted its positive effects on patients in terms of physical and psychological well-being.

Objectives: Evaluate empathy among caregivers.

Methods: This is a cross-sectional study, conducted over a 1-month period and enrolling nursing staff working at Farhat Hached Academic hospital. Empathy was assessed using the Jefferson Scale of physician's empathy (JSPE) scale.

Results: A total of 92 caregivers were enrolled in this study. The average age was 40.41 years with a sex ratio of 0.95. The most represented category was nurses (64.1%) with an average seniority of 17.2 years. The average empathy score was 98.4. Scores above half were reported in 69.5% of cases. The presence of empathy was significantly associated with female gender ($p = 0.002$).

Conclusions: Empathy is a key point in the patient-caregiver relationship. Thus, the nursing staff must be aware of this concept in order to improve the quality of care.

The opportunity for e-mental health to overcome stigma and discrimination

K. Subramaniam^{1*}, A. Greenshaw² and A. Thapliyal³

¹Global Medical Affairs, Viatrix, Auckland, New Zealand; ²Dept of Psychiatry, University of Alberta, Edmonton, Canada and ³e-Mental Health International Collaborative, Auckland, New Zealand

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1141

Introduction: Many with mental illness do not seek treatment, often due to stigma; be it public, self, or institutional type. To improve outcomes, stigma needs addressing.

Objectives: Understand the opportunity for e-mental health to help overcome stigma and, to provide an expert opinion to foster its adoption.

Methods: We conducted literature searches using the terms ((mental health) AND ((stigma) OR (discrimination))) AND (((((digital tools) OR (digital services)) OR (healthcare apps)) OR (digital solutions)) OR (digital technology)), limited to 2007 – 2023, identifying 223 citations, 9 of which were relevant for this evaluation, including 4 systematic reviews (Table 1).

Results: Literature reports suggest that e-mental health may be useful for addressing stigma and reducing the treatment gap. While it was not consistently as good as face-to-face services, e-mental health tools were frequently shown to be effective in reducing stigma, improving mental health literacy, and increasing help-seeking behaviors. Tools included web-based breathing, meditation, and CBT; suicide prevention apps; and online videos and games. Experts from a 2022 global Think Tank session convened by eMHIC, opined and emphasised that embracing e-mental health must not leave people behind nor reinforce inequality and that structural barriers must first be acknowledged and overcome. Creating a shared understanding of the challenge and of terminology is essential, as is codesigning any solution together with people with lived experience.

Conclusions: Published data suggest that e-mental health is promising to reduce stigma and discrimination, with the potential to foster help-seeking and treatment engagement. Adoption requires attention to derailers and must foster inclusivity. There is an imperative to adopt e-mental health, especially evidence-based solutions.

Table 1. Systematic literature reviews

Randomized controlled trial of work-map: telehealth metacognitive intervention for work performance enhancement of adults with attention-deficit/hyperactivity disorder

N. Grinblat* and S. Rosenblum

Department of Occupational Therapy, Faculty of Social Welfare & Health Sciences, University of Haifa, Haifa, Israel

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1142

Introduction: The literature has emphasized the importance of implementing evidence-based occupational therapy teleinterventions to enhance work participation in adults with attention-deficit/hyperactivity disorder (ADHD).

Objectives: This study aimed to evaluate the efficacy of an innovative metacognitive self-tailored teleintervention for adults with ADHD performance at work enhancement (Work-MAP). The outcome measures were efficacy of and satisfaction with the performance of self-selected work goals (Canadian Occupational Performance Measure), executive functions (Behavior Rating Inventory of Executive Function-Adult), and quality of life (Adult ADHD Quality of Life Questionnaire).

Methods: In this randomized controlled trial, participants were 46 adults with ADHD. Group A ($n = 31$) received the synchronous, hybrid-telehealth intervention in 11 weekly 1-hour individual sessions, while Group B ($n = 15$) completed the same intervention after a waiting phase.

Results: Following the intervention, participants demonstrated and maintained significant improvements in all outcome measures (strong-to-moderate significant effects) to the 3-month follow-up.

Conclusions: Work-MAP seems to be effective intervention for enhancing work participation (i.e., performance at work), executive functions, and quality of life of adults with ADHD. Future studies with larger samples and additional objective measures are needed to further validate these findings.

Chatbots for Well-Being: Exploring the Impact of Artificial Intelligence on Mood Enhancement and Mental Health

R. M. Lopes*, A. F. Silva, A. C. A. Rodrigues and V. Melo

Psychiatry and Mental Health Department, Centro Hospitalar Médio Tejo, Tomar, Portugal

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1143

Introduction: Over the past few years, Psychiatry has undergone a significant transformation with the integration of Artificial Intelligence (AI). This shift has been driven by the increasing demand for mental health services, as well as advances in AI technology. AI analyzes extensive datasets, including text, voice, and behavioral data, aiding in mental health diagnosis and treatment. Consequently, a range of AI-based interventions has been developed, including chatbots, virtual therapists and apps featuring cognitive-behavioral therapy (CBT) modules. Notably, chatbots, as conversational agents, have emerged as valuable tools, assisting users in monitoring emotions and providing evidence-based resources, well-being support, psychoeducation and adaptive coping strategies.

Objectives: This study aims to investigate the impact of AI chatbots on improving mental health, evaluate their strengths and weaknesses and explore their potential for early detection and intervention in mental health issues.

Methods: A literature review was conducted through PubMed and Google Scholar databases, using keywords ‘artificial intelligence’, ‘chatbot’ and ‘mental health’. The selection focused on the most relevant articles published between January 2021 and September 2023.

Results: Mental health chatbots are highly personalized, with a primary focus on addressing issues such as depression or anxiety within specific clinical population groups. Through the integration of Natural Language Processing (NLP) techniques and rule-based AI algorithms, these chatbots closely simulate human interactions and effectively instruct users in therapeutic techniques. While chatbots integrating CBT principles have gained widespread use and extensive research attention, some also incorporate alternative therapeutic approaches, including dialectical behavior therapy, motivational interviewing, acceptance and commitment therapy, positive psychology or mindfulness-based stress reduction. AI chatbots provide substantial advantages in terms of accessibility, cost-effectiveness and improved access to mental health support services. Nonetheless, they also exhibit limitations, including the absence of human connection, limited expertise, potential for misdiagnosis, privacy concerns, risk of bias and limitations in risk assessment accuracy.

Conclusions: AI-based chatbots hold the potential to enhance patient outcomes by enabling early detection and intervention in mental health issues. However, their implementation in mental health should be approached with caution. Further studies are essential to thoroughly evaluate their effectiveness and safety.

EPV0439

Starting well to stay well - randomised controlled trial of Whitu, an app for improving the well-being of university students

H. Thabrew

Psychological Medicine, University of Auckland, Auckland, New Zealand

doi: 10.1192/j.eurpsy.2024.1144

Introduction: University students often face challenges to their well-being and up to a third develop mental health problems. Given high rates of smartphone use among this group, app-based digital mental health interventions may play a role in preventing these

problems. Previously demonstrated to improve well-being and mental health outcomes in young people aged 16-25, ‘Whitu: seven ways in seven days’ is a well-being app based on positive psychology, cognitive behaviour therapy (CBT) and psychoeducation principles.

Objectives: This randomised controlled trial was undertaken to evaluate the efficacy, usability and acceptability of Whitu with first year university students.

Methods: Ninety first year university students were recruited via a social media advertising campaign to take part in a prospective randomised controlled trial of Whitu against a standard university self-help website, with 45 participants in each arm. Primary outcomes were changes in well-being on the World Health Organisation 5-item well-being index (WHO-5) and short Warwick-Edinburgh mental well-being scale (SWEMWBS). Secondary outcomes were changes in depression on the Centre for Epidemiological Studies Depression Scale (CES-D), anxiety on the Generalised Anxiety Disorder seven item scale (GAD-7), self-compassion on the Self Compassion Scale- Short Form (SCS-SF), stress on the 10-item Perceived Stress Scale (PSS-10), sleep on the single-item Sleep Quality Scale (SQS), and self-reported acceptability of the app. Outcomes were evaluated at baseline, four weeks (primary study endpoint) and three months.

Results: At 4 weeks, participants in the intervention group experienced significantly higher mental well-being and significantly lower depression compared to controls. Emotional well-being among the Whitu group was greater in the intervention group at 3 months. Other outcomes did not differ between groups. User feedback was positive, with 88% of those who provided feedback saying they would recommend the app to a friend.

Conclusions: Our findings provide preliminary evidence that Whitu is an acceptable and more effective, scalable and multi-modal means of improving some aspects of well-being and mental health among university students than direction to a self-help website.

⁵Centralny Ośrodek Badań i Karier, Naczelna Izba Lekarska, Warsaw, Poland

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1145

Introduction: Increasing popularity of Generative AI systems such as GPT provides us with new dilemmas concerning the future of diagnosis and novel tools to improve daily psychiatrists’s work.

Objectives: The aim of the study was to assess the abilities of generative AI to diagnose and propose treatment in comparison with real psychiatrists and performing a Turing test.

Methods: We examined the ability to diagnose and propose treatment of various Generative AI versions (CHatGPT/CHATGPTpro etc.) and then compare the results with 10 clinicians performing the same task. Then a group of 10 psychiatry specialists not involved in the first evaluation assessed whether the diagnosis and treatment were established by Generative AI or a clinician.

Results: The results showed that the generative AI systems were able to provide valid diagnosis in most of the cases with favour to newer and most proficient version of CHATGPT. Proposed treatment results were less accurate. The comparison between human and AI group was hard to accurately assess, with tendency to favouring psychiatrists group assessment as the right decision. There is huge need to further explore the possibilities and limitations of Generative AI use in psychiatry.

Conclusions: There is huge need to further explore the possibilities and limitations of Generative AI use in psychiatry.

Evaluation of an App-based brief Cognitive Behavioral Therapy for individuals with Nonsuicidal Self-injury

S. Kang*, S. M. Zoh and J.-W. Hur

Department of Psychology, Korea University, Seoul, Korea, Republic Of

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1146

Introduction: Nonsuicidal self-injury (NSSI), the deliberate and direct destruction of one's own body tissue without suicidal intent, has represented a significant public health concern among adolescents and young adults worldwide, yet they have limited access to evidence-based interventions. App-based digital therapy, with its advantages of high cost-effectiveness, accessibility, and user receptivity, could be an effective intervention for NSSI. We expected that the use of an app-based brief cognitive-behavioral therapy (CBT) would improve depressive symptoms and emotion dysregulation, the most prevalent symptoms among individuals with NSSI.

Objectives: This study aimed to evaluate the efficacy of a 3-week app-based brief CBT program focusing on cognitive distortion correction for individuals with NSSI.

Methods: A total of 34 participants who engaged in NSSI were included in the final analysis, with 18 individuals assigned to the 'app group' and 16 to the 'waitlist group.' The brief CBT program consisted of three quizzes designed to prompt the users to identify cognitive distortions embedded in a series of short scenarios, develop more realistic perspectives, and imagine advising to significant others. The app group was instructed to complete three quizzes per day for three weeks, while the waitlist group received no intervention.

Results: Baseline and follow-up assessments of depression and emotion regulation were conducted. After the 3-week program, the app group showed a significant reduction in depressive symptoms ($F = 8.30$, $P = .007$) compared to the waitlist group. There was no group difference regarding emotion regulation.

Conclusions: Depression is a prominent symptom in individuals with NSSI. Our findings suggest that an app-based brief CBT

intervention targeting cognitive distortions can effectively alleviate depression in individuals with NSSI. The results also highlight the need for digital interventions that are tailored and designed to improve emotion regulation in this population.

Mitigating Psychological Symptoms in Public Safety Personnel Through Supportive Text Messaging Program

G. Obuobi-Donkor^{1*}, R. Shalaby², E. Eboreime¹, B. Agyapong², R. D. L. Dias¹ and V. Agyapong^{1,2}

¹Department of Psychiatry, Dalhousie University, Halifax and

²Department of Psychiatry, University of Alberta, Edmonton, Canada

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1147

Introduction: Public safety personnel (PSPs) often suffer from mental health issues due to the challenging and intricate nature of their work. Various barriers may prevent them from seeking necessary support and treatment. Therefore, implementing innovative and cost-effective interventions can potentially enhance the mental well-being of PSPs.

Objectives: The study sought to assess the influence of the Text4PTSI program on symptoms of depression, anxiety, trauma, and stress, as well as the resilience of public safety personnel after six months of receiving supportive text message intervention.

Methods: PSP subscribed to the Text4PTSI program and received daily supportive 1 SMS text messages for six months. Participants were invited to complete standardized self-rated web-based questionnaires to assess depression, anxiety, posttraumatic stress disorder (PTSD), and resilience symptoms measured on the Patient Health Questionnaire-9 (PHQ-9), Generalized Anxiety Disorder-7 scale (GAD-7), Posttraumatic Stress Disorder Checklist-Civilian Version (PCL-C), and the Brief Resilience Scale (BRS), respectively. The assessment of mental health conditions was conducted at enrolment, six weeks, three months, and six months after enrollment.

Results: One hundred and thirty-one subscribers participated in the Text4PTSI program. A total of 31 participants completed the baseline survey, and 107 total surveys were recorded at all follow-up time points. The baseline prevalence of likely major depressive disorder (MDD) was 47.1%, likely generalized anxiety disorder (GAD) was 37.5%, low resilience was 22.2%, and likely PTSD was 13.3%. At six months post-intervention, the prevalence of psychological conditions. There was a decrease in the mean scores on the PHQ-9, GAD-7, PCL-C, and the BRS from baseline to post-intervention by 25.8%, 24.7%, 9.5%, and 0.3%, respectively. However, the decrease was only statistically significant for the mean change in GAD-7 scores with a low effect size ($t(15) = 2.73$, $p = 0.02$).

Conclusions: The results of this study suggest a reduction in the prevalence of likely MDD as well as the severity of anxiety symptoms from baseline to post-intervention for subscribers of the Text4PTSI program. The program has the potential to complement existing services, aiding in mental health support for public safety personnel.

Hindering and facilitating factors in the implementation of digital mental health interventions within community settingsK. Turmaine^{1*} and K. Chevreul^{1,2}¹ECEVE1123, Inserm/Université de Paris Cité and ²ECEVE1123, URC Robert Debré, Paris, France

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1148

Introduction: The digitalisation of the society has made inevitable the development and use of digital health. In mental health care, the use of digital tools has been questioned, although their capacity to improve accessibility to evidence-based information and tackle stigma has been recognised. The paradox of these virtual tools is that they need to rely on local resources to get used and disseminated.

Objectives: To identify the factors from the context that could help or hinder the set-up of an effective intervention in digital mental health.

Methods: Between 2018 and 2020, a digital mental health intervention, based on the promotion of StopBlues, a digital tool targeting psychic distress and suicide in the adult general population, was conducted in 32 willing French localities. In each of the latter, a focal person was designated among the officials to organise the promotion locally and liaise with the research team. Employing interviews and observations, we identified the factors from the context that were favouring or hindering the intervention.

Results: The qualitative approach unveiled the existing dynamics between local stakeholders and difficulties faced by the focal persons. It appeared that the political context particularly influenced the outcome of the intervention. In parallel, the endorsement by local hospitals and psychiatrists was equally crucial confirming the key role they play when they champion a cause at the forefront.

Conclusions: Real-world evaluations using both qualitative and quantitative methods of digital mental health interventions have to be implemented in order to understand how they can help people. If these interventions are in line with the 1986 Ottawa Charter in terms of patient empowerment, they still need to be supported by local stakeholders, both at the political and medical levels.

Workplace mental health resilience: usability and impact study of a mental health coping mobile app on a corporate settingR. Maçorano^{1*}, F. Canais¹, M. Ribas², M. Parreira³ and H. A. Ferreira¹¹Neurosciences, Faculty of Sciences of the University of Lisbon, Lisbon;²Psychology and ³Neuropsychology, NeuroGime, Braga, Portugal

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1149

Introduction: Mental health resilience is crucial to professional wellbeing and productivity, being that 57% of company employees are reporting burnout. Additionally, early-stage preventive mental

health interventions are not common, and typically employees only have access to mid-stage professional care.

Objectives: The aim of this project is to provide employees with a preventive self-coping tool, enabling open and inclusive care. Specifically, the aim is to assess the receptivity, usability and impact of the usage of a mobile app that provides coping strategies based on positive psychology and a burnout-risk screening.

Methods: A mobile app was used with the purpose of being accessible to everyone, independently of their financial capacity. The app also promotes inclusiveness, by aggregating several approaches and methods for mental health coping, which are recommended given the needs of each user. The app was released to a large Portuguese company with 700 employees, in which employees could download it voluntarily.

Results: After 7 months, the results showed 37% receptivity rate, 24% improvement on anxiety levels, 36% improvement on workplace wellbeing, 23% increase on mental health self-coping skills, and 21% improvement on burnout-risk levels. These metrics were acquired via app's back-end, self-reporting, and our model for burnout-risk screening.

Conclusions: First results showcase the positive impact of adding such a mobile solution to the employees' mental healthcare. Next steps will be conducting a longer study, adding control groups and productivity assessment.

EPV0446

Investigating LSA - a 'legal high' analogue to LSD, frequently used in the digital realm with relatively unknown effects

P. Castro* and J. Maia

FMABC, Santo André, Brazil

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1150

Introduction: Psychedelics are substances consumed for recreational use, the majority of these psychoactive substances are illegal and hard to obtain. Therefore, there is a demand for psychedelics legal and easier to access, these types of drugs are called 'legal highs'. LSA (lysergic acid amide) is one of these new psychoactive substances, this drug is searched because it is known to have an effect similar to LSD. LSA has negative effects on body functioning not fully understood by the medical field.

Objectives: This project aims to conduct a systematic review of the scientific health literature on LSA.

Methods: The following information was included in this review: articles reporting original data on physical effects, neurobiological effects, various bodily symptoms, social and cultural aspects in humans related to LSA, published in English, Portuguese, Spanish, Italian, and French. Studies involving animals, in vitro research, botanical studies, and non-original research were excluded. The following keywords were searched in the PubMed, Google Scholar, and Web of Science databases: (ergine or d-lysergic acid amide or LSA or d-lysergamide or lysergic acid amide). This study followed the PRISMA statement for systematic reviews and PRISMA checklist. The resulting data were tabulated and analyzed according to relevance.

Results: LSA, also known as ergine, is an ergot alkaloid with a chemical formula very similar to LSD. Ergine is found in plants of the Convolvulaceae family and is primarily consumed through chewing the seeds of these plants, soaking them in alcohol, or preparing an extract. The amount of LSA in each seed is inconsistent, making it unpredictable how much will be consumed, and these seeds may contain other harmful compounds.

LSA is a partial agonist and antagonist of serotonergic receptors, with a preference for 5-HT_{1A} and 5-HT₂, and stimulation of D₂ is related to nausea. It can cause symptoms including euphoria, hallucinations, anxiety, nausea, weakness, fatigue, tremors, and elevated blood pressure. In some cases, the use of LSA is associated with the use of other drugs, and there are case reports of LSA-induced PRES (Posterior Reversible Encephalopathy Syndrome), post-use suicides and the need for hospitalization due to psychosis-like states.

Studies conducted on the quality of information about LSA on digital platforms indicate misinformation with incorrect data that can be harmful to those who ingest the drug. Additionally, there are studies suggesting that LSA may improve symptoms of cluster headaches.

Conclusions: LSA is a legal drug in most countries, with widespread misinformation on the internet and limited control over its use. There are potential serious adverse effects caused by the drug, and it is often associated with other psychoactive substances. Greater knowledge about the drug is needed for diagnosing its use and abuse, as well as for educating the public.

Psychological intervention online for adolescent: acceptability of Online Emotional Self-Regulation Improvement program

C. López Soler^{1*}, A. Martínez¹, V. Fernandez², M. Castro³ and J. L. Vicente¹

¹Personality, Assessment and psychological treatment; ²Medical Psychology and ³Evolutionary and Educational Psychology, University of Murcia, Murcia, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1151

Introduction: Given that child and adolescent mental health has been affected by several factors in recent years, such as the distance between home and specialized centers that provide psychological care to children, the lack of care resources, or the lockdown caused by the COVID-19 pandemic, online psychological treatments are becoming increasingly common among the child and adolescent population, although it is necessary to develop this type of treatment for children at psychosocial risk, since these have been developed mostly for the general population. To this aim, the Online Emotional Self-Regulation Improvement program (Mejora de la Auto-regulación para Menores, Online MAM@) was developed.

Objectives: To assess the acceptability of the Online Emotional Self-Regulation Improvement program, by the adolescent.

Methods: The intervention program was applied to a total of n = 32 children (n = 17 girls) between 11 and 15 years of age. The program consists of 7 target emotions to be worked on, and the acceptance, usability, usefulness, enjoyment of each module and

barriers to use by the children were assessed with an adaptation of the Venkatesh and Davis scale. These measures were taken post-test, once the intervention module was completed. The program was applied online for five weeks by the children, and their regular therapists contacted them to provide them with weekly access codes and reminders in case they were not completing the modules.

Results: It was observed that the best rated module was the anger module, the most useful module was the sadness module, the module considered to have the highest usability was the fear module, and the most enjoyed module was the sadness module, although all the modules had very high scores above the average and no significant differences were found in the rating of the modules between sexes. As for the most common barriers to use among the children, problems were found with the completion of the intervention, since they often forgot to access the web, and these did not apply what they had learned outside the intervention program.

Conclusions: The Online Emotional Self-Regulation Improvement program is the first program developed in Spanish language for adolescents at psychosocial risk, and may represent a breakthrough to consolidate these programs in the national scene and bring the therapeutic possibilities for adolescents to the same level as in other parts of the world. Focusing on future versions of the program, it would be advisable to reduce its length and incorporate activities outside the treatment program to guarantee a generalization of what is learned in the intervention program in everyday life situations.

A study of the personality trait-focused digital mental health intervention

S. Jeong¹, H. Kim¹, S. K. Lho², S. Mun², I. Hwang², S. Kim², H. Lim², H. Kim¹, W. Moon² and M.-S. Shin^{1,3*}

¹Psychiatry, Seoul National University Hospital; ²40FY inc and ³Seoul National University College of Medicine, Seoul, Korea, Republic Of

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1152

Introduction: Mental healthcare services that address a variety of primary complaints which are highly related to maladaptive personality traits among the general population are important to prevent developing psychiatric disorders.

Objectives: This study aimed to examine the effectiveness of a digital mental health service (named "Mindling") that focuses on maladaptive personality traits in the general population.

Methods: Participants were recruited through a South Korean community website and screened for adults between the ages of 18 and 60 in terms of personality traits such as perfectionism, low self-esteem, social isolation, or anxiety. Participants were allocated to four intervention programs (Riggy, Pleaser, Shelly, and Jumpy) based on their screening results and were randomly assigned to digital treatment and waitlist groups. Each intervention program was conducted online for 10 weeks. The primary outcomes were all measured by self-report questionnaires; in addition to stress levels, each program included measures of perfectionism (Riggy), low self-esteem (Pleaser), loneliness (Shelly), and anxiety (Jumpy). The secondary outcomes included self-efficacy, depression, and other

psychological states. All participants completed pre-treatment (baseline), intervention (week 5), and post-treatment (week 10) assessments, and the treatment group completed a separate follow-up assessment (week 14).

Results: In the treatment group, 70.05% of the participants completed the full course of the digital intervention. The mean scores for each primary outcome measure and some secondary outcome measures were significantly different between baseline and post-treatment in the treatment group for the Total, Riggy, Pleaser, Shelly, and Jumpy programs, but these differences were not observed in the waitlist group. In addition, mean differences between the treatment and waitlist groups at post-treatment assessment were significant for all primary outcome measures and some secondary outcome measures. Specifically, the levels of stress (Total program), perfectionism (Riggy), loneliness (Shelly), and anxiety (Jumpy) were significantly lower in the treatment group, while self-esteem (Pleaser) was higher. In addition, the mean differences between post-treatment and follow-up assessment data were not statistically significant for all primary outcome measures and nearly all secondary outcome measures.

Conclusions: This study validated the effectiveness of the digital intervention program targeting maladaptive personality traits and suggested its sustainable effects.

Eating disorder and bipolar mental illness through genome wide association studies

B. Abdelmoula*, R. Rhaïem, A. Charfi, S. Kotti, I. Masmoudi, Y. Marsaoui and N. Bouayed Abdelmoula

Genomics of Signalopathies at the service of Precision Medicine - LR23ES07, Medical University of Sfax, Sfax, Tunisia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1153

Introduction: Besides the role played by environmental factors and their epigenetic influences, scientific researchers showed that the susceptibility to develop an eating disorder among bipolar people is due to genetic factors.

Objectives: To review the genetic factors behind eating disorders, highlight the role of genetics and epigenetics in the comorbidity of bipolar and eating disorders.

Methods: To delineate the role of genetics and epigenetics in eating disorders and bipolar disorders as two related mental illness, we comprehensively reviewed the scientific literature using GWAS (genome wide association studies) catalog databases to find genome-wide association studies carried out on patients with bipolar disorder EFO_0005203 and eating disorder comorbid condition (anorexia nervosa, binge eating, bulimia nervosa) EFO_0005203.

Results: GWAS of eating disorders were found in 33 studies with 324 associations whereas those of bipolar disorder were found in 114 studies with 1469 associations. GWAS of eating disorders

within bipolar disorders revealed 182 and 134 associations, as well as 10 and 8 publications respectively. Only anorexia nervosa and binge eating were studied in association with bipolar disorders. The genetic variants were protein coding genes (CUBN, FAM228B, FXR1, etc.), non-coding RNA genes (SOX2-OT, MMADHC-DT, etc.), and pseudo-genes (RNU1-23P, CACYBPP2, etc.).

Conclusions: About 300 genetic variants are associated with eating disorder as a comorbid condition of bipolar disorders. These variants may play a crucial role in the causes and mechanisms of eating disorders and should be more investigated towards more precise clinical and genetic entities.

EPV0454

Schizophrenia and eating disorders: Epidemiological and clinical characteristics

E. Herelli, M. Lagha, F. Askri*, I. Ben Romdhane, H. Wided and R. Labbane

PSYCHIATRY C, RAZI HOSPITAL, MANOUBA, Tunisia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1154

Introduction: Schizophrenia is a common mental illness with a wide range of symptoms.

Given the high metabolic comorbidity observed in schizophrenia and the metabolic side-effects induced by the antipsychotics used in practice, the detection of eating disorders is crucial.

These disorders may occur at the same time as psychotic symptoms or independently of them.

Objectives: we aim to provide an overview of eating disorders in schizophrenia.

Methods: We conducted a systematic search using the 2 bibliographic databases PubMed and Google scholar including the following keywords: "Schizophrenia", "Eating disorders", "Reward mechanisms".

Results: Eating disorders are a frequent comorbidity in schizophrenia.

Authors have reported that some patients with schizophrenia have an increased appetite and craving for fatty foods, increased caloric intake and frequency of consumption, which may be associated with increased disinhibition.

According to the literature, binge eating and night eating are frequently observed in patients with schizophrenia, with a prevalence of around 10%.

Studies have shown that people suffering from psychosis and treated with antipsychotics have high rates of binge eating, ranging from 4.4% to 16% for binge eating and from 8.9% to 45% for binge eating symptoms (without reaching the diagnostic threshold for binge eating).

Rates ranging from 16.1% to 64% for cravings were reported.

Anorexia nervosa appears to affect between 1% and 4% of schizophrenic patients.

Conclusions: Despite their frequent association with schizophrenia, eating disorders remain little studied. However, it is important to detect these disorders and elucidate the underlying psychopathological and neurobiological mechanisms in order to

better manage metabolic comorbidity and improve patients' quality of life.

Psychological understanding of Anorexia nervosa gained from combined clinical care

H. Szilárd¹, X. Gonda¹, Á. Menus¹, J. Bognár², D. Pólya^{3*}, J. Biliczki⁴, Z. Bana⁵, Z. Nemoda⁶ and J. Réthelyi¹

¹Psychiatry and Psychotherapy; ²Pediatrics Clinic no.1.; ³Faculty of Medicine, Semmelweis University; ⁴Psychiatry, Peterfy Hospital; ⁵Clinical Psychology and ⁶Molecular Biology, Semmelweis University, Budapest, Hungary

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1155

Introduction: Anorexia nervosa (AN) is a debilitating illness with rapidly increasing incidence. The longer it lasts the more difficult is to cure. Although in the majority of the cases the main treatment is psychotherapy severe cases require inpatient admission for life saving support. The presentation expounds the combined therapeutic approach that anorexia nervosa patients of Semmelweis University Psychiatry and Psychotherapy Department provided with. Currently the backbone of psychotherapy for AN is cognitive behavioral therapy (CBT), schema therapy and katathym imaginative psychotherapy (KIP) combined with psychodrama.

Objectives: One of the aims of our research is to identify the most relevant focus of psychotherapy by identification of specific personality traits in patients with AN, who will be compared with healthy controls. Furthermore, two subgroups of patients will be compared with each other: the milder version of AN (BMI above 16) with the more severe form of AN who are required inpatient admission.

Methods: Women with AN (age:18-45) have been compared to age-matched controls on MINI and SCID-5-AMPD interview variables and on the scales of online questionnaires, such as EDI-I, MZQ, DIS-Q, SCL-90, PHQ-9, STAI, CTQ and YPI.

Results: Clinical care highlighted important underlying psychological causes such as inadequate mirroring, absence of the father, or on the contrary, overly intimate relationship with the father, and relentless inner voice as a consequence of unintegrated inner aspects. The SCID-5-AMPD pointed out affected areas of personality such as Identity, Self-directedness, Negative affectivity, Intimacy, Alienation. Importantly, neither trauma scales (measured by CTQ), nor dissociation (measured by DIS-Q) differed significantly between patients and healthy controls.

Conclusions: Planning psychotherapy could benefit from the identified foci. Anti-depressive medication must be considered in order to improve outcome of inpatient admission. The CTQ probably does not measure the subtle but chronic inadequacy of attachment and mirroring that apparently are typical in AN. The reliable identification of the typical dissociative inner voice that often seen in anorexia nervosa may need another questionnaire apart from DIS-Q.

The research is supported by bilateral science and technology (S&T) cooperation project 2019-2.1.11-TÉT-2020-00242

Anorexia nervosa and hyperphagic episodes : About five clinical cases

I. Belabbes

hospital arazi, sale, Morocco

doi: 10.1192/j.eurpsy.2024.1156

Introduction: Eating disorders affect almost one million people in France. More than half of them have not been screened for the disorder, and are still unable to access treatment!

Objectives: To shed light on the clinical characteristics and management of patients with eating disorders

Methods: We report on a series of clinical situations involving patients presenting with binge eating disorder at the adolescent unit of the Gonesse hospital.

Results: Our sample included 5 patients, all female, aged between 13 and 16 years. They presented with anorexia nervosa with or without hyperphagia. Comorbidities included depression, anxiety disorders, chronic illness and suicidality.

In some cases, treatment is based on re-feeding via a nasogastric tube. In others, behavioral treatment was sufficient. Pharmacological treatment for comorbidities was prescribed.

Conclusions: Untreated eating disorders can be a source of deterioration in patients' quality of life and high mortality. Early detection and diagnosis is essential for better patient management.

Eating disorders: the increase in requests for help and the optimization of resources

M. Campana¹, M. Colombi^{2*}, P. Milanese¹, A. Greco² and C. Mucci²

¹department of mental health and addictions, ASST Bergamo Est, Seriate and ²Department of Human and Social Sciences, University of Bergamo, Bergamo, Italy

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1157

Introduction: This work aims to provide an updated overview of the eating disorders (EDs) which are a widespread pathology nowadays. Informations related to the clinical-nosographic characteristics, an in-depth analysis about systemic-relational theories and historical evolution are provided. In addition, current informations about epidemiological data, recovery, treatment related implications, new neuroscientific theories and risk factors are shown. Given the complexity of these disorders, the lack of resources and the increasing demands for treatment, the main object is related to the construction of a questionnaire to manage the waiting lists.

Objectives: Building a waiting list management model for EDs, Study and compare advantages and disadvantages of the source allocation ethical models (utilitarianism, prioritarianism, egalitarianism). Analyze EDs leading experts (doctors, dietitians, psychologists, psychiatrists) and EDs patients positioning with respect to

priority treatment factors. Promote constructive dialog between EDs experts from different backgrounds and EDs patients.

Methods: In order to know the various treatment alternatives available, the different levels and reference structures are illustrated. In addition, it is also suggested different reasoning based on the ethical models of egalitarianism, utilitarianism and prioritarianism in order to build a waiting list management model, which is the maximum goal of this work. This model needs to be supported by a series of validated tools such as the clinical interview and self-administered questionnaires to investigate psychopathological aspects and psychiatric symptoms. Going into more details, a questionnaire is proposed to the EDs leading experts, so that they can provide their own priority factors list and related thoughts in order to build “the most ethical” waiting list.

Results: It is expected that both patients and clinicians tend to give priority to patients with greater psychophysical severity, not exclusively on the basis of physical parameters. Further hypothesis related to clinicians lead us believe that they tend to use utilitarian logics, in compliance with the demonstrated efficacy of early intervention. An evaluation that could lead to a disagreement between experts and patients is related to prioritize patients in the initial phase of the disease, which could be supported by clinicians, but not by patients, probably in connection with their personal experiences. In fact, this favoritism could have a negative impact on the care of the most serious cases who risk to be left to themselves.

Conclusions: This work aims to encourage a constructive dialogue between experts and patients with EDs in order to build a functional intervention model which should be “the most ethical as possible” in order to save the greatest number of lives in respect of mental suffering.

In People who Identify as Gender Minority People the Social Cure Model and in People who Identify as LGBTQ* People the Intragroup Status and Health Model might Explain the Link between Identity Centrality and Body Appreciation

N. Komlenac*, K. Stockburger, J. Birke and M. Hochleitner
Gender Medicine and Diversity Unit, Medical University of Innsbruck, Innsbruck, Austria

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1158

Introduction: Sexual and gender minority (SGM) people are often found to have lower levels of body appreciation than do cis-heteronormative people.

Objectives: The current study utilizes the social cure model and the intragroup status and health model to investigate whether identification with a SGM social group and identity centrality (i.e., the degree to which a specific social identity is important to an individual) is linked to experiences of hostile behaviors because of a person's looks or body and consequently, to body appreciation.

Methods: A cross-sectional online-questionnaire study was conducted with 1,680 German-speaking participants (49.2% cisgender women, 37.7% cisgender men, 9.0% non-binary, 4.1% transgender; $M_{age} = 32.7$, $SD = 12.5$). The Multidimensional and Multicomponent

Measure of Social Identification, the Body Appreciation Scale-2, the Perceived Stigmatization Questionnaire and the Sociocultural Attitudes Towards Appearance Questionnaire-4, revised were used. A manifest path model was calculated.

Results: People who identified as gender minority (GM) people and LGBTQ* people reported lower levels of body appreciation. Sexual minority (SM) individuals who identified with a social group other than LGBTQ* people reported levels of body appreciation similar to those of individuals who identified as women. Individuals who identified as GM people experienced fewer instances of hostile behaviors because of their looks or body the higher their level of identity centrality was. On the other hand, individuals who identified as LGBTQ* people more frequently encountered hostile behaviors because of their looks or body when their identity centrality was strong. Frequent experiences of hostile behaviors because of a person's looks or body was linked to poor body appreciation in all social groups.

Conclusions: Identity centrality might help alleviate experiences of discrimination, especially in people who identify as GM people, as the social cure model suggests. In line with the intragroup status and health model, individuals who strongly identify as LGBTQ* people might be more visible as SM people and experience more discrimination than do SM people who identify with another social group.

Avoidant Restrictive Food Intake Disorder in a 28 year old man: a case report

P. Setién Preciados*, E. Arroyo Sánchez and C. Díaz Mayoral

Servicio de Psiquiatría, Hospital Universitario Príncipe de Asturias, Alcalá de Henares, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1159

Introduction: Avoidant Restrictive Food Intake Disorder is a disorder included among the eating disorders criteria group. Prevalence and incidence rates of ARFID in the general population remain largely unknown. Despite ongoing variability in the interpretation of diagnostic criteria in clinical practice, good progress has been made regarding recognition and assessment of ARFID. Different approaches to treatment are currently being explored, with reported outcomes for ARFID vary, consistent with the heterogeneity of the disorder. At present, there is insufficient evidence to determine the likely course and prognosis.

Objectives: Review what avoidant restrictive food intake disorder consists of, the challenges it presents, as well as its prognosis and potential treatments.

Methods: Presentation of a patient's case and review of existing literature, in regards to ARFID.

Results: The patient in question is not clear he can be diagnosed of avoidant restrictive food intake disorder given his OCD symptoms, which are intertwined. That said, he does not have body dysmorphic phobia and does check for all the ARFID criteria. Their prognosis is not good, having failed several psychological and pharmacological treatments.

In literature, there is not much evidence around the disease because of its novelty, being recently included in the DSM 5 as a new class of

eating disorders (EDs), not finding high quality studies (meta analysis, systematic review). ARFID is characterised by a lack of interest in eating or avoiding specific types of foods because of their sensory characteristics. This avoidance results in decreased nutritional intake, eventually causing nutritional deficiencies. In severe cases, ARFID can lead to dependence on oral nutritional supplements, which interferes with psychosocial functioning. The prevalence of ARFID can be as high as 3% in the general population, and it is often associated with gastrointestinal symptom. Given the high prevalence of ARFID, a rapid and systematic nutrition survey should be conducted during every consultation. Its treatment should also be adapted depending on the severity of the nutritional problem and may involve hospitalisation with multidisciplinary care (paediatrician, nutritional therapist, dietitian, psychologists, and speech therapists).

In regards to potential treatments, there is no evidence-based psychological treatment suitable for all forms of ARFID at this time. Several groups are currently evaluating the efficacy of new psychological treatments for ARFID, particularly, family-based and cognitive-behavioural approaches, but results have not yet been published.

Conclusions: Future directions for research could be usefully informed by closer collaboration with other fields, including feeding disorders, emotion processing and regulation, neurodevelopment, and appetite.

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1160

Introduction: Aggressive behaviors have been reported to be more frequent in people with eating disorders (ED), especially bulimia nervosa (BN). Network Analysis (NA) is particularly useful for examining the interactions among symptoms of comorbid conditions through the identification of "bridge symptoms," defined as those symptoms playing a key role in the connection between two syndromic clusters.

Objectives: The aim of the present study was to investigate the association of ED core symptoms and ED-related psychopathology with aggressiveness in a clinical sample of women with BN through NA.

Methods: A NA was conducted, including ED symptoms and aggressiveness measures. The bridge function was implied to identify symptoms bridging ED symptoms and aggressiveness.

Results: The most connected nodes among communities were asceticism and impulsivity from ED-related psychopathology, drive for thinness from ED- core psychopathology and guilt and suspicion from aggressiveness domain. In particular, drive for thinness

connected ED-core community to verbal hostility, while impulsivity connected ED-related symptoms to guilt and suspicion of aggressiveness community.

Conclusions: In conclusion the present study showed that in people with BN guilt is the specific negative emotion of the hostile dimensions that may be bidirectionally associated with ED symptoms.

Emotional non-acceptance mediates the relationship between insecure attachment and specific psychopathology in women with eating disorders

S. Donato^{1*}, N. Attianese¹, M. Battipaglia¹, R. Ceres¹, R. Cerra¹, A. M. Monteleone¹, P. Monteleone² and G. Cascino²

¹University of Campania "L. Vanvitelli", Naples and ²University of Salerno, Salerno, Italy

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1161

Introduction: Insecure attachment is considered a general risk factor for eating disorders (ED). Emotion dysregulation has been proposed as one of the possible mechanisms by which attachment insecurity may affect ED psychopathology.

Objectives: Aim of the present study was to investigate whether difficulties in acceptance of emotions or emotional clarity may mediate the connection between insecure attachment and ED psychopathology.

Methods: One hundred and twenty patients participated and completed the Italian version of Eating Disorder Inventory-2 (EDI-2), Experience in Close Relationship questionnaire (ECR) and Difficulties in Emotion Regulation Scale (DERS). A mediator path model was performed, in which insecure attachment dimensions were set as independent variables, ED specific psychopathology measures as dependent variables, and non-acceptance of emotion and lack of emotional clarity as mediators.

Results: The association between both attachment avoidance and anxiety and ED specific symptoms was mediated by emotional non-acceptance, but not by emotional clarity.

Conclusions: This study showed the importance to address emotion regulation in individuals with ED, focussing on improving emotional acceptance. Exploring early developmental processes which lead to non-acceptance of emotions could improve this psychological trait in people with ED.

Addiction Transfer Post Bariatric Surgery- A Case Report

S. Haugh^{1*}, H. Belay¹ and P. Cromwell²

¹Department of Psychiatry, Connolly Hospital and ²National Bariatric Unit Ireland, St Vincents University Hospital, Dublin, Ireland

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1162

Introduction: Bariatric surgery is an effective treatment for patients with obesity. Rates of obesity are increasing worldwide as are the number of bariatric procedures performed. Following bariatric surgery patients have increased contact with psychiatric services, there is an increased risk of deliberate self-harm, suicide attempts and completed suicide. Compared to the general population there is 8 fold higher than average suicide rate. In Ireland wait lists for bariatric surgery are long, resulting in many patients seeking surgery abroad. Bariatric ‘tourism’ often results in reduced psychological supports both pre and post op as well as reduced pre surgical screening for psychiatric illness. Bariatric surgery is also associated with ‘addiction transfer’. The literature suggests that patients often substitute the maladaptive coping mechanism of eating with other impulsive behaviors such as substance misuse or gambling.

Objectives: Case report highlighting the issue of addiction transfer among patients that have undergone bariatric surgery.

Methods: Case report: A 38 year old woman admitted to the acute psychiatric unit with self harm, suicidal ideation, low mood, and recent overdose of venlafaxine. On initial presentation, she was intoxicated with alcohol, her toxicology was positive for cocaine and benzodiazepines. She had undergone a gastric bypass 14 months previous, having travelled abroad to have the procedure. She had not attended for any bariatric follow up with her GP post operatively. She was not taking any vitamins post operatively despite advice from the clinic. The patient was admitted to the acute psychiatric unit. She admitted to drinking excessively in the last year. She denied any history of mood disturbance or substance or alcohol misuse prior to surgery. She had no previous contacts with psychiatric services. Her GP had commenced her on venlafaxine for low mood 6 months prior to psychiatric admission. She was admitted to the acute unit for 5 days after which she left against medical advice. She was followed up in the day hospital and referred to addiction services.

Results: case report

Conclusions: There is growing evidence about the psychiatric and addiction implications of bariatric surgery. Offering psychological support for patients post operatively is essential. Unfortunately, because of long wait lists in Ireland many patients chose to travel abroad and often are unable to avail of MDT support. The emerging field of bariatric psychiatry could provide a useful addition to the bariatric specialist services.

The role of gender in the prevalence of eating disorders

G. Strada Herrera*, I. López Claramunt,
B. Serván Rendón-Luna and L. M. Sanz Martín

Instituto de Psiquiatría y Salud Mental, Hospital Clínico San Carlos, Madrid, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1163

Introduction: Eating disorders have a key paper at the ongoing society. A key symptom of the Anorexia Nervosa and the Bulimia Nervosa is the alteration of the corporal image which observes that

it continues being present after remitting the most flowery symptomatology. In terms of gender, we can observe that the eating disorders have a higher incidence in the feminine gender.

Objectives: Research how body image affects eating disorders and how the role of gender is a risk factor for developing Anorexia Nervosa or Bulimia Nervosa.

Methods: A systematic review was conducted using PubMed. Twelve studies were identified in order to do this review.

Results: At the twelve surveys included at the review we can observe that the incidence of Anorexia Nervosa and Bulimia Nervosa is higher in women than men. There are many facts that take part on the development of eating disorders, but there is consensus to understand them with a biopsicosocial point of view (interaction between the environment and biological facts). Body image disturbance takes part in both men and women, but it affects them in different ways.

Conclusions: Body image disturbances are a crucial factor when considering eating disorders' symptomatology. One of the main components that affects its alteration is the internalization of standards of beauty. Women tend to focus on thin body types, meanwhile men's attention tends to point to muscular and defined body types. Nevertheless, it must be taken into account that today's gender conception may appear as one of the most important roles to understand Anorexia and Bulimia aetiology. Regarding gender, in nowadays society exists a dichotomy where masculinity and femininity lie in total opposites poles; but if the gender approach socially changed, Anorexia and Bulimia might take a different portrayal.

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1164

Introduction: Psychotic experiences (PE) and disordered eating (DE) are frequently observed among the general population, especially in childhood and adolescence. However, the relationship between the two groups of disorders is still unclear.

Objectives: To explore the hypothesis that the pathways from PEs to DE are mediated by body-image disturbances in a sample of adolescents

Methods: We conducted a 12-month longitudinal study on high school students from four different high schools from the Ariana governorate, from April 2022 to April 2023.

Participants were evaluated at baseline then every 6 months with a target length of follow-up of 1 year.

The questionnaire contained

Questions about socio demographic variables

The Eating Attitude Test (EAT-26)

The Multidimensionnal Body Self-Relations Questionnaire Appearance Scale (MBSRQ-AS)

The Community Assessment of Psychic Experiences (CAPE-42)

Results: 1) Sample characteristics

Sample was constituted of 510 individuals. Of those, 312 (61.2%) were females. Mean age was of 16.05 (SD=1.01) years.

The majority of the students resided in urban areas, accounting for 97.8% of the total.

When it comes to family income, 4.1% of the students' families had an income of less than 1000 Tunisian Dinars (TD), 25.9% had an income between 1000 and 2000 TD, 32.2% had an income ranging from 2000 to 3000 TD, and the remaining 37.8% had a family income of over 3000 TD.

The EAT-26, MBSRQ-AS and CAPE-42 scores are shown in table 1.

Table 1. The longitudinal evolution of study variables

	Baseline	T 6 months	T 12 months	p	Partial Eta Squared η^2
Disordered eating (EAT-26)	11.9 ± 9.4	11.9 ± 9.7	12.6 ± 10.2	.080	.006
Self-classified weight (Body image)	6.0 ± 1.7	5.9 ± 1.6	6.0 ± 1.6	.946	.001
Body areas satisfaction	30.9 ± 6.4	31.8 ± 6.4	31.4 ± 6.8	.025	.010
Overweight preoccupation	9.3 ± 3.6	9.2 ± 3.7	9.2 ± 3.7	.545	.001
Appearance Orientation	41.0 ± 5.4	41.6 ± 5.4	41.6 ± 5.5	.007	.014
CAPE positive dimension (total)	39.6 ± 8.7	39.1 ± 9.1	39.7 ± 9.5	.756	.001
Body Mass index	21.6 ± 3.4	21.5 ± 3.2	21.7 ± 3.2	.034	.009

2) Findings of the mediating analysis

Disordered Eating scores had no significant effect in subjects across time. However, the effect of the interaction between baseline Overweight Preoccupation with Disordered Eating across time was statistically significant ($p=0.036$). Overweight Preoccupation ($Z=85.095$, $p<0.001$), Body Area Satisfaction ($Z=25.053$, $p<0.001$), and CAPE positive dimension ($Z=59.931$, $p<0.001$) scores had significant main effects between subjects. (figure 1 and figure 2)

Image:

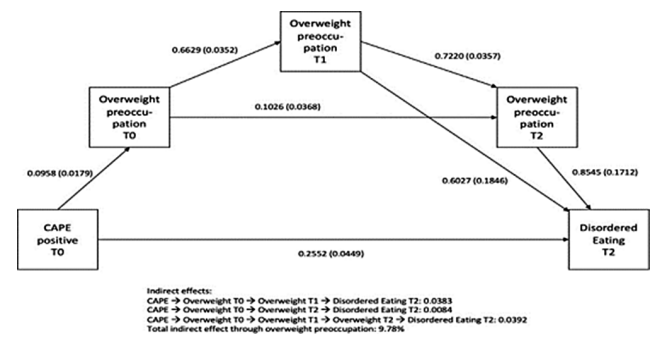

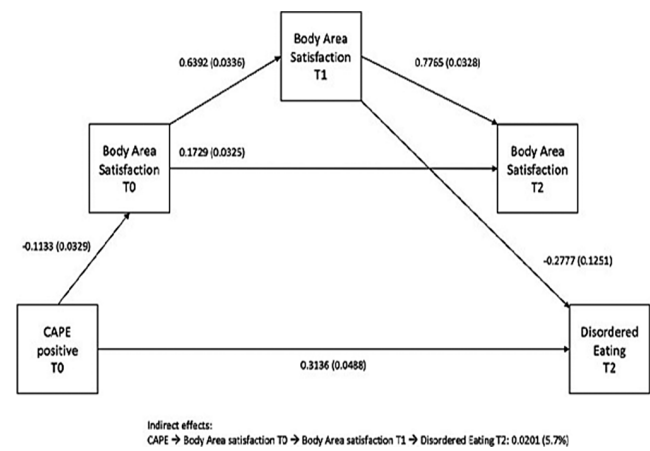

Image 2:

Conclusions: Findings showed that body image disturbances mediated the prospective association between PEs and DE. Adolescents with increased PEs were more likely to experience body image disturbances and, in turn, DE symptoms. These findings offer promising new avenues for prevention and early intervention.

The presence of personality traits of borderline personality disorder in anorexia nervosa and obesity

F. Mustać^{1*}, T. Galijašević², E. Podolski², M. Matovinović³ and D. Marčinko¹

¹Department of Psychiatry and Psychological Medicine, University Hospital Centre Zagreb; ²School of Medicine and ³Department Of Endocrinology and Diabetology, Internal Clinic, University Hospital Centre Zagreb, Zagreb, Croatia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1165

Introduction: While in eating disorders such as anorexia nervosa, the comorbidity of pathological personality traits is very common, and accordingly the personality traits of borderline personality disorder is considered very frequent and coexisting. The treatment of anorexia nervosa is based primarily on the psychotherapy and work on pathological personality traits even more than the treatment of the syndrome and the consequences of malnutrition itself. That achieves a longer-term and more reliable solution than symptomatic treatment of anorexia nervosa which usually does not bring satisfactory results. On the other hand, in patients with obesity, pathological personality traits, especially those of borderline personality disorder, are still very rarely associated, since obesity is usually not even considered a disorder, but a variation in the population.

Objectives: The aim of this paper is to investigate the pathological personality traits of borderline personality disorder in people with obesity.

Methods: Investigating relevant scientific and professional literature from the field of personality pathology and eating disorders.

Results: When obesity is related to impulse control disorder in the sense of emotional eating under increased stress according to today's relevant literature, it can definitely be related to personality traits of borderline personality disorder, i.e. the presence of elements of borderline personality organization and prementalization models. Such an inability to deal with negative emotions such as increased anxiety or rejection sensitivity, which results in overeating and the related feeling of shame that overwhelms the person, regardless of whether he/she/they has any of the certain forms of compulsive behaviour afterwards, can be related to impulsive behaviour and the "all or nothing" way of thoughts. This is also confirmed by cases when certain people have a history of both one and the other disorder. Thus, some people have, for example, malnutrition in adolescence as part of anorexia nervosa, only to have problems with obesity after some time with a healthy body mass.

Conclusions: Since pathological personality traits in people with anorexia nervosa and obesity give indications of common characteristics in the form of borderline personality disorder traits, i.e. borderline personality organization and prementalization models in both disorders, future research will certainly shed light on the connection between these eating disorders.

Impact of child maltreatment on bulimic behaviors among the tunisian general population

M. Turki, A. Hadj Ali, A. Chaaben, N. Halouani, M. A. Megdiche*, S. Ellouze and J. Aloulou

Psychiatry B department, Hedi Chaker university hospital, Sfax, Tunisia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1166

Introduction: Child maltreatment (CM) refers to all forms of physical or psychological violence, sexual abuse, and neglect of a person under the age of 18, resulting in actual or potential harm to

their health, survival, development, or dignity. It is recognized as a predictor of psychological difficulties in adulthood, such as bulimic behavior.

Objectives: The aim of our study was to assess the link between CM and bulimic behaviors in the Tunisian general population.

Methods: We conducted a cross-sectional, descriptive, and analytical study among Facebook group members, using an online questionnaire, from February 17, 2023, to May 26, 2023. All respondents over the age of 18 were included in the study. CM was assessed using the Childhood Trauma Questionnaire (CTQ), which provides information on five types of maltreatment: emotional abuse (EA), physical abuse (PA), sexual abuse (SA), emotional neglect (EN), and physical neglect (PN). The Bulimic Investigatory Test, Edinburgh (BITE) was used to screen and assess the intensity of bulimic behavior.

Results: A total of 528 responses were included in the study. The mean age of the sample was 33.3 ± 11.95 years. Mean AE, AP, AS, NE, NP, and overall CTQ scores were 8.30; 6.58; 6.38; 10.14; 7.26, and 49.72, respectively. A history of severe AE, AP, AS, NE, or NP was reported by 13.1%, 10.8%, 8.5%, 11.6% and 8.3% of respondents, respectively. The mean BITE score was 10.76 ± 6.85 and 6.6% of our population were at high risk of developing bulimic behavior. In the bivariate study, the BITE score was significantly correlated with all forms of MI. The strongest correlation was with AE ($r=0.310$; $p<0.001$).

In the multivariate study, only AE was associated with bulimic behaviors.

Conclusions: This study highlighted a positive association between various forms of child neglect and abuse, and bulimic behaviors. It is therefore worth noting that interventions for these disorders may be more effective if they target not only the behavior itself but also underlying risk factors such as maltreatment.

EPV0470

Bulimic behaviors in the tunisian general population: prevalence and associated factors

A. Hadj Ali, M. Turki, M. A. Megdiche*, S. Ellouze, G. Chakchouk, N. Halouani and J. Aloulou

Psychiatry B department, Hedi Chaker university hospital, Sfax, Tunisia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1167

Introduction: Bulimic behaviors (BB) are a major public health problem, due to their prognosis and serious psychological, somatic, and social consequences. The exact etiopathogenesis of BB is still poorly understood, and the literature suggests the interaction of multiple factors.

Objectives: The aim of our study was to estimate the prevalence of BB in the Tunisian general population and to identify the associated risk factors.

Methods: We conducted a cross-sectional, descriptive, and analytical study of Facebook group members, using an online questionnaire, from February 17, 2023, to May 26, 2023. All respondents over the age of 18 were included in the study. All participants filled

out a socio-demographic questionnaire. Body mass index (BMI) was calculated from weight and height. The Bulimic Investigatory Test, Edinburgh (BITE) was used to screen and assess the intensity of bulimic behaviors.

Results: A total of 528 responses were included in the study. The mean age of the sample was 33.3 ± 11.95 years, and the M/F sex ratio was 0.41. Subjects were unmarried in 63.4% of cases, of low socio-economic status in 19.5%, with a university education in 75.2%, and with a psychiatric history in 25.6% of cases. The mean BMI was 25.15 ± 4.98 . The mean BITE score was 10.76 ± 6.85 , and 6.6% of our population were at high risk of developing BB.

In the bivariate study, female gender ($p < 0.001$), unmarried marital status ($p = 0.001$), university education ($p < 0.001$), and the presence of a psychiatric history ($p < 0.001$) were significantly associated with a high risk of developing BB. Moreover, the BITE score was negatively correlated with age ($r = -0.231$; $p < 0.001$) and positively correlated with BMI ($r = 0.307$; $p < 0.001$).

Conclusions: This study highlighted the magnitude of the risk of bulimic behaviors in the Tunisian general population and the need to set up programs to prevent and control these disorders.

EPV0471

Clinical features of depressive states in eating disorders

A. Barkhatova*, A. Smolnikova and S. Sorokin

Department of endogenous mental disorders and affective states, Mental health research center, Moscow, Russian Federation

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1168

Introduction: Eating disorders (ED) are one of the most pressing problems of modern society. Eating disorders, due to their heterogeneity, can be considered both an independent form of mental disorders and as part of the manifestations of other mental illnesses. In the vast majority of cases within these pathologies, eating disorder coexists with depressive symptoms, which significantly worsens the prognosis of the disease.

Objectives: Identification of the association of depressive disorders with eating disorders to improve the criteria for nosological diagnosis, prognosis and therapeutic approaches.

Methods: A total of 74 patients aged from 15 to 25 years old (all female, average age 16.2), who were on outpatient and inpatient observation of the clinic were studied.

Results: The study made it possible to establish the characteristics of depressive disorders and the nature of the current course of depression associated with eating disorders. In eating disorders with a predominance of **anorexia nervosa**, the structure of depression was more dominated by the asthenia radical with symptoms of apathy, melancholia, anhedonia, irritability, episodes of anxiety after eating, and sleep disturbances. Patients noted a decrease in performance, mental activity, and a narrowing of their range of interests and communication. Depression became severe as exhaustion progressed. For eating disorders with **bulimia nervosa**, depressive states varied in the severity and polymorphism of their

manifestations. Their structure was largely dominated by the apatho-asthenic radical of affect, along with asthenia and anxiety, which often reached the level of panic states. Often, along with this, there were pronounced a guilt feeling and low self-esteem ideas with self-deprecation and self-hatred, which led to the manifestation of auto-aggressive behavior (both non-suicidal and suicidal). Depression reached a severe degree as exhaustion progressed, as well as against the background of more frequent attacks of over-eating and vomiting.

Conclusions: The identified associations between depressive disorders and eating disorders allow us to form a clearer picture of the expected course of psychiatric disease and optimize therapeutic intervention algorithms.

Disclosure of Interest: None Declared

EPV0472

Perceptions of Obesity in Old Age: A Qualitative Study

S. von Humboldt^{1*}, N. Ilyas² and I. Leal¹

¹William James Center for Research, ISPA – Instituto Universitário, Lisbon, Portugal and ²Center for Clinical Psychology, University of the Punjab, Lahore, Pakistan

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1169

Introduction: The relationship between obesity and mental health in old age is complex and widely impacted by different biological, psychological, and social factors.

Objectives: The primary objectives of this qualitative research study are: a) To understand the influence of obesity on older adults' well-being; b) to assess emotional experiences related to obesity in old age and; c) to explore how obesity influences the mental health of older adults.

Methods: This study included 346 participants aged 65 to 84 years ($M = 73.9$; $SD = 5.61$) from three different nationalities (English, Spanish, and Portuguese). All interviews went through content analysis.

Results: This study identified four main themes regarding the influence of obesity on older adults' well-being: (1) Insatisfaction with Body Image (66%); (2) Feeling embarrassed (65%); (3) Feeling Social Isolated (57%); and (4) Lost Opportunities (46%). Three main themes for emotional experiences were frequently verbalized by the participants: (1) Shame (81%); (2) Guilt (78%); and (2) Incompetence (76%). Finally, three main influences in mental health due to obesity were reported: (1) Self-concept (88%); (2) Stress (78%); and (3) Melancholia (63%).

Conclusions: These results highlighted that obesity negatively influences older adults' well-being and emotional experiences and has serious mental health-related negative outcomes for older adults. Interventions like community-based weight loss programs can be effective in controlling weight and improving the social interaction of obese older adults.

Keywords: Emotional experiences; mental health; obesity; older adults; well-being.

Orthorexia and perfectionism in medical students in Tunisia

A. Mellouli*, S. Ellouze, N. Boussaid, M. Turki, A. Zribi, N. Halouani and J. Aloulou

Psychiatry B, Hedi Chaker University Hospital, Sfax, Tunisia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1170

Introduction: Orthorexia is defined as a dependence on healthy food or an obsession to consume healthy food. One area deemed influential upon disordered eating and dietary intake is perfectionism.

Objectives: To investigate the relationship between orthorexia and perfectionism in medical students.

Methods: We conducted a cross-sectional, descriptive, and analytical study in the faculty of medicine of Sfax (Tunisia), between February and April 2023. A self-reported questionnaire was distributed to students via social media. We used ORTO-15 for the assessment of orthorexia, and the Big Three Perfectionism Scale (BTPS) to assess perfectionism.

Results: The research has enrolled 220 students. Their mean age was 21.40 ± 1.68 years, with female predominance (70%). The ORTO-15 mean total score was 36.88 ± 6.76 . A total of 60% of participants had an orthorexic behavior. The BTPS mean total score was 45.52 ± 12.45 with a mean score of 13.25 ± 4.35 for rigid perfectionism, 18.31 ± 6.37 for self-critical perfectionism, and 13.99 ± 5.47 for narcissistic perfectionism.

Students with orthorexic behavior had significantly higher scores of perfectionism ($p = 0.048$).

Conclusions: Our study has drawn a significant association between orthorexia and perfectionism among medical students. This result suggests that students experiencing highly critical and judgemental beliefs associated with perfectionism are more susceptible to orthorexic eating behaviors.

The Portuguese short version of the Eating Disorder Examination Questionnaire: Validity and Reliability in men across multiple ages

A. Silva¹, A. Macedo², C. Marques², M. J. Brito², A. T. Pereira² and C. Coelho^{2*}

¹Faculty of Medicine, University of Coimbra, Coimbra, Portugal and

²Institute of Psychological Medicine, Faculty of Medicine, University of Coimbra, Coimbra, Portugal

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1171

Introduction: The Eating Disorder Examination Questionnaire short version (EDE-Q7) presented better psychometric properties than the Fairburn's 28-items original version, not only in girls (Machado et al. 2018), but also in older women (Pereira et al. 2021; Pereira et al. 2022). It comprises 7 items in three subscales: Dietary Restraint/DR; Shape and Weight Overvaluation/SWO and

Body Dissatisfaction/BD. In a more recent clinical study in men (Laskowski et al. 2023) the factors associated with body concerns and dissatisfaction weren't fully represented in the questionnaire, possibly indicating differences in body ideals, specially relating to musculature.

Objectives: We aimed to analyze the psychometric properties of the Portuguese version of EDE-Q7 in males.

Methods: Participants were 227 male individuals with a mean age of 30.41 years (± 13.96 ; range: 14-73 years). They answered an online survey including the Portuguese versions of the Screen for Disordered Eating/SDE; the Body Image Concern Inventory/BICI and the Muscle Dysmorphia subscale of the Eating Disorder Assessment for Men/DM-EDAM.

Results: Confirmatory Factor Analysis showed that the second order model presented good fit ($\chi^2/df=2.437$; RMSEA=.0794; CFI=.986 TLI=.974, GFI=.967). Cronbach's alpha was .856 for the total, .876 for DR and .917 for SWO and .900 for BD. All items contributed to internal consistency and presented high internal validity. Pearson's correlations of EDE-Q7 with BICI (.465), DM-EDAM (.384) and SDE (.361) were significant ($p < .001$) and moderate.

Conclusions: Also in men, the Portuguese version of EDE-Q7 demonstrates good validity (construct and convergent) and reliability.

Disclosure of Interest: None Declared

EPV0476

Muscle dysmorphia subscale of eating disorder assessment for men: validity and reliability of the Portuguese version in men across multiple ages

A. Silva¹, A. Macedo², M. J. Brito², C. Marques², A. T. Pereira² and M. Bajouco^{2*}

¹Faculty of Medicine, University of Coimbra, Coimbra, Portugal and

²Institute of Psychological Medicine, Faculty of Medicine, University of Coimbra, Coimbra, Portugal

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1172

Introduction: Although symptom presentation varies by gender, almost all eating disorder/ED instruments have been developed and validated on females. The Eating Disorder Assessment for Men (EDAM; Stanford & Lemberg 2012) is a male specific self-report measure, composed of four sub-scales, proved to be useful to assess gender differences in ED presentations (Nagata et al. 2021). The MD comprises 5 items about the overwhelming concern with muscularity and the false perception of having an underdeveloped body.

Objectives: Having already valid measures of body image and eating behaviors in men, we now aim to analyze the psychometric properties of the Portuguese version of MD, in order to have a quick and rigorous measure of this specific construct.

Methods: Participants were 227 male individuals (mean age=30.41 years ± 13.96 ; range: 14-73 years). They answered an online survey including the preliminary DM and the Portuguese validated versions of the Eating Disorder Examination Questionnaire (EDE-Q7) and the Body Image Concern Inventory (BICI).

Results: Confirmatory Factor Analysis showed that the unidimensional model presented good fit indexes ($\chi^2/df=.6829$; RMSEA=.0000; CFI=1.00 TLI=1.01, GFI=.995). Cronbach's alfa was .891; all the items contributed to the internal consistency and had high internal validity. Pearson correlations of DM with EDE-Q7 and BICI were significant ($p<.001$) and moderate-high, respectively,.384 and .522.

Conclusions: The Portuguese preliminary version of DM-EDAM demonstrated validity (construct and convergent) and reliability. can be used for clinical and research purposes, namely in an ongoing project we have in progress, about body image, disordered eating, gender and age.

Disclosure of Interest: None Declared

EPV0477

The Portuguese version of the screen for disordered eating: validity and reliability in men across multiple ages

A. T. Pereira¹, A. Silva², M. J. Brito¹, C. Marques¹, A. Araújo¹, A. Macedo¹ and S. Renca^{1*}

¹Institute of Psychological Medicine and ²Faculty of Medicine, University of Coimbra, Coimbra, Portugal

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1173

Introduction: The Screen for Disordered Eating/SDE was created as a primary care screening method for eating disorders, including binge eating disorder (Maguen et al. 2018). The SDE comprises five items (yes/no answers), extracted from other validated self-reported questionnaires assessing eating psychopathology. Its validity and reliability has proved in a Portuguese psychometric study, that only included woman (Pereira et al. 2022). It psychometric properties have yet to be evaluated in men.

Objectives: We aim to assess the psychometric properties of the Portuguese version of SDE in males.

Methods: Participants were 227 male individuals with a mean age of 30.41 years (± 13.96 ; range: 14-73). They answered an online survey including the Portuguese preliminary versions of the seven-item Eating Disorder Examination Questionnaire/EDE-Q7; the Body Image Concern Inventory/BICI and the Muscle Dysmorphia subscale of the Eating Disorder Assessment for Men/DM-EDAM.

Results: Confirmatory Factor Analysis showed good fit for the unidimensional model ($\chi^2/df=1.483$; RMSEA=.0460; CFI=.980 TLI=.961, GFI=.988). Cronbach's alpha was .621 which although inferior to .7 can be explained by the small number of items and the fact that each one assesses different dimensions. All items contributed to the internal consistency and presented high internal validity. Pearson's correlations of SDE with BICI (.317) and EDE-Q7 (.361) were significant and moderate. The correlation with DM-EDAM was non-significant, probably due to its focus on muscle dysmorphia, which is not included in SDE's items.

Conclusions: The Portuguese version of SDE demonstrated adequate validity (construct and convergent) and reliability.

Disclosure of Interest: None Declared

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1174

Introduction: In recent times, Health Professionals (HPs) people may feel a sense of discomfort and nervousness when disconnected from their smartphones, causing the emergence of the new phenomenon of "No Mobile Phone Phobia," or Nomophobia.

Objectives: We aim to study lifestyle-related factors that influence HPs' Nomophobia.

Methods: From April- June 2023, a global cross-sectional study was conducted using the modified Nomophobia questionnaire (NMP-Q). The original 20 NMP-Q questions (Qs) were reduced to 14 to avoid repetitive Qs with similar meanings. The Qs were categorized into 4 sections, A- Not Being Able to Access Information; B- Losing Connectedness; C- Not Being Able to Communicate; and D- Giving Up Convenience. A new section, "E-Daily Habits", and "F- Smartphone Type", and "Hours Spent Daily" were added. Before the launch, it was internally and externally validated by trained psychiatrists as well as experienced researchers. We utilized social media, WhatsApp, text and emails to share it with HPs of different specialties worldwide. The survey was anonymous and IRB-exempt.

Results: Total 105 countries' HPs participation led to 12,253 responses. Total 47.3% of HPs agreed/strongly agreed (A/SA) that they prefer to use their smartphone before bedtime. Over half (57.8%) of HPs A/SA checked their notifications immediately after waking up in the morning. Only 19.4 % of HPs A/SA that woke up in the middle of the night to check notifications. Total 40.5% of HPs A/SA, 22% were neutral, and 37.3% of HPs disagreed /strongly disagreed (D/SD) with using smartphones while eating their meals. A total of 52.7% of HPs preferred smartphone usage over exercising as a break, while 45.9% of HPs A/SA that they chose smartphones over exploring other hobbies for relaxation. A total of 44.2% of respondents A/SA with smartphone usage in the restroom, 39.8% D/SD. 37.4% of participants D/SD with getting distracted by notifications and resisted the urge to answer any calls or texts while performing a focused task, whereas 39.6% A/SA and 23% were neutral. A total of 80% of respondents met the modified criteria for moderate-severe nomophobia.

Conclusions: In a large-scale survey-based study on Nomophobia, additional Qs in NMP-Q may help recognize that nomophobia can be a result of daily lifestyle decisions rather than an isolated issue.

Serotonin Syndrome Following Low-Dose Sertraline: A Case Report

C. Y. Chan

general psychiatry, institute of mental health, singapore, Singapore
doi: 10.1192/j.eurpsy.2024.1175

Introduction: Serotonin syndrome is a potentially life-threatening condition that is precipitated by the use of serotonergic medications, Selective Serotonin Reuptake Inhibitors (SSRIs) and Monoamine Oxidase Inhibitors (MAOIs). It usually occurs when high doses of serotonergic drugs are prescribed. It is a medical emergency that requires prompt recognition, cessation of offending drugs and supportive therapy.

Objectives: We present a case of serotonin syndrome that occurred in a patient who was prescribed a low dose of sertraline, and aim to highlight the importance of early detection of this severe condition.

Methods: Details of the case were described. Information was gathered based on medical records.

Results: Patient M was a 29-year-old Malay male with a history of major depressive disorder, who was previously trialed on fluvoxamine 100mg every night but subsequently switched to and maintained on sertraline 75mg every night in 2020. He then defaulted follow up appointments. In 2023, he presented to the emergency services for a suicide attempt and was diagnosed with major depressive disorder with psychotic features. He was restarted on sertraline 50mg every night and risperidone 0.5mg every night was newly started. Two days later, sertraline was increased to 100mg every night. Two days following this increase, he was noted to have altered mental state, fever of 39.3-degree celsius, tachycardia of 120 beats per minute, ocular clonus and generalized hyperreflexia. Sertraline and risperidone were immediately stopped. Blood tests including creatine kinase, lumbar puncture and magnetic resonance imaging (MRI) of the brain did not show any abnormalities. After stopping of the medications, the patient's symptoms resolved within 24 hours. Based on clinical symptoms and a normal creatine kinase level, neuroleptic malignant syndrome (NMS) was ruled out. Subsequently, he was restarted on risperidone 0.5mg and mirtazapine 7.5mg every night. He developed symptoms of serotonin syndrome with a low dose of sertraline. Symptoms resolved after the discontinuation of the SSRI.

Conclusions: In this case, differential diagnoses of serotonin syndrome were also considered, such as NMS, encephalitis, meningitis and thyroid storm. NMS was less likely due to the rapid onset of onset and resolution of symptoms. Encephalitis and meningitis were unlikely in view of normal MRI brain and lumbar puncture findings.

There have been case reports of serotonin syndrome developing with lower doses of an SSRI in the pediatric population. There is, however, a lack of literature describing serotonin syndrome with low doses of SSRI in the adult population. To avoid a missed diagnosis, clinicians should monitor closely for SSRI toxicity, including serotonin syndrome, even when low doses of serotonergic drugs are used.

Psychiatric emergencies and trauma : the impact of stress in emergency nurses

N. Baabouchi*

psychiatry, arrazi hospital, rabat, Morocco

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1176

Introduction: Mental health at work is increasingly an essential element to assess, especially in sectors with a high risk of psychological and physical stress. Working in a healthcare environment and particularly work in a psychiatric environment can constitute a psychological risk for workers. Among the risks faced by emergency psychiatric medical staff is the risk of developing PTSD (post traumatic stress disorder), which occurs after a traumatic event and results in moral suffering and physical complications that profoundly alter life: personal, social and professional life.

Objectives: Screening psychiatric emergency nurses for post-traumatic stress disorders.

Methods: This is a cross-sectional study carried out in the psychiatric emergency department of the Arrazi University Hospital in Salé, using an anonymous questionnaire distributed to nurses. It includes a 1st part on sociodemographic and professional data, a 2nd part focused on the evaluation of mental health through the GHQ12 and a 3rd part which evaluates post-traumatic stress made by the scale of post-traumatic stress disorder (PCLs).

Results: 60 pourcent of women are more able to have ptsd disorder 40 pourcent men 95 pourcent are under the age of 30 and 5 pourcent have more than 30 years

80 pourcent have worked less than 5 years in the emergency hospital and 20 pourcent have worked more 73 pourcent have scored more than 44 in pcls score

23 pourcent have scored less than 44 in pcls score

Conclusions: This work highlighted an extremely high rate of exposure to a violent event among psychiatric emergency nurses, even if in this study the prevalence of PTSD found among nurses is lower than expected, in this professional environment overexposure a violence requires special attention to protect and prevent the development of PTSD in professionals

How to have an acute gastroenteritis and an Anxiety Disorder at the same time: Cannabinoid hyperemesis syndrome (CHS) Case Series

P. A. Hernández Liebo^{1*}, J. Romay González¹, C. Sevilla Díez¹, O. S. Anabitarte Bautista¹, L. Cayón de la Hoz¹, G. E. Cortez Astudillo², M. Polo Gay¹, R. Obeso Menéndez¹, M. Hoyuelos Cob¹ and M. Gómez Revuelta¹

¹Psychiatry, Hospital Universitario Marqués de Valdecilla and

²Psychiatry, Hospital de Sierrallana, Santander, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1177

Introduction: Cannabinoid hyperemesis syndrome (CHS) is an underrecognized condition characterized by acute episodes of

intractable nausea and vomiting, colic abdominal pain and restlessness related to chronic cannabis use. Antiemetics commonly fail to alleviate the severe nausea and vomiting. A very particular finding is the symptomatic relief with hot water. Antipsychotics (such as haloperidol), benzodiazepines and/or capsaicin cream appear to be the most efficacious in the treatment of this unique disorder. Precisely, it has been studied that transient relief of symptoms with topic capsaicin or hot water share the same pathophysiology. Nevertheless, abstinence from cannabis remains the most effective way of mitigating morbidity associated with CHS.

Objectives: The objective is to study this phenomenon in our hospital and to alert of its existence in order to avoid a suspected misdiagnosis and overdiagnosis.

Methods: We report a case series of seven patients who attended the Emergency Room (ER) of a third level hospital located in Cantabria (Spain) where a psychiatric evaluation was demanded.

Results: The reasons for consultation were agitation and/or compulsive vomit provocation and showers. They were all women, with a median age of 29 years (range 21 to 38), who all smoked cannabis and in probable high doses (seven to up to twenty joints per day, information was missing in three of the patients) and probable long duration of consumption (more than nine years up to twenty-three, information was missing in three of the patients).

One of the most striking findings is the time to diagnosis, being the median of years of more than eight (range from two to twenty-one). In all of the cases there is a hyperfrequentation to the ER for this reason (not counting other emergency centres we have in Cantabria which we don't have access to), being the average of almost twenty-two times (thirteen up to thirty times), not diagnosing it until last visits. Another interesting fact is that Psychiatric evaluation is done approximately in a third of the visits, being the department that makes all of the diagnosis except in one case. In all of the cases there are a lot of diagnostic orientation doubts from different medical departments, being the two most common psychiatric misdiagnosis: *Other Specified Anxiety Disorder* and *Other Specified Feeding or Eating Disorder*. Two of the patients were hospitalized in an acute psychiatric unit for this reason, one of them nine times and the other patient, twice.

Conclusions: CHS has a very particular presentation which makes its recognition very simple. From our experience, it is an unknown entity for most of the doctors, something that needs to change in order to make a correct therapeutic management. Larger studies need to be done to make this findings more solid and for further information.

EPV0482

Risks Associated with Prescribing Zolpidem: A Case Report and Literature Review

S. Jacob*, A. Dore, O. Ali, H. Raai and L. Troneci

Psychiatry, St. Barnabas Hospital, Bronx, United States

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1178

Introduction: Zolpidem is a nonbenzodiazepine, which acts as a sedative- hypnotic that binds to GABA (A) receptors at the same location as benzodiazepines and increases GABA effects in the central nervous system (Kovacic *et al.* Oxidative medicine and cellular longevity 2009, 2(1), 52–57). Literature shows that behavioral changes including amnesia, hallucinations, and other neurocognitive effects are some of the known side effects (Edinoff *et al.* Health psychology research 2021, 9(1), 24927). We present a case about Ms. A, a female in her sixties with a history of major depressive disorder with psychotic symptoms who was brought into the hospital by the EMS under police custody after stabbing her granddaughter with a knife. During the evaluation she was dissociating with impaired memory of the circumstances of her presentation. Collateral information about Ms. A revealed that she had no history of being violent, or any history of psychoactive substance use. Ms. A's home psychiatric medications consisted of Sertraline 100mg, Bupropion 150 mg, Zolpidem 5mg.

Objectives: To better understand the potential risks with prescribing zolpidem in patient with insomnia.

Methods: In depth literature review about zolpidem. In addition, observation of Ms. A in the emergency with a full medical workup including but not limited to urine drug screen, brain imaging, lumbar puncture, etc.

Results: Ms.A medical workup was positive for a urinalysis revealing asymptomatic bacteriuria and she was treated empirically with cefdinir. Her medication regimen consisted of Bupropion 150 mg and Sertraline 100m, both daily. Zolpidem was discontinued and changed to Clonazepam 0.5mg for insomnia. She was also started on Olanzapine 5mg in the AM and 10mg in the PM. Her mental status was noted to have improved after discontinuation of Zolpidem. Patient received one dose in the hospital but after two days since discontinuation her mental status improved. Upon literature review previous reports have been published citing cases of patients on Zolpidem physically acting out while sleeping in a parasomnia-like behavior, with no recollection of memories upon awakening. (Inagaki *et al.* Primary care companion to the Journal of clinical psychiatry 2010, 12(6)). There are case reports of Zolpidem associated homicide (Paradis *et al.* The primary care companion for CNS disorders 2012, 14(4)).

Conclusions: One limitation of our study is the patient was noted to have a sudden change in behavior with altered mental status which may be attributed to an underlying asymptomatic bacteriuria. It should be noted that this may have been an incidental finding. This does not exclude the possibility of Zolpidem as the primary cause of the change of her altered mental status or further exacerbating the change in her mental status. Though Zolpidem can be therapeutic and safe, we as clinicians have to be aware of the potential side effects of Zolpidem when prescribing medications.

Triage mistakes in the Psychiatry Emergency Room: do we really know how to rule out organicity?

H. Andreu*, A. Giménez-Palomo, L. Bueno, E. Cesari, O. De Juan, J. I. Mena, I. Ochandiano, L. Olivier, S. Salmerón and M. Sagué-Vilavella

Psychiatry and Psychology Department, Institut Clínic de Neurociències, Hospital Clínic de Barcelona, Barcelona, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1179

Introduction: In Spain and other European countries, patients coming to the emergency room (ER) are usually classified as “organic” or “psychiatric” on arrival, but this may be complicated when psychiatric history is present as the focus can be misplaced (Leeman. *IJPM* 1975;6(4):544–40; Alam *et al.* *Psychiatr. Clin. North Am.* 2017;40(3):425–33).

Objectives: To describe three cases seen in the psychiatric emergency room (PER) in which triage errors occurred and to review whether it is widespread for psychiatric patients with organic pathology or in need of medical care to be wrongly triaged.

Methods: We retrospectively reviewed three cases seen in the PER of Hospital Clínic in July 2023 in which triage errors happened. Triage error was considered when patients triaged directly to the PER presented symptoms that either needed medical treatment or required medical clearance before being considered purely psychiatric.

Results: Case 1: A 27-year-old woman with history of depressive syndrome was triaged for a speech disturbance that had occurred fifteen minutes after intercourse. After being evaluated, she was referred to neurology where she was diagnosed with an acute ischaemic stroke in left middle cerebral artery territory, requiring thrombectomy and posterior admission to neurology.

Case 2: A 50-year-old man with history of alcohol use disorder was brought to the PER after saying that “he was seeing people doing magic” at home. When evaluated, significant distal tremor, tachycardia and hypertension were observed, being compatible with withdrawal symptoms, so he was transferred to the ER. There he was monitored and treated, finally requiring admission to internal medicine due to persistent symptoms.

Case 3: A 26-year-old man with history of substance use disorder was triaged for loss of consciousness and “spasms”. After evaluation, he was transferred to the ER, where organic screening was carried out, being oriented as a probable tonic-clonic seizure and discharged with outpatient follow-up.

Conclusions: The cases presented are instances in which somatic diseases in patients pre-labelled with psychiatric histories were wrongly assumed to be recurrences of their psychiatric disorders. In all cases, they needed to be re-examined by the corresponding medical specialty and required diagnostic tests, in two cases hospital admission was needed. Emergency physicians and emergency psychiatrists often disagree on how to medically clear patients (Alam *et al.* *Psychiatr. Clin. North Am.* 2017;40(3):425–33; Janiak *et al.* *JEM.* 2012;43(5):866–70), some authors have even proposed protocols for doing this in a more systematic way (Shah *et al.* *JEM.* 2012;43(5):871–5). To avoid a delay in diagnosis and treatment and the consequences that may result from it, establishing guidelines for proper triage of patients with psychiatric history should be considered.

Towards an increased attention on ADHD symptoms and traits in young adults: prevalence data from screening tools in a psychiatric outpatient clinic

C. Sanguineti¹, V. Nistico^{1,2,3}, I. Folatti¹, G. Santangelo¹, R. Faggioli⁴, A. Bertani⁵, O. Gambini^{1,3,4} and B. Demartini^{3,3,4,4*}

¹Health Science Department, University of Milan; ²Department of Psychology, University of Milan Bicocca; ³Aldo Ravelli Research Center for Neurotechnology and Experimental Brain Therapeutics, University of Milan; ⁴UO Psichiatria 51 e 52 and ⁵Centro Giovani Ettore Ponti, ASST Santi Paolo e Carlo, Presidio San Paolo, Milan, Italy

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1180

Introduction: Attention-Deficit/Hyperactivity Disorder (ADHD) is a heterogeneous neurodevelopmental disorder encompassing developmentally inappropriate inattentiveness, hyperactivity, and increased impulsivity (DSM-5). Symptoms presentation is different for different stages of life; moreover, individuals with ADHD symptomatology can develop abilities and strategies that help them adapt and mask the distinctive features of the condition, thus reducing the functional impairment usually seen in ADHD subjects, and ultimately not receiving neither a clinical diagnosis nor a proper therapeutic support. They might express their lack of well-being through other transdiagnostic symptoms, and finally reach psychiatric attention for potential comorbidities. Hence, it was argued that the existence of children and adolescents with sub-threshold and underrecognized symptoms that subsequently develop into a full diagnosis suggests that ADHD should be significantly more considered in adult mental health settings.

Objectives: Here we aimed to analyse the prevalence of ADHD symptoms and traits in a heterogeneous clinical psychiatric sample of young adults (aged 18 to 24 years old), who referred to a specialized outpatient clinic for various psychiatric and psychological disturbances.

Methods: 259 participants completed three validated self-report screening questionnaires for ADHD: the Wender Utah Rating Scale (WURS), the Adult Attention-Deficit/Hyperactivity Disorder Self-Report Screening Scale for DSM-5 (ASRS-5), and the Conners' adult ADHD rating scale (CAARS).

Results: 12.4% of our sample scored above the cut-off at both the WURS and the ASRS-5 and was considered at risk of ADHD.

Conclusions: The prevalence rate in our sample is higher than the one found in the adult general population (6.76%), and in the lower range of the one found in the adult clinical population (6.9% to 38.8%). We discuss the potential role of sociodemographics (age, sex, gender identity, and employment) and comorbidity factors. Differences in the clinical presentation of ADHD according to sex assigned at birth and age should be considered during every psychiatric evaluation to minimize the risk of underdiagnosis. We advocate for further studies investigating the prevalence of ADHD in different psychiatric services for adults, and for a stronger presence of specialistic ADHD services and trained clinicians on the territory: this would increase diagnostic reliability, consequently providing a better treatment for ADHD in adults, and facilitate the transition from pediatric to adult's services.

The relationship between homelessness and psychiatric disorders in an inpatient sample

C. V. Vass*, G. Gazdag and G. V. Vida

Psychiatry and Psychiatric Rehabilitation, Jahn Ferenc South-Pest Hospital, Budapest, Hungary

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1181

Introduction: There are more than ten thousand homeless people in Hungary. Earlier studies confirmed the connection between mental health issues and homelessness. Furthermore, homeless care places a significant burden on the healthcare system, with psychiatric departments being no exception.

Objectives: to compare demographic and treatment characteristics of homeless and not homeless inpatients in the psychiatric department of Jahn Ferenc South Pest Hospital (JFSPH), and thus providing a different perspective compared to previous studies, shedding light on the relationships from a different angle.

Methods: In our retrospective study, we analyzed all inpatients' data treated in the psychiatric department of JFSPH over a 4-month period (03/2023-07/2023). Patients were divided into two groups: those with housing and those who were homeless. We compared the two groups based on the following variables: gender, age, length of inpatient treatment, diagnosis, psychiatric history, employment status; smoking, alcohol and drug use; valid health insurance, invalidity pension and guardianship status; and long-acting injectable antipsychotic treatment.

Results: The percentage of homeless individuals treated in the psychiatric department of JFSPH was 18%. There was a significant difference in the length of inpatient stay between the two groups, homeless patients spent more than 100% longer time under inpatient treatment. Regarding psychiatric history, there was no significant difference between the two patient groups. When examining the employment status of the sample, we found significantly more unemployed patients in the homeless group. Comparing to the control group, there were significantly more alcohol consumers, smokers, and substance users among the homeless. Long-acting antipsychotic injections were administered significantly more frequently to homeless patients. A significantly higher percentage of homeless individuals were declared invalidated, and a significantly higher proportion of them were placed under guardianship compared to the group with housing. Homeless individuals were significantly more likely to have no social insurance compared to the control group.

Conclusions: In summary, we can conclude that significant differences have been found between the homeless and not homeless groups in most of the examined variables. These results implicate that the inpatient care of homeless patients poses significant burden on the inpatient system. Early prevention and effective rehabilitation of substance use disorders could decrease this burden. Establishing a proper social safety network and enhancing community psychiatric care could potentially also relieve the burden of inpatient care system.

EPV0489

Problem focused coping strategies and high self-compassion can be seen as protective factors to lower stress, negative emotional reactions to job and anxietyE. N. Gruber^{1*} and S. Martić Biocina²¹Department R, Mental Health Centre Sct. Hans, Roskilde, Denmark and ²Department of Social Psychiatry, University Psychiatric Hospital Vrapče, Zagreb, Croatia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1182

Introduction: Previous research has shown that:

- problem focused coping strategies aim to change the reaction to the stressful situations
- self-compassion may reduce anxiety and depression. It is associated with happiness, it increases with age, it is negatively correlated with perceived stress and in older adults seems to be associated with higher levels of wisdom, integration, acceptance of one's past life experiences and higher levels of meaning in life.
- job related low LPLA (Low pleasurable Low arousal emotions) and high LPHA (Low pleasurable High arousal emotions) levels correlate to depression, anxiety, and stress.

Objectives: Case report of 60 years old computer scientist

Methods: Psychiatric interview and scales:

Self-reported questionnaires: The Brief-COPE, The Self-Compassion Scale (SCS-SF), The Perceived Stress Scale (PSS 10), The Depression Anxiety Stress Scale (DASS-10), The Job-related Affective Well-being Scale (JAWS), The Subjective Happiness Scale (SHS), The Meaning in Life Questionnaire (MLQ)

Results: 60 years old male computer scientist, single, without children, multiple times a week in recreative activities and physical activities. He is not satisfied with close friendships, he sleeps 6 hours in day, he didn't have traumatic experiences in life. He is not religious. He works 45 hours per week, from that 5-10 hours weekly works at the site of primary employment.

The Brief-COPE: High score for using problem focused coping strategies-acceptance, planning, positive reframing, and informational support. Maladaptive coping strategies used in lower grade: self-blame and self-distraction.

SCS-SF: Much higher levels of self-compassion than the norms established by previous research.

DASS-10: low.

SHS: lower happiness level than the norms established by previous research.

JAWS: High negative emotional reactions to job and low level of overall job-related affective wellbeing together with lower LPHA, higher LPHA, and lower LPLA in comparison to previous research. According to previous research this person is not satisfied with his job and have a lot of negative emotions regarding his job.

PSS 10: Levels of perceived stress are lower than the norms established by previous research.

MLQ: this person scored below 24 on the scale- presence of meaning and below 24 on the scale search for meaning. According to previous research person with this score do not feel their life has a

valued meaning and purpose and they do not not actively explore that meaning or seeking meaning.

Conclusions: Problem focused coping strategies and high self-compassion can be seen as protective factors to lower stress, negative emotional reactions to job and anxiety

Autism Spectrum Disorders traits in a sample of young adults referring to a generalized mental health outpatient clinic

V. Nistico^{1,2,3}, I. Folatti¹, G. Santangelo^{1*}, C. Sanguineti¹, S. Inci¹, R. Faggioli⁴, A. Bertani⁵, O. Gambini^{1,3,4} and B. Demartini^{3,3,4,4}

¹Health Science Department, University of Milan; ²Department of Psychology, University of Milan Bicocca; ³Aldo Ravelli Research Center for Neurotechnology and Experimental Brain Therapeutics, University of Milan; ⁴UO Psichiatria 51 e 52 and ⁵Centro Giovani Ettore Ponti, ASST Santi Paolo e Carlo, Presidio San Paolo, Milan, Italy

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1183

Introduction: The diagnosis of Autism Spectrum Disorders is currently witnessing several changes, with direct consequences on the prevalence rates in the general population. However, little is known about ASD traits prevalence in clinical samples, and how much these traits interact with other mental health conditions, especially in young adults, a critical age for the outbreak of many psychiatric diseases.

Objectives: The aim of this study was to assess the prevalence of ASD traits in a sample of young adults (aged between 18 and 24 years old) referring to a specialized mental health outpatient clinic.

Methods: We administered to 259 patients the Autism Quotient (AQ) and the Ritvo Autism and Asperger Diagnostic Scale-Revised (RAADS-R), along with a detailed sociodemographic and anamnestic interview.

Results: We found that 16.2% of our sample scored above the cut-off at both scales (a percentage that went down to 13.13% when restricting the RAADS-R cut-off at >119, as suggested for clinical samples).

Conclusions: This prevalence seems considerably higher than the one reported in the general population, and not negligible. The association with sociodemographic features such as sex assigned at birth, gender identity and employment status, and the validity of the screening tools we implemented, are discussed. In conclusion, we suggest that an assessment for autistic traits should be implemented in young adults seeking help for unspecified psychiatric symptoms and psychological suffering and that, despite the not unanimous consensus over self-report screening tools, a positivity to both the AQ and the RAADS-R should lead the clinician to conduct a full diagnostic evaluation with structured or semi-structured interviews.

Epidemiological profile of long-term leave for psychiatric illnesses

S. Chemingui¹, M. Mersni¹, M. BANI¹, H. Ben Said¹, H. KHIARI^{2*}, I. YOUSSEF¹, N. Mechergui¹, D. Brahim¹, G. BAHRI¹, I. YAICH³, C. Ben Said³, N. BRAM³ and N. LADHARI¹

¹Occupational pathology and fitness for work department Charles Nicolle Hospital, tunis, Tunisia; ²Occupational pathology and fitness for work department, Charles Nicolle Hospital and ³Forensic Psychiatry department, Razi Hospital, La Manouba, Tunis, Tunisia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1184

Introduction: Long-term leave for psychiatric illness is the most frequently prescribed reason for leave, and appears to be on the increase in recent years.

Objectives: To draw up a sociodemographic, occupational and clinical profile of workers who have taken long-term sick leave for psychiatric illness

Methods: Retrospective descriptive study involving the medical files of workers from both the public and private sectors, having benefited from long-term sick leave over a period going from August 17, 2022 to September 12, 2023, referred to the occupational medicine and pathology department of Charles Nicolle Hospital in Tunis for medical fitness-for-work assessment. Data collection was based on a pre-established synoptic form.

Results: During the study period, we identified 639 long-term sick leave prescribed for psychiatric illnesses. Our study population was predominantly female, with a sex ratio of 0.29 and a mean age of 46.82 ± 25.06 years. Sixty percent of employees were married. The most represented occupational category was nurses (33%). Average job seniority was 17.21±10.41 years. Depressive syndrome was the most common psychiatric pathology in our population (80.3%), followed by bipolar disorder (6.4%) and anxiety disorder (5%). Long-term sick leave was prescribed by a psychiatrist working in the private sector in 90.3% of cases. The average duration of leave was 63.70±31.58 days. The triggering factor was work-related and social in 33.6% and 30.1% of cases respectively. The agents returned to work after the long-term sick leave in 92% of cases.

Conclusions: Long-term sick leave for psychiatric reasons is a handicap to productivity in society. Non-occupational factors are thought to be responsible for these mental health disorders. Setting up and improving social structures in the workplace would reduce the number of cases of long-term sick leave

Parents' Assessment of Their Children's Use of Technology

M. Tepetaş^{1*}, A. Ünsal¹ and G. S. Tepetaş Cengiz²

¹Medical Faculty, Eskişehir Osmangazi University, Eskişehir and ²Mehmet Tanrıkulu Health Services Vocational School, Bolu Abant İzzet Baysal University, Bolu, Türkiye

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1185

Introduction: The use of technology in many areas of daily life is widespread among both children and adults. Excessive and inappropriate use of technological aids causes significant problems in physical, psychomotor, psychological and social stages of development, especially in childhood. One of the reasons for some problems that arise in adulthood, such as communication problems, anxiety disorders, obesity, musculoskeletal disorders and tendency to violence is the excessive and inappropriate use of technology in childhood. For this reason, it is of great importance to complete the developmental stages in childhood in a healthy way.

Objectives: The aim of this study was to qualitatively assess the technology use habits of 48-72 month old preschool children and their parents.

Methods: The study is a qualitative research conducted among the parents of children in Eskişehir and Bolu between March and June 2023. A semi-structured form was used for the personal interviews with the 25 parents who constituted the study group. The interviews were recorded. The audio recordings were then transcribed and a thematic content analysis was conducted. The main themes of the interviews concerned the habits of parents' and children's in the use of technology at home, the content used on technological devices and how it is controlled, and the arrangements for technology use at home.

Results: In the interviews, parents reported that when they needed to use technological devices, they most often chose a time and place when the children were not present or asleep. When children spent more time at home, this was the most common reason for increased technology use, while the most common reason for decreased use was that children spent more time outside the home. Most parents limited the amount of time their children's daily technology using time. It was found that children generally complied with these restrictions, and when they did not, they often expressed themselves with reactions such as sulking/angry/crying.

Conclusions: This study emphasizes that the most important factor determining children's attitudes towards technology use is their parents' attitudes towards technology use. In order for children to develop a positive attitude towards technology use, it can be beneficial for parents to regulate and control their children's technology use as well as their own.

doi: 10.1192/j.eurpsy.2024.1186

Introduction: Emotion regulation is the conscious or automatic control of emotions to adapt, cope, and maintain well-being. Effective emotion regulation is central to mental health, impacting work, and relationships. University students, facing academic pressures and social transitions, represent a unique demographic where emotion regulation challenges are particularly relevant.

Objectives: This study aimed to explore the emotion regulation difficulties in university students.

Methods: A descriptive study was led from August to September 2023. An online questionnaire was distributed to a population of Tunisian university students. We administered a socio-demographic questionnaire and the Arabic version of the difficulties in emotion regulation scale short form (DRES-SF), a self-report measure developed to assess clinically relevant difficulties in emotion regulation.

Results: Participants in this study consisted of 307 undergraduate students, with 78.1% being women and 21.9% men, representing various academic disciplines at Tunis el Manar University in Tunisia. The mean age of the participants was 22 years, with a standard deviation of 2.84. In the assessment of emotional regulation difficulties, participants reported a mean total score of 42.47 ± 12.68 . Participants who repeated years in college had more difficulties in emotional regulation ($p < 0.05$). Limited access to emotion regulation strategies had a mean score of 7.64 ± 3.0 , while nonacceptance of emotional responses was rated at 7.40 ± 3.17 . Additionally, impulse control difficulties were reported with a mean score of 6.46 ± 3.31 , and difficulties in engaging in goal-directed behavior were observed with a mean score of 9.44 ± 3.18 . Moreover, participants expressed a lack of emotional awareness, which was quantified with a mean score of 8.45 ± 2.69 , and a lack of emotional clarity, which yielded a mean score of 7.12 ± 2.69 . Additionally, a significant association was noted between gender ($p < 0.05$), age ($p < 0.05$), and the lack of emotional awareness, suggesting potential gender and age-related variations in emotional regulation difficulties within this university sample.

Conclusions: Overall, these findings suggest the necessity of emotion regulation training in the university setting. Further studies are important to understand the impact of emotional regulation difficulties.

Patterns of antipsychotic prescription in inpatient and outpatient psychiatric settings: a real world study

T. G. Prodi^{1*}, E. Piccoli¹, C. Bucca¹, A. Tomasoni¹ and B. Dell'Oso^{1,2,3,4}

¹University of Milan, Department of Mental Health, Department of Biomedical and Clinical Sciences "Luigi Sacco"; ²University of Milan, Aldo Ravelli" Center for Nanotechnology and Neurostimulation, Milan, Italy; ³Stanford University, Department of Psychiatry and Behavioral Sciences, Stanford, United States and ⁴University of Milan, Centro per lo studio dei meccanismi molecolari alla base delle patologie neuro-psico-geriatriche, Milan, Italy

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1187

Introduction: Antipsychotic (AP) are increasingly prescribed off-label and used as, but not limited to, anti-aggressive, anti-impulsive, and anti-suicidal medication. The use of second-generation AP (SGAs) has progressively increased compared to first-generation AP (FGAs). FGAs cause more extrapyramidal motor side effects

and tardive dyskinesia than SGAs, whereas SGAs generally cause more weight gain and cardiometabolic adverse effects.

Objectives: Aim of this observational study was to describe the socio-demographic and clinical features of the patients receiving new AP treatment and the features of the pharmacological treatment itself in “real world” context. Furthermore, we aimed to compare socio-demographic and clinical characteristics of the subjects who were prescribed either FGAs or SGAs.

Methods: Data were collected on the latest new AP prescriptions issued across different settings (two psychiatric wards; five out-patients clinics; and one rehabilitation community) belonging to ASST Fatebenefratelli Sacco (located in Milan) in reverse chronological order from May 2023.

Socio-demographic and clinical variables of the subjects who received new AP treatment were collected through medical records. We compared age, age at onset, age at first pharmacological treatment, duration of illness, duration of untreated illness, treatment duration, number of hospitalization and admissions to Day Hospital services, involuntary commitments and suicidal attempts in patients who received either FGAs or SGAs. Chi-square was used for qualitative variables and t-test for quantitative variables. Data were collected anonymously and analyzed using SPSS v.27.

Results: The sample included 155 new AP prescriptions, out of which 29.2% were formulated in the psychiatric wards, 66.9% in the outpatient clinics and 3.9% in the rehabilitative community. Mean age of the subjects was 41.1 ± 16.9 years, 53.2% were male.

The most represented diagnoses were psychotic disorders (32.2%), personality disorders (24.8%), bipolar disorder (16.1%) and depressive disorder (12.8%).

90.7% of new AP prescriptions were SGAs. The most prescribed were aripiprazole (30.5%), quetiapine (21.2%) and olanzapine (15.2%); while the most prescribed FGAs were haloperidol (5.3%), zuclopenthixol (2%) and chlorpromazine (1.3%). 26.2% of the prescriptions were in monotherapy and 83.8% were for oral administration.

The reasons for introduction were partial or absent response to previous treatments (52.3%), disease onset (23.5%), non-compliance (8.3%), adverse effects to previous treatments (6.8%) or other (9.1%). Patients treated with FGA had a longer duration of untreated illness ($p < 0.001$) and a greater number of lifetime hospitalizations ($p < 0.001$) and involuntary commitments ($p = 0.002$).

Conclusions: Patients treated with SGAs have a shorter duration of untreated illness and also lower chance of lifetime hospitalization and involuntary commitment.

Change in risk status of psychiatric patients admitted to Crisis and Home Treatment Team: an evaluation in the UK

U. Raja*, A. Misra and N. Kar

Black Country Healthcare NHS Foundation Trust, Wolverhampton, United Kingdom

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1188

Introduction: The Crisis and Home Treatment Teams (CRHT) in psychiatry manages patients with risk to self and others in the community. The number of patients under CRHT who attempt or die of suicide is high in the UK (Hunt et al BJPsych Bull. 2016;40:172-4). The CRHT is an option to help support patients in managing their risk using various interventions and also aim to prevent admission to acute psychiatric wards where possible.

Objectives: We intended to study the change in risk to self and others and the factors associated with it during the intervention from a CRHT taking care of adult patients in the West Midlands region of England.

Methods: The study was conducted as a service evaluation of patients admitted under the CRHT. Data was collected from the case records, for 100 patients for whom details were available. Risk to self and others were checked, along with overall risk as red (highest risk), amber (intermediate risk) and green (low risk). Demographic and clinical information was collected and the data quality was checked.

Results: There were 46 male and 54 female patients in the study, with mean age of 40.4 ± 12.4 and 40.2 ± 12.8 Years respectively (not significant). They were comparable in number of diagnoses (mean 1.2 each) and number of days (22.2 ± 13.1 v 20.2 ± 17.8) in CRHT respectively. There was no significant association of risk with gender (56.3% females and 44.2% of males), being on benefits or type of accommodation the service users live at. Similarly, there was no significant difference of risk of self-harm based on ethnicity; it was noted that 61.2% of patients of British White ethnicity had a risk of self on admission compared to 41.7% Black and ethnic minority patients. On admission, 89% of patients were categorised as red, amber 8% and 1% green; which changed to 18%, 2% and 77% respectively (missing data was not included, so percentages do not add up to 100%). The risk to self was present in 46% on admission and 18% on discharge ($p < 0.005$); and in 14% this risk continued without change. The risk to others on admission was recorded in 12% which was at 1% on the point of discharge ($p < 0.05$). Eight people had both risk to self and others. In 15 patients the risk continued to remain in red category, while in two patients it changed from amber to red.

Conclusions: The risk levels for patients admitted under the CRHT improved. The majority with overall high risk changed to majority presenting as low risk on discharge. The percentage of patients portraying a risk to self and others also decreased from admission to discharge. Although there was considerable decrease in risk, a proportion of patients did not have any change, or even an increase in their risk, which highlights need for additional risk management strategy for these patients in CRHT.

The Sense of Resilience of health care professionals in Latvia measured by Antonovsky's Sense of Coherence Scale

D. Janovskis^{1*} and R. Eglitis²

¹Department of Medicine, MD Resident and ²Department of Psychology, Mag. Psych., LU (Latvian University), Riga, Latvia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1189

Introduction: In this research work the sense of resilience was studied, which is an essential factor in reducing the stress of health care workers, it also helps to maintain the sustainability of the work of medical specialists and prevents the burnout syndrome. Aaron Antonovsky's Sense of Coherence scale was used in this study, which helps to determine how health care professionals are able to preserve their mental and physical health.

Objectives: This study is aimed to determine the differences in components of Antonovsky's Sense of Coherence scale for various health care specialists and to describe the factor structure of Coherence scale for health care specialists in Latvia, that forms the sense of resilience for health care specialists.

Methods: The questionnaire used in the study is Antonovsky's Sense of Coherence scale's (Antonovsky, 1987) Latvian version, that was translated into Latvian and adapted in the research work of A. Veylande, N. Bahmačova (2000). 202 respondents who are representatives of medical professions took part in this study. The obtained data were entered into the MS Excel computer program and were statistically processed using the SPSS 22 computer program.

Results: Looking at the obtained results of this study, it can be stated that Medical Doctors- Specialists have statistically significantly higher Comprehensibility scores than Medical Orderlies ($p = 0.01$, $r = 0.24$), while Medical Doctors- Specialists and Medical Doctors-Residents have statistically significantly higher Manageability scores than Medical Orderlies ($p = 0.04$, $r = 0.21$). Based on the analysis of the results, it has been determined that Doctors-Specialists ($p = 0.00$, $r = 0.32$) and Doctors-Residents ($p = 0.00$, $r = 0.34$) have statistically significantly higher Meaningfulness indicators than Medical Orderlies, as well as Doctors-Specialists ($p = 0.00$, $r = 0.29$) and Doctors-Residents ($p = 0.00$, $r = 0.31$) have statistically significantly higher Meaningfulness scores than Medical Nurses.

Conclusions: Higher scores of the three components of Antonovsky's scale for Medical Doctors-Specialists and Medical Doctors-Residents compared to Medical Orderlies and Medical Nurses could be explained by a lower overall time that Doctors spend in the department with patients. Higher education helps to overcome stress at work and to become aware of possible strategies for improving the joy of life, ways to reduce stress at work and to relax from work.

Descriptive study of patients admitted to a Psychiatric Home Hospitalization Unit in Santa Coloma de Gramenet and Badalona

J. Marti Bonany*, D. Garcia Hernandez, D. Tolosa Merlos, R. Romar Navia, R. B. Sauras Quetcuti, M. J. Ambros Ghisilieri, G. A. Mateu Codina, D. Garcia Fuentes, A. M. Coratu, G. De Iturbe Catania, R. Sanchez Gonzalez, M. T. Campillo Sanz and A. Riera Soler

Salut Mental Institut, Hospital del Mar, Barcelona, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1190

Introduction: Hospital at home for psychiatric patients is a new emerging resource of delivering acute mental health care in the community. The main objective of this program is to provide intense care to patients with severe mental disorders at home as an alternative to acute admission.

Although home hospitalisation has begun to develop widely in recent years there is a notable lack of studies

The CAEM Psychiatric Home Hospitalization Unit (HAD-CAEM) has been operating since 2018 and takes place in Santa Coloma de Gramenet; and from March 2022 also in a part of Badalona. Both are sociodemographically depressed areas near Barcelona.

Objectives: The aim of this study is to describe the characteristics of patients attended at the Psychiatric Home Hospitalization Unit of our hospital and to study differences according to area and place of referral.

Methods: Socio-demographic and clinical data were collected retrospectively at admission and discharge of all patients treated at HAD-CAEM between March 2022 to february 2023.

Statistical analysis was performed by using SPSS program.

Results: 85 patients were included in the study. 45.9% were women. The mean age was 45.5 years (SD 15.58 years). The main diagnoses of the sample were psychosis and schizophrenia (38.8%), Bipolar disorder (23.53%), Depressive disorder (21.18%), schizoaffective disorder (8.24%) and others (8,24%).

54 (63.53%) patients were from Santa Coloma area and 35 (41.18%) from Badalona area.

The total mean duration of admission was 40.22 days (SD 26.18 days), with a mean follow-up of 10.09 visits (SD 5.39 visits) and 2.41 teleassistance (SD 2.62).

The mean duration of admission for Santa Coloma patients was 43.98 days (SD 28.59), and for Badalona patients 33.68 days (SD 20.13). Trend without significance is observed ($t = 1.77$, $p = 0.08$) We found differences in the mean duration of admission according to referral location. Acute psychiatric unit 33.25 days (SD 18.06), Mental health Center 51.93 days (SD 33.45), Emergencies 34.28 days (SD 19.69) ($F = 5.1$, $p = 0.008$).

Conclusions: Sociodemographic and clinical characteristics obtained in our study are consistent with those reported in previous studies. The duration of admission of patients referred from the mental health center is longer than those referred from the acute psychiatric or emergency unit. Home hospitalization teams have been increasing in recent years, being an alternative to traditional hospitalization.

Sociodemographic and Clinical Determinants of Psychiatric Hospitalization in Northern Greece: A descriptive study

G. N. Porfyri^{1*}, P. Papadopoulou¹, M. V. Karakasi² and A. Vlachaki¹

¹Psychiatry Department, General Hospital of Papanikolaou, Thessaloniki and ²Psychiatry Department, University General Hospital of Alexandroupolis, Alexandroupolis, Greece

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1191

Introduction: According to data, psychiatric re-admissions rates vary from 10%-80%, while they negatively affect the patients' quality of life and life expectancy. The limitation of multiple psychiatric hospitalizations represents a clinical challenge for all mental health professionals.

Objectives: To investigate risk factors of hospitalization in a sample of psychiatric patients in Northern Greece.

Methods: 1,633 records of psychiatry inpatients were examined retrospectively throughout the 10-year records of the Psychiatry Department of Papanikolaou General Hospital in northern Greece. The research was conducted between 2013 and August 2023. The sample was divided into subgroups according to gender, diagnosis, and year of hospitalization. A bivariate analysis was performed to examine relationships between the examined variables: (a.) place of residence; (b.) age; (c.) type of admission; (c.) hospitalization duration; (d.) number of lifetime hospitalizations; (e.) lifetime prosecutor's orders for coercive examination; and (f.) lifetime suicide attempts.

Results: A fairly equivalent number of males and females was included in the study (M: 874; F: 759). The mean age of the sample was 44.7 years with males being younger than females (males 43.23; females 46.39). Males residing out of the co-capital as well as females residing within the co-capital of Greece, Thessaloniki, disclosed higher odds of being hospitalized ($p < 0.03$). Coercive hospitalizations represented 47% of cases, bore the highest duration (20.7 days), and involved the youngest patients. Coercively hospitalized male patients outnumbered their female counterparts ($p < 0.001$). Voluntary urgent hospitalizations duration was estimated at 17.04 days, followed by outpatient admissions (12.64 days) and transfers from other clinics (11.35 days). 37% of patients experienced psychosis while 35% experienced affective disorders. Males were more affected by psychosis (Odds Ratio: 1.35; $p < 0.001$). Females were more liable to affective disorders (OR: 1.78; $p < 0.001$). 7% of the sample had committed suicide attempts, with single suicide attempts being ten times higher than multiple suicide attempts ($p < 0.001$). Females were more than twice as likely as males to commit a suicide attempt ($p < 0.001$). Females tended more to be hospitalized self-willingly ($p = 0.0015$) and to voluntarily terminate hospitalizations prematurely ($p = 0.0014$). Patients with a single hospitalization were seven-fold compared to those with multiple hospitalizations ($p < 0.001$). The average lifetime hospitalization number for a patient was one hospitalization, while the average for a patient with previous hospitalizations was three.

Conclusions: Being in position to identify the patients in high-risk for hospitalization -as well as for suicide attempt- the clinician can proceed to initiatives such as treatment modifications or further involving the patient's family.

EPV0505

Assessing the Impact of the Different Psychiatric Disorders on the Profiles of Psychiatric Hospitalization: A descriptive study in a Greek Hospital

G. N. Porfyri^{1*}, P. Papadopoulou¹, M. V. Karakasi² and A. Vlachaki¹

¹Psychiatry Department, General Hospital of Papanikolaou, Thessaloniki and ²Psychiatry Department, University General Hospital of Alexandroupolis, Alexandroupolis, Greece

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1192

Introduction: The prevalence of psychiatric re-admission ranges from 15% to 60%, escalating even more in the first year after admission, affecting the patients' quality of life. Furthermore, the diagnosis of psychotic or affective disorders represents a risk factor

of psychiatric re-admission, highlighting the diagnosis impact to the "profile" of psychiatric hospitalization.

Objectives: To compare the different "Hospitalization Profiles" in association to the patients' diagnostic categories.

Methods: Overall, 1,633 records of psychiatry inpatients were examined retrospectively throughout the 10-year records of the Psychiatry Department of Papanikolaou General Hospital in northern Greece. The research was conducted between 2013 and August 2023. The sample was divided into subgroups according to gender, diagnoses - according to the International Classification of Diseases (ICD-10)-, and year of hospitalization. A bivariate analysis was performed to examine relationships between the variables: (a.) place of residence; (b.) age; (c.) type of admission; (c.) hospitalization duration; (d.) number of lifetime hospitalizations; (e.) lifetime prosecutor's orders for coercive examination; (f.) lifetime suicide attempts.

Results: Developmental disorders (F80-89) stood for the youngest average age of hospitalization (26 years) and lowest average hospitalization duration (7 days). Neurodegenerative disorders (F00-09) represented the diagnostic category with the oldest mean age of hospitalization (66 years). Intellectual disorders (F70-79) yielded the longest average hospitalization duration (21 days). Patients with intellectual disorders were found to be facing homelessness at a higher rate (4.76%) than patients of any other diagnostic entity ($p = 0.096$). Psychotic and substance use disorder patients obtained equivalently ($p = 0.18$) the highest rates of coercive hospitalizations (63% and 71%, respectively); compared to other diagnostic categories ($p = 0.0008$). Dual diagnosis and anxiety disorders projected equivalently ($p = 0.9$) the highest rate of premature voluntary discharge (6.9% and 6.4%, respectively). Dual diagnosis, personality disorders, and affective disorders also recorded the highest rates of suicidality (11-15%; with no significant statistical difference among the three diagnostic entities $p > 0.1$) among hospitalized patients of all diagnostic categories ($p < 0.05$).

Conclusions: Interestingly, the study's results reveal the pathologies of the Greek society, with the most representative example being this of patients suffering from intellectual disorders simultaneously presenting the highest risk of homelessness. Further studies are needed, focusing on the sub-populations of psychiatric patients as well as their status in terms of social security, health care providing, quality of life and life expectancy.

Psychiatric disorders in professional drivers and fitness for work

W. Ayed¹, G. BAHRI¹, M. Mersni¹, D. BRAHIM¹, L. HOUISSA^{1*}, I. YOUSSEF¹, N. MECHERGUI¹, M. BANI¹, H. BENSaid¹, I. YAICH², C. BENSaid², N. BRAM² and N. LADHARI¹

¹Occupational pathology and fitness for work department Charles Nicolle hospital, Faculty of medicine of Tunis, Tunis El Manar University, Tunis and ²Forensic Psychiatry department, Razi Hospital, Faculty of medicine of Tunis, Tunis El Manar University, MANNOUBA, Tunisia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1193

Introduction: The driver's job is a safety job requiring a meticulous neuropsychological assessment, which can affect the decision on fitness to drive. Professional driving benefits from codified regulations concerning neuropsychological disorders.

Objectives: To describe the socio-professional characteristics of drivers with psychiatric illnesses

To specify the impact of these pathologies on decisions on fitness for work

Methods: Retrospective descriptive study of drivers with psychiatric disorders who consulted the occupational pathology and fitness for work department of the Charles Nicolle Hospital for fitness for work assessment during the period from January 2016 to January 2023.

Results: Out of 98 drivers who consulted our department for an aptitude assessment, nine (n=9) patients had a psychiatric disorder. The average age was 45±7 years. They were all men. They were bus (n=7), light car (n=1), and lorry (n=1) drivers. They belonged to the transport (n=7) and service (n=2) sectors. Length of service ranged from one year to 35 years. The pathologies presented by the patients were: anxiety-depressive disorder (n=7), bipolar disorder (n=1) and drug-addiction (n=1). They were being treated with antidepressants (n=7), anxiolytics (n=3), and thymoregulators (n=1). The medico-legal decision was to avoid professional driving (n=7) and to avoid professional driving at night (n=2).

Conclusions: psychiatric illnesses can compromise fitness to work. The role of the occupational physician in the primary and secondary prevention of people at risk is important.

Characteristics of online shopping behaviour among Tunisians consumers

M. Mnif, F. Guermazi, R. Masmoudi, W. Abid*, I. Feki, I. Baati and J. Masmoudi

CHU Hedi Chakeur psychiatry A department, Sfax, Tunisia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1194

Introduction: During the COVID-19 pandemic confinement, the number of people shopping online has increased all over the world. To date, little is known about the online shopping behaviours of Tunisians consumers.

Objectives: Evaluate the characteristics of internet shopping among Tunisian consumers.

Methods: A cross-sectional, descriptive and analytical study was conducted among subjects who had already made at least one online purchase. Data was collected using a self-questionnaire published by GOOGLE FORMS. We used a survey form collecting socio-demographic data, personal history and characteristics of online shopping behaviour.

Results: A total of 137 participants aged 34.62 ± 9.82 years took part in this study.

All participants had made at least one online purchase, with 43.8% (N=60) purchasing "More than once a year". The products purchased were most often textiles and shoes (50.4%; N=69). The main reasons consumers gave for buying online were special offers (37.2%, N=51), reduced prices (25.5%, N=35) and free delivery

(14.6%, N=20). Almost half of the participants (N=63; 46%) said that they had visited physical shops less since they started shopping online. Regarding the average online shopping budget, 44.5% of consumers (N=61) spent less than 50 dinars/month and 18.2% (N=16) did not use all the products they bought online. Almost half of participants (N=68, 49.6%) feared that their credit card information would be at risk. The majority of respondents (88.9%) thought they might receive a faulty product following online shopping.

Conclusions: Our study has enabled us to identify certain factors that may act as a blocker for online purchasing. So that, establishing strategic actions for the continuous improvement of online shopping services with the reduction of subjectivity in customer perception will be helpful.

Use of long-acting treatments in adult social care. Experience of an Acute Inpatient Mental Health Unit

C. Rodríguez Gómez-Carreño* and A. Sarrió Yuste

Psychiatry, HGUCR, Ciudad Real, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1195

Introduction: In recent years, the number of social exclusion patients who go to the emergency room for psychiatric evaluation, has increased significantly. This fact may be due to the circumstances associated with migration: economic problems, house searching, moving away from the family origin,... These situations can cause stress before, during and after adaptation, which is a risk factor for presenting psychotic symptoms.

Objectives: The objective of this study is present another alternative treatment for adults with social exclusion with psychotic symptoms or Psychotic Disorder. Presenting through a case of Acute Inpatient Mental Health Unit.

Methods: A 25 year old men was referred to the emergency department due to an episode of agitation. As relevant psychiatric history, a previous admission to psychiatry's hospitalization with a diagnosis of Schizophrenia. Upon discharge, the patient has not been followed up in Mental Health, although he has gone to the emergency room on several occasions where it is reflected that no psychotic decompensation has been observed. He emigrated to Spain two years ago, since then he has been homeless, working intermittently in agriculture.

At our assessment, after having ruled out consumption of toxic substances, the patient presented a neglected and cachetic appearance. He says that he is worried because some people can not see him and others can.

We admit the patient for study and treatment. Involuntary admission.

Results: During the hospitalization, a joint approach was carried out with Social Work and it was decided to start depot treatment in order to promote therapeutic adherence. In this case, it was decided to apply paliperidone depot every sin month. For this, an induction regimen was followed: first, monthly paliperidone 100mg depot was administered, 4 days later, monthly paliperidone 150mg depot and 4 days later, the biannual injection.

Other depot treatment alternatives would have been aripiprazole or risperidone. However, the duration of the depot treatment is shorter than in the case of paliperidone, since today the presentation formulas are monthly and quarterly, respectively.

Conclusions: Long-acting antipsychotics are an effective alternative for the treatment of patients with Schizophrenia, especially for those in whom we can not ensure good therapeutic adherence. In addition, the induction regimen allows treatment to be administered more quickly than that carried out in Mental Health outpatient programs, thus reducing the average hospital stay.

In recent years, great advances have been made in the treatment of psychotic symptoms thanks to depot drugs, which allows for numerous effective alternatives for the treatment of these patients. The figure of the Social Worker for the evaluation of the patient and subsequent follow-up is essential in this case.

Euthanasia and assisted suicide in people with mental disorders: a case report

M. Martin De Argila Lorente^{1*}, B. Franco Lovaco¹, M. González Guembe¹, M. Fresnillo Palomera¹ and C. Díaz Mayoral²

¹Psychiatry, Hospital Dr. Rodríguez Lafora and ²Psychiatry, Hospital Universitario Príncipe de Asturias, Madrid, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1196

Introduction: Until 2020, only Belgium, Luxembourg, Switzerland, and the Netherlands legalized euthanasia and assisted suicide in Europe. Spain joined this list in March 2021 with the Euthanasia Regulation Law. However, the practice of euthanasia and assisted suicide in individuals with severe mental disorders is complex due to potential cognitive and decision-making challenges. Psychiatrists play a vital role in evaluating such requests.

Objectives: the case of a patient with recurrent depressive disorder requesting euthanasia is presented, followed by a theoretical review of the subject.

Methods: A case is presented with a bibliographic review.

Results: An 89-year-old man with a history of one prior brief psychiatric hospitalization for depression three years ago was admitted after attempting suicide with an overdose of medication. He reports depressive symptoms of several years of evolution. Medical tests came back normal, but he had a urinary catheter due to voiding issues. He was initially on a medication regimen of amitriptyline, clomethiazole, and fluvoxamine. Despite his depressive state, he maintained his cognitive and decision-making abilities. Medication adjustments were made, including discontinuing amitriptyline and switching fluvoxamine to amitriptyline. His depressive symptoms worsened after three days, leading to the addition of trazodone to his treatment. He also developed urinary symptoms and was diagnosed with a urinary tract infection and metastatic prostate cancer during urological evaluation. Emotionally, he became more apathetic,

anergic, and anhedonic, frequently expressing a desire for euthanasia, even with medication changes. Hyponatremia led to the discontinuation of duloxetine and the introduction of venlafaxine. To address anxiety and sleep problems, clomethiazole was replaced with mirtazapine. Upon learning of his cancer diagnosis, his mood deteriorated further, along with increased anxiety and continued mentions of euthanasia. Lorazepam was introduced, and he was informed of his right to request euthanasia after discussing therapeutic options with urology. Following this consultation, the patient became calmer, stopped expressing thoughts of death, and began making short-term plans, including the possibility of receiving palliative care at home upon discharge.

Conclusions: Euthanasia and assisted suicide in severe mental disorders are complex due to ethical and medical challenges. Patients must understand their condition, prognosis, and have decision-making capacity. Assessing their suffering is crucial. Coexisting mental and organic issues complicate the request's origin. In SMD, determining irreversibility is tricky, as these are often chronic, non-terminal conditions. Exhausting treatment options is essential before considering euthanasia, despite patient treatment refusal. Limited research underscores the need for more studies.

Disclosure of Interest: None Declared

An ethical dilemma: the role of the psychiatrist in physician assisted suicide and/or euthanasia

S. Jesus Magueta*, A. L. Costa, G. Simões, A. I. Gomes, C. Madaíl Grego and P. Garrido

Departamento de Psiquiatria e Saúde Mental, Centro Hospitalar do Baixo Vouga, Aveiro, Portugal

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1197

Introduction: Questions regarding death have generated debates and art since the dawn of civilization. These themes permeate through various areas of study, including religion, philosophy, ethics, medicine and humanities. Various countries have been revising their laws regarding the end of life, especially on the right to aid and choice in the end in the context of medical and psychological suffering. Physician-Assisted Suicide (PAS) and euthanasia are methods by which people, mostly terminal patients, seek to end their lives with the help of medical professionals. PAS and euthanasia have been the target of heated debates in politics and in medicine, with the question of ethics centering most of these.

Objectives: The authors aim to explore PAS and euthanasia in the context of the ethical debate. Based on the pillars of ethics, based on the principal of do no harm and beneficence, the authors explore the role of the Psychiatrist, if any, in these end of life issues.

Methods: The authors performed a brief narrative review of the available literature, with recourse to various databases such as PubMed and Scopus. The search terms utilized in isolation or combination included: *physician assisted suicide, euthanasia, psychiatry, mental illness* and *ethical issues*. Taking into consideration the widespread discussion of these themes in the public forum, news articles were included based on their merit and relevance to the explored topic.

Results: The ethical debate appears to rest between the pillars of first, do no harm, the principles of beneficence and nonmaleficence and aut. Here, the conflict between the first and last appear, where the killing of any patient, whether directly or indirectly is clearly contrary to the principle of primum non nocere. However, the prolonging of suffering in a terminal patient, appears to contradict the principles of nonmaleficence. The Psychiatrist is called to evaluate competence to choose, which is allied to autonomy. Other sources explore the role of the Psychiatrist in permitting a suicide to occur, when the profession is dedicated to the prevention of suicide. From the literature, the psychiatric evaluation is rarely regularly carried out, usually being solicited in cases where mental illness which might compromise the capacity to choose is suspected.

Conclusions: In ethical debates, clear cut answers are rarely every developed, with the nuance and greyscale of difficult topics usually dividing those that fervently champion each cause. Psychiatric evaluation is usually invoked when patient autonomy, especially in terms of capacity, is called into question. Questions remain as to whether the presence of the psychiatrist should be a regular one in these procedures or if it should be carried out in a selective manner. There is little consensus in regards to this role, which merits further conversation in the various forums of medical and ethical communication.

Attitude of tunisian psychiatry residents toward internet searches for patient informations

Y. Ben Youssef, M. Lagha, S. Boudriga*, M. Methni, I. Ben Romdhane, W. Homri and R. Labbane

Department C, El Razi Hospital, Mannouba, Tunisia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1198

Introduction: In the age of digital information, the volume of personal information available online continues to grow. Examining patients' online profiles has become common for various reasons especially in psychiatry, despite ethical concerns. Therefore, it is interesting to explore the attitudes of tunisian psychiatric residents in this regard.

Objectives: This study aimed to identify the purposes that make psychiatry residents consult their patients' profiles on social media and to evaluate the consequences of being friends with them or following them on the treatment course and on the doctor-patient relationship.

Methods: This was a cross-sectional descriptive study from August to September. A questionnaire on Google form was distributed to psychiatry Tunisian residents. The study evaluated the frequency and causes of patient profiles consultation on social networks, its role and impact in the doctor-patient relationship

Results: The study population included 53 psychiatry residents with a mean age of 28 (+5) years and a sex ratio of 0.127. Among the responders, 53 % were in their first or second year of residency. And the predominant workplace was El Razi Hospital : a university hospital.

For the frequency of patient profiles consultation on social networks : 87% of treating psychiatrists declared consulting their patients' profiles on social media at least once. The purposes of consulting patient's profiles noted in our study were: looking for signs of pre-morbid functioning (n=32), looking for clinical features of the current episode (n=30). They do it also to verify the informations provided by the patient (n= 18) ,have an idea of their private lives (marital status ,employment, hobbies,...)(n=11) , or locate a family member (n=5). It can be also out of curiosity (n=21). And this made the psychiatry residents empathetic towards the patient (n=10) .

But, in 91% of cases, patient's permission was not taken .

Moreover, 4 of treating psychiatrists declared being friends with their patients or following their profiles on social media. Two of them regret it. The friend or follow request was an initiative from the patient, in all cases.

Conclusions: The attitudes of psychiatry residents regarding the consultation of patients' profiles on social networks were not clear. However, as the boundaries of the digital doctor-patient relationship remain undefined, it is imperative to develop clear guidelines and educational resources.

Psychiatric premises for abortion in Poland - ethical, legal and clinical issues

W. E. Kosmowski

Department of Psychiatry, Nicolaus Copernicus University, Bydgoszcz, Poland

doi: 10.1192/j.eurpsy.2024.1199

Introduction: After judgment of the Constitutional Tribunal of 22.10.2020, there are two premises for abortion: when pregnancy was caused by rape or pregnancy is the threat for health and life of a mother. Then some people indicated that the latter should be interpreted more broadly. So far, jurisprudence has interpreted health threats only in relation to physical health, currently – cases classified as mental health threats are included.

Objectives: The aim of this paper is first to analyze different aspects of this phenomenon: clinical, philosophical, including ethical and legal. The second goal is to point out the best actions for psychiatrists.

Methods: The methodology of this paper corresponds to the pastoral paradigm: diagnosis, reflection, action. At first, the arguments of opponents and proponents of the concept of psychiatric premises for abortion were extracted. Then they were assessed from a logical and essential point of view. Finally, some conclusions and guides were included to enable psychiatrists to act appropriately, including ethical, clinical and legal aspects.

Results: Statements and letters from various institutions and societies were analyzed, including the Presidium of the Supreme Medical Council, Polish Pediatrics Society, the Expert Team on Bioethics of the Polish Bishops' Conference, the Bioethics Committee of the Polish Academy of Sciences, Patient's Rights Ombudsman, Commissioner for Human Rights. The key arguments for psychiatric premises are presented in the Table 1.

Table 1.

Argument	Description
Etiological	the only cause of mental disorders during pregnancy is the pregnancy itself or fetal diseases
Therapeutical	abortion is a method of treating mental disorders during pregnancy
Prognostic	possible long- and short-term complications after the abortion procedure do not pose a significant threat to the woman's life and health
Consultation-Liaison	the task of the consultant psychiatrist is to indicate what actions other doctors should take
Ethical	the value of the fetus's life is negligible compared to values such as the mother's mental state or well-being
Political	such conduct is beneficial to state policy and the good of society
Legal	such procedures are legal

According to opponents, using the premise of mental health risks to terminate a pregnancy would be an example of the psychiatrization of life and the abuse of psychiatry for political purposes. There would be a danger of associating psychiatry as a tool for performing abortions, which would perpetuate the phenomenon of stigmatization – of both doctors and patients. Each of the arguments for this has been negated.

Conclusions: This problem illustrates an attempt to replace the paradigm of traditional personalistic ethics with utilitarianism. The concept of psychiatric premises for abortion is contrary to the principles of double effect and proportionality. It is also against the Polish Code of Medical Ethics: art. 39 and art. 54.

Non-compliance as ethical dilemma for kidney transplantation

L. Rossini Gajsak^{1*} and L. Zibar^{2,3}

¹Department of Integrative Psychiatry, University Psychiatric Hospital Sveti Ivan; ²Department for Nephrology, Internal Clinic, Clinical Hospital Merkur, Zagreb and ³Faculty of Medicine, Department for Pathophysiology, University Juraj Strossmayer, Osijek, Croatia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1200

Introduction: Allocating a kidney transplant to a non-compliant recipient could present a triple damage: to the donor (and family of a deceased donor), for the recipient (who will experience rejection) and for another potential recipient on the waiting list (who missed the chance for the transplant). Having in mind that kidney transplantation (TX) is the best choice of renal replacement therapy, a thorough individual endeavor to predict the outcome of a TX in a non-compliant candidate is necessary to avoid a worse option. Non-compliance could origin from maladaptation, psychological limitations or a psychiatric condition.

Objectives: Here we present a 46 years old male patient on chronic hemodialysis (HD) for 4 years due to end stage diabetic kidney

disease. He is extremely non-adherent to HD related recommendations, occasionally skipping the sessions, gaining up to 10 kg weight overload between the sessions and avoided visiting psychiatrist, so far. Our objectives were to explore the presence and severity of non-compliance as ethical dilemma for kidney transplantation.

Methods: Reviewing the patient's medical data.

Results: Unlike to non-obedience to dietary and behavioral medical advice, this patient is very much adherent to pharmacological medication. Staying on HD he is constantly on the edge of vital danger, risking pulmonary edema or hyperkalemia related cardiac events. The most important compliance in a kidney transplant patient is adherence to immunosuppressive therapy. In this particular patient we could predict adherence to immunosuppressive medication after a TX and getting rid of volume overload and hyperkalemia once restoring kidney transplant function.

Conclusions: Pretransplant non-compliance in kidney transplant candidate is not always an obstacle for kidney TX. In some cases, as in the one here described, a TX is better option than staying on HD, avoiding the previously described triple ethical damage - to the donor, the recipient and patients waiting on list, while we could predict a good outcome of the TX. Including psychiatrist into the work up and management should not be skipped.

The attitude of Tunisian medicine resident toward euthanasia

A. Touiti^{1,2*}, C. Ben Said^{1,2} and N. Bram^{1,2}

¹Forensic Psychiatry Departement, Razi Hospital, La Manouba and ²Faculty of Medecine of Tunis, Tunis El Manar University, Tunis, Tunisia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1201

Introduction: Euthanasia is the active deliberate ending of life by another person at the explicit request of a patient who is suffering from an incurable condition deemed unbearable by him or her. young doctors in tunisia might be exposed in their daily practice to a request of (E). In some countries the procedure is regulated by law while in others the issue has not been discussed. Before assessing the public opinion the medical core has to be implicated in the debate about the subject. Within the limits of our knowledge this is the first study on the subject in the countries of North Africa

Objectives: To describe the attitudes of tunisian medicine resident toward euthanasia

Methods: The validated questionnaire of physicians' Attitudes and opinions on assisted suicide and euthanasia was distributed via mails addresses to 50 tunisian resident. The participation was entirely voluntary and anonymity was guaranteed.

Results: Thirty seven medicine resident participate to the study the response rate was 74%. The average age of participants was 28.2years old. The majority; 23 were female and 29 had religious beliefs. The most represented speciality was family medicine with 6 participants. Only 2 of doctors were practicing in Europe. About 8 of young doctors were requested for (E). Tunisian medicine residents are generally supportive of the legalization of euthanasia (29), but many have concerns about their own participation in the procedure.

Conclusions: Ethical and legal complexities surround the topic of euthanasia. It is imperative to deepen our understanding of this practice within the context of the North Africa region, in order to formulate a comprehensive and well-informed policy.

Change in Quality of Life After the Relocation of a National Forensic Hospital: A Dundrum Forensic Redevelopment Evaluation Study (D-FOREST)

A. O'Reilly¹, M. U. Waqar^{1,2,*}, M. U. Iqbal^{1,2}, H. Amin^{1,2}, H. G. Kennedy² and M. Davoren^{1,2}

¹Central Mental Hospital, National Forensic Mental Health Service, Portrane and ²Dundrum Centre for Forensic Excellence, Trinity College Dublin, Dublin, Ireland

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1202

Introduction: Forensic psychiatric services address the therapeutic needs of mentally disordered offenders in a secure setting. Clinical, ethical, and legal considerations underpinning treatment emphasize that the Quality of Life (QOL) of patients admitted to forensic hospitals should be optimised.

Objectives: This study aims to examine changes in the QOL in Ireland's National Forensic Mental Health Service following its relocation from the historic 1850 site in Dundrum to a new campus in Portrane, Dublin.

Methods: This multisite prospective longitudinal study is part of the Dundrum Forensic Redevelopment Evaluation Study (D-FOREST). Repeated measures were taken for all inpatients in the service at regular six-monthly intervals. The WHOQOL-BREF questionnaire was offered to all inpatients and an anonymised EssenCES questionnaire was simultaneously used to measure atmosphere in the wards. Data were obtained at five time points for each individual patient and ward. WHOQOL-BREF ratings were obtained across five time points with comparisons for four time intervals, including immediately before and after relocation. For 101 subjects across the four time intervals, 215 sets of data were obtained; 140 before and 65 after relocation with 10 community patients who did not move. Using Generalised Estimating Equations (GEE) to correct for multiple comparisons over time, the effect of relocation, with community patients as a control, was analysed by ward cluster and whether patients moved between wards. Observations were categorised according to security level — high dependency, medium secure, rehabilitation, or community — and trichotomised based on positive moves to less secure wards, more secure wards (negative moves), or no moves.

Results: The hospital's relocation was associated with a significant increase in environmental QOL (Wald $X^2=15.9$, $df=1$, $p<0.001$), even when controlling for cluster location, positive and negative moves. When controlling for ward atmosphere, environmental QOL remained significantly increased after relocation (Wald

$X^2=10.0$, $df=1$, $p=0.002$). EssenCES scores were obtained within the hospital for three time points before relocation and two time points afterward. No significant differences were found in the three subscales before and after the relocation. All three EssenCES subscales progressively improved with decreasing security level (Patient's Cohesion: Wald $X^2=958.3$, $df=1$, $p<0.001$; Experienced Safety: Wald $X^2=152.9$, $df=5$, $p<0.001$; Therapeutic Hold: Wald $X^2=33.6$, $df=3$, $p<0.001$).

Conclusions: The GEE model showed that the hospital's relocation improved self-reported environmental QOL. The cluster location made significant differences, as expected for a system of stratified therapeutic security, with a steady improvement in scores on all three atmosphere subscales.

The interplay of aggression and psychopathy in a correctional treatment setting

A. Voulgaris^{1,*}, P. Briken¹ and E. Stückl¹

¹Institute for Sex Research, Sexual Medicine and Forensic Psychiatry, Medical University Hamburg, Hamburg, Germany

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1203

Introduction: Aggression is a relevant risk factor for criminal behavior. Psychopathy is known to correlate with a higher risk for violent offenses and research suggests that successful therapy of psychopathy is complicated.

Objectives: Our goal was to explore the overlap between psychopathy and aggression and the specific influence of psychopathic traits on change in aggression during correctional therapy.

Methods: A pre-post-study rating psychopathy and aggression in men imprisoned for sexual and non-sexual violent offenses aged between 20 and 67 ($M=37.6$, $SD 11.6$) was conducted. The participants filled out standardized pre- and post-treatment ratings after admission and after an average of 16 months ($n=144$ for pre-rating, $n=89$ for post-rating). Psychopathy was measured via the PCL-R and aggression with the BDHI (Buss-Durkee Hostility Inventory).

We calculated two-tailed Pearson correlations for BDHI Pre-, Post-, and Change Scores and the PCL-R. Further, the BDHI pre-post-differences were compared using independent t-Tests, effect sizes were calculated using Cohen's d (small, medium, and large effect sizes are $d = .20$, $.50$, and $.80$). Also, unpaired t-tests were carried out to compare between participants with lower and higher PCL-R sum scores (median split, $mdn = 16.8$, $M=16.8$, $SD=7.0$).

Results: Psychopathy facets 3 and 4 (lifestyle, antisocial) and the sum score correlate significantly with the pre-, and post-BDHI total score and the subscale direct hostility but not with indirect hostility. Regarding BDHI change scores, only the interpersonal facet of PCL-R correlated significantly with direct hostility and the total BDHI score. In the whole population, a significant reduction of the BDHI was only found in the subscale indirect hostility ($p=.015$, $cohens d = .26$). In the subgroup of individuals with lower PCL-R (<16.8) showed a reduction of indirect hostility ($p<.001$, $cohens$

$d = .50$) and the total BDHI score ($p = .003$, cohens $d = .42$). Interestingly, in the group with higher PCL-R scores no significant reduction of self-assessed hostility via BDHI was observable during therapy.

Conclusions: We identified a significant correlation between psychopathy and aggression, especially regarding facets three, four, and the sum score. Only the interpersonal facet correlated with the change in aggression during treatment in prison. In the group with higher psychopathic traits, no change in aggression was achievable during therapy. Thus, in the aspect of aggression and hostility, our data suggest that higher psychopathic traits may be viewed as a complicating factor for successful therapy.

The Romanian forensic psychiatry system related to the admission of patients- aspects of the criminal law

C. E. Anghel^{1,2*}, C. Băcilă^{1,2} and M. Tănase³

¹Faculty of Medicine, The "Lucian Blaga" University; ²Scientific Research Collective in Neurosciences - The "Dr. Gheorghe Preda" Clinical Hospital of Psychiatry and ³The "Dr. Gheorghe Preda" Clinical Hospital of Psychiatry, Sibiu, Romania

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1204

Introduction: In the Romanian forensic psychiatric and legal system, the legislation allows people diagnosed with mental disorders and who have committed a crime, without discrimination, to come under the Criminal Code, thus applying the safety measure of medical hospitalization. Although it is a complex measure, which requires increased attention in its application, any omission on the part of the authorities could lead to the violation of various human rights. The role of this measure is to improve the mental state of perpetrators, who represent, both for them and for society, an important danger. Approaching from this perspective we can say that this legal framework defines and limits the circumstances in which this measure can be produced to prevent the violation of human rights.

Objectives: The objective of this presentation was to carry out an analysis of the applying criteria for the safety measure of medical hospitalization, as well as the procedural aspects, in the national institutions where the perpetrators serve their sentences, called "psychiatric and security hospitals"

Methods: In this way, in our research we wanted to discover the most frequent pathologies blamed to be the cause of crimes and determined the application of these measures.

Results: All the results were evaluated and integrated according to the objective of this study.

Conclusions: In parallel with this analysis, we wanted to identify the main aspects that make the activity difficult and also to be able to offer the possibility of creating some solutions to improve the forensic psychiatric and legal system.

Stigma Associated with Mental Illness: Perspectives of Judges and Lawyers in Lebanon

R. Mroue¹, M. Cherro², G. Kassir², N. Dandan² and E. Ghossoub^{2*}

¹Faculty of Medicine, American University of Beirut and ²Department of Psychiatry, American University of Beirut Medical Center, Beirut, Lebanon

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1205

Introduction: Legal professionals frequently encounter forensic mental health issues in the criminal justice system. These issues can significantly impact the outcome of cases, making it essential to understand the attitudes and perceptions of these experts towards mental illness. Despite a high number of individuals with mental illness in prisons, the availability of forensic mental health services is limited. While prior research has shown widespread stigma towards mental illness, there hasn't been a study assessing the attitudes of judges and lawyers.

Objectives: This study aims to investigate the stigma related to mental health among Lebanese legal professionals.

Methods: An online questionnaire was sent to judges and lawyers practicing in Lebanon. The survey included a section on demographics and personal data with the following scales: Reported and intended behavior scale (RIBS) which measures mental health stigma-related behavior and Perceived devaluation and discrimination scale (PDD) measuring the extent to which a person believes that most people will devalue or discriminate against someone with a mental illness.

Results: A total of 215 participants, with a mean age of 38.69 and a mean 13.16 years of experience, completed the questionnaire. Most were female (62.8%) and worked as civil attorneys (47.4%). Only a minority received instruction on mental health or mental health law during training (10.7% and 8.8%). About a quarter believed their education on mental health issues was sufficient (27%). Participants with positive attitudes (RIBS) were more likely to have a family member with a mental illness (p value = .001), feel comfortable handling cases involving mental health (p value = .001), and have lived with someone with a mental illness (p value = .007). Feeling adequately educated about mental health issues was associated with lower perceived stigma (PDDs, p value = .021). No significant associations with stigma scores were found for factors like age, gender, occupation, years of experience, contact with a mental health professional, taking psychotropic medications, disclosing personal mental health issues to friends or co-workers, receiving education on mental illness or mental health law, or working with individuals with mental health issues.

Conclusions: The findings imply that enhancing mental health education and awareness within the legal profession could be a key strategy to reduce stigma and improve the overall treatment of individuals with mental health issues within the criminal justice system in Lebanon.

Development and establishment of a patient advisory board for forensic psychiatric patients - Insights and experiences from the PART project

E. Drewelow^{1*}, M. Daum², F. Ferra¹, K. Gerullis¹, I. Kilimann², O. Klein³, P. Walde¹, S. Teipel² and B. Völm¹

¹Clinic for Forensic Psychiatry; ²Clinic for Psychosomatic Medicine and Psychotherapy, Rostock University Medical Center and ³(DZNE), Deutsches Zentrum für Neurodegenerative Erkrankungen, Rostock, Germany

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1206

Introduction: Participatory research (PF) actively involves people with lived experience (pwle), e.g. for a disease, in research. This improves the relevance, quality and impact of research and can help to raise third-party funds, increase recruitment numbers, select research methods. Pwle can support all stages of the research process, including dissemination. While PF is already standard in other countries, Germany is still lagging behind. Our participatory advisory board aims to create a sustainable structure to involve underrepresented patients.

Objectives: In the PART advisory board, pwle and researchers should actively cooperate in projects in the field of forensic psychiatry. In preparation to establish the advisory board procedures, key documents and training material were developed. In addition experiences, opinions, ideas and concerns of stakeholders and pwle in relation to PF were collected.

Methods: Guided interviews were conducted with stakeholders (clinical, research) and focus groups with in-patient pwle from forensic psychiatry. They were asked how they imagine the structure, tasks and goals of a participatory advisory board, what opportunities and obstacles they see. Anticipated framework conditions and support needs for the successful implementation were also asked. The interviews and focus groups were audio-recorded and transcribed. Data was analysed with MAXQDA using thematic analysis.

Results: In total, 8 expert interviews and 2 focus groups with 15 pwle were conducted in the first half of the year 2023. The analysis so far shows great interest in PF, although the term is mostly unknown and experience seems to be limited. The respondents identified opportunities for participatory research, but also challenges that need to be overcome in terms of its implementation. Both groups emphasise the importance of PF, especially in the field of mental illness, and express ideas for its implementation.

Conclusions: The results will be incorporated into the structure of the advisory board, so that PF in the field of forensic psychiatry will be more successful and the exchange between researchers and pwle will be facilitated. Detailed results as well as impressions from the first meeting(s) of the advisory board will be presented at the EPA conference.

The preferences of Hungarian judges with regard to forensic psychiatry and forensic psychology experts

B. Baran¹, F. Á. Szabó^{1*}, A. Lisincki¹, L. Vida¹, P. Czobor¹, É. Jekkel¹ and B. Szuromi²

¹Psychiatry and Psychotherapy, Semmelweis University and ²National Institute of Mental Health, Neurology, Neurosurgery -Nyíró Gyula Center, Budapest, Hungary

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1207

Introduction: Although Hungarian forensic psychiatry has a historical legacy dating back to the 1890s, for the past few years there has been a dramatically increasing shortage of forensic psychiatry experts in Hungary, which affects both health care practices and the judiciary.

Objectives: In order to join the international academic unity of forensic psychiatry including research, education and treatment besides expert witnessing, our workgroup aims to facilitate the development of high-level quality standards in modern forensic psychiatry in Hungary. Based on our pilot study on this topic, in the current nationwide study we attempted to delineate the preferences of Hungarian judges regarding the role of forensic psychiatry and forensic psychology experts in both criminal and civil legal proceedings.

Methods: With the help of the National Office of the Courts, Hungarian judges were asked to complete a questionnaire that - besides personal characteristics - comprised specific questions in several areas including; hearing the experts; their preferences when assigning experts; the value of the expert's oral statement in court; the extent of their reliance on the psychiatric or legal knowledge of the experts; and the ways judges assess their own psychiatric and psychological knowledge. They were also asked to disclose their opinion about the attributes of optimally applicable expert opinions. Respondents provided their answers as rating on a 10-point Likert scale; or as percentage estimates. Besides descriptive statistics, we investigated the difference between the two groups of judges using Chi-square statistics and ANOVA with respect to the association between the answers and the main personal characteristics of judges.

Results: The dataset contains >400 completed questionnaires, returned from all over the country, and the analyses are ongoing. Preliminary results are available for a sample of 125 respondents: 53 criminal court and 72 civil court judges, with 64 of them having a maximum of 14 years and 61 having more than 14 years of work experience. Rating the characteristics of assigned experts, we found a significant association between being a criminal court judge and assigning an expert who is considered as an "acknowledged authority" by peers ($p=0.002$). Finding it crucial what the assessed people report on the legal case itself was significantly associated with civil court judges ($p=0.026$).

Conclusions: In the absence of any available nationwide information in Hungary, our study is expected to provide much-needed and fundamental information to the current practice of forensic psychiatry in the country.

Disclosure of Interest: None Declared

EPV0525

A patient's trajectory with autism spectrum disorder leading to forensic psychiatric institutionalisationJ. A. Déri^{1,2*}, A. Dvorak¹ and R. Oberndorfer^{1,2}¹Forensic Therapeutic Centre Göllersdorf, Göllersdorf and ²Clinical Division of Social Psychiatry, Department of Psychiatry and Psychotherapy, Medical University of Vienna, Vienna, Austria

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1208

Introduction: Autism-spectrum-disorder (ASD) is a heterogeneous neurodevelopmental condition with a wide range of symptoms. Typical deficits, such as impairment in social communication and interactions, can lead to violent behaviours. However, ASD is often underdiagnosed and little is known about patients with ASD in forensic institutions.

Objectives: To highlight the diagnostic challenges and offending behaviour of people with ASD in the context of the criminal justice system (CJS) through a case report.

Methods: The case report is based on exploration, third party anamnesis, medical documentations and court files

Results: A 25-year-old man was placed in detention in 2021 after having committed a dangerous threat to unknown persons and was considered not guilty by reason of insanity. Since early childhood the patient presented with extreme mood swings and impulsive-aggressive outbursts that led to criminal mischief later on. During elementary school he developed concentration problems as well as specific learning deficits. Due to his deviant social behaviour, he was rejected from his peer group. Over the course of the years, he showed no significant responses to different psychopharmacological treatment approaches. His social anxiety grew and ultimately, he started experimenting with various drugs and drinking excessive amounts of alcohol, which induced multiple psychotic episodes. Due to the psychotic exacerbations, he was repeatedly admitted to psychiatric units for acute treatment, however the autistic disorder remained untreated. At the time of the crime an independent psychiatric assessor diagnosed schizophrenia simplex and multiple drug abuse. The patient had been in psychiatric treatment since the age of 5 and received multiple diagnoses such as combined personality disorder, different subtypes of schizophrenia, ADHD, Tourette syndrome, depressive disorder and ASD at the age of 14. Nevertheless, prior to his detention he had never received a complex therapy focusing on his ASD. According to the verdict he was admitted to a medium secure forensic ward in Lower Austria, where he was treated with antipsychotic and anxiolytic medication. Furthermore, he participated in the day-structuring treatment program ensuring routine.

Conclusions: Neurodevelopmental disorders such as ASD often impose a diagnostic challenge, particularly without intellectual disability. This can lead to under- and misdiagnosis, inadequate treatment or even criminal behaviour. Impaired theory of mind, poor emotional regulation and problems with moral reasoning should be recognized and treated specifically early on to prevent further damage to both the individual and society.

Epidemiological, clinical, and forensic approach to a series of defendants examined in criminal psychiatric expertiseM. Kacem*, W. Bouali, M. Abdelaziz, S. Brahim and L. Zarrouk
Psychiatric department, Taher Sfar Hospital of Mahdia, Mahdia, Tunisia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1209

Introduction: The transgression of the law can be a deliberate act by a lucid adult, but it can also be the result of a deficiency in judgment and discernment due to lack of age or insanity. Psychiatric expertises are more and more solicited in the penal field with the objective of identifying the causal link between mental illness and the criminal act.

Objectives: The objective of this work was to give an overview of the subjects expertised, the offences and the pathologies encountered through the report of a psychiatric expertise activity in criminal law.

Methods: It is a retrospective descriptive study carried out on the criminal psychiatric expertises made for a forensic act in the psychiatric department of Mahdia during the period from January 1, 2003 to March 30, 2022.

Results: In total, we collected 101 defendants. The average age of our study population was 35±12.07 years. The majority of our study sample was male (98%), from an urban area (50%). 46.6% had primary education and only 11.2% had higher education. The defendants were single in 57.8% of the cases, and almost half (45.7%) had no occupation. Two-thirds of the accused (61.2%) had experienced emotional deprivation at a young age. The problematic use of psychoactive substances was found in 10.3%, as well as alcohol consumption in 46.6%. Moreover, 39.7% of the patients had a personal psychiatric history and 19% had been incarcerated at least once. The forensic acts were mostly against people (62.9%) dominated by physical aggression (33.6%) followed by homicide or its attempt in 19% of the cases. The majority of patients were not related to their victims (62.1%). The nosographic diagnosis found was a personality disorder in 32.75% of cases, followed by schizophrenic disorders in 22.4% of cases.

Conclusions: Psychiatric expertise is a useful, complex and noble clinical act. Determining the predictive factors of a possible acting out allows to specify the objectives of interventions aiming at limiting the acts of violence, hospitalizations and incarcerations of patients suffering from mental disorders.

Fatal pulmonary embolism related to anti-psychotics: forensic implications. About four autopsies cases with review of the literatureM. Kacem*, W. Bouali, Y. Mahjoub, S. Brahim and L. Zarrouk
Psychiatric department, Taher Sfar Hospital of Mahdia, Mahdia, Tunisia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1210

Introduction: The association between the intake of antipsychotic drugs and the occurrence of thromboembolic complications is widely described in the literature. The occurrence of this complication may call into question the medical responsibility of the attending physician.

Objectives: The objective of this work is to describe the pathophysiological mechanisms involved in the occurrence of thromboembolic complications in a patient under antipsychotic treatment, whether or not associated with physical restraint and to discuss the forensic implications.

Methods: Our study is retrospective on cases of fatal pulmonary embolism, discovered at autopsy, in connection with the taking of antipsychotics. The autopsies were carried out in the Department of Forensic Medicine of the Tahar Sfar University Hospital in Mahdia. The cases were collected over a period of 04 years. A review of the literature was carried out. We only selected articles published until February 2021 and dealing with cases of patients on antipsychotics, diagnosed with pulmonary embolism by performing a chest CT scan or during an autopsy.

Results: 915 autopsy cases were performed during the study period. Twenty cases of pulmonary embolism, discovered at autopsy, were collected. Four cases were related to the taking of antipsychotics (incidence 0.004%), including two men and two women, aged between 25 and 52 years. They were all on antipsychotic treatment for at least 5 years, with the exception of one case who was put on 3 antipsychotics, 7 days before his death, with indication of physical restraint. After analysis of the memorial data, the external examination and the autopsy, the results of additional examinations, the death was attributed, in the 4 cases, to a massive fibrino-cruoric pulmonary embolism. A selection of 45 studies regarding thromboembolic complications associated with taking antipsychotics, was included in the final review.

Conclusions: The reported cases provided additional evidence on the involvement of antipsychotics in the occurrence of thromboembolic complications. Psychiatrists should be careful when prescribing these treatments. The establishment of therapeutic guidelines, taking into account the thromboembolic risk factors, becomes essential, in order to avoid the occurrence of a complication which could engage both the vital prognosis of patients and the responsibility of the physician.

Study of the sociodemographic, clinical and criminological characteristics of Tunisian female offenders

N. Smaoui¹, O. Bouattour^{1,2*}, I. Gassara¹, R. Feki¹, M. Bou Ali Maalej¹, J. Ben Thabet¹, L. Zouari¹, M. Maalej¹, N. Charfi¹ and S. Omri^{1,3}

¹Psychiatry C department, Hedi Chaker university hospital; ²Faculty of Medicine, Sfax and ³University of Sfax, SFAX, Tunisia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1211

Introduction: The psychopathology of female crime perpetrators is not well understood since female criminality rates have remained distinctly lower than male criminality.

This study draws on over 20 years of psychiatric expertises to identify sociodemographic, clinical, and forensic characteristics of female perpetrators.

Objectives:

- To describe the epidemiological and clinical profile of female offenders examined for criminal psychiatric expertise.
- Describe the criminological and forensic characteristics of these women.

Methods: Retrospective and descriptive study, which focused on 56 criminal psychiatric expertise files of female offenders, examined at the psychiatric department "C" at the CHU Hedi Chaker in Sfax, Tunisia, over a period of 24 years.

For each offender, we examined the expert report and the judicial research report. We then transcribed the socio-demographic and clinical information, as well as the criminological and forensic characteristics, onto a pre-established form.

Results: The accused women in our study had an average age of 35 years and 06 months, and 67.86% of the cases were under 40 years of age, with an educational level no higher than primary school in 62.5% of cases. They were unemployed in 71.4% of cases. Among the accused examined, 76.8% had mental disorders, including 46.6% with personality disorders, 16.3% with intellectual disability, 16.3% with bipolar disorder, 9.3% with depressive disorder, 9.3% with psychotic disorder, and 2.3% with substance use disorder (anxiolytic). We recorded 55.4% offences against persons, including 37.5% homicides and attempted homicides, and 44.6% offences against property, including 23.2% thefts. Dementia in the legal sense was identified in 30.4% of cases. Bipolar disorder accounted for 41.1% of legally demented subjects.

Conclusions: It emerges that the profile of the female criminal is that of a woman under 40, with a low educational and economic level, and most often with an antisocial personality or intellectual disability. It would therefore be important to step up primary prevention work by better educating these at-risk women and to combat the factors contributing to dangerousness among the mentally ill by optimizing their psychiatric care.

The results of Wisconsin Card Sorting Test in patients under forensic observation of their mental states in violent and non-violent subgroups

N. Kőszegi^{1*}, A. Lisincki², B. Baran² and É. Jekkel²

¹Department of Paediatrics and ²Department of Psychiatry and Psychotherapy, Semmelweis University, Budapest, Hungary

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1212

Introduction: Previous studies showed, that reduced executive function can be associated with antisocial and aggressive behavior. For the measurement of executive functions numerous standardized neuropsychological tests are available.

Objectives: We thought to compare the results of an executive function examination with Wisconsin Card Sorting Test (WCST) of patients observed at the Semmelweis University's Department of Psychiatry and Psychotherapy to normative data from published database. We also performed a subgroup analysis between the violent and non-violent groups of the patients.

Methods: After data clearance our dataset consisted of 20 patients, who were divided into two groups based on whether the crime they committed before their admission was violent according to the Cornell scale. The analyzed parameters were the number of perseverative errors, the percentage of perseverative errors, and the number of completed categories. For comparison, the data bank from the 1993 edition of the WCST manual as normative data was used. The deviation from the healthy average for all three parameters was compared between the violent and non-violent groups using a two-sample T-test.

Results: There was significant difference between the patient and normal populations in all the 3 analyzed WCST parameters: the mean difference was $9,37 \pm 2,764$, ($p=0,0008$) in the number of perseverative errors, $14,04 \pm 2,21$ ($p<0,0001$) in the percentage of perseverative errors and $-2,39 \pm 0,34$ ($p<0,0001$) in the number of completed categories (Table 1).

Table 1: The difference between the average scores of healthy individuals grouped by age (from the 1993 WCST manual) and the scores of the patients.

Observed parameter	Average difference (Patient-normal)	SD	Confidence interval (95%)	P value
number of completed categories	-2,39	0,343	-3,064 — 1,716	<0,0001
number of perseverative errors	9,37	2,764	3,936 — 14,804	0,0008
percentage of perseverative errors	14,04	2,212	9,692 — 18,388	<0,0001

On the other hand, there were no significant differences between the violent and non-violent subgroups in the average deviations (from the normative data) of the number of perseverative errors, the percentage of perseverative errors and the number of completed categories (with p-values of 0.092, 0.34 and 0.59, respectively).

Conclusions: As a limitation, it is important to note that due to the low sample size, and our sample's heterogeneity in terms of psychiatric diagnosis, drawing reliable conclusions is not possible. However, our results were in line with previous similar research in the forensic psychiatric population (though not under forensic mental state observation) regarding the significant deviations in two examined WCST parameters when compared to normative data. Additionally our study did not find significant difference between the violent and non-violent subgroups of the patients.

Reaching the limits of antipsychotic treatment: the upper end of severe schizophrenia in forensic institutions - a case report

V. Watzal^{1,2,3*} and T. Stompe^{1,3}

¹Department of Psychiatry and Psychotherapy; ²Comprehensive Center for Clinical Neurosciences and Mental Health, Medical University of Vienna, Vienna and ³Forensic therapeutic center Goellersdorf, Goellersdorf, Austria

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1213

Introduction: Severe schizophrenia is often closely related to delinquency resulting in relative overrepresentation of these manifestations of disease in forensic institutions.

Objectives: The aim of the present work is to report the therapeutic challenges in a case of severe schizophrenia in a forensic institution from a clinical viewpoint as a basis for discussion.

Methods: The case report is based on the available clinical documentation, exploratory interviews as well as a structured clinical interview (PANSS).

Results: Presenting a case of a 41-year-old, male Caucasian inpatient suffering from a catatonic schizophrenia, we report the challenges in treatment of chronic, major schizophrenic disease resistant to antipsychotic medication. Without any previous criminal convictions, he has been institutionalized in a forensic psychiatry after a bodily harm to a random stranger about three years ago. Regarding medical history, information is limited to a few inpatient admissions prior to detention documenting intravenous opioid and cocaine abuse. Initially, the patient presented sexual disinhibition and ongoing endangerment of others with frequent assaults to other patients and prison guards. From a psychopathological viewpoint several phenomena such as delusional intuition, acoustic, tactile and coenaesthetic hallucinations, echolalia, mannerisms and thought diffusions reflect the severe course of the disease (PANSS: P 34/49, N 38/49, G 73/112; total 145/210). Therapeutic attempts with an antipsychotic combination of risperidone, olanzapine and quetiapine as well as valproic acid resulted in insufficient recovery with persistent physical assaults and florid psychosis. In reaction to that zuclopenthixol for impulse control was added. As from the beginning of this year a switch of medication by gradually replacing risperidone and zuclopenthixol with haloperidol and clozapine showed modest success. Under the current medication and therapeutic drug levels the patient does not pose endangerment to others. However, regular tonic-eye fits require supplementary treatment with biperiden, and the patient still presents frequent periods of self-harm punching himself, verbal lack of impulse control and the psychopathological phenomena described before. In addition to pharmacological treatment the patient receives psychotherapeutic one-on-one conversations. Despite approaching all limits of the available antipsychotic repertoire, psychopathology is only insufficiently controlled leading considerations to electroconvulsive therapy as a treatment of last resort.

Conclusions: Certainly, the present case is exemplary for a severely ill population of patients reaching – after a long and untreated course of disease - a chronic stage that does not sufficiently respond to a multitude of treatment attempts despite proper compliance raising the urgent need for further treatment options.

What effects does peer support work have and how to implement it into forensic hospitals? A Review of Reviews

P. Walde and B. A. Völm*

Forensic Psychiatry, Rostock University Medical Center, Rostock, Germany

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1214

Introduction: Despite promising research there is still hesitation in implementing peer support work in some hospitals. Especially in forensic hospitals reservations are held against peer support workers.

Objectives: We aim to give an overview of reviews about the effects of peer support work in psychiatric settings and its implementation. Special emphasis on implications for forensic psychiatric settings shall be given.

Methods: Five electronic databases and archives of four relevant journals were searched in December 2019 and updated in April 2022. In addition, references of articles were searched and relevant authors were contacted for unpublished data. Results of reviews were clustered by one author and checked by another.

Results: 22 reviews were identified of which 15 reported on effects of peer support work and six on factors influencing its implementation and one review on both. Several effects of peer support work on clinical, psychosocial, organizational and other outcomes (e.g., cost savings) were described. Psychosocial outcomes were the most promising ones whereas no effects were described in most reviews for clinical, organizational and other outcomes. Factors influencing the implementation of peer support work were described during preparation, recruitment, early employment and further development of the peer support worker's roles. Most factors, beneficial and challenging, were described for the preparation stage of the implementation process.

Conclusions: The authors of the reviews often reported concerns about the low quality of the included studies. Therefore, the present results have to be considered as preliminary. Nevertheless, it is clear that peer support has a positive influence on psychosocial factors and thus complements classic therapeutic approaches. To achieve the best possible effect, the implementation of peer support needs to be carefully planned. Further studies are necessary in order to be able to consider the effect of recovery support in a more differentiated way.

The Relationship between Cyber Violence Victimization and Adverse Childhood Experiences

S. E. Ilgin^{1*}, Ö. Yanartaş¹ and O. Polat²

¹Psychiatry, Marmara University Research & Training Hospital and

²Forensic Medicine, Acibadem University, Istanbul, Türkiye

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1215

Introduction: Nowadays, following the increasing digital technologies, the cyber aspect of violence is becoming more common (Willard, Journal of Adolescent Health 2007; 41) At this point, we can think that cyber violence victimization, environmental factors such as childhood traumas, exposure to violence, and moreover psychological and biological factors play a role (Fan et al., Front. Psychol 2021;12)

Objectives: Our aim was to conduct a study to determine the prevalence of cyber violence victimization among university students and to examine whether this prevalence would be related to negative childhood traumas.

Methods: We reached university students in many cities of Turkey through an online survey between 01 January 2023 and 31 March 2023. A total of 600 students participated. In our survey, we used the Turkish forms of the Childhood Adverse Experiences Scale and the Cyber Victimization Scale, for which sociodemographic data, validity and reliability studies have been completed in Turkish.

Results: University students from 8 different provinces participated in our study. According to the results of our study, it was evaluated that university students who had negative childhood experiences were more likely to become cyber victims. We are exposed to many traumas from the moment we are born, and this exposure is the relationship with the mother, then relatives, friends, teachers, colleagues, etc. It continues throughout life through relationships. There is a moderate relationship between victimization of blocking and damaging behaviors in cyberspace and negative childhood relationships ($r = 0.304$), a low level relationship between victimization of sexual bullying in cyberspace and negative childhood relationships ($r = 0.289$), and victimization of spreading rumors in cyberspace. A low degree of correlation ($r = 0.277$) was found between and negative childhood relationships. ($p < 0.05$)

Conclusions: The widespread use of technology today facilitates the digitalization of violence, as in every field. As a result, cyber violence, like other types of violence, may be associated with childhood traumas, and this can be prevented by being exposed to the least trauma during childhood, and moreover, if we look from Bronfenbrenner's perspective, if the next generation grows up in a suitable ecological environment, cyber violence victimization can be prevented to that extent.

CRISPR/Cas9 genome editing clinical trials for neurodevelopmental disorders

B. Abdelmoula* and N. Bouayed Abdelmoula

Genomics of Signalopathies at the service of Precision Medicine -LR23ES07, Medical University of Sfax, Sfax, Tunisia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1216

Introduction: Recently, the new therapeutic approach based on genome editing using the CRISPR/Cas9 system has been applied to treat cancer and other monogenetic disorders. CRISPR/Cas9 allows

specific correction of the altered gene without affecting the rest of the genome.

Objectives: The aim of this study was to report the current CRISPR/Cas9 genome editing clinical trials in neurodevelopmental and mental disorders.

Methods: We conducted a search via the ClinicalTrials platform to describe clinical trials that have been conducted using the CRISPR/Cas9 genome-editing tool in neurodevelopmental disorders.

Results: Our research revealed three clinical trials that used the CRISPR/Cas9 tool for diagnostic and therapeutic purposes. The first study aimed to investigate the pathological role of KMT2D mutations in 40 Kabuki syndrome patients in order to facilitate the identification and characterization of therapeutic strategies to improve symptoms, to identify the consequences of KMT2D mutations on epigenetic marker changes and cellular structural changes and to finally attempt gene correction by CRISPR/Cas9. The therapeutic approach was an epigenome editing approach aimed at increasing the expression of the wild-type KMT2D allele to restore the functional activity of a histone H3-lysine 4 (H3K4)-methyltransferase (MLL4) in treated mesenchymal stem cells. The second clinical trial aimed to validate gene editing based on CRISPR/Cas9 technology combined with AAV delivery for the correction of the most common MECP2 mutations in Rett syndrome both in vitro and in vivo. The third GENEPI clinical trial aimed to identify acetylation profiles as epigenetic markers to assess the causality of CREBBP and EP300 variants in Rubinstein-Taybi syndrome, which is considered as a genetic model of neurodevelopmental abnormality with an epigenetic component.

Conclusions: CRISPR/Cas9 clinical trials in polygenic conditions, such as psychiatric disorders, could be envisaged at the level of the epigenetic component of these pathologies. This therapy could be applied ex vivo to perform tissue-specific gene editing.

Female virilization related to congenital adrenal hyperplasia and psychological distress

B. Abdelmoula*, N. Ramma, M. Ben Yedder, I. Bouaziz and N. Bouayed Abdelmoula

Genomics of Signalopathies at the service of Precision Medicine - LR23ES07, Medical University of Sfax, Sfax, Tunisia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1217

Introduction: In females, congenital adrenal hyperplasia (CAH), a spectrum of inherited genetic conditions related to the disruption of adrenal steroidogenesis, is among the most common conditions leading to inappropriate virilization. For adolescent and adult women, progression of hirsutism may have many psychological concerns.

Objectives: To explore the psychological distress of a young Tunisian woman who sought medical help and psychological support at a late stage, after suffering from genital ambiguity and severe virilization.

Methods: Harboring phenotypic male transformation at puberty, our patient attended genetic counselling for cytogenetics assessment. Clinical, biological, psychological and genetic explorations were thus carried out.

Results: A 17-year-old female was born from first-degree consanguineous parents, and had healthy siblings (a sister and three brothers). After a single menstrual episode at puberty, she developed amenorrhea and an unexpected progressive virilization, including hirsutism with an inappropriate beard that she had to shave every day and a male voice. Clinical examination revealed a male morphotype with an enlarged clitoris that resemble a penis, male-type pubic hair, underdeveloped of breasts, abnormal cutaneous hyperpigmentation, and a short stature. Pelvic ultrasound revealed a small uterus, but with no visualized gonads. Genetic exploration showed a female 46,XX karyotype and the absence of Y chromosome sequences. Diagnosis of a non-classic CAH was confirmed. Psychological assessment found that the psychological development of the sexual identity corresponded to the assignment of the female sex. A severe psychological suffering due to the non-acceptance of her virile appearance impaired the quality of her daily personal and social life. Stigmata of a depressive syndrome were also revealed.

Conclusions: Particular attention to the psychological assessment of patients with CAH is recommended, as changes in physical appearance have a detrimental impact on psychological and mental well-being.

DNA methylation risk scores for depression, not today

E. Van Assche^{1*}, C. Hohoff¹ and B. T. Baune^{1,2,3}

¹Klinik für Psychische Gesundheit, University of Münster, Münster, Germany; ²Department of Psychiatry and ³The Florey Institute of Neuroscience and Mental Health, University of Melbourne, Melbourne, Australia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1218

Introduction: After the success of polygenic risk scores (PRS) that embed a useful summary of genomic information in a comprehensive score, the wish to develop summary statistics for DNA methylation had become more pressing. Developing such a score faces challenges, as the score has to be specific and sensitive as well. Epidemiological research on DNA methylation and depression would benefit from such score.

Objectives: Here, we test a score trained on incident depression (case-control), i.e., a list of published weights for particular CpGs, for its validity in the context of depression severity as measured using MADRS in our sample with depressed patients only.

Methods: DNA methylation was assessed using the Illumina Infinium MethylationEPIC 850k BeadChip on a sample of 119 patients with a diagnosis of MDD. After data cleaning, 113 participants were included in the analysis ($M_{age} = 47$ years, 57.98% women, $M_{MADRS} = 27.7$). Data processing was conducted using the RnBeads package. From the published reference for the overall sample, a list of 196 CpGs was provided, 170 of these were present in our dataset and used for the score. The list of non-smokers comprised 144 CpGs, of which 124 were available. The score per individual was built using M-values, using the formula: $S(\text{weight} \times \text{DNA methylation value})$. The score was tested in association with depression and other typical confounders using multiple regression in

R. Confounders included ancestry, BMI, age, sex, and 6 cell types. We tested both scores in our sample: smokers and non-smokers.

Results: In contrast to our expectations, none of the regression analyses showed a significant association with depression (MADRS-score). Nonetheless, a significant association was seen with biological sex for both analysis (overall: $p=0.036$, non-smokers: $p=0.026$). A reduced model with only this predictor explained 5% and 4% of the variance of the summary score calculated (R^2), respectively (overall: $p=0.013$; non-smokers: $p=0.019$). One of the ancestry components was marginally significant too in the non-smoker summary score ($p=0.065$). This was not the case anymore in the reduced model.

Conclusions: Our results show that caution is still in place when using methylation risk scores as specificity and sensitivity might not yet be optimized. The score built for depression incidence does not seem fitting for depression severity at this moment. The use of DNA methylation, a marker that is generally sensitive to confounding factors, for a risk score, might pose more challenges in the context of reliable summary statistics, in particular also for cross-trait examination, which is currently a typical use of polygenic risk scores.

EPV0537

Behavioral and neurocognitive phenotypes in Crigler-Najjar syndrome in Tunisia

N. Bouayed Abdelmoula*, R. Zekri, F. Bouaziz, K. Bensalem, M. Feki, A. Etteyeb and B. Abdelmoula

Genomics of Signalopathies at the service of Precision Medicine -LR23ES07, Medical University of Sfax, Sfax, Tunisia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1219

Introduction: Crigler-Najjar 1 (CN1) due to exon 3 mutations of the UGT1A1 gene is a not rare genetic disease in Tunisia with a founder effect. CN1 syndrome is very severe, and most of CN1 Tunisian patients die soon after birth, within a maximum of one year, due to kernicterus. Liver transplantation, which is the only available therapeutic method for CN1, remains unreachable.

Objectives: The aim of this study was to report behavioral and neurocognitive phenotypes in CN1 patients who survived to school enrollment.

Methods: We have selected all patients evaluated from 2004 to 2010, both clinically and molecularly, for a deficiency of bilirubin-UGT enzyme activity leading to a pathological elevation of unconjugated bilirubin with a suspicion of CN1 syndrome. Direct sequencing of targeted PCR amplification products was performed for molecular analysis of UGT1A1. Behavioral and mental features of patients were studied through our genetic counselling.

Results: We identified 15 patients with the homozygous c.1070 A>G Tunisian mutation. Their age at diagnosis ranged from one week to 9 months for 13 patients. Six of them died within a month of molecular investigation. Only two boys were of school age, i.e. 6 and 9 years. The first had been hospitalized at 3 months year-old for a prolonged jaundice treated with phenobarbital and phototherapy. His psychomotor and neurological development was normal, with

school attendance at the age of six. The second patient presented with an unexplored jaundice at the age of 3 days, which was later complicated by seizures and treated with phenobarbital. Despite neurological and motor sequelae associated to language impairments with slurred speech, he attended school at the age of six.

Conclusions: The neurological and behavioral profile of CN1 patients depends on familial and medical management. Quick diagnosis, close follow up and early liver transplantation can improve prognosis.

Interaction analysis of monoaminergic polymorphisms and childhood environment related to personality functioning in patients with Borderline Personality Disorder

E. Salgo*, Z. Nemoda, E. Kenézlői, E. Lévy, L. Balogh, B. Bajzát, J. Réthelyi and Z. S. Unoka

Semmelweis University, Budapest, Hungary

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1220

Introduction: Neurobiological studies have shown that genetic variations affecting the intensity of monoamine neurotransmission play an important role in aggressive behavior and borderline personality traits. Also, the effect of family environment has been repeatedly shown on aggressive behavior and interpersonal functioning. Population-based longitudinal studies pointed out interactions between the so-called monoaminergic sensitivity alleles and childhood adversities.

Objectives: Our study aimed to analyze the associations between the most studied variable number tandem repeats of monoaminergic genes and the different psychological factors in adult patient and healthy control groups, checking for the moderating effects of the parental occupation and education, childhood abuse and trauma.

Methods: The recruited 73 patients with BPD diagnosis and 98 healthy controls were assessed by the Structured Clinical Interview for DSM-5. Participants filled out online questionnaires including the Level of Personality Functioning Scale – short version (LPFS-SR) and the Buss-Perry Aggression Questionnaire (BPQ). Childhood social environment and traumatic experiences were assessed by the Barratt Simplified Measure of Social Status and the Early Trauma Inventory or the Childhood Trauma Questionnaire. Genomic DNA samples were obtained either from peripheral blood, saliva or buccal swabs using the desalting technique. Functional dopaminergic and serotonergic polymorphisms were chosen based on previous findings, implicating them as sensitivity gene variants, e.g., the variable-number tandem-repeats of the dopamine D4 receptor, serotonin transporter and the monoamine oxidase-A (MAO-A) genes. Since the MAO-A gene is located on the X chromosome, sex-stratified analyses were also carried out.

Results: Family environment indexed by the Barratt Simplified Measure Social Status had significant effect on anger, hostility and interpersonal functioning ($p < 0.01$). In the pooled sample of patients and controls, individuals carrying the high activity alleles of MAOA had elevated scores on the BPQ subscales. When analysis

was limited to female participants, the genetic effect stayed significant only at the anger scale of the BPQ.

Conclusions: Family environment had pronounced effect on aggressive behavior and personality functioning, interaction with common monoaminergic genetic variants was detected only in women.

This study was supported by the National Research Development and Innovation Office grants NKFI K 129195 and NKFI K 135437.

EPV0541

Pain and gain of predictive genetic testing: Particular case of fragile X syndrome

N. Bouayed Abdelmoula*, N. Ramma and B. Abdelmoula

Genomics of Signalopathies at the service of Precision Medicine - LR23ES07, Medical University of Sfax, Sfax, Tunisia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1221

Introduction: The purpose of predictive genetic tests is to identify carriers or the onset of a disease in pre-symptomatic individuals. Prediction is linked to a negative psychological impact (anxiety, depression, etc.), depending on the perception of risk, the severity of the disease, and the availability and effectiveness of treatments.

Objectives: Here, we report on genetic counselling during predictive genetic testing offered to an Arab family affected by fragile X condition (FXS) caused by the unstable expansion of a CGG repeat (CGGR) in the FMR1 gene.

Methods: A 10-year-old boy who harbored a mental retardation was referred to our genetic counselling for genetic testing as he was suspected to be affected by FXS. Screening of FMR1 gene mutations was conducted for the index case and his mother. A predictive genetic testing for the family members (brothers, sisters and others) was offered, focusing on knowledge of genetics and medical risks of FXS.

Results: FMR1 molecular analysis showed a full mutation (300 to 2000 CGGR) for the boy and a large premutation (100 CGGR) for the mother. During genetic counselling, the family was informed about the significance of the genetic results. In FXS initiated by an expansion of over 200 CGGR. While mental retarded males usually harbor the full mutation, the mother carry a premutation (70 to 200 CGGR). The deficiency of FMR protein (FMRP) in the neurons of affected males leads to brain developmental abnormalities. Some pre-mutated children may show signs of the autism spectrum disorder and females may develop FMR1-related premature ovarian insufficiency. An increased risk of a late onset fragile X tremor ataxia syndrome is identified in pre-mutated men (55 to 200 CGGR) and less in women.

Conclusions: The reduction or loss of FMRP leads to multisystem damage. Neuropsychiatric disorders such as mental retardation, speech and language delay, autism spectrum disorder, sensory hyperexcitation, social anxiety, abnormal eye contact, shyness and aggressive behaviour are common in individuals with the mutation. Affected women are often under-diagnosed because mental retardation is not constant, but minor disorders including a borderline IQ with learning difficulties and emotional

disturbances have been reported. Conditions associated with fragile X premutation, a term proposed by the European Fragile X Network (FXPAC), seem to be characterized by many physical and psychological health symptoms. Anxiety, depression, sleep disorders and mood disorders are more common in permuted individuals. However, new reports suggested that FXS patients could be at unusually low risk of cancers, because FMRP is over-expressed in multiple cancer tissues.

EPV0542

Dysmorphic physical appearance and psychosocial burdens in Klippel-Feil condition

N. Bouayed Abdelmoula*, R. Rannen and B. Abdelmoula

Genomics of Signalopathies at the service of Precision Medicine - LR23ES07, Medical University of Sfax, Sfax, Tunisia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1222

Introduction: Klippel-Feil abnormality (KFA) is an association of bone defects characterized by a triad: fusion of the cervical vertebrae and consequent short neck, low hairline and a limited motion in the neck. KFA may be a feature of another disorder, such as MURCS association. Familial mutations in the GDF6 (KFS1 8q22), MEOX1 (KFS2 17q21), GDF3 (KFS3 12p13) and MYO18B (KFS4 22q11) genes cause inherited KFA.

Objectives: The aim of this study was to report dysmorphic features and psychological burdens in two sisters with Klippel-Feil condition.

Methods: Two sisters with amenorrhea and dysmorphic clinical features were examined at our genetic counselling. Assessment of dysmorphic and behavioral features and karyotyping using RHG banding were performed.

Results: Familial history revealed consanguineous parents and seven other healthy sisters. Physical examination shown typical triad of KFA. Karyotyping showed 46,XX formula in both patients. The first 22-year-old sister had body asymmetry with size difference between the two sides at the level of bones, pectus excavatum of the sternum, an ascent of the left scapula, scoliosis, dental position abnormalities and facial dysmorphism. The second 28-year-old sister had size difference between the two legs and scoliosis, vitiligo and facial dysmorphism. Anxious and depressed, the two sisters had normal learning abilities but shared many personal psychological concerns regarding their physical appearance and their amenorrhea. They were also exposed to significant discrimination and stigma making them feel excluded and ignored because of their visible difference.

Conclusions: Physical appearance has a profound impact on a person's life. To our knowledge, there is no reports that describe specific psychological burdens of KFA. Self-esteem, body image, and quality of life is negatively impacted in the case of dysmorphic physical appearance, always associated to social discrimination. Patients with KFA should be assessed not only for associated congenital defects but also for psychological distresses.

Adverse psychological outcomes in Brugada syndrome: About a Tunisian familial pedigree from Sfax

N. Bouayed Abdelmoula*, B. Abdelmoula, A. Assel, E. Fadhlouai and O. Kaabi

Genomics of Signalopathies at the service of Precision Medicine - LR23ES07, Medical University of Sfax, Sfax, Tunisia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1223

Introduction: Patients with Brugada Syndrome (BS), a rare inherited cardiac channelopathy, with an increased risk of developing arrhythmias, syncope and sudden cardiac death, also present serious adverse psychological outcomes that require medical support to improve their health and well-being as well as those of their families.

Objectives: Here we report psychological concerns of a Tunisian patient who presented to our genetic counselling, with his three children, for molecular exploration of BS type 1.

Methods: Clinical, electrical, biological and psychological characteristics of the patient and his offspring were identified. Cytogenetic exploration using RHG banding and molecular screening of SCN5a gene mutations using High Resolution Melting and sequencing were carried out. Subsequently, genetic counselling was undertaken for all the family members and psychological concerns were reported.

Results: A 51-year-old married man with an academic career was born from a consanguineous couple, with a family history of sudden cardiac death. He was diagnosed with BS1 based on the pathognomonic ST-segment elevation in leads V1–V3, after experiencing palpitations and syncope. He was treated by implantable cardioverter defibrillator. The patient was also being treated for diabetes and dyslipidemia. His children, a girl and two boys, were investigated by ECG, which revealed no electrical disorders. However, both boys reported chest pain on exertion. The 18-year-old girl presented with primary amenorrhea and infantilism, along with a Turner syndrome formula. Molecular analysis revealed none of the targeted mutations in the SCN5a gene. Psychologically, the patient had a phobia of death and reported painful sensations of imminent death at each palpitation. He was anxious about the clinical outcome of his children. The children reported anxiety about their autosomal dominant fathers' disorder.

Conclusions: Approximately 16% of BS patients experience depression and anxiety. More attention needs to be indorsed to the psychological distress of BG patients and their families.

ZNF536 dysfunction enhances spontaneous differentiation of the SH-SY5Y cell line into a neuronal-like phenotype

A. Kurishev, D. Abashkin, E. Marilovtseva, D. Karpov and V. Golimbet*

Clinical Genetics Laboratoty, Mental Health Research Center, Moscow, Russian Federation

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1224

Introduction: Schizophrenia (SZ) is a common psychiatric neuro-developmental disorder with a complex genetic architecture. Genomic association studies indicate the involvement of transcription factors in the pathogenesis of SZ. A recent GWAS showed a significant association of ZNF536 with SZ. To date, the molecular functions of ZNF536 are poorly understood and its possible role in the pathogenesis of SZ is unclear.

Objectives: The aim of this work was to develop a model cell line for study ZNF536-mediated pathogenic mechanisms associated with SZ.

Methods: To assess the spatial interaction of ZNF536 with SZ risk loci, we used the Capture-C method. For ZNF536 deletion, SH-SY5Y was sequentially transduced with two lentiviral vectors. The first expressed Cas9 under the control of a tetracycline regulated promoter and the second expressed a pair of sgRNAs for ZNF536 deletion. Puromycin was used to select transduced cells. Stably transduced cells were then treated with oxytetracycline to induce Cas9 expression. In parallel, SH-SY5Y were transduced with lentiviral constructs of Cas9 and sgRNA carrying a spacer lacking targets in the human genome to obtain a negative control. Individual clones were obtained by the limiting dilution method. The ZNF536 deletion was confirmed by PCR and Sanger sequencing.

Results: A spatial interaction of ZNF536 with SZ risk loci was found, suggesting its involvement in SZ pathogenesis. Using the CRISPR/Cas9 system, we obtained several clones with heterozygous deletion of ZNF536. We observed that their growth and proliferation were significantly slowed down. In addition, the mutant clones spontaneously differentiate into a neuron-like phenotype in low-serum medium.

Conclusions: We established a cellular model to study ZNF536-mediated mechanisms associated with SZ.

Korean Medication Algorithm Project for Bipolar Disorder 2022: Treatment Strategy According to Safety and Tolerability

S. Y. Park^{1*}, W.-M. Bahk², Y. S. Woo², D.-I. Jon³, M.-D. Kim⁴ and I. Sohn¹

¹Department of Psychiatry, Keyo Hospital, Uiwang; ²Department of Psychiatry, Yeouido St. Mary's Hospital, College of Medicine, The Catholic University of Korea, Seoul; ³Department of Psychiatry, Hallym University Sacred Heart Hospital, Hallym University College of Medicine, Anyang and ⁴Department of Psychiatry, Jeju National University Hospital, Jeju, Korea, Republic Of

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1225

Introduction: Accordingly, the Korean Medication Algorithm Project for Bipolar Disorder (KMAP-BP) working committee, composed of domestic experts, developed Korea's first KMAP-BP in 2002 and later in 2006, 2010, and 2010. A revised version of KMAP-BP was announced every four years four times in 2014 and

2018.6-10). The treatment strategy considering the safety and tolerability of KMAP-BP 2022 was developed by collecting opinions from domestic bipolar disorder experts.

Objectives: Safety and tolerability of drugs are very important factors in the treatment of bipolar disorder. An expert opinion survey was conducted on treatment strategies in various special clinical situations, such as significant weight gain, characteristic drug side effects, low drug adherence, pregnant and reproductive women, and genetic counseling.

Methods: A written survey about treatment strategies related to safety and tolerability was prepared and focused on significant weight gain, characteristic drug side effects, low drug adherence, pregnant and reproductive women, and genetic counseling. Ninety-three experts of the review committee completed the survey.

Results: In the case of weight gain occurring during drug treatment, it was preferred to replace it with a drug that caused less weight gain, such as lamotrigine, aripiprazole, or ziprasidone. If there was a significant weight gain due to the treatment drug, it was preferred to intervene as soon as possible. In the case of hyperprolactinemia, it was selected to change the medication and discontinue it for benign rash caused by lamotrigine. In improving drug adherence, the preference for long-acting injections increased. Antipsychotics can be used with great caution in pregnant or reproductive women.

Conclusions: Treatment strategies in various clinical situations related to safety and tolerability in drug treatment for bipolar disorder were described. It is hoped that it will be useful in practical clinical situations.

Implementation in the Motek Caren system with virtual reality of an existing motor rehabilitation programme for people with Down's syndrome in order to increase its effectiveness

M. A. Ciolek^{1*}, K. Kamińska¹, A. Szczegielniak¹, K. Krysta² and M. Krzysztanek²

¹Medical University of Silesia, Katowice, Poland and ²Psychiatric Rehabilitation, Medical University of Silesia, Katowice, Poland

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1226

Introduction: Down's syndrome often requires specialized rehabilitation methods in order to effectively improve cognitive and motor functioning. The growing interest in technologies to support rehabilitation is opening up new and promising perspectives for improving the quality of life of people diagnosed with this syndrome. One of these technologies is the Computer Assisted Rehabilitation Environment (CAREN) system from Motek.

Objectives: The aim of the planned research project is to explore the potential of using the CAREN system in the rehabilitation of people with Down's syndrome.

Methods: The study included 10 participants with Down's syndrome (men and women aged 18 to 50 years) without the presence

of organic musculoskeletal disease or other somatic causes impairing motor performance. Before the training test, the participants were assessed by two psychological tests: 1) ACE III - Addenbrooke's Cognitive Examination III Scale (ACE-III), which assesses attention and orientation, memory, verbal fluency, language and visuospatial functions and 2) the TONI 4 Non-Verbal Intelligence Test, which is a test used to measure general intelligence. The tests were carried out using the MOTTEK CAREN device, which consists of a treadmill for motor training and a virtual reality screen on which different scenes are displayed for the participant to see during the test. Integrated motion capture technology was used to assess movement capabilities of the patients.. The screen displayed different types of applications in the form of virtual reality, in which the participant had to cope with various tasks accommodating different psychomotor skills, for example: crossing a virtual bridge, walking through a forest. The test took about 45 minutes per person. Two training sessions were conducted for each of the 10 patients with a one-month interval between them.

Results: The Motek Caren System has proven to be a promising rehabilitation method for people with Down's syndrome, compared to previous experience with different rehabilitation methods and existing research in the field.

Conclusions: Results emphasize the necessity for further investigations and future research should involve more participants. The project has the potential to integrate modern technology with traditional forms of therapy to improve the quality of life and functioning of people affected by this syndrome.

Quality of life in the people with disability: individual's perception

M. M. Matsumoto*, D. Cardilli-Dias and D. R. Molini-Avejónas

Speech-Language Pathology, University of São Paulo, São Paulo, Brazil

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1227

Introduction: There are few studies about how people with intellectual disability (ID) perceive their own quality of life (QoL), with research being focus, mainly, in the opinion of caregivers and/or family. Thinking about QoL, the World Health Organization developed an instrument that measures QoL, the WHOQOL. In Brazil, this instrument was adapted, validated and translated for people with ID and their caregivers.

Objectives: The aim of this study was to increase knowledge and understanding of how people with ID perceive their own QoL.

Methods: This study was approved by the Ethics and Research Committee. Sample of 51 individuals aged between 19 and 54 years (G1), with medical diagnosis of ID, who did not present physical/mental disabilities and/or mental disorders and 31 caregivers (G2). G1 answered the WHOQOL-DIS-ID questionnaire and G2 answered the WHOQOL-DISID Proxy questionnaire. The results were statistically analyzed considering p-value ≤ 0.05.

Results: The individuals with ID presented higher score on the psychological and lower score in the discrimination domain. The caregivers presented higher scores on the physical and

lower scores in the autonomy domain. Regard the comparison between self-perception and the perception of caregivers, on Table 1, it was possible to observe significant differences in Psychological, Social, Environmental and all domains for the Disabilities Module.

Table 1. Correlation between Domains

Domain	Mean G1	Mean G2	SD G1	SD G2	Median G1	Median G2	P value
Physical Capacity	72,3	68,8	17,1	19,1	78,5	71,4	0,32
Psychological	80,1	67,7	17,5	17,9	83,3	66,6	<0,01*
Social Relationships	68,8	54,3	22,6	21,6	66,6	50	<0,01*
Environment	73,9	63,3	14,5	18,4	75	68,7	<0,01*
Discrimination	43,1	55,1	25,4	16,7	50	50	0,04*
Autonomy	65,5	41,9	31,4	25,2	66,6	50	<0,01*
Inclusion	77,0	58,9	16,1	20,1	75	54,1	<0,01*

Conclusions: It is critical that people with ID participate in the creation and/or changes of inclusion policies and actions. Since the relationship between the perception of self-reported QoL and reported by caregivers are different and converge only in the physical domain.

Aggressive and prosocial behaviors in adolescents from the department of Cordoba, Colombia

E. P. Ruiz Gonzalez* and M. N. Muñoz Argel
Universidad Pontificia Bolivariana, Montería, Colombia
*Corresponding author.
doi: 10.1192/j.eurpsy.2024.1228

Introduction: Prosocial behaviors are voluntary behaviors that are performed for the benefit of other people and promote harmonious relationships with others. This type of enhanced behavior could reduce physical and verbal aggressive acts in adolescents.
Objectives: analyze the association between aggressive and prosocial behaviors in adolescents
Methods: The study was non-experimental of a transactional - correlational type, two evaluation instruments validated in the context were applied to 500 adolescents attending school in the department of Córdoba. The type of sampling was non-probabilistic.
Results: A Pearson correlation was performed, previously verifying the normality of the data, which showed a statistically significant, negative association between the prosocial behaviors and the aggressive behaviors of those evaluated (Table 1).

Table 1: Correlation between prosocial behavior and aggressive behavior.

PROSOCIAL BEHAVIOUR		
AGGRESSIVE BEHAVIOR	Pearson correlation	-,197**
	Sig. (bilateral)	,004
	N	500

Conclusions: Negative associations were identified between the two variables under study, that is, as prosocial behavior increases, aggressive behaviors could decrease. This finding serves as a basis for carrying out future intervention strategies in adolescents in the department of Córdoba.

Impact of emotional intelligence on anxiodepressive disorders in nursing staff in the intensive care unit

M. Kahloul¹, I. Kacem^{2*}, A. Ghenim², M. Ajmi¹, W. Naija¹, A. Chaouch¹ and N. Mrizak²
¹Anesthesia and Intensive Care Department, Sahloul Academic Hospital and ²Occupational Medicine Department, Farhat Hached Academic hospital, Sousse, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2024.1229

Introduction: Working in the intensive care unit (ICU) often involves intensely stressful and emotional situations, which can be strong predictors of poor mental health. Healthcare workers are required to perceive, understand, manage, and use their emotions to provide quality care.
Objectives: To evaluate the impact of emotional intelligence (EI) on anxiodepressive disorders in nursing staff in the ICU.
Methods: This was a descriptive, cross-sectional, analytical study conducted among nursing staff in the ICUs of two hospitals in Tunisia. Data were collected over a 3-month period. EI was assessed using the SSEIT self-report test, and the hospital anxiety and depression scale (HADS) was used to measure anxiodepressive disorders. Sociodemographic aspects were also taken into account.
Results: We included 92 healthcare workers. The majority were women (67.4%) with an average age of 25 to 54 years. Nurses represented 58.7% of the study population. About half had less than 5 years of occupational seniority. In terms of lifestyle habits, 76% were smokers, 90.2% did not consume alcohol, and 53% had no leisure activities. The majority had no personal, family, or medical psychiatric history.
The mean EI score was 109.9, ranging from 62 to 150. Anxiety was present in 43.49% of participants and depression in 51.08%. A significant association was observed between anxiety and the perception of emotions (p=0.0196) and the management of others' emotions (p=0.0261).
As for depression, a significant association was observed between perception of emotions and depression (p=0.0259), as well as between management of others' emotions and depression (p=0.0126). EI was positively associated with HADS (p=0.0281), with a correlation value of 0.114.

Conclusions: Caregivers with anxiodepressive disorders had significantly lower levels of EI than those without anxiodepressive disorders, suggesting that EI maybe a protective factor against these disorders

EPV0550

Empathy as a predictor of burnout syndrome in health professionals of the Colombian Caribbean

E. P. Ruiz Gonzalez¹, M. N. Muñoz Argel¹,
A. M. M. Romero Otalvaro², M. G. Garcia Castañeda^{1*} and
M. C. Crespi³

¹Universidad Pontificia Bolivariana; ²Universidad de Cordoba, Montería, Colombia and ³Universidad de Buenos Aires, Buenos Aires, Argentina

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1230

Introduction: Empathy is an essential skill in the doctor-patient relationship since it contributes to improve aspects of health care and patient satisfaction. Nevertheless, burnout research projects have been developed in recent years.

Objectives: To examine the predictive capacity that empathy has on burnout syndrome in health professionals.

Methods: A non-experimental, cross-sectional design was proposed. The type of study was correlational-descriptive since it was sought out to explore a functional relation through the prognosis of a criterion variable. Sample: 200 (100 female and 100 male).

Results: First, the variance of cognitive and Affective Empathy was dug out in the emotional exhaustion criterion scale. Results accounted for 15% of variability in emotional exhaustion. (Corrected R² = .15, F = 17,56, p = 0,00). The best predictor of emotional exhaustion refers to Cognitive Empathy. (B = -.27, p = 0.00). It does not seem that Affective Empathy acts as a predictor variable of Emotional Exhaustion. (Table 1).

Table 1 Multiple linear regression analysis considering Emotional Exhaustion as a criterion.

TECA	Corrected R ²	F	B	p
Cognitive Empathy	.15	17,5	-.27**	0,00
Affective Empathy			-.14	.13

The predictive capacity of Empathy in relation to Depersonalization was estimated (Corrected R² = .20, F = 25,4, p = 0.00). Cognitive and affective empathy were included as predictor variables and MBI as a criterion variable (Table 2). On one hand, the best predictor of Depersonalization is the Cognitive Empathy. On the other hand, regarding Affective Empathy, it does not act as a predictor of Depersonalization.

Table 2 Multiple linear regression analysis considering Depersonalization as a criterion.

TECA	Corrected R ²	F	B	p
Cognitive Empathy	.20	25,4	-.32**	0,00
Affective Empathy			-.15	.84

Lastly, the predictive capacity of Empathy in relation to Personal Achievement was figured out. (Corrected R² = .19, F = 23,4, p = 0.00). Cognitive Empathy is the best predictor for Personal Fulfillment (Table 3).

Table 3 Multiple linear regression analysis considering Personal Fulfillment as a criterion.

TECA	Corrected R ²	F	β	p
Cognitive Empathy	.20	25,4	.43**	0,00
Affective Empathy			.00	.96

Conclusions: It was noticed that through a linear multiple regression analysis, the variable that best explains Emotional Exhaustion is Cognitive Empathy. Those results are replicated for Depersonalization and Personal Fulfillment.

Disclosure of Interest: None Declared

EPV0551

Evaluating emotional competencies in health professionals in a city in Colombia

E. P. Ruiz Gonzalez¹, M. N. Muñoz Argel^{1*}, S. Garcia² and
A. Sierra¹

¹Universidad Pontificia Bolivariana and ²Fundacion Saecivi@gmail.com, Montería, Colombia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1231

Introduction: Emotional competencies, according to Bisquerra Alzina & Escoda (2007), refer to “knowledge, skills and attitudes necessary to understand, express and appropriately regulate emotional phenomena” (p. 22) in the management of emotions with oneself and with the other.

Objectives: Measure the emotional competencies Empathy, Emotional Expression and Emotional Regulation in health professionals in healthcare centers.

Methods: Quantitative descriptive. The Inventory of Emotional Competencies for Adults (Mikulic, Crespi, Radusky, 2015) was applied to 30 participants (doctor, psychologist, nurse, dentist).

Results: The grouped measurements show skills at a medium and high level.

Table 1. Measurement of empathy capacity, emotional regulation capacity and emotional expression capacity

		Frequency	Percent
Empathy	Medium	27	90,0
	High	3	10,0
Emotional Regulation	Medium	15	50,0
	High	15	50,0
Emotional Expression	Medium	26	86,7
	High	4	13,3
Total		30	100,0

The emotional reaction of congruence with the emotional state of the other, empathy, shows a medium level (Table 1), a result consistent with the study by Ruiz González (2019), in the Colombian population, where a medium level of empathy is observed in doctors.

In the strategy for management, support, increase and suppression of the current affective state to self-soothe and find a state of relaxation, it is at an average value between medium and high (table 1.)

In the ability to start and maintain conversations, express one's own thoughts and feelings clearly, both in verbal and non-verbal communication, and demonstrate to others that they have been well understood, the level is mostly medium (table 1.)

Conclusions: The levels of emotional competencies evaluated are mostly in the middle in the assessment by dimensions, empathy registered a lower level in contrast to other dimensions. Taking into consideration professional practice, response to organic and mental human vulnerability, it is a field for promoting the well-being of the health professional.

Disclosure of Interest: None Declared

EPV0552

Gaping gaps in rural mental health care: understanding causes and prioritizing solutions

R. Gupta

Institute of Mental Health, Pt.BD Sharma University of Health Sciences, Rohtak, India

doi: 10.1192/j.eurpsy.2024.1232

Introduction: Mental health is crucial and is the backbone of all dimensions of health; physical, social and spiritual. Mental health has multiple interfaces and it is important to bring mental health to the center stage as it is the key regulator of all human activities. Unfortunately, there are alarming gaps in mental health care especially in rural areas which require attention of mental health professionals and policy makers. The study aims to understand the causes of these gaps and suggest possible and practical solutions to bridge them.

Objectives: To study the spectrum of mental health gaps present in rural areas of Haryana, a state in the northern part of India and find culturally sensitive and relevant solutions keeping in view the socio economic realities and prevalent legal framework.

Methods: Any factor having bearing on mental health but is operative sub-optimally would be considered as mental health gap for the current investigation. Rural camps were organized in 10 villages to assess the service gap at three different levels: overt (measurable), covert (including attitudinal) and ancillary (including those embedded in the psychiatry evaluation and treatment). The camps were organized by following these three basic steps: 1) Evaluating the geographic and demographic details of the villages selected. This was done by meeting the key stakeholders of the villages and the official health and service statistics available on the government website 2) Camp by multidisciplinary team in the villages with an advance intimation. The team members evaluated the mental health care awareness and the felt needs by interviewing all the villagers attending the camp on that particular day. 3) Post camp review by the team to analyze the service gaps and steps to address and narrow the gaps.

Results: Apart from inadequate availability of professional and infrastructural resources, there were many attitudinal and ancillary gaps serving as obstacles to treatment seeking. Trust gaps leading to poor acceptance and legislation not congruent with the socio cultural needs were key impediments. Rural people had more faith in Spiritual leaders and faith healers for their mental health issues and medical help was sought only when they have signs of physical illness. Mental health and illnesses were not on priority. Availability, accessibility and affordability of health services were important factors needing immediate attention.

Conclusions: Rural services need to be augmented by de professionalization and task shifting is the key to address and cover the yawning gaps in the services. Massive, coordinated, multidisciplinary and sustainable efforts are needed to bridge the multitude of gaps keeping in view poverty and illiteracy as compounding factors.

Exploring Mental Health Issues in HCV-Positive Pregnant Women: A Qualitative Study

A. Syed^{1*} and S. S. Hashmi²

¹First Faculty of Medicine, Charles University, Prague Czechia and

²Department Of Applied Psychology, National University Of Modern Languages, Karachi, Pakistan

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1233

Introduction: The research was conducted to explore the mental health issues, including anxiety, depression, low mood, emotional irrationality, and stressors related to pregnancy in the tertiary care hospital, in Karachi, after getting diagnosed with a life-threatening virus of hepatitis C and to determine the factors associated with depression among HCV-infected pregnant women. There appears to be a dearth of literature on this particular topic, and depression in HCV-infected pregnant women might not be dealt with effectively till this gap in the literature is addressed. The findings are to aid counselors in the formulation of treatment plans to help the patients during pregnancy and it helped to address the gaps in the antenatal care plans and support provided to the vulnerable population like HCV-Infected pregnant women.

Objectives: To explore what are the anxieties, stressors, and fears of HCV-infected young mothers. To explore the experiences of infected young mothers with HCV.

Methods: We have used a qualitative design of the study and a convenient, purposeful sampling technique to acquire the data. In Karachi, Pakistan, a tertiary care hospital will host this trial. Young moms who registered HCV+ infections between January 2022 and June 2022 were included in the study. The tertiary healthcare setting was used for the investigation. The suggested number of 10 young moms with HCV who had been detected during pregnancy and came to the clinic for treatment were selected, those who provided consent and who were neither pregnant nor extremely unwell at the time of the study were eligible. The average age of the inhabitants was 26. There were 42.85% undergraduate mothers, 28.57% mothers with graduate degrees, and 28.57% mothers with postgraduate degrees in the population. Thematic analysis was utilized to evaluate the data, and the themes were generated by looking at the data and creating codes to look into the transcription's content.

Results: According to the findings, the referral system appeared to place a significant burden on individuals who were already dealing with the potentially fatal hepatitis C infection and were pregnant. In the antenatal period, when there should have been two different doctors' visits, they were compelled to go to the same clinic.

Conclusions: The finding addressed the importance of specialized care setting in the tertiary care hospital in Karachi, Pakistan. There is a requirement of training programs for the development of soft skills of health care professionals and there must be awareness sessions to promote and mobilize the understanding of the spread of this disease.

To this research finding the importance of comprehensive health care support was identified. And it also depicts the importance of inclusive antenatal program design.

Evaluation of mental health using MHC-SF in patients with paget's bone disease

A. Feki^{1*}, I. SELLAMI^{2,2}, C. Abid¹, A. Abbes², Z. Gassara¹, S. Ben jema¹, M. Ezzeddine¹, M. H. Kallel¹, H. Fourati¹, R. Akrou¹ and S. Baklouti¹

¹Rheumatology and ²occupational medicine, Hedi chaker hospital, Sfax, Tunisia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1234

Introduction: Paget's disease is a chronic bone disorder, that is characterized by increased and disorganized bone remodelling, which can lead to bone pain, bone complications such as deformities and fractures, neurological and cardiovascular complications. This physical impact can alter patients' mental health and lead to anxiety or depression.

Objectives: This study aimed to assess the mental health in patients diagnosed with paget's bone disease

Methods: Paget's disease patients were assessed by The Mental Health Continuum Short Form (MHC-SF) score. It consists of

14 items that were selected to represent each fact of well-being: 3 emotional well-being items (reflects hedonic well-being), 6 psychological well-being items, and 5 social well-being items (when combined, reflects eudemonic well-being). Items scores are summed, yielding a total score ranging from 0 to 70. Higher scores indicate greater levels of positive well-being.

Results: Thirty patients were included. 60% were men and 40% were women. The average age was 65 years. Socio-economic level was low in 3.3%, average in 86.7%, good in 10% of cases. 93.3% were married and 6.7% were single. For the medical history, 80% had a previous history and 20% did not. Clinically, 83.3% had pain and 16.7% had no pain. Concerning the disease location, 4 had involvement of the skull, 15 of the spine, 13 of the sacrum, 13 of the femur, 1 of the tibia, 1 of the calcaneus and 3 of the humerus. As for complications, 36.7% had no complications, 56.7% had osteoarticular complications, 3.3% had neurological complications and 3.3% had cardio-vascular complications. Concerning treatment, 90% received bisphosphonate and 10% did not.

For the mental health questionnaire, the mean score was 36.4.

53.3% of patients had poor mental health, 43.3% were moderately healthy and 3.3% were thriving.

No significant associations were noted between level of mental health and age, pain level, complications, location of the disease, alkaline phosphatase and treatment $p > 0.05$.

Conclusions: The impact of paget's disease is not only physical but also psychological. The MHC-SF is useful to detect the mental illness.

Determinants of Burnout syndrome among healthcare workers in Sahloul hospital, Tunisia: A cross sectional study

A. Feki^{1*}, O. Thabet², C. Sridi¹ and S. Ksibi¹

¹Occupational medicine, Sahloul Hospital and ²faculty of medicine of sousse, Sousse, Tunisia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1235

Introduction: Healthcare workers are at increased risk of Burnout due to the stressful demands of their job.

Objectives: The aim of this study was to assess the prevalence and the related factors of burnout in healthcare workers at the Sahloul University Hospital, Tunisia

Methods: Data were collected from a cross sectional study using a questionnaire exploring socio-demographic and professional data, lifestyle habits and pathological history. Burnout was assessed using the French version of the Maslach Burnout Inventory (MBI).

Results: Our study included 135 healthcare workers. The average age was 41.7 ± 9.15 years. 81.5% of the sample was female. Nurses accounted for 60% of staff. More than half (51.1%) worked shifts, with night work in 32.6%. A pathological history was noted in 17.8% of healthcare workers, and a history of work-related accidents in 40.7%. The prevalence of burnout in our study population was 42.6%, with a high emotional exhaustion score in 47.4%, a high depersonalization score in 23.7% and a low personal

accomplishment score in 73.3%. Burnout was significantly associated with alcoholism ($p=0.016$), shift work ($p=0.037$) and the presence of stress at work ($p=0.048$).

Conclusions: The prevalence of burnout was high in our study population, hence the importance of setting up a burnout prevention strategy in hospitals.

Perception of Violence by Psychiatric Nurses: Behind the scenes

S. Hamzaoui, K. Mahfoudh, S. Walha, D. Mezri, A. Ouertani, U. Ouali, A. Aissa* and R. Jomli

Psychiatry A, Razi Hospital, Manouba, Tunisia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1236

Introduction: Violence in psychiatric settings poses significant challenges for healthcare professionals, particularly nurses. This study examines psychiatric nurses' perceptions of violence and its impact on the quality of care they provide.

Objectives: The primary objective is to assess the influence of violence on the quality of care in psychiatric settings, with a focus on the experiences and perspectives of nurses.

Methods: We employed a questionnaire-based survey administered to 30 psychiatric nurses working in both inpatient and outpatient psychiatric units of the Razi hospital Manouba. The survey gathered information on the prevalence of violence, types of violence encountered, and the impact on nursing practice.

Results: Of the 30 respondents, 75% identified as female and 25% identified as male. Most of them had more than five years of experience. The primary results revealed that all the psychiatric nurses reported experiencing at least one incident of violence during their psychiatric nursing careers. Regarding exposure to verbal violence, the results indicated that 52% encountered it sometimes, 22% often, 17% very often. Regarding physical violence, 30% experienced it rarely, 26% sometimes, 13% often, and 13% very often. For sexual violence, 56% reported never experiencing it, 8% rarely, 26% sometimes, and 8% very often. These incidents had varying effects on nurses' emotional well-being, job satisfaction, and the quality of care they were able to provide. 53% of nurses reported experiencing emotional distress and feelings of anxiety as a result of violence, 13% felt anger and frustration. One nurse declared he was not affected emotionally. Most of the respondents (75%) indicated that their job satisfaction had been negatively affected by violent incidents. 40% of respondents stated that violence has a negative impact on their relationship with patients, but they make efforts to maintain care quality. Whereas, 20% found ways to strengthen connections despite challenging experiences. The most commonly endorsed strategies to cope with violence included attempting to master their emotions by remaining calm and patient (78% of respondents), seeking assistance or the presence of other healthcare team members (65%), and maintaining a safe distance from patients (69%). Fewer participants reported raising their voice and adopting a position of authority (30%), while

a minority indicated engaging in additional training on the management of violent situations (20%). These results illustrate the diverse range of personal coping strategies.

Conclusions: Violence in psychiatric settings has a multifaceted impact on psychiatric nurses, affecting both their emotional well-being and the quality of care they provide. Strategies for managing and preventing violence, as well as supporting nurses in coping with these challenges, are essential for maintaining high-quality psychiatric care.

Augmenting pharmacotherapy with physical exercise: review of the principles

A. R. Szczegieliński* and R. Pudło

Department of Psychoprophylaxis, Medical University of Silesia, Katowice, Poland

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1237

Introduction: Observed structural and functional changes in the central nervous system as a result of physical exercise are beneficial from biological, psychological and social standpoint. The studies published so far confirm that physical exercise, understood as planned, ordered and repetitive activity, can improve severity of symptoms, general functioning, and quality of life in patients with mood disorders, schizophrenia/psychotic disorders, anxiety, PTSD or addictions. This seems to be particularly important in relation to the growing number of patients facing resistance to classical pharmacological treatment as well as its side effects (e.g. metabolic syndrome, cardiovascular complications).

Objectives: Review of effective implementation of treatment programs based on physical exercise within mental health services.

Methods: Scoping review was performed by identifying relevant studies available in the PubMed and Scopus databases that were 1) peer-reviewed 2) in English language 3) focused on physical exercises 4) published within the last 10 years. Selection of the studies from the initial group of search results was performed manually.

Results: Majority of studies present programs covering relatively small, diverse groups of patients with mixed types of physical exercise modalities and intensity introduced, which makes generalization to basic principles very difficult. Needs assessment of patients from various diagnostic categories is vital in the process of implementation and evaluation. Barriers indicated by service users include lack of psychoeducation on perceived benefits, limitations within healthcare system (e.g., time limits, cost, access), side effects of medication, and psychosocial factors such as isolation. The assessment of factors engaging and motivating to maintain physical activity seems particularly important.

Conclusions: Identification of patients that may especially benefit from the inclusion of physical exercise, and recognition of therapeutic programs' elements that ensure the maintenance of the physical activity require further research.

Mental Health Status and Fear of COVID-19 in Young Adult Male Inmates in PortugalC. Laranjeira^{1,2*}, W. Baccon³ and R. Mendes^{1,4}¹School of Health Sciences; ²ciTechCare, Polytechnic University of Leiria, Leiria, Portugal; ³Nursing Department, State University of Maringá, Maringá, Brazil and ⁴Estabelecimento Prisional de Leiria, Leiria, Portugal

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1238

Introduction: Incarcerated individuals are subject to a heightened risk of both mental and physical ailments. Hence, it is important to conduct regular assessments of their mental well-being and other potential health hazards.

Objectives: The aim of this study is to examine the subjective experience of fear related to COVID-19 and the psychological consequences of the pandemic among a cohort of young adult male convicts.

Methods: A research design using an institutional-based quantitative cross-sectional approach was used. The data collecting period was from July to September 2022, during which data was gathered at a juvenile correctional facility located in the center area of Portugal. The researchers used questionnaires to gather data pertaining to demographic and health attributes, fear related to COVID-19, as well as measures of depression, anxiety, stress, and resilient coping.

Results: The study included a cohort of 60 incarcerated males who had been imprisoned for a duration exceeding 2 years. The prevalence of stress was found to be the highest among offenders, with around 75% reporting this symptom. Anxiety was the second most often reported symptom, with 38.3% of inmates experiencing it, followed closely by depression, which was reported by 36.7% of the inmate population. The average score on the Fear of COVID-19 Scale was 17.38 ± 4.80 , suggesting that participants generally reported mild levels of fear. A total of 38 subjects, accounting for 63.3% of the sample, had low scores in resilience. The participants' responses indicated that their perceptions of mental health were within a fairly high range, with an average score of 3.62 ± 0.87 . Similarly, their perceptions of physical health were also moderately high, with an average score of 3.73 ± 0.95 . In terms of global health, participants reported a slightly lower average score of 3.27 ± 0.82 for the preceding month. The Pearson correlation matrix revealed statistically significant associations between fear of COVID-19 and characteristics linked to mental health, with the strength of these associations ranging from moderate to high ($p < 0.001$). The identification of predictive variables for fear of COVID-19 was accomplished by the use of a multiple linear regression model. Four predictors were identified in the study, namely age, perception of mental health, and overall levels of anxiety and stress. These predictors together account for about 49.7% of the variance in the outcome variable.

Conclusions: The findings of our research indicate a significant prevalence of stress among incarcerated individuals, accompanied by moderate levels of anxiety and depression. Our research has the potential to provide valuable insights for policymakers, mental health professionals, public health specialists, and other relevant stakeholders in the identification and effective management of pandemic-induced anxieties and mental health symptoms.

Multidisciplinary users oriented approach in the community mental health careG. Racetovic^{1*}, S. Grujic Timarac² and M. Latinovic³¹Community Mental Health Center, HEALTH CENTER Prijedor;²Psychiatric Department, Hospital "Dr. Mladen Stojanovic", Prijedorand ³Deputy of the Minister, Ministry of Health of Republic of Srpska, Banja Luka, Bosnia and Herzegovina

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1239

Introduction: For more than 25 years, Bosnia and Herzegovina (BH) has maintained and improved reform processes in the field of mental health (MH) care. In the last 13 years, the results of the reform are visible, and they focused on the quality of services oriented to people with mental disorders (PMD), as well as raising the quality of specific services to the general population. The developed network of community mental health centers (CMHC) as the leading concept of the reform (community psychiatry) enabled affordable, timely and adequate protection of mental health in whole country, while relying on other resources, primarily clinical and hospital capacities and centers for social work.

Objectives: Reform orientation had several directions: broad promotion and prevention, protection of the rights of the people with mental health disorders, quality education and more specific qualifications and competencies of mental health professionals and public promotion as a part of destigmatization.

Methods: Overview of the mental health reform in last two decades.

Results: In last more than 25 years reforming processes were focused mainly to users of mental health services. Specific legislative was created and recently upgraded through Mental Health Protection Law, as unique document focused to users, mental health professionals and services, and general population as well. Users organization were formed and have important role in creation of further directions in the reform. Main principles in daily care for users are community based with case management and intersectoral collaboration through joint discharge planning. Also, special focus is given to media reporting about mental health as well as to children and adolescents, prenatal psychiatry and elderly.

Conclusions: Republic of Srpska and Bosnia and Herzegovina made significant steps and visible changes in the quality of mental health services focused to users needs. Further activities will be oriented to continuous destigmatization of the people with mental health disorders, psychiatry and mental health professionals and further implementation of results achieved in reforming processes in our county.

Factors associated with the quality of conflict management among anesthesia techniciansA. Ghenim¹, M. Kahloul², I. Kacem^{1*}, A. Aloui¹, A. Chouchane¹, M. Ajmi², W. Naija², M. Maoua¹ and N. Mrizak¹¹Occupational Medicine Department, Farhat Hached Academic hospital and ²Sahloul Academic Hospital, Anesthesia and Intensive Care Department, Sousse, Tunisia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1240

Introduction: A conflict arises when one or more individuals, groups or organizations disagree, creating internal or external tensions that can cause damage. This is particularly serious in operating theatres, where decisions involving life or death are common. Indeed, in this particular context, the multiplicity of stakeholders, the divergence of opinions and decisions related to patient care, the frequency of critical situations, stress and the limitation of resources are established causes of disagreement and tension.

Objectives: To identify factors associated with the alteration of conflict management quality among anesthesia and resuscitation technicians (ART).

Methods: This is an observational, multicenter, cross-sectional and analytical study, enrolling all ART exercising at the two teaching hospitals of Sousse (Tunisia) over a two month period (March 1, 2022 to April 30, 2022). Conflict management was assessed using the Conflict Handling Style Scale.

Results: Our study involved 50 participants, only eight of whom reported having had previous training in communication and conflict management. Conflicts in the hospital were rated frequent to very frequent by 58% of participants. Task conflicts were the most reported (74%). The main causes of conflict were lack of leadership (60%), unequal distribution of tasks (42%) and workload (28%). The main repercussions of the conflicts were the delay in patients care (60%), therapeutic errors (42%), and the cancellation or postponement of some acts (34%). The main factors associated with impaired conflict management abilities were age < 40 years ($p=0.03$), tobacco consumption ($p=0.001$), and number of dependent children < 2 ($p<10^{-3}$).

Conclusions: In light of our results, it would be useful and urgent to develop the soft skills of our human resources, particularly in terms of communication and conflict management.

The impact of working conditions on the mental health of workers in a confectionery factory

H. Daoud¹, I. Sellami^{1,2,*}, C. Ben Chabene³, M. A. Ghrab¹, A. Haddar¹, M. Hajjaji^{1,2}, K. Jmal Hammami^{1,2} and M. L. Masmoudi^{1,2}

¹Occupational Medicine, Hedi Chaker Hospital; ²Sfax University, Sfax and ³Occupational Medicine, Tunis, Tunisia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1241

Introduction: Mental health is a critical factor influencing employee well-being and performance in companies. However, many factors within professional environments can either positively or negatively impact employees' psychological well-being.

Objectives: This study aims to assess mental health among workers in a confectionery factory and its association with job satisfaction.

Methods: We conducted a cross-sectional study among workers in a private confectionery in Sfax. Questionnaires and workplace assessments were collected over a period from December 2022 to July 2023 using a pre-established questionnaire. Mental health assessment was performed using the 21-item Depression,

Anxiety, and Stress Questionnaire (DASS21). The degree of job satisfaction was assessed using a visual analog scale ranging from 0 to 10.

Results: Our study included 200 participants, with 61% being female. Severe to very severe symptoms of depression, anxiety, and stress were found in 4.5%, 17%, and 10.5% of our participants, respectively. Among our workers, 22.5% reported being not very satisfied or not satisfied. Bivariate analysis revealed lower levels of satisfaction among the most anxious ($p = 0.000$), the most depressed ($p = 0.000$), and the most stressed ($p = 0.000$) workers.

Conclusions: The decline in mental health is closely linked to job dissatisfaction. Implementing measures to enhance employee job satisfaction and providing adequate support resources for mental well-being are essential steps to promote a healthier workplace and improve employee well-being.

Assessment of job satisfaction and work ability in a confectionery factory : A Cross-Sectional Study

H. Daoud¹, I. Sellami^{1,2,*}, C. Ben Chabene³, A. Haddar¹, M. A. Ghrab¹, K. Jmal Hammami^{1,2}, M. Hajjaji^{1,2} and M. L. Masmoudi^{1,2}

¹Occupational medicine, Hedi Chaker Hospital; ²Sfax University, Sfax and ³Occupational medicine, Tunis, Tunisia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1242

Introduction: Job satisfaction is a fundamental pillar of the modern workplace. Recognizing the significance of job satisfaction and actively promoting it has become a strategic imperative in today's work environment.

Objectives: The present study aimed to assess job satisfaction and work ability among workers in a confectionery factory.

Methods: A cross-sectional study conducted in a Sfax confectionery factory included 200 workers. Data were collected between December 2022 and July 2023 using a pre-established questionnaire. This questionnaire encompassed an evaluation of socio-demographic and professional data, measuring the degree of professional satisfaction and the level of work ability using a visual analogue scale ranging from 0 to 10.

Results: The gender ratio was 0.64. The mean age was 33.2 ± 8.8 years. Among our workers, 77.5% reported being satisfied with their work. The average perceived work ability score was 8.15 ± 2.087 . Employees with higher levels of satisfaction were more likely to have increased work capacity ($p = 0.000$). Elevated job satisfaction not only boosts work capacity but can also reduce stress levels, improve overall mental well-being, and contribute to a healthier workplace environment. These factors collectively lead to higher work ability.

Conclusions: These findings emphasize the importance of prioritizing employee well-being to enhance overall productivity and company success. Fostering a work environment that prioritizes job satisfaction can lead to a more productive and successful workplace.

ACOMPANYA'M a novel multimodal intervention plan

I. Insa Pineda^{1,2*}, I. Rueda Bárcena¹, C. Lamborena Ramos¹,
F. de Pedro Melgarejo¹, A. Planas Bas¹, T. Prieto Toribio¹,
E. Lujan Lujan¹ and M. Ribas Siñol³

¹Child and Adolescent mental Health Area; ²Child and Adolescent Mental Health Research Group, Hospital Sant Joan de Déu, Esplugues de Llobregat and ³Mental Health, Parc Sanitari Sant Joan de Déu, Sant Boi de Llobregat, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1243

Introduction: The Residential Educational Therapeutic Unit Accompany from Hospital Sant Joan de Déu Barcelona, is a device integrated into the public health network, intended for the comprehensive care of **children and adolescents under 18 years of age who suffer from an illness complex mental disorder**, at serious risk of becoming chronic and generating significant disabilities at a functional, cognitive and emotional level. It was a result from a joint venture between the Department of Social Rights and the Department of Health. The device was created to respond to the increase in behavioral problems and mental health disorders of children under guardianship.

Objectives: General Objective

To improve the quality of life in the physical, mental and social spheres of vulnerable children and adolescents with serious complex mental pathology through a biopsychosocial and community care model that integrates health, social, family and educational care and which is aimed at the recovery of the person's life project.

Specific Objectives

To offer intensive intervention, personalized and in a co-responsible manner, that is to say, that integrates the therapeutic, education, social services and child protection teams.

Promote the community and social reintegration avoiding stigmatization and social exclusion.

Improve the intra-family relationship and the burden perceived by caregivers.

Decrease the number of renunciations of parental authority of a minor.

Methods: The unit has a capacity for **28 beds**: 23 places for children/adolescents under guardianship of the administration and 5 places for cases that are at risk of family claudication due to their therapeutic and educational needs.

There are 5 coexisting therapeutic units. The apartments are referred as 'homes' and their organization is designed to encourage the active participation of residents with the professionals who attend them.

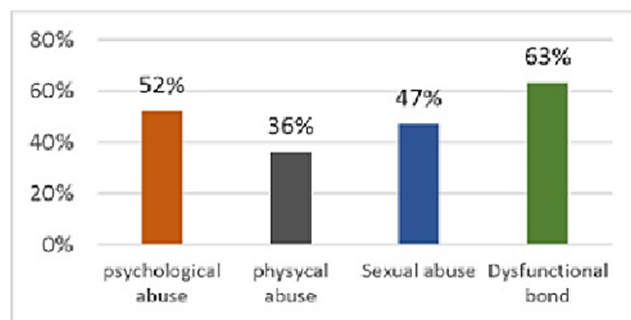

The Unit has a multidisciplinary team made up of the following professionals: Psychiatrists, Nurses, clinical psychologists, Social Workers, Educational worker, nursing assistants, administrative.

Results: - **110 children and adolescents have been taken care**, with an **average cumulative stay of 13 months**. In all cases in which the family had the guardianship of the patient, family claudication has been avoided. There is a 36% discharge of those patients under guardian that have returned to their original family home 100% of the cases have been linked to an educational center adapted to their needs or to a training project

EPV0569

Implementation of a peer support intervention for family members of involuntarily hospitalised patients

I. Wells^{1*}, K. Wintsch² and D. Giacco¹

¹University of Warwick, Coventry and ²Queen Mary University of London, London, United Kingdom

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1244

Introduction: Peer support has been identified as successful in improving patient wellbeing and empowerment and there is evidence that peer support can also help their family members (FMs). A peer support programme for FMs, developed in Germany, significantly improved FMs' quality of life. We have worked to adapt this support programme for delivery in England. We will report the results of this adaptation process and of the implementation of peer support for FMs.

Objectives: To examine the feasibility of the peer support programme developed and assess whether it can be delivered using a "train-the-trainer" approach.

Methods: The peer support programme is being implemented in two stages. In stage one, FMs with experience of supporting an involuntarily hospitalised patient (family peer supporters (FPSs)) receive an online training programme consisting of four sessions. These sessions, provided by the research team and FMs with lived experience of caring for an involuntarily hospitalised patient, teach FPSs skills in communication, reflection, coping and dialogue (promotion of equal communication between FMs, professionals and patients). FPSs then use these skills to deliver support to FMs of patients who are currently involuntarily hospitalised. This support is delivered for up to three months. The impact of this programme is assessed through one-to-one interviews with FPSs and FMs. Questionnaires are also provided to FMs measuring their quality of life, caregiving burden and psychological wellbeing before and after receiving support from FPSs.

In stage two, a modified version of the training programme (based on FPS feedback) is provided to a new group of FPSs. This training will be delivered by FPSs from stage one. After receiving the training programme, stage two FPSs will deliver support to other FMs as described for stage one. Assessment of the modified programme will mirror stage one.

Results: Provision of the stage one training programme is complete, and delivery of support is in progress with modifications being made for stage two. Eight FPSs and six out of a target of 12 FMs have been recruited for stage one. FPSs reported the training programme to be a positive experience, highlighting that it was engaging, easy to understand and gave them the confidence to support other FMs. Technical difficulties and an overload of information were cited as areas to improve for the next stage.

Conclusions: FPSs described the peer support training programme as a positive experience overall. However, improvements need to be

made for stage two which is in progress. A more comprehensive report of our findings, including the impact of this peer support programme and the feasibility of implementing it in England, will be provided as the programme progresses.

EPV0570

Exploring The Impact of Positive Behaviour Support Plans on Adult Acute Mental Health Staff Practice

J. M. Plant and J. Beezhold*

Norfolk and Suffolk NHS Foundation Trust, Norfolk, United Kingdom

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1245

Introduction: There is a national movement to reduce restrictive interventions due to the harm and distress they can cause which has been reflected in NHS trust policies and practices. NHS trust policies state that all in-patients who may require restrictive interventions must have a Positive Behaviour Support Plan (PBSP) based on a functional analysis of what drives and triggers their behaviour. A PBSP is intended to facilitate understanding and help manage behaviours that challenge by teaching new skills and ways to communicate a person's needs. Previous research on the use of PBSPs on adult acute mental health wards is limited but research on PICU wards has shown PBSPs have not been implemented into mental health care as intended.

Objectives: Trust policies identify that PBSPs should be implemented to reduce the use of restrictive interventions. However, it is unknown whether PBSPs are being used as part of routine practice on the acute mental health ward. The degree to which staff are aware of patients PBSPs and how they use them to guide their practice is unclear. The service evaluation aims to understand the perspectives, attitudes, and experiences of staff who are responsible for using and implementing PBSPs on the ward. The evaluation aims to investigate how PBSP informs practice and to identify the barriers and facilitators to implementing PBSPs on the ward.

Methods: A volunteer sample of clinical staff members (including Doctors, Nurses, Psychotherapists, Occupational Therapists, and Clinical Support Workers) who are responsible for implementing PBSPs on an acute mental health ward in the East of England took part in a focus group which lasted up to an hour. There were four focus groups with between two and four participants per group. A total of thirteen staff members participated in the focus groups. The focus groups lasted up to one hour and were guided by a topic guide. Two members of the project team facilitated the group. Focus groups were audio recorded.

Results: Thematic synthesis will be the overarching approach used to synthesise the qualitative data from the focus groups. The audio recordings will be transcribed. Analysis will be conducted on a within-case basis prior to cross-case analysis aimed to identify common themes. Two evaluators will work together to code, analyse, and synthesise the extracted data.

Conclusions: Based on the results, training may be developed to improve the understanding and implementation of the PBSPs on the ward. The findings may also result in changes to the way PBSPs are used. The results will be presented to the trust chief executives

and used to inform how to best support individuals who may be at risk of requiring restrictive interventions.

EPV0571

Context of implementation of mental health framework in Blumenau, Brazil (evidence based)

M. A. Cigognini

Institute of Neuroscience & Behavior, Blumenau, Brazil

doi: 10.1192/j.eurpsy.2024.1246

Introduction: Promoting high quality mental health (MS) services is an obligation of many social agents due to the impact of these diseases on the population. Making care increasingly evidence-based does not depend exclusively on technical training, but also on gradual and functional changes in the structure of an institution. Improving the quality of services in MH is a predominantly social intervention, in which it is necessary to group and interpret complex data. They represent real-time interventions in a real world by teams delivering health services.

Objectives: Describe the context where the MH service (iNC) is inserted, its main characteristics and purposes.

Methods: Mixed study identifying the location, socio-demographic data, characteristics and fundamentals of an organization providing services in MH that proposes to act based on evidence.

Results: iNC is a private secondary care institution located in the city of Blumenau, Vale do Itajaí, state of Santa Catarina, Brazil (FIG 1). Vale do Itajaí is a mesoregion with approximately 1.5 million inhabitants composed of small regions: Blumenau, Itajaí Ituporanga and Rio do Sul. Most of the population is of German and Italian descent. Blumenau has 361,261 inhabitants, an average monthly income of 2.9 minimum wages, 97% of schooling between 6-14 years old and the number of deaths of 6.48 (1000 live births). iNC is located in the center of the city (3-story building) with a clinical staff idealized for 3 psychiatrists, 16 psychologists, 4 nutritionists, 1 nurse, 1 nursing technician and 1 physical educator in face-to-face and online, individual and in-person sessions group. Performs care for adult patients between 18-70 years. Its missions are: to promote MS care from an interdisciplinary perspective, to provide health interventions supported by the best individualized scientific evidence and to encourage teaching and research in the field of MH. Its guiding principles are: psychopathology and nosology (DSM-5 and CID-11), neuroscience and psychopharmacology, mood, anxiety, sleep, eating and obesity disorders (FIG 2), psychological treatments and psychoeducation, assessment instruments in MH and neuropsychology, evidence-based medicine, health promotion and disease prevention.

Conclusions: Identifying, measuring and quantifying a local assistance service in MH can help in its development and allow comparisons over time. The improvement of services depends on multiple factors and is necessary for their development, both for researchers, implementers, health professionals and patients.

EPV0572

Mindset and emotional intelligence in pre-service teachers

M. J. Gutierrez Cobo^{1*}, R. Cabello¹, A. Megías-Robles² and P. Fernández-Berrocal²

¹Developmental and educational psychology and ²Basic psychology, University of Málaga, Málaga, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1247

Introduction: Pre-service teachers must confront emotionally demanding situations associated with the profession, and they must be prepared for it. Previous literature has shown that two variables are important for managing mental health in this population: emotional intelligence (EI) and mindset. EI is the ability to perceive, facilitate, understand, and manage emotions, while mindset refers to beliefs about the malleability of various life domains. According to their mindsets, those who believe that attributes are malleable are called incremental theorists, and those who believe attributes are fixed are entity theorists.

Objectives: This study aimed to explore the influence of intelligence and EI mindset on self-report and ability EI in a sample of 224 female pre-school pre-service teachers ($M = 21.27$, $SD = 4.72$).

Methods: Participants completed a questionnaire battery, including intelligence mindset, EI mindset, the Mayer-Salovey-Caruso Emotional Intelligence Test, the Trait Meta-Mood scale, and paternal and maternal educational status.

Results: The results showed that incremental EI theories — but not intelligence — were related to higher scores on self-report and ability EI. Specifically, being an incremental theorist of EI predicted 11% and 20% of the variance in global EI and the managing branch of ability EI, respectively

Conclusions: These results suggest that EI mindset training programs could be implemented and evaluated to explore their impact on the EI of female pre-service teachers

Relationship Between Quality of Life and Academic Performance in a Sample of Colombian University Students

M. Paredes Bermúdez*, M. Bayona Velásquez, M. Lora Monsalve, J. Viloria Escobar and K. L. Perez Correa²

Magdalena, Instituto Nacional de Formación Técnica Profesional Humberto Velásquez García, Cienaga and ²Magdalena, Universidad Cooperativa de Colombia, Santa Marta, Colombia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1248

Introduction: Quality of life encompasses a multidimensional component that includes aspects of lifestyle, health, housing, personal satisfactions, which can affect the academic performance of students in their university studies.

Objectives: To determine the relationship between the quality of life and academic performance of students at the National Institute

of Professional Technical Training “Humberto Velásquez García” in Ciénaga, Colombia.

Methods: Cross-sectional observational study involving a sample of 344 undergraduate students who completed the WHOQOL-BREF questionnaire, a sociodemographic form, and were asked about their academic performance in the last semester. Data were analyzed using RStudio, where categorical variables were interpreted through relative and absolute frequencies, and quantitative variables through medians. Bivariate analysis was conducted using non-parametric tests such as Mann-Whitney U and Kruskal-Wallis for group comparisons, and Kendall for correlations.

Results: Academic performance had a median of 4.00, and the quality of life had a median of 47.57. The Mann-Whitney U test showed $p=0.03$ for gender-based performance comparison. Kruskal-Wallis comparison by age group regarding performance showed $p=0.003$. The correlation between academic performance and quality of life showed $\tau=0.120$ and $p=0.004$.

Conclusions: The median academic performance is above the approval point, but the quality of life is below average levels (on a scale of 1 to 100). There are significant differences in median performance among gender and age groups, as well as a very low, positive, and statistically significant correlation between academic performance and levels of quality of life.

doi: 10.1192/j.eurpsy.2024.1249

Introduction: Heavy academic loads imposed on medical students explain why it is so important for a university to pay more attention to the issues of maintaining their students' mental health.

Objectives: To compare the level of mental health and the need for mental health services in domestic and international medical students

Methods: The survey covered 305 domestic and 241 international university students of the Faculty of Medicine. Their mental health level was measured with the SCL-90R questionnaire, their interest to mental health services - by means of a 5-point questionnaire.

Results: The data achieved by measuring the level of mental health with the SCL-90R revealed that in both groups this level is within standard limits. However, the international students showed a higher level of psychopathological distress reflected by GSI index ($\chi^2=2.14$; $p=.03$). Both groups have experienced a visit to a psychiatrist or psychotherapist (12.13% and 8.3% correspondingly). Some of them have undergone treatment in connection with their

emotional and behavioral problems (3.28% и 3.73%). Currently, they claim, with the same frequency, that they are in need of a psychiatrist's or psychotherapist's help (14.43% и 13.28%). Domestic students, as compared with international students show higher need ($\chi^2=24.55$; $p=.001$) for a psychologist's help (34.75% and 16.18%). With different frequency, 65.15% of the international students and 89.5% of the domestic students consider mental health services as necessary.

Conclusions: When providing medical support to medical students, it is important to take into account their need for mental health services and to keep in mind their different cultural backgrounds.

How to manage work-related stress in healthcare professionals: organizational and individual interventions.

P. Catapano*, M. Luciano, S. Cipolla, S. Pascolo, G. Sampogna, F. Perris, F. Catapano and A. Fiorillo

Department of Psychiatry, University of Campania “Luigi Vanvitelli”, Naples, Italy

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1250

Introduction: Workplaces can be source of significant stress for employees, leading to a series of mental health problems, such as burnout syndrome. Healthcare professionals and other helping professions are especially vulnerable to work-related stress.

Objectives: The aim of the present review is to assess available intervention aiming at improving work-related stress symptoms.

Methods: We conducted a thorough search of relevant articles on PubMed, APA PsycInfo, and Scopus databases, using specific keywords such as “occupational stress,” “stress,” “anxiety,” “depression,” “health personnel,” “health care facilities, manpower and services,” “prevention,” and “control.”

Results: Although significant methodological heterogeneity has been found among studies, regarding assessment tools, target population, and intervention types, we can still draw some satisfactory results. Healthcare professionals have access to various interventions to manage work-related stress symptoms, which can be classified into three categories: 1) individual cognitive-behavioral therapy approaches, 2) relaxation techniques at the individual level, and 3) organizational-level interventions. Mindfulness techniques, relaxation techniques, emotional freedom techniques, and integrated interventions have demonstrated effectiveness in alleviating work-related stress.

Conclusions: To prevent work-related stress among healthcare professionals, interventions should be targeted towards specific categories of healthcare workers based on factors such as age, tasks, and patient types. Well-structured and reliable randomized controlled trials focusing on the most promising interventions, such as mindfulness, need to be carried out in larger samples and with a solid methodology in order to confirm these evidences.

An integrative, systemic day-clinic approach for the treatment of psychiatric disorders in young adults: a detailed study of two cases

U. Altunoez*, A. Osiak, M. Anthoff, G. Rietig, M. Bald, S. Akbas and I. T. Graef-Calliess

KRH Wunstorf Psychiatric Hospital, Wunstorf, Germany

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1251

Introduction: More than 75% of the psychiatric disorders arise before the age of 30. Adolescence and young adulthood pose numerous developmental challenges like identity development, educational and occupational concerns, gaining autonomy and boundary-setting skills. The adolescent crises, which can involve a broad spectrum of psychiatric symptoms, demands a multidisciplinary approach to diagnosis and treatment.

Objectives: Our goal is to present a best practice example of an interdisciplinary day clinic through two case presentations, aiming improving innovative strategies for assessment/treatment of psychiatric disorders in young adulthood.

Methods: Via two comprehensive case presentations, we will introduce a psychotherapeutic day-clinic concept from a psychiatric training hospital in Germany.

Results: The day clinic's interdisciplinary team uses therapeutic approaches like dynamic, cognitive-behavioral, and systemic therapy to understand young adults beyond just their symptoms. Milieu-therapeutic methods, family constellations, socio-therapeutic approaches and non-verbal therapies are incorporated into our concept.

Case 1: A 20-year-old male patient, previously diagnosed with schizophrenia, was referred due to symptoms of living in an unreal world with perceived magical abilities and family conflicts. In the evaluation the features of high-functioning autism spectrum disorder (ASD) were more prominent than the psychotic symptoms. Developmental history and diagnostic tools yielded the diagnosis of ASD. Magical abilities in an unreal world appears to align more closely with repetitive/restrictive patterns of behavior, hereby we excluded in the follow-up the diagnosis of schizophrenia. Psychoeducation, social-skills-training and family interventions helped him to comprehend his strengths and discover a clearer direction in his life.

Case 2: Another 20-year-old male patient was referred with depressive symptoms, a sense of emptiness and self-mutilation. Following routine evaluation, we employed systemic methods (genogram constellations) to gain deeper insight into the patient's psychopathology. His mother's migration history from Thailand, coupled with unfulfilled aspirations, echoed in his recurring thought: "Where are my roots?" During follow-up, we recognized his passive stance toward therapeutic change, addressed through a systemic intervention known as 'taking the side of non-change.' This shifted his position from resistance to openness. Non-verbal approaches, family interventions, and corrective in-vivo experiences significantly contributed to his stabilization.

Conclusions: Specialized psychiatric centers tailored to the unique needs of young adults play a critical role in evaluating, diagnosing, and treating psychiatric crises during this developmental stage. Achieving this requires the implementation of interdisciplinary holistic therapeutic approaches.

Improving Access to Psilocybin-Assisted Therapy: Barriers, Challenges, and Recommendations

V. Tsang* and C. Roney

UBC, Vancouver, Canada

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1252

Introduction: Psilocybin-assisted therapy (PAT) has demonstrated significant potential in alleviating anxiety, depression, and psychological distress among individuals with terminal illnesses. However, numerous barriers prevent equitable access to this transformative treatment.

Objectives: This study seeks to gather the perspectives of patients on the waitlist of PAT.

Methods: Semi-structured interviews highlight the challenges faced by patients seeking PAT and their care providers and propose recommendations to enhance accessibility.

Results: Through a case study of Roots to Thrive, a non-profit healthcare practice offering group-based PAT, obstacles such as complex application processes, fear of judgement, logistical and financial constraints, and systemic inequities are revealed. Moreover, Health Canada's stringent control of PAT access via clinical trials and the Special Access Program (SAP) presents challenges for primary care providers and hinders the involvement of trained practitioners. The moral distress experienced by patients and providers due to delayed or denied access further emphasizes the urgency of addressing these barriers.

Conclusions: Advocates are calling for streamlined referral systems, expedited services for end-of-life patients, formal billing infrastructure, practitioner education, expanded coverage, legislative adjustments, post-therapy support, and collaboration with non-profit organizations and Indigenous Healers to promote equitable and effective PAT. By implementing these recommendations, barriers to PAT can be overcome, allowing more individuals to benefit from this therapy and find relief from the psychological distress associated with their conditions.

Providing psychiatric diagnosis and intervention in patients with chronic medical illness in the community: A novel collaboration between the Psychiatry team and the community team in a Singapore restructured hospital

W. S. Lee*, G. S. Lim, H. Y. Goh and Y. S. Chan

Psychiatry, Tan Tock Seng Hospital, Singapore, Singapore

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1253

Introduction: Home nursing and medical services have an established role in delivering chronic medical care to populations which face difficulty accessing physical clinics. Those with chronic medical conditions and reduced mobility face a higher likelihood of suffering from psychiatric co-morbidity. However, till date there

has been limited research done on home-based psychiatric care in this population.

Since 2021, the Psychiatry department of Tan Tock Seng Hospital (TTSH) has been collaborating with TTSH Community Health Team (CHT) to manage potential psychiatric issues in community patients.

These patients would be discussed in a weekly multidisciplinary setting. If indicated, home visit by both teams for home-based assessment and treatment would be arranged, allowing for detection and treatment of psychiatric illness.

Objectives: To demonstrate that the collaboration between the psychiatry team and CHT leads to diagnosis and treatment of psychiatric illness in a population that might otherwise have been unable to access psychiatric services.

Methods: We performed a retrospective study on all referrals from the CHT to the psychiatry team, within the 2-year period of August 2021 to August 2023. We collected demographic information, psychiatric history prior to referral, reason for referral, outcome of multidisciplinary discussion, and outcome of the home visits (including diagnoses made, and medications initiated).

Results: A total of 92 patients were referred by the CHT to the psychiatry team. Most were elderly with multiple medical co-morbidities; of note, a history of stroke was present in 24 of the referred patients.

Common reasons for referral include suspected mental illness, risk assessment, and management of behavioural issues.

28 of the referred patients did not have a prior psychiatric history at the point of referral. Among these, home visits involving the psychiatric team were done for 16 patients. 11 (68%) of these home visits led to diagnosis of a new psychiatric illness. 9 of these patients were initiated on psychotropic medications in the home setting.

Conclusions: A significant proportion of patients (68% of home visits without prior psychiatric diagnosis) were newly diagnosed with psychiatric illness, allowing early psychiatric intervention to be delivered. This was achieved in a population with a high prevalence of multiple medical comorbidity and barriers to clinic-based psychiatric evaluation and treatment.

We propose future comparative studies into how the collaboration between the psychiatric team and community health team can improve the quality of life and caregiver experience of patients with chronic medical problems, as well as how the service had improved the confidence of the community health team in identifying and managing patients with possible psychiatric issues.

Prevalence of burnout and its correlation with resilience among healthcare professionals in Morocco

H. Guider^{1*}, A. El Alaiki¹, W. Fadil², H. Hami¹ and F. Hadrya²

¹Laboratory of Biology and Health, Faculty of Sciences, Ibn Tofail University, Kenitra and ²University Hassan First of Settat, Higher Institute of Health Sciences, Health Sciences and Technologies Laboratory, Settat, Morocco

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1254

Introduction: Burnout syndrome arises as a result of chronic workplace stress that has either been inadequately managed or entirely unaddressed, leading to symptomatic manifestations of emotional exhaustion (EE), depersonalization (DP), and a decreased sense of professional accomplishment (PA).

Objectives: This study evaluated the prevalence of burnout and investigated its correlation with resilience among healthcare professionals in Morocco.

Methods: A self-administered questionnaire survey was conducted in April 2023, comprehensively using the Connor-Davidson Resilience Scale (CD-RISC) and the Maslach Burnout Inventory (MBI) among 296 healthcare professionals stationed across three institutions located in the Casablanca-Settat region.

Results: A total of 158 responses were obtained. Surprisingly, the results indicate that EE was highly prevalent, impacting 43.7% of respondents, while DP was notably affected 44.9% of participants. Conversely, PA was diminished in 58.2% of the respondents. It is worth noting that 44.3% of the participants displayed reduced levels of resilience. Furthermore, statistically significant correlations were observed between resilience and all three dimensions of burnout. Upon gender stratification, the analysis showed that resilience was significantly associated with two burnout dimensions, EE and PA, among male respondents, whereas among their female counterparts, resilience demonstrated a noteworthy correlation with all three dimensions of burnout.

Conclusions: These findings emphasize the pervasive nature of burnout among healthcare professionals and highlight deficiencies in resilience. It is crucial to consider these factors when crafting healthcare policies and devising focused approaches to effectively prevent and manage burnout.

Stress and its impact on healthcare professionals: A study on prevalence and coping strategies

M. A. Lafraxo¹, H. Guider^{1*}, Z. Boumaaize¹, H. Darif², Y. El Madhi³, A. Soulaymani¹ and H. Hami¹

¹Laboratory of Biology and Health, Faculty of Sciences, Ibn Tofail University, Kenitra; ²Scientific Institute, Mohammed V University and ³Regional Center for Education and Training Professions, Rabat, Morocco

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1255

Introduction: Stress is a significant issue among healthcare professionals and impacts both their personal well-being and the quality of care they provide.

Objectives: This study evaluated the prevalence of stress among healthcare professionals and investigated the possible effect of physical activity on perceived stress levels.

Methods: In 2019, a cross-sectional observational study of 30 nurses was conducted at the Hassan II Oncology Center in Oujda. A self-administered survey was used to gather information regarding the participants' sociodemographic and professional characteristics. The Perceived Stress Scale was employed to gauge stress levels, whereas the Ricci-Gagnon questionnaire was used to determine physical activity levels and engagement in sports.

Results: The study findings indicate that the sample had moderate levels of stress measured by the Perceived Stress Scale (PSS) and struggled with managing stress in diverse situations. Physical activity was common among 87% of the participants, as indicated by the Ricci-Gagnon questionnaire. In addition, a statistically significant correlation was found between stress levels and family situation ($p = 0.05$). The Perceived Stress Scale and the Ricci-Gagnon questionnaire exhibited high internal consistency, with Cronbach's alpha values of 0.79 and 0.64, respectively.

Conclusions: The study results have raised significant concerns regarding the effectiveness of different coping strategies in managing stress. In particular, the results indicate that engagement in physical activity and sports does not significantly affect stress levels. Thus, stress management training is recommended as the best strategy for stress prevention.

Exploring psychological distress among psychiatric nurses in Tunisia

H. Khiari^{1*}, A. Hakiri¹, M. Bouchendira² and R. Ghachem¹

¹Psychiatry B and ²Psychiatry G, Razi hospital, Mannouba, Tunisia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1256

Introduction: Nurses working in psychiatric departments regularly encounter intricate, stress-inducing, and emotionally challenging situations. The mental well-being of these nurses directly influences the quality of care they deliver.

Objectives: To assess the prevalence of psychological distress among psychiatric nurses and to identify the socio-demographic and clinical factors associated with it.

Methods: Cross-sectional, descriptive, and analytical study conducted over the course of one month from October 11th to November 8th 2023. Participants included were psychiatric nurses working in Razi Hospital, Tunisia. We collected data using pre-established questionnaire which included socio-demographic and clinical data of the participants. The assessment of psychological distress was conducted using the Depression, Anxiety and Stress Scale (DASS-21), validated in Arabic. Statistical analysis was performed using the Statistical Package for Social Sciences (SPSS) in its 25th version

Results: We collected data from 55 nurses working in Razi psychiatry hospital during the time of the study. Among them, 80% ($n=44$) were female. Their median age was 35 (Min=25, Max=62). Most of participants were married (81.8%, $n=45$) and 70.9 ($n=39$) had kids. In our sample, 5.5% ($n=3$) and 23.6% ($n=13$) had respectively personal psychiatric and somatic history. Some addictive behaviors were identified among our participants, especially smoking (14.5%, $n=379$) and alcohol use (3.6%, $n=2$). Regarding working conditions, 81.8% ($n=45$) were assigned shift work. They worked in the men's ward (43.6%, $n=24$), the women's ward (34.5%, $n=19$), or in both (21.8%, $n=12$). Furthermore, 45.5% ($n=25$) reported witnessing a suicide attempt during their work, and 74.5% ($n=41$) were victims of aggression, primarily by patients (82.5%, $n=33$). Sixty percent ($n=33$) said expressed a desire to transfer.

Moderate to extremely severe depression, anxiety and stress was observed in respectively 34.5% ($n=19$), 61.8% ($n=34$) and 36.4% ($n=20$) of cases.

A significant association was found between stress among psychiatry nurses and personal somatic history ($p < 10^{-3}$). No further links were found between depression, anxiety, stress and other clinical factors.

Conclusions: These results emphasize the difficult working environment within psychiatric settings, emphasizing the critical requirement for specific interventions aimed at improving the mental health and well-being of psychiatric nurses.

Demographic Factors, Cumulative Stressors, and Psychological Well-being

M. THEODORATOU^{1,2*}, A. PETROU¹ and A. KALAITZAKI³

¹Social Sciences, Hellenic Open University, Patras, Greece; ²Health Sciences, Neapolis University Pafos, Pafos, Cyprus and ³Social Work, Hellenic Mediterranean University, Heraklio, Greece

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1257

Introduction: The COVID-19 pandemic and the Ukrainian war appear to have adverse mental health effects. These global crises have raised concerns about the long-term psychological well-being of individuals across different demographic groups.

Objectives: The objective of this study was to evaluate the cumulative mental health effects of the COVID-19 pandemic and the Ukrainian war, emphasizing the relationship between demographic factors and mental health outcomes.

Methods: This was a cross-sectional online survey using convenience and snowballing methods of recruitment. A sample of 170 participants completed demographic questions and Likert-scale assessments using a range of psychometric scales for measuring general psychological distress, perceived stress, personal resilience, traumatic life events, emotional and social effects of trauma, and potential growth after trauma. Participants were requested to respond to the traumatic experiences of the COVID-19 pandemic and the Ukraine war.

Results: Gender differences were evident, with women reporting higher levels of psychological distress and post-traumatic growth. Family size had a negative correlation with psychological disturbance. Family status exhibited a positive correlation with traumatic event recall. Specifically, individuals who were either unmarried or divorced demonstrated increased memory recall for such events and levels of psychological distress. Conversely, participants in married or cohabiting relationships displayed diminished recall and lower psychological distress levels. Financial strain strongly correlated with compromised psychological well-being.

Conclusions: These findings highlight the association of demographic factors with cumulative stressors, underscoring the importance of personalized psychosocial interventions. Such interventions can enhance mental well-being and resilience in adversity, ultimately promoting improved psychological health.

Psychological Stressor Of End Stage Chronic Kidney Disease Patients On Dialysis. A Battle For Life

S. S. Hashmi¹ and A. Syed^{2*}

¹Department Of Applied Psychology, National University of Modern Languages, Karachi, Pakistan and ²First Faculty of Medicine, Charles University, Prague Czechia, Prague, Czech Republic

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1258

Introduction: Patients with chronic kidney disease (CKD) may choose to undergo dialysis. Factors that may have led patients to prescribe psychological interventions related to dialysis are poorly understood in the literature. The purpose of this study was to explore multi-level factors surrounding dialysis modalities such as Diagnosed Mood Disorders, Existential crises, Triggering events, Social support, and Distrust towards the process of dialysis.

Objectives: The study aims to investigate the psychological battle of the client while going through the process of dialysis. The study reveals multiple mood disorders and existential crises leading to depression among chronic kidney disease patients. Therefore the study was conducted with the aim of providing a therapeutic guide line in future once the factors are investigated in detail.

Methods: Semi-structured qualitative interviews were conducted in a dialysis clinic in Karachi where 19 participants participated in this qualitative study. The age ranges from 40-76. Initiating with informed consent followed by surveys assessing demographic and clinical information were administered to participants following their interviews.

Results: Qualitative findings suggested that patients were dealing with Clinical Mood Disorders without being provided treatment. Moreover, the cohesive family support enabled them to continue with daily living activities; however, the patients with low support triggering adverse events in life lost their lives in follow-up sessions. Furthermore, nephrology care doesn't seem sufficient as they are dealing with existential crises of hopelessness, regret, condemnation, and elevated death anxiety. In CKD the misinterpretation of dialysis by cognitively substituting it as End of life increased the clinical symptoms of Mood disorders. Thus the risk factors increase disturbing the quality of life.

Conclusions: Findings point to broader factors affecting dialysis modalities with Mood disorders. The low social support and adverse triggering events precipitate the risk factors of dialysis treatment. Furthermore, distrust towards dialysis and existential crisis are recommended for therapeutic interventions

Perceived stigma and associated factors among family caregivers of patients with severe mental disorders

R. Masmoudi, W. Abid*, E. Ben salem, R. Ouali, I. Feki, I. Baati and J. Masmoudi

psychiatry A department, Hedi chaker university hospital, Sfax, Tunisia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1259

Introduction: Giving care to someone who is experiencing mental distress is a difficult and challenging task that could be detrimental to the caregiver's overall quality of life. Stigma associated with mental illness is one of the most important mental health issues faced by these caregivers.

Objectives: Our aims were to assess perceived stigma among family caregivers of patients with severe mental disorders and to identify its associated factors.

Methods: We conducted a descriptive and analytical cross-sectional study among family caregivers of patients followed at the psychiatry outpatient clinic of the Hedi Chaker University Hospital in Sfax, during the period from February 2022 to July 2022.

A structured interview questionnaire was designed to collect socio-demographic data of both patients and their caregivers. We used the Stigma Devaluation Scale (SDS) to assess stigma.

Results: A total of 90 family caregivers of severely mentally ill patients were included: 26 men and 64 women, with an average age of 50.68 ± 11.67 years.

Patients' parents accounted for 40% of family caregivers. The majority of family caregivers (83.3%) had no more than secondary education. Married people represented 70% of cases.

The median age of patients was 42 years. Schizophrenia was the diagnosis in 68.9% of cases. The mean duration of illness was 16.23 years.

Daily assistance lasted from 4 to 8 hours in 30% of cases and more than 8 hours in 66.7% of cases.

The mean score (SDS12) for family-focused stigma was 13.12 ± 2.34 with ranges from 8 to 18.

Perceived stigma scores were significantly higher among caregivers caring for non-married patients (p=0.04), with an age <50 years (p=0.04), and with a higher level of education (p=0.02).

Long duration of providing care (> 8 hours per day) (p=0.05) and insufficient information about the illness (p=0.02) were significantly associated with perceived stigma.

Conclusions: The clinicians managing patients with severe mental disorders must focus on stigma and psychological distress among the caregivers and plan intervention strategies to reduce stigma.

Disclosure of Interest: None Declared

EPV0588

Resilience and burden in family caregivers of patients with severe mental disorders

R. Masmoudi, W. Abid*, E. Ben salem, R. Ouali, I. Feki, I. Baati and J. Masmoudi

psychiatry A department, hedi chaker university hospital, sfax, Tunisia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1260

Introduction: Family caregivers of patients suffering from severe psychiatric disorders may present with health problems, lower quality of life, and painful emotions, which can seriously compromise their well-being when they do not receive appropriate professional support.

Objectives: The aims of this study were to assess the level of burden and resilience in family caregivers of patients with severe mental disorders and to determine associated factors.

Methods: We conducted a descriptive and analytical cross-sectional study among family caregivers of patients followed at the psychiatry outpatient clinic of the Hedi Chaker University Hospital in Sfax, during the period from February 2022 to July 2022.

We used the Connor–Davidson Resilience Scale (CD-RISC) to assess resilience and the Zarit Burden Inventory to assess the level of burden. Higher scores indicate higher resilience and greater burden.

Results: The sample included 90 family caregivers of patients with severe mental disorders. The average age was 50.68. They were the parents of patients in 40% of cases. Professionally active caregivers accounted for 57.8% of cases. Thirty family caregivers had a somatic disorder history (33.3%).

The median age of patients was 42 years. Ten patients (11.1%) were financially independent. The diagnosis was schizophrenia in 68.9% of cases. The mean duration of illness was 16.23 years. Irregular follow-up was noted in 10 patients (11.1%).

The mean scores of the Zarit Burden scale and the CD-RISC were 41.86 ± 10.33 and 58.46 ± 9.18 respectively.

Unemployed caregivers and parents experienced a higher burden ($p=0.001$, $p=0.03$ respectively). The level of burden was higher in caregivers taking care of financially dependent patients ($p=0.03$), with a duration of the disease greater than 15 years ($p=0.04$), and with irregular follow-up ($p=0.008$).

A low level of resilience in caregivers was correlated with spousal relationship ($p=0.001$), cohabitation with the patient ($p=0.05$), widowhood ($p=0.01$), low level of education ($p=0.02$), the presence of a somatic disorder history in the caregivers ($p=0.04$).

A negative correlation was observed between CD-RISC and Zarit scores ($p=0.04$; $r=-0.21$).

Conclusions: Family caregivers of mentally ill patients experienced a significant level of caregiver burden, and it was lower in caregivers with higher levels of resilience. Psycho-educational programs directed toward family caregivers are highly recommended.

Exploring Child-Parent Relationship Therapy -CPRT- Impact on Externalised Behaviours of Foster Children Experienced Complex Trauma: A Case Study

S. Hatam^{1*}, S. Moss², C. Cubillo³, S. Parsafar¹ and D. Berry⁴

¹Faculty of Health; ²Charles Darwin University; ³healing circle psychology, Darwin and ⁴interplay play therapy australia, Perth, Australia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1261

Introduction: Many foster children experience traumatic events that result in a wide range of disruptive behaviours, such as temper tantrums, superficially charming, no sincere remorse, and so forth. These problematic behaviours are challenging to the implementation of holistic therapeutic interventions.

Objectives: The purpose of the current study is to explore the effectiveness of employing Child-Parent Relationship Therapy (CPRT) on externalised behaviours of a traumatised child at home and in social interactions.

Methods: This study used a case study to explore the influence of CPRT on externalised behaviours of traumatised foster children.

The case study focused on the externalised problematic behaviours of an Australian Aboriginal child fostered under long-term care at 18 months by a Caucasian family. The foster parent and the foster child received a 10-session structured CPRT across ten weeks. The child's externalised behaviours were evaluated through the Child Behaviour Checklist (CBCL) form.

Results: The findings describe the process of a 10-session structured CPRT with a foster child who exhibits externalised disruptive behaviours because of abandonment and complex trauma. The themes in the foster parent's role and the play therapy approach relate to traumatic events and attachment issues. The results indicated a slight reduction in these behaviours. According to the follow-up interview, the child still showed aggressive behaviours in social interactions but not at home. Interviews with the foster parent indicated both the parent and child require additional support and further sessions of CPRT.

Conclusions: This case study identified an improvement in externalised behaviours for foster children with experience of complex trauma and abandonment after a 10-session CPRT. Further research is required to explore the effectiveness of a longer-term session of CPRT alongside additional support services for foster parents.

Improving Mental Health of Medical Students through Movement, Art, and Interpersonal Relations

E. Ajándék¹ and V. Boros^{2*}

¹Division of Integrative Medicine, Semmelweis University and ²Collection Management, Museum of Ethnography, Budapest, Hungary

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1262

Introduction: Burnout, and symptoms of distress amongst medical students is becoming increasingly common due to the uncertainty of the Hungarian healthcare system. Change itself may be the cause of stress. Since the pandemic, the workload has been growing among health care workers. Anxiety is increasing even for beginner practitioners.

Objectives: Our examination intends to improve the mental health of the students with a variety of methods to help them develop resilience towards everyday stress, such as:

1. increasing body awareness
2. exploring the inner drivers of vocations by self-esteem, worth symbols and emblems
3. supporting relationships and interpersonality

Methods: We had advertised a monthly course in the mailing system of the students of the Semmelweis University (Neptun). Each occasion would go as far as 240 minutes in length. Selection criteria were: guaranteeing participation in the sessions. Any applicant suffering from mental health problems requiring medical attention, or the applicant regularly skipping occasions of the session would lead to his or her getting dismissed. Courses consists of musical aerob movement and receptive art therapy tools (exl. „Self-exhibition”). The aim was to interpret ones identity via images individually. In

advance of the first occasion, the applicants were interviewed to talk about themselves their career, mental health and issues, why they want to participate in the sessions. The closing interviews are still in progress. The examination was permitted by the SE-RKEB.

Method of examination: Qualitative: personal interviews, exploring talks about the artworks ("Self-Exhibition" collage), made during the course.

Results: 20 individuals started the course and 10 of them finished. The Body and Mind movements (Body Art - fusion of functional and breathing exercises, yoga and therapeutic exercises) has proven to have great importance throughout the session. The prescribed length of it in time was the third of each occasion. The joint analysis and interpretation of various artworks, images, visual narratives, even, the discussion of experiences in form of structured group activities has noticeably helped the interpersonality and social connections being formed for each individual who participated. The homeworks (eg.: Self Exhibition-collage, own worth emblem-collage etc.) and the active conduction of a diary has helped both to achieve results and have more involvement in the group.

Image:

Image 2:

Conclusions: Closing interviews are still in progress.

Disclosure of Interest: None Declared

An Observational Study of the Progression of Patients' Mental Health Symptoms Six Weeks Following Discharge From the Hospital

W. Mao^{1*}, R. Shalaby¹, E. Eboime², E. Owusu¹, H. Elgendy¹, N. Shalaby¹, B. Agyapong¹, N. Nkire¹, A. Nichols³ and V. I. Agyapong^{1,2}

¹Psychiatry, University of Alberta, Edmonton; ²Psychiatry, Dalhousie University, Halifax and ³Queen Elizabeth II Hospital, Alberta Health Services, Grande Prairie, Canada

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1263

Introduction: Transitioning from mental health inpatient care to community care is often a vulnerable time in the treatment process where additional risks and anxiety may arise.

Objectives: The objective of this paper was to evaluate the progression of mental health symptoms in patients six weeks after their discharge from the hospital as the first phase of an ongoing innovative supportive program. In this study, factors that may contribute to the presence or absence of anxiety and depression symptoms, and the quality of life following a return to the community were examined. The results of this study provide evidence and baseline data for future phases of the project.

Methods: An observational design was used in this study. We collected sociodemographic and clinical data using REDCap at discharge and six weeks later. Anxiety, depression, and well-being symptoms were assessed using the Generalized Anxiety Disorder (GAD-7) questionnaire, the Patient Health Questionnaire-9 (PHQ-9), and the World Health Organization-Five Well-Being Index (WHO-5) respectively. Descriptive, Chi-square, independent T-test, and multivariate regression analyses were conducted.

Results: The survey was completed by 88 participants out of 144 (61.1% response rate). A statistically non-significant reduction in anxiety and depression symptoms was found six weeks after returning to the community based on the Chi-squared/Fisher exact test and independent t-test. As well, the mean anxiety and depression scores showed a non-significant marginal reduction after discharge compared to baseline. In the period following discharge, a non-significant increase in participants experiencing low well-being symptoms was observed, as well as a decline in the mean well-being scores. Based on logistic regression models, only baseline symptoms were significant predictors of symptoms six weeks after inpatient discharge.

Assessing Personality Disorders of People Who Abuse Family Members

A. Mihai^{1*}, B. Otilia² and M. Dan Valeriu Nicolae¹

¹Psychiatry and ²Paediatric Psychiatry, Mureş County Hospital, Targu-Mures, Romania

*Corresponding author.
doi: 10.1192/j.eurpsy.2024.1264

Introduction: Men’s violence against women continues to be a major public health problem worldwide. The long-term consequences require a proper management of resources and a thorough screening protocol. The most extensive study on domestic violence was published in 2005 by the World Health Organization (WHO) and has been updated regularly ever since.

Objectives: The aim of this study was to outline a personality profile for people who could be considered domestic abusers and to provide statistical data on personality disorders which are most common among this group of population.

Methods: The quantitative data was collected by administering two scales SCID II and Karolinska Scale.

Inclusion criteria: People who are physically aggressive with family members.

Exclusion criteria: people who are diagnosed with psychosis, people who show aggression with people other than family members

Results: We included 70 people who admit to having committed acts of physical aggression directed towards family members, who agreed to take part in the study. The scales which were applied are Karolinska scale and SCID II. We identified, using SCID II, DSM IV TR and ICD 10 the following personality disorders types in the

70 intrafamilial aggressors - 10% antisocial personality disorder, 27% borderline personality disorder of which 14% with impulsive emotional instability, 3% obsessive-compulsive personality disorder, 1.4% mixed personality disorder anxious and paranoid.

Conclusions: Being able to recognise a personality pattern shows great benefits for screening the patients at risk to develop an aggressive behaviour directed towards family member, thus being a great tool in prevention of long-term consequences associated with living in a hostile environment.

Socio-emotional competencies in teachers of educational institutions in the department of cordoba, a comparative study between men and women

E. P. Ruiz Gonzalez¹, M. N. Muñoz Argel¹,
A. M. Romero Otalvaro^{2*} and M. G. Gracia Castañeda¹

¹Universidad Pontificia Bolivariana and ²Universidad de Cordoba, Montería, Colombia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1265

Introduction: According to Bisquerra Alzina (2003), competencies are defined as a set of knowledge, capabilities, skills and attitudes, necessary to understand, express and regulate emotional phenomena appropriately and which are fundamental in the teaching profession since they are closely related to students' performance and mental health.

Objectives: compare socio-emotional skills in two groups of participants: female and male

Methods: A non-experimental, cross-sectional design was proposed for this study. The scope of this research is descriptive, in the sense, that it seeks to establish measures in regard to specific variables. Sample (100 female and 100 male).

Results: Results revealed that the evaluated teachers show average level of socio-emotional competencies, (Table 1). The highest scores were encountered in relation to the optimism competence. It suggests that teachers have the ability to obtain favorable balances from adverse situations presented in their daily lives.

Table 1: Distribution of socio-emotional competency levels in the professionals evaluated

	LOW %	MEDIUM %	HIGHT %
EMOTIONAL AWARENESS	19	80	1
SELF EFFICACY	32	66	2
EMOTIONAL REGULATION	17	81	2
EMOTIONAL EXPRESSION	6	85	9
PROSOCIALITY	6	85	9
ASSERTIVENESS	6	82	12
OPTIMISM	0	21	79
EMOTIONAL AUTONOMY	25	71	4
EMPATHY	8	85	7

Findings showed that there exists a statistically significant difference ($P=0,000$) in the empathy and self-efficacy dimensions. Women obtained higher scores in these two abilities in regard to men. (Table 2). No differences were observed in the rest of the competences evaluated.

Table 2: Differences according to men and women

	FEMALE	MALE
SELF EFFICACY	1,78	1,61
EMPATHY	2,02	1,96

Conclusions: Although teachers' socio-emotional competences were classified in medium levels, it is necessary to implement an intervention design that allows to strengthen those dimensions since they could improve not only the relationships with their students but also teachers' mental health.

Analysis of the reasons for consultation in psychiatric emergency triage

S. Cruz^{1*}, S. R. Ferre² and F. V. Español³

¹Hospital Universitario de Jaen, Jaén; ²Hospital Universitario de Jaen and ³Hospital Unversitario de Jaén, Jaen, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1266

Introduction: The chain of care in psychiatric emergencies should be reviewed to improve assistance.

Objectives: Our objective was to determine the reality behind the reasons for consultation assigned in triage as "Psychiatry Assessment" and "Psychiatric Patient", examining diagnoses to the discharge of said patients

Methods: To this end, reasons for triage consultation and patient diagnoses are retrospectively collected who were evaluated by the main author in the emergency room of Hospital de Jaén between June 23, 2019 and May 31, 2020. They were selected following these criteria; inclusion: patients with psychiatry consultation, evaluated by the first signatory of the text and with reasons for consultation in triage: "Psychiatric patient" or "Assessment by Psychiatry". As exclusion criteria: high due to escape. Among the 224 patients evaluated, we found 35 who met criteria

Results: Of the total reasons of consultation collected at beginning, 16.6% corresponds to "Assessment by Psychiatry" (13.9%) and "Patient psychiatric" (2.7%), this being group the second reason for most frequent consultation after of "Anxiety" with 33%. Relating these reasons for consultation with the discharge diagnoses made in these patients, we found that the percentage of patients in each diagnosis would be: Regarding the action plan followed after the evaluation and diagnosis of these patients, it is reported that 45% of them required admission, 37% were referred to Mental Health Unit, 9% to family doctor and 6% to the Drug Addiction Center. - 11.4% of pharmacological intakes; 8.6% of psychotic episodes, symptoms anxiety, treatment renewal and mood disorders personality; respectively; 5.7% of autolytic attempts,

autolytic ideation, schizoaffective disorder, bipolar disorder, heteroaggressiveness and depression; respectively; 2.9% of adverse effects to drugs among others diagnostics

Conclusions: It is appreciated that the reasons for consultation triated as “Psychiatric patient” or “Psychiatry assessment” does not provide real information about the clinical characteristics of the patient to be evaluated in the emergency room, having a wide range of diagnoses encompassed in these terms. This fact does not allow discern the fundamental reason why the patient goes to the emergency room, nor receive assistance adequate to the problem it presents, nor a correct regulation of waiting and logistical planning. We believe it is advisable to review the use of these terms in the practice of the psychiatric emergencies training all professionals involved in the triage chain and we value the need to count on all emergency services with a standardized triage method for the psychiatric emergencies.

Microaggressions towards People with Mental Illness

C. H. Ayhan^{1*}, O. Sukut², H. Bilgin², F. Tanhan³ and K. Aslan¹

¹Psychiatric and Mental Health Nursing, Van Yuzuncu Yil University, Van; ²Psychiatric and Mental Health Nursing, Istanbul University-Cerrahpasa, Istanbul and ³Guidance and Psychological Counseling, Van Yuzuncu Yil University, Van, Türkiye

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1267

Introduction: Microaggressions, or subtle expressions of discrimination directed towards individuals because of their membership in marginalized social groups, are the subject of a growing body of literature (Sue, 2010). As a result of growing understanding of politically correct beliefs over time, they've been defined as subtler types of discrimination that have replaced formerly overt discrimination. Microaggressions differ from traditional prejudice in that they are frequently perpetrated by well-intentioned people who are oblivious of the negative implications and consequences of their conduct. Microaggressions have been documented in a variety of social groups, including racial/ethnic minorities (Sue et al., 2008; Torres et al., 2010), gender (Swim et al., 2001), sexual orientation (Shelton and Delgado-Romero, 2011), and ability status (Shelton and Delgado-Romero, 2011). Many people with mental illnesses have reported social rejection experiences that are similar to microaggressions, according to research (Cechnicki et al., 2011; Lundberg et al., 2009; Wright et al., 2000; Yanos et al., 2001).

Objectives: Existing measures of stigmatizing attitudes and behaviors may not capture much of the nuance in behavior that people with mental illness report to be particularly upsetting, so we thought it would be important to examine reliability and validity of the mental illness microaggressions scale-perpetrator version (MIMS-P) for measuring microaggression behavior in the general public in Turkey.

Methods: The methodological study will be conducted to establish the validity and reliability of the The mental illness

microaggressions scale-perpetrator version (MIMS-P) scale to Turkish Culture and to determine the microaggression levels against individuals with mental illness in the general population. The sample of the study will consist of individuals who are reached through an online questionnaire and who agree to participate in the study. Individuals who have psychiatric disorders will not be included in the study.

Results: Data collection process is still ongoing. Description of studies and the key findings will be presented.

Conclusions: The MIMS-P is designed to aid future study on the frequency of endorsement of microaggressions performed against people with mental illnesses, with the ultimate goal of understanding the mechanisms that lead to these acts.

The development of an extra scale to measure microaggressions from the perspective of people with mental illnesses who encounter them is one of the future research objectives.

With a better knowledge of these viewpoints and how they interact, effective therapies and public policy initiatives for reducing stigma against mental illness can be developed.

Crisis resolution teams: are we doing things well?

J. J. Martínez Jambrina*, L. P. Gómez, A. M. G. Alvarez, C. P. Miranda, S. P. Alvarez, N. A. Alvargonzalez and I. F. Arias

Psychiatry, Hospital San Agustín, Avilés, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1268

Introduction: Crisis resolution teams (CRTs) are a crucial component of mental health care, providing timely support to individuals experiencing acute mental health crises. This abstract delves into the concept of crisis and seeks to identify the patients who stand to benefit from these specialized services.

Objectives: Defining crisis within the context of CRTs can be complex. It encompasses not only immediate emergencies but also broader mental health distress.

Research suggests that suitable candidates for CRT interventions are those facing acute mental health crises: This includes individuals experiencing suicidal ideation, severe agitation, or severe emotional distress.

La “Escala de Evaluación de Resolución de Crisis” (Crisis Resolution Team Assessment Tool, CRTAT) de Sonia Johnson es una herramienta diseñada para para medir la efectividad de los CRT y la duración de la intervención en crisis. Establece un límite de seis semanas como el período máximo durante el cual se debe ofrecer la atención en crisis.

Existen otras escalas de evaluación para medir la eficacia de la resolución de crisis:

1. **Escala de Intensidad de Crisis (CIS):** se utiliza para medir la gravedad de la crisis y la necesidad de intervención inmediata.
2. **Escala de Evaluación de Crisis de Brage Hansen (BCES):** se enfoca en la evaluación de crisis suicidas y evalúa la intensidad de la ideación suicida y la urgencia de la intervención.
3. **Escala de Evaluación de Crisis de Eriksson (ECAS):** Diseñada para evaluar la intensidad de la crisis en pacientes psiquiátricos,

la ECAS se centra en la agitación, la ansiedad y la angustia emocional.

Methods: - Studies have explored the effectiveness of CRTs and the perspectives of service users. Understanding how patients perceive crisis and CRT services is crucial for tailoring interventions effectively.

Results:

Conclusions: - CRTs play a vital role in mental health care, offering timely support to individuals experiencing crises. While defining crisis is complex, suitable candidates often include those in acute distress requiring immediate intervention. Understanding the perspectives of service users and the diverse nature of crisis experiences informs effective crisis resolution strategies.

Principles of a personalized approach in psychosocial interventions for cardiac surgery patients

O. Nikolaeva^{1,2}, V. Babokin^{2,3}, N. Trofimov^{2,3} and S. S. Fakhraei^{4*}

¹Department of Hospital Therapy, Ulianov Chuvash State University;

²Chuvash Republic Cardiology Clinic; ³Department of Surgical Diseases and ⁴Medical Faculty, Ulianov Chuvash State University, Cheboksary, Russian Federation

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1269

Introduction: Cardiac surgery patients, former cardiac patients, face additional sources of stress connected with surgical intervention.

Objectives: To devise the main principles of a personalized approach in psychosocial interventions for cardiac surgery patients.

Methods: We have devised these principles based on the analysis of contemporary scientific literature and the operational experience of the Cardiology Clinic of the Chuvash Republic located in the city of Cheboksary.

Results: A personalized approach in psychosocial interventions for cardiac surgery patients is used at all levels of medical support. It implies taking into consideration in every specific patient a unique correlation of their clinic-anamnestic peculiarities, clinic-psychological risk factors of the condition's gravity and their psychological resources. At the same time, all the psychological interventions must focus on the personality and comply with the clinic specificity of the actual somatic and mental condition of the cardiac surgery patients. The underlying principles of the personalized approach in psychosocial interventions for cardiac surgery patients include the principles of accessibility, openness, continuity, collaboration, integration, differentiation, variation, participation, awareness and prevention.

Conclusions: Relying on the personalized approach in psychosocial interventions for cardiac surgery patients allows working out a personalized treatment and rehabilitation course for an individual patient.

Responses to serious adverse incidents in mental health care settings: a qualitative study of a complex patient safety system

N. Anderson* and R. Nathan

Cheshire and Wirral Partnership NHS Foundation Trust, Chester, United Kingdom

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1270

Introduction: Individual patient safety processes (such as reporting, investigating, learning and improving patient outcomes) activated following serious adverse incidents (e.g. patient suicide) are not distinct or standalone. Rather, they are embedded within a complex system of multiple interdependent processes enacted by individuals who are subject to an array of implicit and explicit influences (Nathan *et al.* BJPsych Advances 2022; 1-11). Although some specific elements of the response to adverse incidents have been examined, no previous empirical research has set out to study the complex interacting system within which these elements are situated.

Objectives: This study's aim was to characterise a complex patient safety system and to identify types of processes across that system that have an impact on the goal of improving patient safety.

Methods: Recorded 1:1 semi-structured interviews were undertaken with staff in a range of patient safety roles across a mental health care system to elicit accounts of the system response to serious adverse incidents. These interviews were transcribed, and the transcriptions were subject to thematic analysis using the *Framework Method* for qualitative research in health care settings (Gale *et al.* BMC Med. Res. Methodol. 2013; 13.1; 1-8). This preliminary study relates to the analysis of 8 interviews.

Results: The following six main types of influences on the effectiveness of patient safety system responses to adverse incidents were identified:

1. **Differing functions/expectations of investigations into serious incidents** (due to differing demands of different parties, such as the health provider, the family, the coroner, etc);
2. **Differing methodologies used to investigate serious adverse incidents** (although system-based generally preferred, there was a noted risk that this approach may fail to identify occasional examples of poor practice);
3. **Relationship between incident investigation processes and patient safety processes** (with a particular potential for the latter to dominate the system at the expense of the former);
4. **System complexity** (multiple interacting processes/processors at multiple levels within the health provider and wider health system);
5. **Operationalising recommendations from investigations** (with the potential for adverse unintended patient safety consequences);
6. **Influence of national directives**

Conclusions: As well as paying attention to individual components of the safety system (e.g. investigation methodology and organisational culture), the development of an effective patient safety system is dependent on an understanding of the complex interacting

processes across the system. This study sheds empirical light on key influences that act across a mental health provider system. Both researchers of patient safety and providers intending to improve their approach to patient safety should take account of such systemic influences on effectiveness.

Syrian refugees' experiences while receiving mental health services and psychiatric nursing care: A qualitative study

G. Öztürk^{1*}, K. Timarcioglu², G. Dikec¹, E. Karali³, H. Nacaroglu⁴, H. F. Cakir⁵ and A. K. H. Seren¹

¹Nursing, Fenerbahçe University, Istanbul; ²Community Health Center, Turkish Red Cross, Sanliurfa, Türkiye; ³New Cross Hospital, 3Royal Wolverhampton Trust, Wolverhampton, United Kingdom; ⁴Community Health Center, Turkish Red Cross, Kahramanmaraş and ⁵Disaster Risk Reduction, 4University of Health Sciences Mental Health and Neurological Diseases Education and Research Hospital, Istanbul, Türkiye

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1271

Introduction: Millions of people have migrated because of violence, wars, disasters, and human rights violations, all of which have increased rapidly in recent years. Türkiye has hosted millions of refugees since 2010. Few studies have focused on the mental health needs of refugees or how these needs have been addressed in Türkiye.

Objectives: This study examined the experiences of Syrian refugees in a community center in Türkiye as they access mental health services and receive psychiatric nursing care.

Methods: A qualitative design was adopted in the study. Data were collected from southern Türkiye between November and December 2021. The researchers conducted three semistructured focus group interviews following Colaizzi's phenomenological method to analyze the qualitative data. A total of 19 Syrian refugees participated in the focus group interviews.

Results: Three key themes related to immigrants' experiences of receiving mental health services and nursing care were identified: barriers to receiving mental health services, coping with negative experiences in Türkiye, and satisfaction with mental health services. The participants identified the barriers they experienced while receiving health services as those pertaining to language, discrimination, and stigmatization. They also mentioned the methods of coping with these negative experiences in Türkiye. Despite their negative experiences, they expressed satisfaction with the mental health services they received, especially psychiatric nursing care.

Conclusions: This study determined that Syrian refugees face barriers to accessing and receiving mental health services. They stated that mental health professionals in Türkiye approach them with empathy, particularly those in psychiatric nursing.

Healthcare professionals may be trained in culturally sensitive care to increase awareness. Studies have frequently examined the experiences of nurses providing care to refugees, but few have focused on evaluating nursing care from the perspective of refugees. Syrian refugees have reported various obstacles in accessing and receiving mental healthcare services. Health professionals, especially psychiatric nurses in mental health psychosocial support centers, must facilitate the processes to eliminate these obstacles.

Evaluation of a scalable psychosocial intervention for refugees in Greece

C. Papatthanasiou^{1*} and A. Kougioumtzi²

¹Department of Psychology, Panteion University of Social and Political Sciences and ²Department of Refugee Care, Association for Regional Development and Mental Health, Athens, Greece

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1272

Introduction: The world of the third millennium is witnessing the highest levels of displacement on record. To meet the specific needs of this vulnerable population, a task-shifting approach is developed, where individuals with refugee background and lived experience are trained and supervised by mental health professionals to provide emotional and practical support to members of their communities.

Objectives: The evaluation of a scalable psychosocial intervention for refugees based on the task-shifting approach.

Methods: The intervention consisted of sessions of Problem Management Plus (PM+) and peer case management delivered by a team of community psychosocial workers (trained refugees). The sample consisted of 173 participants, Arabic- and Farsi-speakers male and female, recognized refugees, and asylum seekers. Anxiety, depression, and psychological distress were measured before and after the intervention using the Generalised Anxiety Disorder-7 (GAD-7), Patient Health Questionnaire - 9 (PHQ-9), and Psychological Outcome Profiles (Psychlops) scales respectively. Repeated measures analysis of variance (ANOVA) was adopted to evaluate the difference in the degree of change across patients' characteristics over the follow up period. Statistical significance was set at $p < 0.05$ and analyses were conducted using SPSS statistical software (version 26.0).

Results: Significant decreases were found in all post-test scales, indicating diminution of anxiety, depression symptoms, and psychological distress. Large effects sizes were found in all scales.

Conclusions: The findings support that task-shifting approach incorporating PM+ and case management is effective for the mental health of refugees. Peer support could be included in a stepped care model for refugee mental health and well-being in high-income countries. For future research a randomized controlled trial is proposed as a study protocol.

EPV0607

Prevalence of alcohol use disorder in migrants from a Portuguese Center for Refugees: a study protocol

D. Magalhaes^{1*}, P. Satuala¹, J. Bastos¹, S. Martins¹, M. Oliveira², T. Sousa² and A. Neto³

¹Mental Health Department, Hospital Prof. Doutor Fernando Fonseca;

²Conselho Português para os Refugiados and ³Unidade de Alcoologia de Lisboa. Divisão de Intervenção nos Comportamentos Aditivos e nas Dependências. Administração Regional de Saúde de Lisboa e Vale do Tejo, Lisbon, Portugal

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1273

Introduction: According to the 2023 statistical report from the Portuguese Migration Observatory, Portugal has received over 72,000 refugees since 2015, with a significant number (56,041) being displaced citizens from Ukraine. This influx includes spontaneous asylum requests. The major countries of origin for refugees in Portugal are Afghanistan, India, Gambia, Pakistan, and Morocco. Notably, refugee populations exhibit elevated incidence rates of specific psychiatric disorders, including post-traumatic stress disorder and depressive disorders. These conditions are independent risk factors for substance use disorders. Furthermore, refugees face unique risks related to their migration journey, increasing their vulnerability to substance use disorders. The prevalence of substance use disorders, especially Alcohol Use Disorder, can reach up to 36% in this population. CAR 1 (Reception Center for Refugees) is a vital social facility in Portugal dedicated to enhancing the reception and integration of asylum seekers and refugees.

Objectives: Our primary objective is to determine the prevalence of potential alcohol problems and unhealthy alcohol use within the Portuguese Refugee Center in Lisbon. Our secondary aim is to comprehensively characterize the migrant population. This includes gathering data regarding demographic information, legal status, country of origin, pre-migration alcohol-related issues, psychiatric diagnoses, history of psychiatric evaluations, self-initiated help-seeking behavior, and self-perceived alcohol-related problems.

Methods: All individuals currently residing in our refugee center (approximately 70 people) will be invited to participate in a comprehensive survey and screening process. Exclusion criteria will apply to individuals with acute psychiatric conditions unable to provide reliable responses. The survey includes the Alcohol Use Disorders Identification Test (AUDIT) and the CAGE questionnaire. Quantitative data obtained from the questionnaires will be analyzed using Microsoft Excel and IBM SPSS 29 software.

Results: We anticipate a high prevalence of positive responses to the AUDIT due to potential alcohol-related issues but expect low responses to the CAGE questionnaire due to limited awareness of alcohol use disorder and a reduced perception of the need for help.

Conclusions: This study could help identify and validate the prevalence of alcohol use disorders among migrants, emphasizing the need for appropriate responses. By shedding light on these challenges, we hope to promote effective responses to alcohol use disorder and encourage the utilization of alcohol screening tests in refugee centers, emphasizing the importance of seeking consultation when needed.

The Traveling Mind: Moderators, Mediators and Pathophysiology of Migration Psychosis

K. Kahil*, L. Daou, A. Chabbouh and E. Ghossoub

Department of Psychiatry, American University of Beirut Medical Center, Beirut, Lebanon

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1274

Introduction: It is well established that migrants have a 2 to 4 times increase in psychosis risk. However, estimates are highly heterogeneous and vary considerably depending on origin and destination country. It also seems that the relationship between migration and psychosis is complex.

Objectives: In this review, we aim to explore the moderators, mediators and mechanisms behind migration psychosis.

Methods: We searched PubMed using the following terms: "psychosis," "psychotic," "migra*", "immigra*", "schizophreni*," "pathogene*". We limited the search to studies published after 2010 and we screened the title, abstract, and full text. We included a total of 47 studies in this narrative review.

Results: Moderators identified in the literature were country of origin, vitamin D deficiency, male sex, and psychosocial adversity (e.g. exposure to war). Mediators were mostly social, namely discrimination, social exclusion and ethnic minority status, low ethnic density, as well as language distance, unstable housing, and unemployment. Most of the studies we retrieved found that substance use did not fully explain the increased risk for psychosis among migrants. We found that potential pathophysiological mechanisms include stress-induced alterations in dopaminergic neurotransmission, functional and structural alterations in ventral anterior cingulate cortex, as well as possible stress-resultant neuroinflammation.

Conclusions: This review highlights the pathway from psychosocial hardships to neurobiological alterations leading to migration psychosis. Further research is needed to translate these findings into developing preventive measures and tailoring treatment modalities to the migrant population.

Suicide risk, hopelessness, interpersonal needs, and mental health in a sample of migrant psychiatric patients: a case-control study

L. Polidori¹, I. Berardelli², S. Sarubbi², G. Sarli¹, C. Corti³, D. Erbuto², M. Pompili⁴ and M. Cifrodelli^{1*}

¹Psychiatry Residency Training Program, Faculty of Medicine and Psychology; ²Suicide Prevention Center, Sant'Andrea Hospital;

³Faculty of Medicine and Psychology, Sapienza University of Rome,

Rome, Italy and ⁴International Consortium for Mood & Psychotic Disorder Research, McLean Hospital, Belmont, United States

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1275

Introduction: Suicide is a multifactorial phenomenon characterized by many biological, psychological, and social-cultural factors. The study of this phenomenon in migrants is complex, with no theoretical framework that can describe the available heterogeneous data. Although Italy has the fourth largest migrant population of EU, only few studies have assessed suicidal risk in migrants.

Objectives: The aim of his study is to assess suicide risk factors (hopelessness; interpersonal needs; traumatic experiences) in a sample of migrant patients, and to evaluate the possible application of the Interpersonal Theory of Suicide (ITS). Moreover, suicidal ideation and attempts were compared between migrants and natives. Lastly, a wider psychometric assessment has been conducted (depressive and anxiety symptoms; autistic traits).

Methods: In this case-control study, we included 50 migrants vs. 50 natives. Data were collected during the same period by gender, age, and diagnosis. We collected sociodemographic and clinical characteristics. We administered the following tests: Columbia Suicide Severity Rating Scale, Interpersonal Needs Questionnaire, Beck Hopelessness Scale, Beck Depression Inventory-II, Hamilton Anxiety Scale, Childhood Trauma Questionnaire, and Adult Autism Subthreshold Spectrum.

Results: There were no differences in sociodemographic characteristics, except for ethnicity. Otherwise, there were significant differences between diagnosis ($p:0.013$), with native reporting more Mood Disorders, and migrants reporting more Anxiety, Obsessive-Compulsive, Trauma-Related, Eating, and Substance Use Disorders. Migrants were more prone to be on treatment with Mood Stabilizers ($p:0.000$). There were significant differences for interpersonal needs, trauma, anxiety, and autistic traits. Migrants show more perceived burdensomeness ($p:0.05$), more physical neglect ($p:0.004$), physical abuse ($p:0.002$), and sexual abuse ($p:0.016$), more anxiety symptoms ($p:0.046$), and more empathy alterations ($p:0.014$). No differences were found for suicidal ideation and attempts, hopelessness, and depressive symptoms.

Conclusions: Despite there were no differences in suicide risk, migrants showed higher rates of perceived burdensomeness (PB) and childhood traumatic experiences (CTE). Both PB and CTE represent cardinal constructs of the ITS. No differences were found for hopelessness and depressive symptoms. Migrants showed higher rates of anxiety symptoms and empathy alterations. Even if suicide rates between migrants and natives were similar, accurate assessment of suicidal risk in migrants is crucial in improving suicide prevention strategies. Suicide risk evaluation in migrants should consider the application of ITS. For an appropriate clinical evaluation of the migrant patients, anxiety dimensions and autistic traits should be investigated.

Between Delusions and Borders: Diagnosing Delusional Disorder in Migratory Contexts

L. M. Carrasqueira^{1*}, M. D. Pereira², I. Marques¹, M. Silva¹ and C. Laureano¹

¹Psychiatry and Mental Health Department, Hospital Centre of Leiria, Leiria and ²Child and adolescent psychiatry, Coimbra Hospital and University Centre, Coimbra, Portugal

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1276

Introduction: The mental health of immigrants is a significant, yet often overlooked, aspect of public health. This case study highlights the intersection of migration and mental health, focusing on a patient with delusional disorder. It is particularly relevant for psychiatrists due to the unique challenges in diagnosing and treating mental health conditions in migrant populations, who often face cultural, linguistic, and systemic barriers in accessing care.

Objectives: The primary objective of this case study is to elucidate the diagnostic and clinical challenges encountered in managing delusional disorder in a migrant patient. The case study presented aims to provide insights into how delusional beliefs can precipitate and perpetuate the process of migration.

Methods: The case study was developed through comprehensive psychiatric interviews during the patient's stay in a Psychiatric Inpatient Unit, supplemented by a targeted literature review on PubMed using "delusion disorder" and "immigration" as keywords.

Results: The patient, a 44-year-old Indian male, was a functional young adult until 2007 when he began exhibiting symptoms of delusional disorder. His delusions progressively evolved from local scenarios to national and eventually to a global scale. The initial delusions were focused on personal and professional conspiracies within his home country, leading to his first internal migration. As the condition worsened, his delusions expanded, fueling a belief in a widespread conspiracy that transcended national borders. This escalation of delusional beliefs became the primary motivation for the patient's international migration. He changed countries four times, each move driven by an attempt to escape the perceived threats and conspiracies associated with his delusional disorder. The patient's journey through various countries was a direct result of the intensifying nature of his condition.

Conclusions: This case study accentuates the profound impact that a delusional disorder can have as a driver and catalyst of international migration, influencing the individual's decision-making process and shaping the migratory experiences. It emphasizes the necessity for psychiatrists to consider the unique socio-cultural contexts of migrant patients in diagnosis and treatment. The case study advocates for a comprehensive treatment approach, integrating psychiatric care with a nuanced understanding of the migrant's experiences and challenges. This multifaceted approach is crucial in addressing the complex needs of patients with delusional disorder in migrant populations.

Sociodemographic and clinical profile of immigrants hospitalized in psychiatric facilities in Tunisia

F. Tabib*, S. Omri, R. Bouaziz, R. Feki, I. Gassara, L. Zouari, J. Ben Thabet, N. Charfi, M. Maalej, N. Smaoui and M. M. Bouali

Department of Psychiatry C, UHC Hedi Chaker, Sfax, Tunisia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1277

Introduction: In an increasingly interconnected world, migration has become a defining characteristic of the 21st century. While immigration offers new beginnings and prospects, it also presents unique challenges, particularly concerning mental health.

The experience of migrating can exert pressure on mental health through factors such as acculturation stress, discrimination, and economic hardships. These challenges can, in turn, contribute to the development of mental health issues.

Objectives: To study the socio-demographic and clinical profile of immigrants hospitalized in the “C” psychiatry department, Hedi Chaker Hospital, in Sfax, Tunisia.

Methods: We conducted a retrospective descriptive study of immigrants hospitalized in the psychiatry department “C”, Hedi Chaker Hospital, Sfax Tunisia from 2011 to 2023. Socioeconomic data and clinical profiles of immigrants were collected from archived files.

Results: The total number of immigrants hospitalized during these 12 years was 32, with an average age of 28.81 years \pm 7.8 years, all of them were males, as the psychiatric department “C” only hospitalizes men.

All were of African origin, of whom 21.9% (n=7) had Libyan nationality, 15.6% (n=5) had Somali nationality and 12.5% (n=4) had Sudanese nationality. Communication with them was possible in 87.5% of cases, primarily through the native Arabic language in 56.3% of instances. Illegal immigration was the most prevalent form, accounting for 75% of cases. During the immigration process, 18.8% of individuals reported experiencing violence.”

The majority of hospitalized immigrants were single (71.9%), had a primary school education (37.5%), a low socio-economic level (81.3%), and no profession (59.4%). 21.9% of them had received social assistance, and 59.4% lived in a refugee camp. Psychoactive substance consumption was reported by 53.1% of our study population.

Regarding the clinical profile of the population, 21.9% had a history of somatic conditions, 43.8% had a psychiatric history, including 9.4% who had attempted suicide, and 34.4% who had experienced traumatic events since arriving in Tunisia. The primary reason for hospitalization was behavioral disorders in 71.9% of cases and suicide attempts in 15.6%. The most prevalent diagnoses were schizophrenia (50%), and bipolar disorder (18.8%). Upon discharge, 15.6% encountered administrative issues.

Conclusions: Hospitalized immigrants exhibit diverse socio-demographic and clinical profiles. These findings underscore the significance of acquiring a deeper understanding of the mental health needs and existing barriers to healthcare within various immigrant communities. This is particularly crucial as immigration continues to be a central focus in Tunisia’s public policies and discussions.

EPV0613

War and Migration – when Mental Health is left behind

A. L. Ramos^{1*} and H. Salgado²

¹Psychiatry, Faculty of Medicine University of Oporto and ²Psychiatry, University Hospital Center of São João, Oporto, Portugal

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1278

Introduction: Wars and armed conflicts are known to have devastating consequences for both physical and mental health of all the people involved. Studies have shown that conflict situations cause more mortality and disability than any major disease and, among

the consequences of war, the impact on mental health of the civilian population is one of the most significant.

Forced migration, compelling people to become internally displaced or refugees who have fled to other countries, is responsible for additional physical and mental health problems. Regardless of the reasons for migration, the process itself can be a highly stressful life event, leading to a higher risk of psychiatric disorders. Refugees are particularly susceptible to mood and anxiety disorders, whose prevalence rates is almost twice as high as those found among non-refugee migrants.

Objectives: Since 2022, with the progression of the conflict between Russia and Ukraine, and the establishment of a real war scenario, many Ukrainians were forced to leave their homeland, to ensure their survival and security. In Europe, many countries took in Ukrainian refugees and Portugal was no exception.

In the Psychiatry Inpatient Service of University Hospital Center of São João, there were admissions of Ukrainian refugees who already had a known mental disease - at that time decompensated - and also new cases, to date without follow-up by the specialty.

Methods: In this work, we will carry out a bibliographical review on the impact of war and migration on mental health and the potential of proper medical approach, based on articles indexed in Pubmed, in the last 10 years.

Furthermore, we will present the cases of war refugees interned in our service between January 2022 and December 2023.

Results: We will describe the psychopathological features and also the sociofamilial circumstances of these patients, as well as explain the intervention and longitudinal support developed in these cases.

Conclusions: As a conclusion, we point out the importance of approaching mental illness in light of the individual’s context, knowing that this context may contain the problem and also the solution. War and forced migration bring increased challenges to psychiatry and, in an increasingly globalized society, geographical, linguistic or cultural barriers cannot impose limits on our best and most appropriate medical treatment.

EPV0614

A Bibliometric Analysis of Refugee Health Publications in the Nursing Field by Visual Mapping Method

G. Ozturk*, G. Dikeç and A. K. H. Seren

Nursing, Fenerbahçe University, Istanbul, Türkiye

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1279

Introduction: Millions of people worldwide are forced to migrate to another country and nurses are the key professional for providing necessary health care to this population. Providing nursing care to refugees or immigrants requires diverse transcultural professional competencies based on standardized guidelines.

Objectives: This study was aimed to examine the bibliographic characteristics of quantitative studies conducted on refugees in the nursing field.

Methods: The data were obtained from articles scanned in the Web of Science Core Collection database. The 1672 articles that were published between 1980-and 2023 and met the inclusion criteria were analyzed using VOSviewer and Microsoft 365 Excel software. The PRISMA 2020 Checklist was used for reporting.

Results: Most publications were made in 2020. The United Kingdom, the United States, Canada, and Australia have the highest number of publications, citations, and international cooperation. Additionally, “mental health” is one of the most used keywords in the studies.

Conclusions: The findings show the importance of empowering nurses working in this field, especially in determining the needs related to mental health services for refugees. The increased migration rates and the growing need for refugee health care highlighted the importance of investment in nursing research within this field. Nurses and researchers should aim to establish partnerships and share best practices with the leading countries. Furthermore, nurses require specialized training to competently evaluate and provide nursing care and mental health services to this vulnerable population. Policymakers must prioritize international collaboration, equitable healthcare, and the integration of mental health services within healthcare systems to improve refugee health and reduce barriers between them and health services.

Reduced resting-state gamma-band power correlate with unaltered glutamate + glutamine levels in patients at clinical-high risk of psychosis

A. S. Tomyshv¹, I. Lebedeva¹, A. Dudina^{1*}, P. Menshchikov², D. Kupriyanov² and M. Omelchenko³

¹Laboratory of Neuroimaging and Multimodal Analysis, Mental Health Research Center; ²Clinical Science, LLC Philips Healthcare Russia and ³Department of youth psychiatry, Mental Health Research Center, Moscow, Russian Federation

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1280

Introduction: There is growing evidence of excitation / inhibition (E/I) balance abnormalities in schizophrenia, which might be associated with abnormal gamma frequency oscillations and glutamate concentrations. However, to the best of our knowledge, only one multimodal study have examined such associations between EEG and metabolite characteristics in patients at clinical-high risk of psychosis (CHR) so far.

Objectives: We aimed to investigate potential associations between GLX (glutamate + glutamine) levels and resting-state gamma-band power in CHR individuals and healthy controls (HC).

Methods: Twenty right-handed male patients (16-27 years, mean age 19.9 ± 2.7) fulfilling CHR criteria and 19 healthy male controls (16-27 years, mean age 21.6 ± 3.6) underwent resting-state EEG (16 leads; 10–20 system) and MR spectroscopy at 3T MRI scanner with voxels of $30 \times 30 \times 30$ mm located in left and right medial prefrontal cortex. Spectral analysis with estimation of gamma-band power (30-45 Hz) were conducted. MEGA-PRESS acquisitions were analyzed with jMRUi (ver. 5.1 Alpha), levels of GLX were calculated as a ratios to creatine + phosphocreatine (GLX/Cr). Gamma-band (30-45 Hz) spectral power and GLX/Cr were compared between groups. Correlations between EEG and metabolite

data were analyzed with regression model including age and chlorpromazine equivalents as covariates.

Results: Compared to healthy controls, patients showed reduced spectral gamma-band power in 6 leads (Table). No alterations in GLX/Cr were detected. Positive correlations between altered gamma-power in all leads (except Cz) and GLX/Cr in left medial prefrontal cortex were revealed in CHR (F3: $r=0.51$, $p=0.006$; F8: $r=0.54$, $p=0.004$; C3: $r=0.37$, $p=0.037$; Pz: $r=0.51$, $p=0.039$; P4: $r=0.56$, $p=0.009$). No correlations in HC group were found. Chlorpromazine equivalents did not correlate with GLX/Cr of gamma power in CHR group.

Table. Results of between-group comparisons corrected for multiple comparisons

Lead	CHR Mean \pm SD	HC Mean \pm SD	p-value	F	Cohen's d	Cohen's d CI 95%
F3	0.97 \pm 0.62	1.4 \pm 0.64	0.0097	7.2	-0.69	-1.22 -0.16
F8	0.84 \pm 0.61	1.45 \pm 1.03	0.0072	7.8	-0.71	-1.24 -0.19
C3	0.97 \pm 0.55	1.44 \pm 0.64	0.0026	9.9	-0.79	-1.32 -0.27
Cz	1.03 \pm 0.61	1.42 \pm 0.52	0.0074	7.7	-0.70	-1.22 -0.18
Pz	1.17 \pm 0.7	1.62 \pm 0.63	0.0098	7.1	-0.68	-1.2 -0.16
P4	1.04 \pm 0.66	1.53 \pm 0.66	0.0051	8.5	-0.74	-1.27 -0.22

Conclusions: The findings suggest that clinical-high risk of psychosis is associated with widespread alterations in resting-state gamma-band power. Positive correlations of such alterations with GLX/Cr and absence of such correlations in HC group are presumably indicative of disturbances in the excitation / inhibition balance in CHR individuals.

This study was supported by RFBR grant 19-29-10040

EPV0616

Widespread cortical and subcortical gray matter loss and an increase of globus pallidus volume in treatment-resistant schizophrenia

A. Dudina^{1*}, D. Tikhonov², V. Kaleda² and I. Lebedeva¹

¹Laboratory of Neuroimaging and Multimodal Analysis and ²Department of Youth Psychiatry, Mental Health Research Center, Moscow, Russian Federation

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1281

Introduction: It is still being discussed whether treatment-resistant schizophrenia (TRS) is a biological subtype which differs from non-treatment-resistant schizophrenia or is it a more severe condition that affects brain worse than non-treatment-resistant schizophrenia. However, there are few and heterogeneous studies and the etiology of TRS remains quite unclear.

Objectives: This study aimed to explore cortical and subcortical morphometric characteristics in TRS patients and its associations with the clinical features. The pilot stage comprises the comparison to the mentally healthy subjects.

Methods: 21 right-handed male patients (mean age 28.99 ± 8.08 years) fulfilling TRS criteria and 21 matched healthy controls

(mean age 29.35 ± 7.41 years) underwent T1-weighted structural MRI at 3T Philips scanner and clinical examination. Images were processed using FreeSurfer 7.1.1. Cortical thickness and area, volumes of subcortical structures and separately volumes of the amygdala nuclei and hippocampal subregions were compared between groups. The morphometry data, PANSS (Positive and Negative Syndrome Scale), CDSS (Calgary Depression Scale for Schizophrenia) and daily chlorpromazine equivalent doses of antipsychotics were included in correlational analysis. Results were considered significant if they retained significance after correction for multiple comparisons.

Results: Compared to healthy controls, TRS patients showed decreased gray matter thickness in frontal, temporal, parietal, occipital, cingulate and insular regions (Figure 1). The temporal lobe showed the most prominent thinning of the cortex. The volumes of the amygdala, hippocampus (Figure 2) and nucleus accumbens, a number of amygdala nuclei and hippocampal subregions bilaterally were also decreased in TRS patients. The volume of the right globus pallidus, on the contrary, was increased (Figure 2). No correlations between altered cortical thickness, PANSS (positive, negative, general psychopathology scales and total score), CDSS and chlorpromazine equivalent doses of antipsychotics were found.

Image:

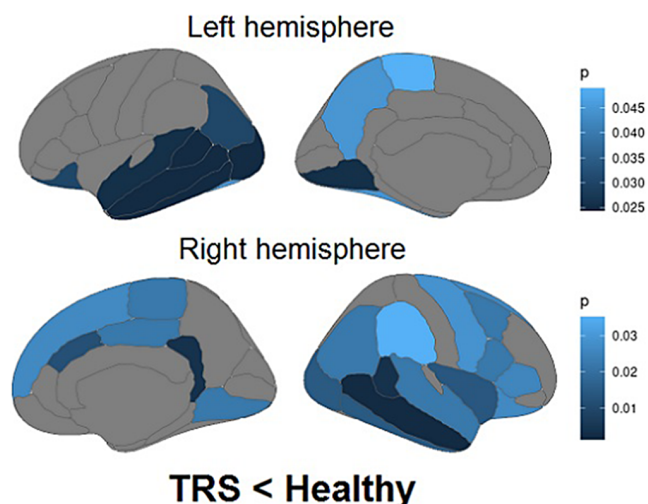

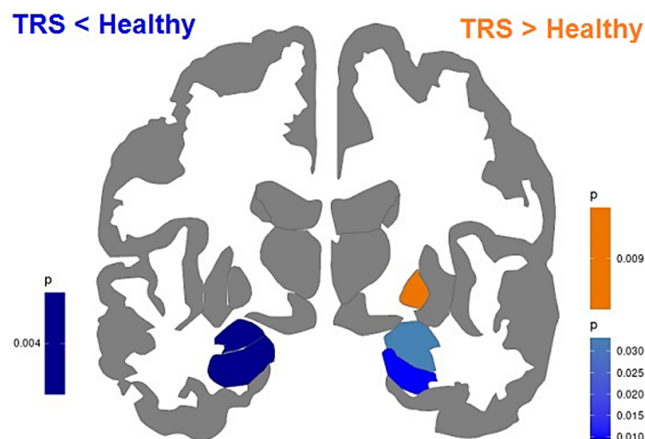

Image 2:

Conclusions: The widespread gray matter cortical and subcortical loss in TRS finds confirmation in the literature. The increased globus pallidus volume is an unexpected and intriguing result. Other studies demonstrated conflicting results on that point. Some studies reported possible therapy influence, others suggested possible associations with symptoms. We did not find any correlations with psychometric or therapy characteristics. It is possible that there are non-linear relationships or relationships that exist only at a certain stage of the disease. As for therapy, patients took individual medication, consisting of various antipsychotics and drugs from other pharmacological groups, and such heterogeneity could affect the results of the study. Further research is going to be carried out.

EPV0617

Brain activity behind the negative and positive emotions: an experimental setting with functional near-infrared spectroscopy (fNIRS)

B. Kabella^{1*}, A. Fehér² and J. Lazáry¹

¹Psychiatry, National Institute of Mental Health- Neurology and Neurosurgery and ²Semmelweis University – Medicine and Health Sciences, Budapest, Hungary

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1282

Introduction: The fNIRS is an optical brain monitoring technique which uses near-infrared spectroscopy for the purpose of functional neuroimaging. Using fNIRS, brain activity is measured by using near-infrared light to estimate cortical hemodynamic activity which occurs in response to neural activity. In the aspect of psychiatry fNIRS is a tool that can potentially facilitate the clinical diagnostic process and identify stages of psychiatric illnesses by providing objective and quantifiable evidences of brain changes. However, this will require specific cerebral haemodynamic patterns to be validated in larger clinical populations with specific psychiatric disorders.

Objectives: Our team decided to set a fNIRS system to find out the difference in prefrontocortical (PFC) activity pattern between healthy and anhedonic population. This abstract has been created for introduce our first findings about the difference in PFC activity under emotionally positively or negatively coloured stimuli in healthy population.

Methods: We have measured 5 healthy adults, non-anhedonic participants under emotionally different visual and acoustic stimuli with the use of NIRX/NIRScout system with the view of our prefronto-temporo-parietal montage.

Fig 1 We divided our experimental tools into 4 individual 20 second long parts:

Passive neutral visual or acoustic stimuli for baseline (watching a black dot or silence)

Passive visual stimuli (watching a single picture)

Active visual stimuli (choosing from photo collage) to detect contrast of cortical background activation

Passive acoustic stimuli (listening sounds)

In total, we defined emotionally, two neutral, four positive and four negative stimuli in our experimental setting.

Softwares: We used HOMER3 for analyzing our datas and estimate hemodynamic response factor (HRF) using general linear matrix

(GLM) regression. We used *AtlasViewer* for reconstructing HRF image onto the Colin27 digitalised brain model. And we also used SPSS for statistical analysis between stimuli types and HRF means. **Results:** **Fig 2** Significant HRF differences were measured in the dominant hemisphere dorsolateral prefrontal cortex (DLPFC) between the influence of each emotionally negative and positive stimuli ($p<0.001$). The level of DLPFC activity was positively influenced by emotionally positive stimuli ($p<0.001$).

Image:

Image 2:

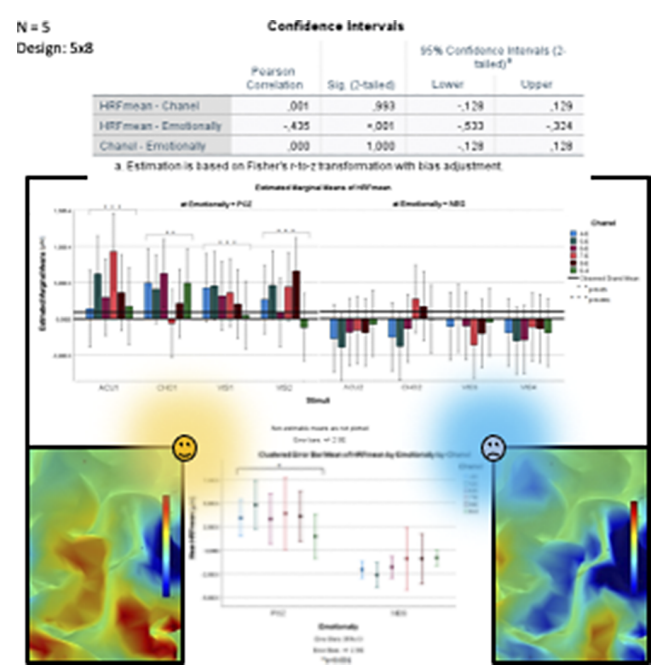

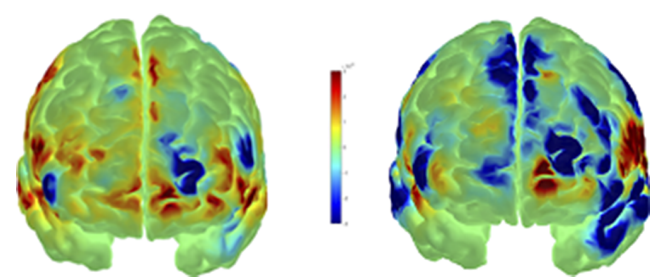

Image 3:

Conclusions: **Fig 3** Our fNIRS experimental system is a suitable tool to measure and model the pattern of prefrontal cortical activity. Based on the measured hemodynamic values, we detected a significant activity difference in the dominant hemisphere DLPFC during emotionally positive and negative stimuli, the extent of which is positively influenced by emotionally positive stimuli. The left DLPFC appears to be a promising target for our next studies of anhedonia.

EPV0619

A Machine Learning Model for Predicting Major Depressive Disorder Using Diffusion-Tensor Imaging Data

J. H. Lee* and D.-K. Lee
Department of Mental Health Research, National Center for Mental Health, Seoul, Korea, Republic Of
*Corresponding author.
doi: 10.1192/j.eurpsy.2024.1283

Introduction: Major Depressive Disorder (MDD) stands as a prevalent psychiatric condition within the general population. Despite extensive research efforts, the identification of definitive diagnostic biomarkers for depressive disorders remains elusive. Currently, machine learning methods are gaining prominence in the diagnosis of medical illnesses.

Objectives: This study aims to construct a machine learning-based prediction model for Major Depressive Disorder (MDD) by harnessing diffusion tensor imaging (DTI) data.

Methods: The DTI datasets comprising MDD (N=83) and Healthy Control (N=70) groups were procured from the cohort study of Anxiety and Depression conducted at the National Center for Mental Health in South Korea. A machine learning method using a decision tree algorithm was employed to select relevant brain regions and establish a robust diagnostic model. Features associated with white matter (WM) tracts were chosen through recursive feature elimination.

Results: Demographic characteristics, including age, sex, and handedness, displayed no significant differences between the MDD and Healthy Control groups. However, the total score of the Beck Depression Inventory was notably higher in individuals with MDD compared to Healthy Controls. A diagnostic model

was crafted using the decision tree algorithms to distinguish between the two groups. The model demonstrated the following classification performance metrics: accuracy ($65.6\% \pm 8.5$), sensitivity ($66.6\% \pm 12.5$), and specificity ($64.7\% \pm 13.6$). Furthermore, through recursive feature elimination, specific neuroanatomical features tied to brain structures such as the inferior cerebellar peduncle, posterior thalamic radiation, cingulum (hippocampus), uncinate fasciculus, and tapetum were identified.

Conclusions: Despite of limited performance of classification, a machine learning-based approach could provide insights into the development of a diagnostic model for MDD using neuroimaging data. Furthermore, these features, derived from DTI-derived data, may have implications for understanding the neural underpinnings of major depressive disorder.

Correlations of altered functional connectivity in resting-state fMRI and symptom severity in tic disorders

J. B. Meeh^{1*}, L. Orth², D. Leiding², U. Habel², I. Neuner^{2,3} and P. Sarkheil¹

¹University of Muenster, Muenster; ²RWTH Aachen University, Aachen and ³Research Center Jülich, Jülich, Germany

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1284

Introduction: Vocal and motor tics are characteristic for Tic disorders (TD) and Tourette's syndrome (APA 2022). Because of the pathophysiology of the disorders not being fully understood and the presence of the externally measurable symptoms; great attention has been paid to the cortico-striatal regions of patients with TD. In addition to the alterations in motor symptoms patients can experience a premonitory urge (PU) which can be felt before a tic (Reese *et al.* Behav. Ther. 2014; 45 177–186). Previous studies found an impact of these urges on sensory perception, attention and social cognition as well as an involvement of the brain regions insula, anterior cingulate cortex (ACC) and the temporoparietal junction (TPJ) (Seeley J. Neurosci. 2019; 39 9878–9882, Kucyi *et al.* J. Neurophysiol. 2012; 108 3382–3392, Uddin *et al.* Brain Topogr. 2019; 32 926–942). These findings lead to the idea of altered functional connectivity of the salience network (SN) in patients with TD.

Objectives: This study aims to investigate the connectivity changes of the SN in patients with TD. We examined functional resting-state scans of patients with TD and searched for possible correlations between the tic and PU severity and the connectivity of the SN.

Methods: 21 Patients (mean age: 30.9 years \pm 10.0 [range = 19–57], 6 females) diagnosed with TD, and 20 healthy controls (mean age: 29.7 years \pm 8.9 [range = 18–50], 5 females) underwent a resting-state fMRI scan. Functional and anatomical images were conducted on a 3T Siemens Prisma fit MRI scanner. PU and tic

severity were measured by the Premonitory Urges for Tics Scale (PUTS) and the Yale Global Tic Severity Scale (YGTSS). The connectivity analysis of the resting-state scans was done using the CONN toolbox v21.a. After pre-processing and de-noising steps, a whole-brain seed-based connectivity analysis was carried out with the seeds being the major cortical nodes of the SN. For the correlation analysis a linear regression of the YGTSS score/PUTS score and the brain connectivity of the seed regions was conducted.

Results: The PUTS score was 25.3 ± 5.4 (range 10–33) and the YGTSS total tic score was 23.1 ± 7.9 (range 10–38) for the patients. The connectivity analysis revealed a significant difference in connectivity between the groups for the ACC, the right insula and the TPJ. A negative correlation between the YGTSS scores and the connectivity of the left insula and the right superior frontal gyrus (SFG) was shown in the correlation analysis. No significant correlation was found for the PUTS scores in the investigated seed regions.

Conclusions: The right SFG mediates motor urgency and inhibitory control. Since we found a negative correlation between the insula and the right SFG regarding to higher YGTSS scores of the patients, our results might shed some light on the pathophysiology regarding lower inhibitory control in patients which experience higher tic severity.

EPV0624

Altered Cortical Gyrification Morphology in Nonsuicidal Self-injury

S. Choi*, H. Moon and J.-W. Hur

Department of Psychology, Korea University, Seoul, Korea, Republic Of

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1285

Introduction: Nonsuicidal self-injury (NSSI) is defined as deliberate and direct damage to one's body tissues without any suicidal intent. NSSI is now recognized as a major risk factor for suicide and is prevalent among adolescents, with prevalence rates ranging from 7.5% to 46.5%, leading to increased interest in the pathophysiology of NSSI. This study aimed to examine cortical gyrification morphology, a neurobiological index of cortical folding and patterning, among unmedicated individuals with NSSI, which is prevalent in adolescents and young adults.

Objectives: The main objective of this study is to compare cortical morphological abnormalities between individuals with NSSI and controls in terms of the local gyrification index (LGI), the ratio of the smooth cortical surface area at each vertex to the corresponding sulcal folds. In addition, we hypothesized that the LGI, a stable neurodevelopmental marker of cortical and subcortical circuit integrity, would correlate with clinical measures in youth with NSSI.

Methods: A total of 101 individuals with NSSI and 100 age-, gender-, and handedness-matched controls completed self-report

questionnaires and structural magnetic resonance imaging (MRI) data were acquired on a 3T Siemens scanner. A surface-based analysis was conducted using the Computational Anatomy Toolbox (CAT12) in Statistical Parametric Mapping (SPM12). Partial correlation analysis was also performed using R software to investigate the association between the LGI values extracted from the region of interest (ROI) and clinical symptoms, including depression, anxiety, emotion dysregulation, and anhedonia in individuals with NSSI.

Results: Individuals with NSSI showed significantly increased LGI in the right insula sulcus and left superior temporal sulcus (STS), along with decreased LGI in the right calcarine and left superior parietal sulcus (SPS), compared to controls (5000 permutation correction, threshold-free cluster enhancement with a threshold of $p < .05$). In addition, higher LGI in left STS was correlated with greater scores of the Beck Anxiety Inventory ($r = 0.22$, $p < .05$) and of the Impulse Control Difficulties subscale of the Difficulties in Emotion Regulation Scale ($r = 0.34$, $p < .001$). Conversely, reduced LGI of the right calcarine was associated with a higher score on the Anhedonia subscale of the Beck Depression Inventory ($r = -0.23$, $p < .05$) within individuals with NSSI.

Conclusions: This study identified hypergyria in the right insular and left STS and hypogryria in the right calcarine and left SPS in individuals with NSSI. The former pattern was associated with anxiety and impulse control difficulties, and the latter was with anhedonia. This study is the first to alter distinct neurodevelopmental patterns of local gyrification and their correlations with clinical manifestations in individuals with NSSI.

²Schizophrenia, CIBERSAM, ISCIII, Barcelona; ³Psychology, Hospital Sagrat Cor, Martorell; ⁴Nursing, Hospital General de Granollers, Granollers; ⁵Psychology, Hospital Sant Rafael and ⁶Psychology, CSMA Vila de Gràcia-Cibeles, Barcelona, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1286

Introduction: Autobiographical memory is known to be disturbed in schizophrenia. In addition, a leading theory of auditory hallucinations (AVH) is that they are intrusive – typically negative – autobiographical memories that are misinterpreted as perceptions.

Objectives: The aim of this study was to examine the brain functional correlates of recall of negatively emotionally valenced

autobiographical memories in patients with schizophrenia, with a longer term aim of comparing patients with and without AVH.

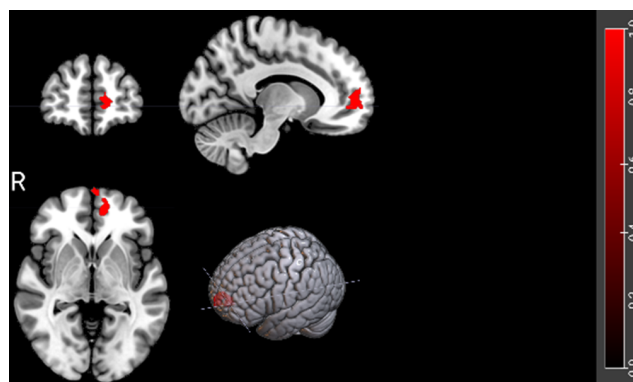

Methods: 11 patients meeting DSM-5 criteria for schizophrenia or schizoaffective disorder and 10 age, sex and estimated premorbid IQ-matched healthy controls have so far taken part.

Participants underwent functional MRI in a 3T scanner while performing a task requiring them to recall autobiographical memories in response to individually tailored pairs of cue words. The cue words were based on autobiographical memories previously elicited in an interview with each patient and were designed to evoke the same memory. The cue words were presented in 10 20-second blocks interspersed with blocks where the subjects viewed cue words that did not evoke autobiographical memories. Brain activations were examined in three contrasts of interest: memory evoking words vs baseline, neutral words vs baseline and memory evoking vs neutral words.

Pre-processing and analysis were carried out with the FEAT module included in the FSL software. Statistical analysis was performed by means of a General Linear Model (GLM) approach.

Results: In the memory evoking vs baseline contrast the patients showed hypoactivation in the medial frontal cortex compared to the healthy controls (Figure 1). There were no differences in activation between the patients and the controls comparing the memory evoking and neutral cues.

Image:

Conclusions: The finding of hypoactivation in the medial frontal cortex compared to low level baseline in patients with schizophrenia suggests dysfunction in the default mode network, which is known to activate during recall of autobiographical memories.

These preliminary results suggest that recall of negative autobiographical memories in patients with schizophrenia is associated with reduced activity in the default mode network. A planned larger sample of patients and controls will be used to examine activations in patients with and without AVH.

Different patterns of MRI structural alterations in schizophrenia spectrum disorders with delusions of influence vs persecution

A. S. Tomyshev¹, A. Dudina^{1*}, D. Romanov^{2,3}, E. Ilina², M. Magomedagaev², G. Kostyuk⁴, A. Andriushchenko⁴, A. Smulevich² and I. Lebedeva¹

¹Laboratory of Neuroimaging and Multimodal Analysis, Mental Health Research Center; ²Department of Psychiatry and Psychosomatics, I.M. Sechenov First Moscow State Medical University; ³Department of borderline mental pathology and psychosomatic disorders, Mental Health Research Center and ⁴Mental-health Clinic No.1 named after N.A. Alexeev, Moscow, Russian Federation

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1287

Introduction: There is strong evidence that delusions are associated with cortical and subcortical structural alterations. However, whether these abnormalities differ in different types of delusions within schizophrenia spectrum disorders remains unclear.

Objectives: We aimed at exploring structural neural patterns underlying influence/persecutory delusions across diagnostic categories within the schizophrenia-spectrum disorders.

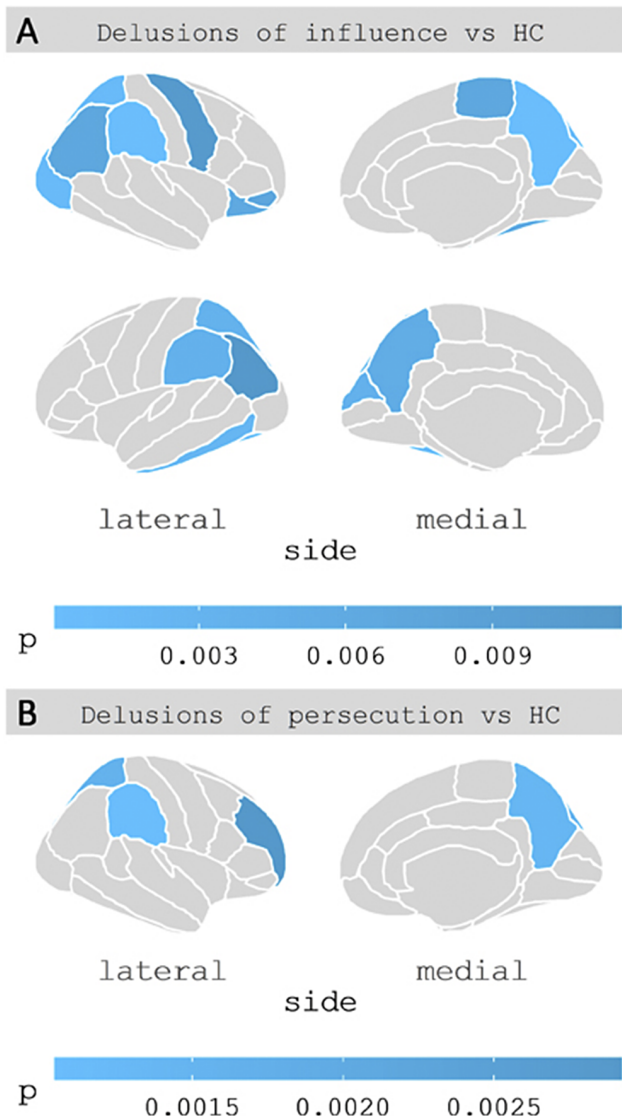

Methods: Twenty six right-handed patients with delusional disorder (n=7) and schizophrenia (n=19), presenting with delusions were divided in two clinical subgroups. The first one was presented with persecutory delusions (n=12, 20.2-55.4 years, mean age 36.0 ±11.6, 2 females) and the second with delusions of influence (n=14, 21.2-47.6 years, mean age 36.7±8.4, 2 females). The control group consist of 26 matched healthy controls (20.2-53.6 years, mean age 36.3±9.9, 4 females). All participants underwent structural MRI at 3T scanner. MRI images were processed via FreeSurfer 6.0 to quantify cortical thickness (CTH) and volumes for subcortical and brainstem (midbrain, pons, superior cerebellar peduncle and medulla) structures.

Results: Compared to healthy controls, patients with delusions of influence showed decreased gray matter thickness in 17 cortical regions (Figure, A), and decreased volumes of thalamus bilaterally (left: $F(1,35)=9.0$, $p=0.005$; Cohen's $d=-0.8$; right: $F(1,35)=8.0$, $p=0.008$; Cohen's $d=-0.8$), left hippocampus ($F(1,35)=8.8$, $p=0.005$; Cohen's $d=-0.8$), midbrain ($F(1,35)=11.0$, $p=0.002$; Cohen's $d=-0.9$) and pons ($F(1,35)=8.2$, $p=0.007$; Cohen's $d=-0.8$). Conversely, patients with delusions of persecution showed decreased thickness only in 4 cortical regions of the right hemisphere (figure, B) and no alterations in subcortical volumes compared to healthy controls.

No differences in cortical or subcortical measures between two clinical subgroups survived corrections for multiple comparisons. No correlations between structural alterations and total PANSS or BABS scores were found in either clinical groups.

Figure. Clusters of decreased cortical thickness according to atlas of Desikan et al. (2006) in delusions of influence (A) and delusions of persecution (B) subgroups compared to healthy controls.

Image:

Conclusions: The findings suggest that patients with delusions of influence have more pronounced cortical, subcortical and brainstem structural deficit as compared to patients with delusions of persecution. However, the limited sample size and the lack of correlations with clinical scores do not allow to conclude definitely whether the revealed structural abnormalities underlies delusions of influence, which should be elucidated via further research.

This study was supported by RFBR grant 21-515-12007

Neurofeedback treatment for Attention Deficit Hyperactivity Disorder in adults

B. Fernández*, J. Barros, E. Machado, E. Maldonado, A. R. Moreira and H. J. Gomes

Psychiatry, ULSNE, Bragança, Portugal

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1288

Introduction: Attention-deficit/hyperactivity disorder (ADHD) is one of the most prevalent neurodevelopment disorders in the world. Clinical guidelines for ADHD recommend multimodal treatment approaches, with current evidence suggesting that medication, including methylphenidate and various amphetamine formulations, in conjunction with psychosocial treatment are most effective in the short-term and long term. Over the last decade, an increasing number of studies investigating non-pharmacological treatments have been published, such as cognitive therapy, Neurofeedback (NF), Transcranial direct current stimulation with the aim of treating ADHD patients.

Objectives: We comprehensively reviewed literature searching for studies on the effectiveness and specificity of NF for the treatment of ADHD. The aim of this review is to understand if there is scientific evidence in using of electroencephalogram (EEG)-Neurofeedback for treating patients with ADHD.

Methods: We did a non systematic review using pubmed and google scholar databases in order to analyze the influence and effects of therapy in patients diagnosed with ADHD and under treatment based on EEG Neurofeedback. We analyzed 18 systematic reviews and meta-analysis and 2 case control studies.

Results: According to the systematic reviews results showed positive and significant effects in the visual memory, attention and visual recognition (spatial working memory). EEG also showed improvement in upper alpha activity in a resting state (open-eyed) measured from the occipital area, which similarly indicated improvement in the cognitive domain (attention). Compared to non-active control treatments, NF appears to have more durable treatment effects, for at least 6 months following treatment.

Conclusions: In conclusion, it is possible to affirm that a neuromodulating effect of the therapy positively influences cognitive processes, mood, and anxiety levels in patients with ADHD and is associated with significant long-term reduction in symptoms. Though limitations exist regarding conclusions about the specific effects of NF, the review documents improvements in school, social, and family environments. However, future efforts should focus on implementing standard neurofeedback protocols, ensuring learning, and optimizing clinically relevant transfer and more studies are needed for a properly powered

comparison of follow-up effects between NF and active treatments and to further control for non-specific effects.

Cognitive Neuroscience of Autism Spectrum Disorder: The Neurobiology of Empathic Process

C. Pinheiro Ramos*, J. Marta, M. J. Freire, S. Mendes and A. Gamito
Setúbal Hospital Center, Setúbal, Portugal

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1289

Introduction: Autism Spectrum Disorders (ASD) is diagnosed when an individual displays irregularity in three key domains: social development, communication, and repetitive behavior/obsessive interests.

The theory of mind-blindness in ASD suggests that individuals on the autism spectrum exhibit deficiencies in the typical empathic process, relative to their mental age.

Empathy comprises two primary components: firstly, the capacity to attribute mental states to both oneself and others, and secondly, experiencing an emotional response that aligns with the mental state of the other person.

Objectives: This study aimed to synthesize the latest evidence about the neuropsychiatric basis of empathy in ASD.

Methods: A review was conducted, drawing on reputable sources (PubMed and Web of Science databases).

Results: A neural basis of empathy has built on a model first proposed by Brothers. It was suggested that social intelligence was a function of three regions: the amygdala, the orbitofrontal and medial frontal cortex, and the superior temporal sulcus and gyrus - the "social brain". Abnormalities in autism have been found in the amygdala, the orbito and the medial frontal cortex.

Amygdala has been implicated primarily in fear perception of facial expressions, as well as in the recognition of other emotions such as sadness and "social" emotions. In addition to fear perception, the amygdala has also been implicated in related processes including eye gaze, affective memory, olfactory learning, and social judgment. To date, findings on amygdala structure in autism have been mixed, with studies indicating reduced and increased volumes, as well as nonsignificant differences.

Conclusions: ASD is one of the most heterogeneous neurodevelopmental disorders, and cognitive theories as well as structural findings have linked likely frontal lobe abnormalities to the social and cognitive profiles of autism.

Future studies may elucidate existing data by taking advantage of new and infrequently used data acquisition technologies such as Transcranial Magnetic Stimulation.

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1290

Introduction: The sense of agency (SoA) indicates a person's ability to feel her/his own motor acts as actually being her/his, and through them to exert control over the course of external events. Disruptions in SoA may profoundly affect the individual's functioning, as observed in several neuropsychiatric disorders.

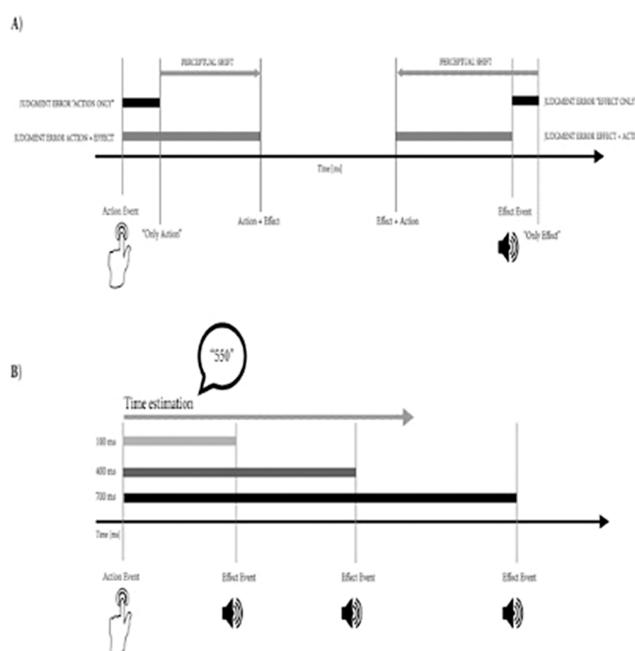

Objectives: This is the first article to systematically review studies that investigated intentional binding (IB), a quantitative proxy for SoA measurement, in neurological and psychiatric patients.

Methods: Eligible were studies of IB involving patients with neurological and/or psychiatric disorders. The research adhered to the guidelines outlined in the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA).

Results: We included 15 studies involving 692 individuals. Risk of bias was low throughout studies. Eligible studies dealt with data from 357 patients with neuropsychiatric disorders matched with 335 HCs. Of included patients, 95 were with schizophrenia (SCZ), 30 with a putative prodromal psychosis (PP), 21 with borderline personality disorder (BPD), 66 with Parkinson's disease (PD), 38 with an autism spectrum disorder (ASD), 29 with functional movement disorders (FMDs), 25 with Gilles de la Tourette syndrome (GTS), 52 with anorexia nervosa (AN; 22 with active disorder and 30 after they had recovered), and 10 with Cortico-Basal syndrome (CBS).

Temporal binding was calculated in eleven studies using variations of the experimental procedure introduced by Haggard et al. (Haggard et al. *Nat Neurosci* 2002;5 382-385)(Figure 1, A), while four studies utilized a different paradigm named interval estimation (IE)(Figure 1, B).

Image:

Conclusions: Abnormally increased action-outcome binding was found in schizophrenia and in patients with Parkinson's disease taking dopaminergic medications or reporting impulsive-compulsive behaviours. A decreased IB effect was observed in Tourette's disorder and functional movement disorders whereas increased action-outcome binding was found in patients with cortico-basal syndrome. The extent of IB deviation from healthy control values correlated with the severity of symptoms in several disorders. Inconsistent effects were found for autism spectrum disorders, anorexia nervosa, and borderline personality disorder. Findings pave the way for treatments specifically targeting SoA in neuropsychiatric disorders where IB is altered.

Anterior insular cortex and the perception of internalized stigma and its components: a scoping review.

N. Lutova¹, E. Gerasimchuk¹, M. Khobeysh¹, M. Bocharova^{1,2*},
O. Makarevich¹ and M. Sorokin¹

¹V.M. Bekhterev National Medical Research Centre for Psychiatry and Neurology, St.Petersburg, Russian Federation and ²King's College London, London, United Kingdom

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1291

Introduction: Personality neuroscience employs a broad range of methods to identify the neurobiological mechanisms of complex psychological phenomena. The role of the insula is often associated with its involvement in emotion processing.

Objectives: The study aims to identify the associations between neural activity in the anterior insula cortex (AInC) and self-stigma (or its components) in a scoping review.

Methods: We searched in PubMed (MEDLINE), PsychINFO, EMBASE via the Ovid platform through September 21st, 2022. Included studies had to use fMRI to assess neurophysiological markers in AInC, and to include a measure of association between fMRI results and a measure of self-stigma and/or its components as assessed by a scale or questionnaire in participants aged 18-65 y.o. The PRISMA-ScR checklist was used.

Results: After full-text screening 10 of 206 original researches were chosen for the final analysis (Table 1).

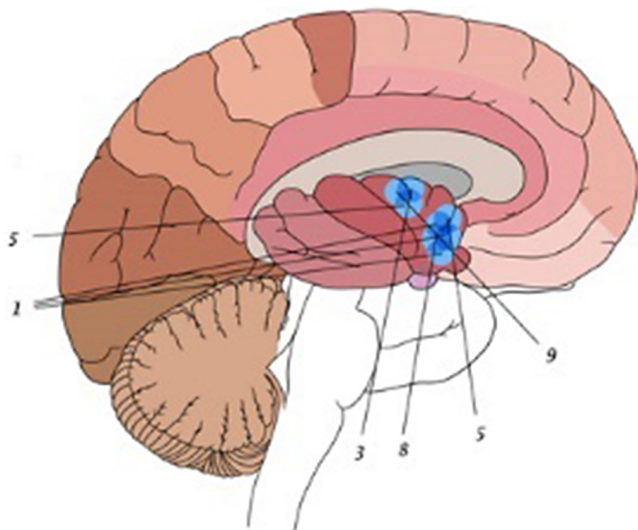

Table 1: Included studies in the analysis.

1	DeWall et al. Soc Cogn Affect Neurosci. 2012; 7(2): 184-192.
2	Masten et al. Neuroimage. 2011; 55(1): 381-388.
3	Kross et al. Proceedings of the National Academy of Sciences. 2011; 108(15): 6270-6275.
4	Bolling et al. Neuroimage. 2011; 54(3): 2462-2471.
5	Lindner et al. PLoS One. 2014; 9(1): e85014.
6	Achterberg et al. Soc Cogn Affect Neurosci. 2016; 11(5): 712-720.
7	Muscattell et al. Brain Behav Immun. 2016; 57: 21-29.
8	Sankar et al. Front Behav Neurosci. 2019;13.
9	Cáceda et al. Clin Neurosci. 2020; 270(5): 619-631.
10	Landa et al. J Psychosom Res. 2020; 128: 109881.

In 5 studies, the results were presented with MNI-space coordinates. Figure 1 illustrates the regions of local activity change maxima according to MNI-space coordinates based on the results of the included studies in the analysis.

Neural activation in the regions of the AInC was positively associated with greater levels of social rejection sensitivity and other components of self-stigma in 9 studies. Reduced activity was observed in only one study (Lindner et al., PLoS One. 2014; 9(1): e85014) among highly self-stigmatized patients with schizophrenia. This finding may reflect a biological manifestation of deficits in self-awareness and affective processing in schizophrenia.

Image:

Conclusions: Associations between neural activity changes in specific brain regions and levels of self-stigma and/or its components, as reported in included neuroimaging studies, have the potential to shed light on the neurobiological mechanisms underlying such a complex psychological phenomenon as stigma.

Disclosure of Interest: None Declared

EPV0634

Use of low-dose Aripiprazole to lower the antipsychotic medication - induced hyperprolactinemia.

P. Argitis^{1*}, A. Karampas², M. Peyioti¹, T. Koukouras¹, M. Demetriou¹, S. Karavia¹ and Z. Chaviaras¹

¹Psychiatric, General Hospital of Corfu, Corfu and ²Psychiatric, General Hospital of Ioannina, Ioannina, Greece

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1292

Introduction: Hyperprolactinemia (HPL) is a condition associated with disturbing consequences. Antipsychotic medications are one of the main causes of nontumoral hyperprolactinemia. Prolactin release in the hypothalamic tuberoinfundibular tract is increased through dopaminergic inhibition, which occurs more frequently with high-potency typical antipsychotics (40%–90%). Less commonly than typical antipsychotics, atypical antipsychotics can also result in hyperprolactinemia. In the presence of symptoms, clinicians frequently struggle with the decision of whether to stop using the suspected offending agent, lower the dosage, switch to another medication, or even add a full or partial dopamine agonist to the patient's current treatment. The issue is exacerbated by the fact that finding a suitable agent for each patient is sometimes a challenging task.

Objectives: Due to the partial D2 receptor agonistic activity of aripiprazole, there is enough dopaminergic tone to continue the inhibition of prolactin release. Aripiprazole has been recommended in literature either as an adjunctive treatment in low doses or as a switch in therapy.

Methods: In the Psychiatric clinic of the General Hospital of Corfu, a low-dose (5mg/day) of aripiprazole is being used as adjunctive therapy in patients with antipsychotic-induced hyperprolactinemia. More specifically in total 42 subjects, 19 male and 22 female, with a mean prolactin level of 862ng/ml, were introduced to the prior therapy. We whereupon conducted prolactin measurements to evaluate the response at the first, the third, and the sixth month of treatment.

Results: Of the 42 subjects, 38 responded with an average reduction of prolactin to the level of 530ng/ml (mean reduction 38,5%).

Conclusions: Having noticed the beneficial effect of low-dose Aripiprazole in patients with antipsychotic-induced hyperprolactinemia, we consider it appropriate that the literature recommendations concerning this additional use of aripiprazole should not be overlooked in clinical practice.

Short-term olfactory deprivation reorganizes brain activityS. Tukaiev^{1,2*}, I. Zyma² and M. Makarchuk²¹Faculty of Communication, Culture, and Society, Institute of Public Health, Università della Svizzera italiana, Lugano, Switzerland and²Institute of Biology and Medicine, Taras Shevchenko National University of Kyiv, Kyiv, Ukraine

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1293

Introduction: Olfactory loss (including short-term) initiates neural reorganization processes in the brain, but the central mechanisms of this largely remain unknown.

Objectives: We aim to conduct a neurophysiological study of neocortical mechanisms for the effects of olfactory sensation on functional activity of human brain under temporary obstruction of nasal breathing.

Methods: 123 healthy volunteers (76 female and 47 male students aged 18 to 23 years) participated in this study. EEG was registered during the rest state (5 min), olfactory blockage (5 min), under odor stimulation with the lemon essential oil (5 min) and renewal of nasal breathing (5 min). We estimated the spectral power density and the levels of coherence of all the frequencies from 0.2 to 35 Hz.

Results: The onset of orthonasal olfactory sensory blockage was accompanied by an increase in the power of processes of local synchronization of beta frequency in the caudal regions of the brain, with simultaneous enhancement of the coherence of the theta band in parietal-occipital zones and a certain enhancement of the interfrontal and intrahemispherical left-side and right-side interactions in the beta2-subband. Thus, the sudden cessation of olfactory detection led to activation of thalamo-cortical loops and top-down control systems (search for the olfactory signal): that is an active orienting process (triangle of increase in F4-T4-P4 connections) with emotional coloring (the caudal localization of the coherence changes in the theta band). The prolongation of the nasal blockage, despite the possibility of activation of the retronasal route of odor perception and odorized air, was accompanied by a definite inhibition of distant interactions in the posterior regions of the brain in the theta-band and a significant decrease in right-brain long-distant and parietooccipital beta2-subband functional connectivity. Restoration of nasal breathing and olfactory perception is accompanied by sufficiently powerful activation of interhemispheric long and short distance information interactions in the theta1,2 and beta1 frequency bands.

Conclusions: Our data indicated that cessation and restoration of olfactory perception lead to an increase cognitive activity, the development of memory processes, the current sensory and cognitive-emotional control of behavioral reactions, focusing attention, assessment of the significant stimulus.

Neuropsychiatric manifestations inaugurating Biermer's disease

S. Bader*, N. Msadek, S. Ellini, R. Damak and M. Cheour

Ibn El Omran psychiatry department, Razi Hospital, Mannouba, Tunisia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1294

Introduction: Vitamin B12 deficiency gives rise to a wide spectrum of hematological, gastrointestinal, psychiatric, and neurological disorders. Notable among the neuropsychiatric symptoms are mood disturbances, cognitive decline, and psychotic manifestations.

Objectives: We present a case of a woman with neuropsychiatric symptoms linked to vitamin B12 deficiency to highlight certain organic aetiologies with psychiatric symptoms in the foreground.

Methods: We discussed through a clinical case and a literature review, the relationship between neuropsychiatric symptoms and vitamin B12 deficiency in the context of Biermer's disease.

Results: We presented a patient aged 51-years-old without neurological or psychiatric history, she was hospitalised in a psychiatry department for behavioral disturbances, hetero-aggression, and incoherent speech. The psychiatric examination revealed distant contact, inappropriate affects, disorganized speech with persecutory delusions, memory problems, and poor insight. Neurological et physical examinations were normal, and cerebral magnetic resonance imaging (MRI) showed no abnormalities. First, haloperidol 25mg was prescribed, however, there was only partial improvement. Complete blood counts revealed macrocytic anemia (Hemoglobin: 8 g/dL, mean corpuscular volume: 106 fL). Her serum B12 assay was 48.19 pmol/L. Given these results we proceed to a Fundic biopsy, performed by fibroscopy, that revealed fundic atrophy and intestinal metaplasia compatible with Biermer's disease. Vitamin B12 replacement therapy began with hydroxocobalamin at 1000 µg/day intramuscularly for 15 days, followed by 1000 µg every 15 days for one month. Subsequently, there was a remarkable improvement in psychotic symptoms and cognitive function. Follow-up assessments demonstrated a return to baseline functioning.

Conclusions: This case, coupled with prior studies, emphasizes the importance of considering vitamin B12 deficiency in the differential diagnosis of neuropsychiatric symptoms. Therefore, prompt diagnosis and treatment of vitamin B12 deficiency are imperative in preventing potential irreversible neurological damage.

Exploring the Potential of Cannabinoids in the Treatment of Tourette's Syndrome

F. Cunha*, I. Santos, N. Castro, R. Andrade, E. Almeida, J. Abreu, J. Martins, R. Vaz and S. Borges

Centro Hospitalar Tondela-Viseu, Viseu, Portugal

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1295

Introduction: Tourette's syndrome (TS) is a disorder characterized by repetitive, involuntary movements, and vocalizations known as tics. While there are existing treatment options, there is a growing need for novel pharmacological approaches to manage the symptoms of TS effectively. This study delves into the emerging field of using cannabinoids as a potential treatment for Tourette's syndrome.

Objectives: The primary objectives of this review are to examine the current evidence base for the use of cannabinoids in the treatment of Tourette's syndrome, to assess the biological rationale supporting the use of cannabinoids in managing tic severity, to provide insights into the results of existing clinical trials involving cannabinoids and Tourette's syndrome, and to draw conclusions regarding the potential efficacy and safety of cannabinoid-based treatments for TS.

Methods: Narrative review of the available scientific literature.

Results: There is a strong biological rationale for how cannabinoids could impact tic severity. The endocannabinoid system plays a crucial role in regulating various physiological processes, including motor control and neurotransmitter release. Activation of cannabinoid receptors in the brain may modulate these processes, potentially reducing tics. While limited, two small randomized, placebo-controlled trials of THC have been conducted in TS patients. These trials suggested potential benefits of cannabis-derived agents in reducing tic frequency and severity. Self-report and examiner rating scales demonstrated significant improvements in tic symptoms. The trials indicated that THC treatment did not result in significant adverse effects in TS patients.

Conclusions: The exploration of cannabinoids as a treatment option for Tourette's syndrome is promising but requires further investigation. The biological mechanisms through which cannabinoids may affect tic severity in TS are sound, suggesting their potential as a therapeutic option. Existing trials with THC have shown encouraging results, demonstrating a reduction in tics without significant adverse effects. However, the limited number of trials warrants caution in drawing definitive conclusions. Despite the promising findings, the overall efficacy and safety of cannabinoid-based treatments remain largely unknown. Further trials are essential to address dosing, active ingredients, optimal administration, and potential long-term effects. Clinical use should be approached with caution. While early evidence is encouraging, additional rigorous studies are needed to establish the safety and efficacy of cannabinoid-based treatments for this disorder.

Investigating Epigenetic and Neuroimaging Profiles in Bipolar Disorder and Behavioral Variant Frontotemporal Dementia: An integrated epigenetic-neuroimaging approach

G. Delvecchio^{1*}, M. Serpente¹, L. Di Consoli¹, E. Rotondo¹, V. Borracci¹, E. Scola², F. M. Triuzzi², M. Castellani³, A. Arighi¹, E. Scarpini¹, D. Galimberti^{1,4} and P. Brambilla^{1,5}

¹Department of Neurosciences and Mental Health; ²Department of Neuroradiology; ³Nuclear Medicine Unit, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico; ⁴Department of Biomedical, Surgical and Dental Sciences and ⁵Department of Pathophysiology and Transplantation, University of Milan, Milan, Italy

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1296

Introduction: Discriminating between bipolar disorder (BD) and behavioral variant Frontotemporal Dementia (bvFTD) is a clinical challenge as it is still based on clinical judgement, which often leads to misdiagnosis. This challenge is particularly pronounced in cases involving the *C9orf72* hexanucleotide expansion, a genetic factor responsible for a substantial portion of familial FTD cases, as in these patients the development of late psychoses is particularly frequent. Moreover, individuals with *C9orf72* bvFTD are also characterized by behavioral changes that resemble those seen in late-life BD, especially during the early stages of the disease. This raises questions about whether the clinical similarities between BD and bvFTD are rooted in specific alterations within the brain networks involved in cognitive processing or in selective genetic and epigenetic mutations. In light of this, our recently published neuroimaging study has shed light on the presence of distinctive structural and metabolic characteristics in elderly individuals with BD and bvFTD. These findings offer valuable neurobiological insights that may lead to differentiate between bvFTD and elderly BD patients.

Objectives: Building on our previous research, this study further explores the existence of similar epigenetic expression patterns in plasma neural derived extra cellular vesicles (NDEs), such as miRNA and lncRNA, and seeks to correlate these epigenetic data with shared or distinct biological markers obtained through structural Magnetic Resonance Imaging and [18F]-fluorodeoxyglucose (FDG)-Positron Emission Tomography (PET).

Methods: We will plan to conduct statistical analyses on epigenetic and neuroimaging data on *C9orf72* and sporadic bvFTD as well as on late- and early-onset BD patients and on healthy controls. Additionally, A PET study will be also performed on a subpopulation of these patients.

Results: Our hypothesis posits that selective epigenetic modifications may impact the brain's structure and function, in a way that can change the glutamatergic neurotransmission in prefrontal regions, with subsequent indirect effects on subcortical areas.

Conclusions: Our findings will not only help identifying the specific biological signatures of BD and bvFTD, which might have important implications not only in prevention but also in differential diagnosis and treatment, but also offer insights into potential targets for slowing the onset and progression of the structural alterations characterizing these disorders.

EPV0642

Gut Microorganisms, Neuroinflammation and Behavioral Changes

B. T. Adebisi

Functional and Molecular Neurobiology, Institute of Anatomy, Cell Biology, Brain and Neurodegeneration, Osogbo, Nigeria
doi: 10.1192/j.eurpsy.2024.1297

Introduction: Recent clinical and preclinical evidences suggested that neuroinflammation is a key factor which interacts with the neurobiological correlates of major depressive disorder, which are the (i) dysregulation of the hypothalamic-pituitary-adrenal axis, (ii) depletion of brain serotonin and (iii) alteration of neurogenesis in the dentate gyrus of the hippocampus.

The gut bacterial has major impact on the brain development, behaviour and host immune system through the microbiota-gut-brain axis.

Objectives: The objective of the research is to establish the role inflammation induced by gut dysbiosis plays in behavioural changes of patients suffering from major depressive disorders.

Methods: Clinical data and preclinical experiments were used to elucidate the role gastrointestinal bacterial play in the development and functional physiology of the nervous system and because of the bidirectional communication between the enteric nervous system in the gut and the central nervous system, through the vagal plexus, blood circulation and endocrine system; it was discovered that the appropriate population of intestinal microbiota affect the immunological state of the brain.

Results: The intestinal microbiota has been able to maintain the attenuation and regulation of pro-inflammatory biomarkers in the brain and such had assisted in the healthy state of the brain; however, a disruption of gastrointestinal organisms in a condition called dysbiosis could result in breakdown of protective gastrointestinal mucosa barrier resulting in leaky gut and consequently, the permeability of the gut lining and migration of some bacteria, to the brain through the vagal networks and other channels.

These pathophysiological cascades appear to be triggered or sustained and reinforced by chronic inflammatory condition involving increased circulating markers of inflammation, which are able to cross the blood brain barrier to activate the microglia.

Conclusions: Studies in depression suggest that inflammatory biomarkers such as C-reactive protein can be used to enrich samples for anti-inflammatory clinical trials for depression that target inflammation-related symptoms such as anhedonia and anxiety.

Although, still at the developmental stages, imaging of neuroinflammation will help establish a target in the brain to further facilitate the testing of anti-inflammatory therapies for depression.

Dynamics of neurocognitive impairments in patients with chronic alcoholism of the second stage

L. Baranskaya^{1*}, E. Babyshkina² and A. Sidenkova²

¹Psychiatry, Psychotherapy and Narcology and ²Ural State Medical University, Yekaterinburg, Russian Federation

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1298

Introduction: Neuropsychological disorders in patients with alcoholism intensively studied since the mid-70s of the last century. Research in this area divided into three groups: the study of premorbid neuropsychological features of alcohol dependence; study of neuropsychological disorders of chronic alcohol use; study of the prognostic value of neuropsychological disorders in patients suffering from alcohol dependence. In domestic neuropsychology, is the necessary information about the neuropsychological characteristics of patients suffering from alcohol dependence, neuropsychological manifestations in cognitive processes.

Objectives: to identify neuropsychological features of patients suffering from alcohol dependence with a diagnosis of stage 2 alcoholic disease

Methods: A neuropsychological examination was carried out according to the method of A.R. Luria of 39 patients aged 29 to 68 years with a diagnosis of stage 2 alcoholic disease. The group of patients is divided into 3 subgroups of alcohol abuse: up to 10 years, 10-20 years; more than 20 years.

Results: Disorders of higher mental functions identified in all subgroups. In chronic alcoholic encephalopathy, there is a tendency to increase cognitive deficits. According to the results of the neuropsychological examination, it was found that the greatest disorders in patients of the first subgroup occur in the implementation of successive processes (memory, thinking), arbitrary regulation of activity, and also relate to the regulatory aspects of memory, attention, thinking and speech.

In patients of the second subgroup, the most numerous in this sample, violations of visual object gnosis were revealed, as well as a violation of the synthesis of information necessary to endow the image of the object with a certain meaning. In patients of the third subgroup, pronounced disorders inherent in the first and second subgroups were found, as well as distortions in the identification of emotions, that is, the inability to compare emotional objects with an emotional standard, which indicates signs affective-cognitive deficit in alcoholic disease of the second stage.

Conclusions: In the study, the dynamics of neuropsychological disorders in patients with alcohol disease of the second stage, depending on the experience of alcohol abuse, found

Embodied cognition and urban design: Thoughts through epigenetic advances

E. Abdelmoula^{1*}, B. Abdelmoula² and N. Bouayed Abdelmoula²

¹LR AMC, Ecole Doctorale Sciences et Ingénierie Architecturales (ED-SIA), Tunis and ²Genomics of Signalopathies at the service of Precision Medicine - LR23ES07, Medical University of Sfax, Sfax, Tunisia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1299

Introduction: In the history of urban planning, the cognitive trend has been a well-established entity since the work of the American urban planner during the mid-'90s; Kevin Lynch. However, for a long time, urban planning has been deprived of the contribution of scientific knowledge from cognitive neurosciences, with a lack of operational recommendations for urban projects.

Objectives: This study aims to reveal the role of embodiment theories in the revolution of urban design and urban projects through emerging findings in epigenetics and post-genomic biology.

Methods: We conducted an exhaustive review of the scientific literature to establish the relationship between embodied cognition and urban design through advances in epigenetics as well as potential applications of such finding. Our inquiry was to find out whether there was a scientific way to measure and quantify the performance of urban spaces.

Results: Our review revealed that, epigenetics and epigenomics have provided new explanations and perspectives to certain debates on the theory of embodied cognition and that of enaction. Epigenetic marks constitute a bodily memory that enables cognition to

emerge as a function of the level of adaptation to the environment. In fact, embodiment refers to thoughts, emotions and behaviors based on sensory experiences and bodily positions, while the enaction is a way of conceiving cognition that focuses on the way in which human organisms and minds organize themselves in interaction with the environment.

Conclusions: Cognition is the result of a level of adaptation to the environment determined by physiological parameters that confer possibilities of action depending on previous interactions with the environment. The regulation of epigenetic marks which are technically quantifiable is now recognized as the fundamental mechanism involved in the brain's ability to create, dismantle or reorganize neural networks throughout life depending on various experiences including environmental ones.

Revisiting Panksepp: a review of his contributions to neuropsychanalysis

S. E. Ilgin^{1*}, S. Hiçdönmez¹ and H. Atalay²

¹Psychiatry, Marmara University Research & Training Hospital and

²Psychiatry, Yeditepe University Hospital, Istanbul, Türkiye

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1300

Introduction: Panksepp paved the way for neuropsychanalysts to better delineate the differences between emotions, feelings, and affect, and their evolutionary purposes. Affect pertains to an individual's capacity to engage in emotional responses to stimuli, events, memories, and thoughts, while feelings denote the conscious perceptions of emotions, which are primarily social in nature.

Feelings are personal and biographical, while affect remains largely impersonal. Panksepp's theory of basic affective systems in mammals, dividing emotions into positive and negative categories, is another major contribution to neuropsychanalysis. Three primary emotions -joy, fear, and disgust- have been identified in humans, which are associated with specific peptides and monoamines (e.g., dopamine and endorphins for joy, norepinephrine and CRH for fear, serotonin and substance P for disgust). These basic emotions are thought to have evolved to address basic life tasks in a phylogenetic and ontogenetic primary stage.

Objectives: This study aims to provide an overview of Jaak Panksepp's theories and assertions on the journal Neuropsychanalysis.

Methods: The authors employed a neuropsychanalytic approach to analyse articles published in the Neuropsychanalysis journal between 2015-2023.

Results: Emotions primarily function to maintain homeostasis and protect the organism, as in fight or flight responses. In social animals, emotions can sometimes be recognized among individuals of the same and different species. The neurobiological basis of emotional transfer and empathy-like behaviors shed light on cross-species emotion transfer.

Conclusions: The facial feedback hypothesis and the interoceptive inference theory are also discussed as examples of theories for the recognition of emotions as well as the neural mechanisms involved in emotion perception and recognition.

Jaak Panksepp's valuable insights shed light on the mysteries of human affect, and lay the foundation for future work in the field.

The role of cerebral-cognitive reserve in the birth of a child with Alzheimer's in late-life individuals

A. Sidenkova

Psychiatry, Ural State Medical University, Yekaterinburg, Russian Federation

doi: 10.1192/j.eurpsy.2024.1301

Introduction: The modern understanding of AD allows us to consider it through the constructs of "vulnerability" and "stability" of the brain in relation to the pathological effects of neurodegeneration. To describe the resistance of the brain to a developing lesion due to a pathological process, the concept of "reserve" is proposed.

Objectives: A systematic review of scientific studies was conducted.

Methods: The review includes an analysis of full-text literature sources.

Results: Resilience models based on reserves are described, which can be broadly divided into cerebral and cognitive reserve models. The quality of the brain substrate underlies the cerebral reserve. Its role and power are determined by the ratio of healthy/affected neurons, the integrity of synaptic connections, and the size of the brain/ It seems to us that the conditions that promote or hinder the functioning of the brain should also be taken into account when characterizing the cerebral reserve. Cognitive reserve is determined by the phenomena of mental processes and functions. It includes the individual's involvement of the individual in various cognitively stimulating activities throughout life. Cognitive reserve plays a decisive role when it comes to determining the effectiveness of the activation of additional areas or the implementation compensatory strategies, behaving more flexibly and dynamically than the passive threshold. Brain and cognitive reserve models cannot be considered mutually exclusive. They reflect different categorical levels: substrate and functional. The cerebral reserve system is the morphological basis of the cognitive reserve. In fact, we can talk about a single cerebral-cognitive reserve.

Conclusions: The reserve concept states that there are individual differences in the adaptability of the functional processes of the brain that allow some people to cope with age-related and disease-related brain changes better than others. The reserve plays a protective role, postponing clinical manifestations and ensuring that adequate cognitive functioning is maintained. There is a transition from the protective role of the reserve to the compensatory function. Even after anatomical signs of brain damage are observed, the time to clinical conversion can be modulated depending on the volume of the reserve. The protection mechanisms underlying the reserve concept are partially controllable, which allows building strategies for correcting cellular homeostasis, brain functions, behavioral and cognitive patterns. Understanding the mechanisms of aging and the determinants of life expectancy will help reduce age-related morbidity and promote healthy aging.

Whole-brain Functional Connectivity Correlates of Brain Structural Aging in Adult Schizophrenia Patients Compared to Healthy Controls

Y. Panikratova¹, A. Tomyshev¹, E. Abdullina¹, A. Dudina^{1*}, V. Kaleda², V. Strelets³ and I. Lebedeva¹

¹Laboratory of Neuroimaging and Multimodal Analysis; ²Department of Youth Psychiatry, Mental Health Research Center and ³Laboratory of Human Higher Nervous Activity, Institute of Higher Nervous Activity and Neurophysiology of RAS, Moscow, Russian Federation

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1302

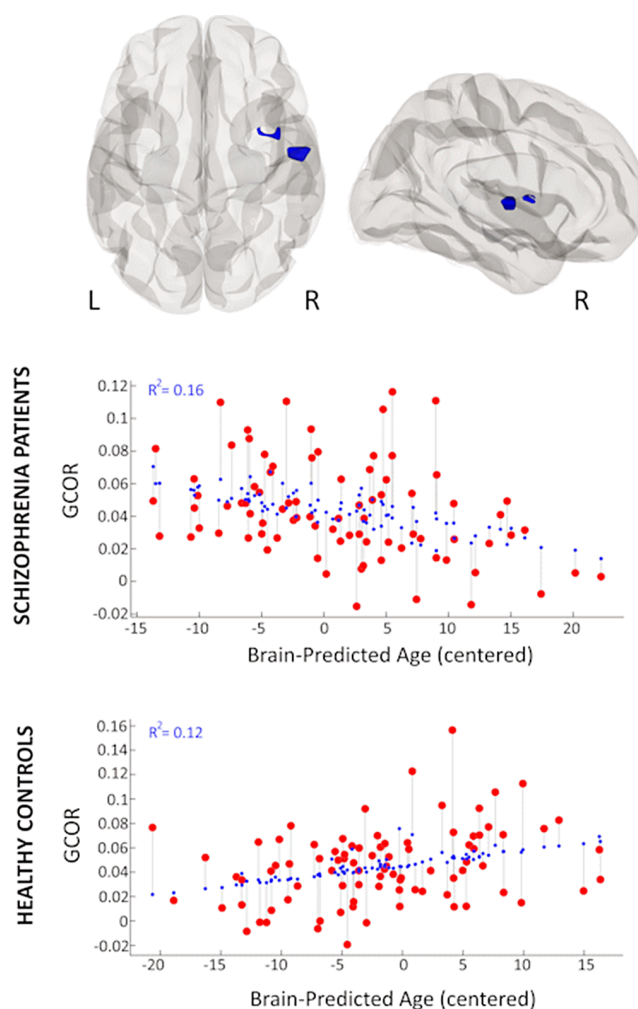

Introduction: Age-related changes of brain functional connectivity, in contrast to brain structure, are understudied in schizophrenia. Importantly, patients with schizophrenia demonstrate an increased difference between the brain-predicted age and chronological age indicating that brain structural aging may be accelerated in this mental disorder (Constantinides et al. Mol Psychiatry 2023; 28 1201-1209). Research on functional connectivity correlates of this process seems to be fruitful.

Objectives: We aimed to search for the brain regions whose resting-state whole-brain functional connectivity is differently associated with brain-predicted age in schizophrenia patients compared to healthy controls.

Methods: Eighty-three male patients with schizophrenia (age range 17.3 – 52.3; mean age 32.1 ± 10.5) and eighty-seven male healthy individuals (age range 18.3 – 53.6; mean age 31.7 ± 10.0) underwent structural MRI and resting-state fMRI (Philips Ingenia 3T scanner). Brain-predicted age was individually estimated using a model trained on independent data based on 68 measures of cortical thickness and surface area, 7 subcortical volumes, lateral ventricular volumes, and total intracranial volume, all derived from T1-weighted MRI scans (Han et al. Mol Psychiatry 2021; 26 5124-39). The associations between the brain-predicted age and the whole-brain global correlation (GCOR) were compared between groups; *t*-contrasts were calculated (one-way ANCOVA covariate interaction via CONN; RRID:SCR_009550; www.nitrc.org/projects/conn). The chronological age was a covariate of no interest.

Results: Schizophrenia patients had a higher difference between brain-predicted age and chronological age ($T(168) = 2.1$; $p = .036$; Cohen's $d = 0.32$; 95% CI 0.02-0.63). Greater brain-predicted age in schizophrenia patients, compared to controls, was associated with lower functional connectivity of a region in the right Heschl's gyrus, planum temporale, as well as central opercular and insular cortex with the rest of the brain ($p < .001$ voxelwise, $p[\text{FDR}] < .05$ clusterwise; Figure 1).

Image:

Conclusions: Our results coincide with earlier findings on accelerated brain structural aging in schizophrenia. To the best of our knowledge, the present study is the first to indicate that this process is coupled with a decline of the whole-brain functional connectivity of a region located in the right temporal, insular, and parietal cortices, and this effect is not driven by chronological age. Further studies are needed to clarify the clinical and cognitive correlates of this decline of functional connectivity.

The study was supported by RSF grant project 22-25-00706.

EPV0648

The Impulsivity-Compulsivity Spectrum: Understanding Brain Mechanisms and Clinical Implications

C. Pinheiro Ramos*, C. Baptista, J. Nogueira, S. Mendes and A. Gamito

Setúbal Hospital Center, Setúbal, Portugal

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1303

Introduction: Impulsivity and compulsivity are natural behaviors controlled by brain mechanisms that are essential for survival in all species. Understanding these brain mechanisms may lead to targeted treatment strategies for these symptom domains when impulsivity and compulsivity become dysfunctional.

Pathological impulsivity and compulsivity characterise a broad range of mental disorders.

Objectives: This study aimed to synthesise the latest evidence about the conceptualization of the impulsivity-compulsivity spectrum.

Methods: A review was conducted, drawing on reputable sources (PubMed and Web of Science databases).

Results: The concept of impulsivity can be defined as a predisposition toward rapid, unplanned reactions to internal or external stimuli without regard to the negative consequences of these reactions to the impulsive individual or to others. However, impulsivity is not always unplanned. Impulsive behaviours can be conceptualised as the core symptoms of a broad range of psychiatric disorders. In contrast, compulsivity refers to repetitive behaviours that are performed according to certain rules or in a stereotypical fashion. Compulsivity is a tendency to repeat the same, often purposeless acts, which are sometimes associated with undesirable consequences.

Impulsivity and compulsivity may be viewed as diametrically opposed, or alternatively, as similar, in that each implies a dysfunction of impulse control. Each involves alterations within a wide range of neural processes, including attention, perception, and coordination of motor or cognitive responses.

Conclusions: The neurobiology of impulsivity and compulsivity may involve inhibitory neurotransmitters, excitatory neurotransmitters, the prefrontal cortex, and/or limbic dysfunction.

Impulsive and compulsive features may present at the same time or at different times during the same illness. Although both compulsive and impulsive disorders may be related to prefrontal cortex dysfunction, compulsive disorders would be related to hyperactivity and impulsive disorders to hypoactivity of the prefrontal cortex. Compulsiveness appears to be associated with increased frontal lobe activity, while impulsiveness may be associated with reduced frontal lobe activity.

Body dysmorphia in a 23 year old patient with obsessive compulsive disorder: a case report

P. Setiën Preciados*, E. Arroyo Sánchez and C. Díaz Mayoral

Servicio de Psiquiatría, Hospital Universitario Príncipe de Asturias, Alcalá de Henares, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1304

Introduction: Body dysmorphic disorder (BDD) was considered an anxiety disorder in the DSM-IV, but in the DSM-V was added to the obsessive-compulsive and related disorders category. BDD is a psychiatric disorder characterised by an excessive, persistent, and distressful preoccupation with a perceived defect in appearance. These perceived defects are slight and are unnoticed by others. People with BDD usually have poor insight and are preoccupied with a perceived physical defect which causes them to check on it repeatedly. This leads to an impairment in psychosocial functioning, depression, and an increase in suicide risk.

Objectives: Review how body dysmorphic disorder (BDD) and obsessive compulsive syndrome intersect, the differences they present in symptomatology, prevalence and treatment.

Methods: Presentation of a patient's case and review of existing literature, in regards to body dysmorphic syndrome and its similarities and differences with respect to obsessive compulsive syndrome.

Results: There are common features between both disorders, which are genetic overlap, physical past traumatic events, sex ratio, trait of perfectionism and body image disturbance.

Studies have found the prevalence of BDD in patients with OCD in a large patient sample was 8.7% to 15% compared to 3% in non-OCD.

The risk of comorbidity of OCD-BDD is three times higher in samples with a primary diagnosis of BDD compared to those with a primary diagnosis of OCD with 27.5% and 10.4%, respectively.

BDD as well as OCD must be managed with pharmacological and psychotherapy treatment. A selective serotonin reuptake inhibitor is the recommended first-line medication for BDD, even if appearance beliefs are delusional in nature.

Serotonin reuptake inhibitor (SRI) doses and trial durations are similar to those used for OCD; higher doses and a longer treatment trial are recommended than those typically used for depression and most other disorders. Cognitive-behavioral therapy that is specifically tailored to BDD is the psychosocial treatment of choice. Simply treating BDD as if it were OCD is not recommended.

Conclusions: There are limitations included a restricted number of studies overall, an absence of studies comparing biological parameters, and the frequent inclusion of participants with comorbid body dysmorphic disorder and obsessive-compulsive disorder. The current nosological status of body dysmorphic disorder is somewhat tenuous and requires further investigation, with particular focus on dimensional, biological and aetiological elements.

The role of immunity and inflammation in obsessive-compulsive disorder and related conditions

S. Palermo¹, R. Gurrieri^{2*}, E. Annuzzi¹, M. Gambini¹, A. Arone¹, A. Coccoglioniti¹, G. D'Angelo¹ and D. Marazziti^{1,3}

¹Department of Clinical and Experimental Medicine; ²Department of Surgical-Medical and Molecular Pathology and Critical Care Medicine, University of Pisa, Pisa and ³Saint Camillus International University of Health and Medical Sciences, UniCamillus, Rome, Italy

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1305

Introduction: In recent years, there has been a growing interest in the potential consequences of disruptions in the inflammatory and immune systems on the onset of obsessive-compulsive disorder (OCD) and associated conditions, such as Paediatric Auto-immune Neuropsychiatric Disorders Associated with Streptococcal Infection (PANDAS) and Tourette syndrome (TS). While this area of inquiry is undeniably captivating, the available data remain somewhat controversial and limited in scope.

Objectives: The aim of this paper is to conduct an exhaustive examination and evaluation of the existing body of literature concerning aberrations in inflammatory and immune system processes within the context of OCD, PANDAS, and TS.

Methods: This narrative review entailed a comprehensive search of English language papers on PubMed and Google Scholar from January 1985 to July 31, 2023.

Results: The data collected up to this point suggest that the underlying mechanisms at play may differ depending on the age of the patients and the specific disorder being investigated. Notably, PANDAS seems to have a stronger connection with infections that trigger autoimmunity, which may not necessarily be limited to those resulting from Group A beta-haemolytic streptococcal (GABHS) infections, as previously assumed. In the case of TS, autoimmunity appears to play a significant role, especially when combined with individual susceptibilities stemming from both genetic and environmental factors. As for adult OCD, while the available data are somewhat scattered and occasionally based on relatively small groups of patients, they do indicate that the immune system and inflammatory processes are involved in the disorder's pathophysiology. However, it remains uncertain whether these processes are primary driving forces or secondary reactions.

Conclusions: In summary, when viewed collectively, the current research findings unveil promising avenues for exploring the underlying causes of OCD and related disorders. They also hold the potential for the development of innovative therapeutic approaches that go beyond the current pharmacological paradigms.

EPV0653

Transcranial magnetic stimulation for obsessive-compulsive disorder - preliminary results of an observational study

I. Mangas Palma*, J. Borges, E. Palha, H. Salgado, P. Alves, P. Sousa Martins and R. Moreira

Serviço de Psiquiatria, Centro Hospitalar Universitário de São João, Porto, Portugal

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1306

Introduction: Obsessive-compulsive disorder (OCD) has a high prevalence and causes a significant reduction in functionality and quality of life.

First and second line treatment is ineffective in a variable percentage of patients. In such cases transcranial magnetic stimulation (TMS) may be considered.

Objectives: The goal of this study is to evaluate the impact of TMS treatment on obsessive-compulsive, anxious and depressive symptomatology in patients with OCD.

Methods: A prospective observational study was conducted, including all patients diagnosed with OCD who underwent TMS in the Psychiatry department of Centro Hospitalar Universitário de São João since March 2023.

Symptomatology was assessed using the Yale Brown Obsessive-Compulsive Scale (Y-BOCS), the Hamilton Anxiety Rating Scale (HAM-A) and the Hamilton Depression Rating Scale (HAM-D) before and after treatment.

Statistical analysis was performed using the SPSS-Statistics program. A significance level of 0.05 was considered.

Results: As of October 31, 2023, nine individuals with OCD completed treatment with TMS, 33% male and with a median age of 40 years (range 33-57).

The median Y-BOCS score pre-TMS was 30 (range 20-33) and post-TMS 28 (range 16-34). The median difference was 2.5 (range -5-14) and was not statistically significant ($p=0.128$).

The median score on the HAM-A pre-TMS was 21 (range 9-41) and post-TMS 18 (range 11-24). The median difference was 0 points (range -4-21) and was not statistically significant ($p=0.345$).

The median HAM-D score pre-TMS was 26 (range 14-40) and post-TMS 19 (range 10-32). The median difference was 2.5 (range -3-20) and was not statistically significant ($p=0.225$).

Conclusions: Preliminary findings suggest that the impact of TMS on obsessive-compulsive, anxious, and depressive symptomatology in patients with OCD does not appear to be clinically or statistically significant.

Further results are necessary to confirm this trend.

Disclosure of Interest: None Declared

EPV0654

Ketamine in the treatment of obsessive-compulsive disorder – a case report and literature review

I. Mangas Palma*, I. da Fonseca Pinto, J. Tavares Coelho and R. Moreira

Serviço de Psiquiatria, Centro Hospitalar Universitário de São João, Porto, Portugal

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1307

Introduction: Obsessive-compulsive disorder (OCD) is a chronic condition characterized by time-consuming and distressing obsessions and/or compulsions, often accompanied by avoidance behaviours. It is a highly prevalent and incident disorder that results in considerable disability and quality of life reduction.

Current pharmacological treatments are hindered by their delayed onset and the limited evidence on how to approach first and second line treatment-resistant patients.

Recent research showcased the involvement of glutamatergic pathways in the pathophysiology of OCD prompting research into the potential therapeutic use of ketamine, which binds to the N-methyl-D-aspartic acid receptor and acts as a non-competitive antagonist of glutamate.

Objectives: The aim of this study is to conduct a literature review on the use of ketamine and its enantiomers as a treatment for OCD and report a clinical case involving an OCD patient who experienced significant improvement following ketamine use.

Methods: A search was performed on PubMed using a combination of keywords and Medical Subject Headings terms, including “Ketamine”, “Esketamine” and “Obsessive-Compulsive Disorder”. Only studies that involved patients with OCD aged ≥18 years who had received ketamine or its enantiomers as an intervention and that reported treatment response using a validated scale were included.

Results: Nine studies were included, 4 case reports, 3 open-label trials and 2 randomized controlled trials, totalling 71 patients. Ketamine was administered intravenously in 7 studies and intranasally in the remaining 2. The results were heterogeneous, with some studies reporting no effect on obsessive-compulsive (OC) symptoms and others demonstrating significant and rapid improvement, albeit some only transitorily.

We present the case of a 42-year-old man who experienced OC symptoms since the age of 20 but was only formally diagnosed with OCD 3 years ago. During his first consultation, the patient described obsessive thoughts related to contamination and dirtiness, accompanied by handwashing rituals and avoidance behaviours (e.g., avoiding touching handles and switches). His Yale-Brown Obsessive Compulsive Scale (Y-BOCS) score was 29. Escitalopram was initiated with a progressive dose titration, resulting in partial improvement (Y-BOCS 23). In a follow-up appointment, the patient disclosed that he had purchased and self-administered a single intravenous dose of 2g of ketamine 2 months earlier for recreational use. This led to an immediate and significant improvement of his OC symptoms. Subsequent re-evaluation 4 months later confirmed that he remained asymptomatic (Y-BOCS 2).

Conclusions: Ketamine may be a therapeutic alternative for OCD patients who are treatment resistant due to its rapid anti-obsessional effect. Further studies with improved designs and larger sample sizes are warranted to better assess the efficacy of ketamine in OCD treatment.

Disclosure of Interest: None Declared

EPV0655

Neuropsychological functions as endophenotype markers in ocd: a long term follow-up

M. Puigalto*, J. Segalas, M. D. P. Alonso and E. Real

Hospital Universitario de Bellvitge, L'Hospitalet de Llobregat, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1308

Introduction: Obsessive Compulsive Disorder (OCD) is characterized by impaired neuropsychological functions that are also influenced by clinical variables and aging.

According to the literature, several of these neuropsychological deficits could be potential endophenotype markers.

Objectives: The present study aimed to study what kind of cognitive deficits OCD patients have and how aging and clinical course modify their cognitive profiles compared with general population.

Methods: This study examined a sample of 60 adult outpatients with OCD diagnosis, who were matched with 70 healthy controls (HC). Cognitive performance in both groups was assessed using a neuropsychological battery including Rey-Osterrieth complex Figure (ROCF) and Digit Span Test (DGS). Based on previous research on neuropsychology of OCD, it was specified that these neuropsychological measures could be divided in two composites. The first composite, Executive function, includes Total Digit Span and the domain of organization of ROCF. The second composite, Non-Verbal Memory, includes the copy of ROCF, immediate recall, delayed recall and recognition of ROCF.

Severity of OCD symptoms was assessed by YBOCS and HDRS was used for symptoms of depression.

Both cognitive performance and clinical data were documented before and after a follow-up of 11 years.

During analysis, group differences between patients with OCD and HC regarding demographic and clinical characteristics at baseline and follow-up were calculated with independent t-tests and Pearson tests. The main analysis tested if the change in cognitive function over time differed between patients and controls. To this end, a linear mixed model was used, examining the interaction between age, gender and time in both groups.

Results: Older age, in patients with OCD and HC, was associated with poorer performance on executive function and nonverbal memory. Executive function was influenced by severity of OCD, and non-verbal memory by depressive symptoms at baseline. While, after the follow-up, as obsessive and affective symptoms improve along de follow-up, there is no significant change in the neuropsychological pattern.

At baseline, patients with OCD showed a poorer performance than HC in areas of nonverbal memory and executive function. After de follow-up, there is a poorer performance in the cognitive function in both groups, as they get older. However, there is no significant difference in this change between patients and HC.

Conclusions: Results suggest that OCD is characterized by the existence of dysfunction in several neuropsychological areas that are influenced by time and clinical variables.

Nevertheless, this alteration is no solely attributable to these factors, as they remain stable through time compared to the general population. Therefore, certain neuropsychological functions might be endophenotype traits of the disorder.

Disclosure of Interest: None Declared

EPV0656

Use of vortioxetine in treating obsessive-compulsive disorder: a case report

B. Jiménez-Fernández*, N. V. Motta-Rojas, X. Iborra-Vicheto and J. Cuevas-Esteban
Psychiatry, Hospital Universitari Germans Trias i Pujol, Badalona, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2024.1309

Introduction: Obsessive-compulsive disorder (OCD) is a chronic disorder with a wide range of manifestations but primarily intrusive thoughts (obsessions) and/or ritualized actions (compulsions) that can cause a huge distress in patients' life. First-line treatment for OCD are selective serotonin reuptake inhibitors (SSRIs). Tricyclic antidepressants are used as second-line treatment due to secondary effects. Also antipsychotics such as aripiprazole are approved for treating OCD. Vortioxetine is has 5-HT3, 5-HT7 and 5-HT1D antagonists, 5-HT1B partial agonist and a 5-HT1A agonist and serotonin transporter inhibitor property. It is used in major depressive and anxiety disorders. A male 48 years old patient with an OCD diagnosis since he was 21, was referred to psychiatry department. Previously, he had no response with SSRIs at full dosage and clomipramine 75mg was effective. At 46 years old, he had an acute myocardial infarction. He also admitted not taking the medication regularly due to sexual disfunction and having affective symptoms related to the distress caused by OCD.

Objectives: To evaluate efficacy of vortioxetine in treating OCD in a patient with contraindications for tricyclic antidepressants and no response to SSRIs.

Methods: Clomipramine dose was reduced until discontinuation. After one week without treatment, basal scores for Hamilton Scale and Dimensional Yale-Brown Obsessive-Compulsive Scale (DY-BOCS) were collected. Same data was collected again after 10 weeks treatment.

Results: The dosage of vortioxetine was progressively titrated until 20mg daily in 3 weeks lapse. Diazepam 5mg was added in case of insomnia or anxiety. Aripiprazole 5mg was added in the third week of treatment as adjunctive treatment due to the recurrence of some intrusive thoughts (discontinued by himself because of akathisia). Finally, the patient reported an improvement in affective and OCD symptoms in the sixth week of treatment that was sustained until the tenth week, when data was recollected. The patient did not refer sexual disfunction.

The pre and post results are summarized in tables 1 and 2.

Dimensional Y-BOCS (0-15)

Table 1. Hamilton Depression Rating Scale (0-52)

Basal	Post 10-week treatment
21	4

	Basal	Post 10-week treatment
Aggressive-related obsessions and compulsions	10	2
Religious-related obsessions and compulsions	5	1
Symmetry and order	7	1
Pollution and cleaning	0	0
Collecting and accumulation	2	0
Miscellaneous	10	3

Conclusions: Vortioxetine might be a promising molecule for treating OCD in patients with contraindications for first and second-line treatments.

Disclosure of Interest: None Declared

Skin picking disorder in the elderly- What is the available evidence?

O. Vasiliu*, A. G. Mangalagiu, B. M. Petrescu, C. A. Candea, C. Tudor, D. Ungureanu, M. Miclos, C. Florescu, A. I. Draghici, R. E. Bratu-Bizic, M. Dobre, A. F. Fainarea and M. C. Patrascu
Dr. Carol Davila University Emergency Central Military Hospital, Bucharest, Romania
*Corresponding author.
doi: 10.1192/j.eurpsy.2024.1310

Introduction: Excoriation disorder (ExD) is a pathology recognized by DSM-5, and it is considered a part of the obsessive-compulsive spectrum. ExD is associated with a high rate of psychiatric comorbidity (e.g., depression, ADHD, substance use disorders, etc.).

Objectives: The main objective of this review was to explore the available evidence to support the diagnosis and treatment of skin picking in elderly population.

Methods: A literature review of the available sources reporting on ExD in elderly patients, realized by searching three electronic databases (PubMed, Cochrane, Clarivate/Web of Science) but also the grey literature. All papers published between January 1990 and July 2023, including the terms “excoriation disorder”, “compulsive skin picking”, “dermatillomania” and “elderly” or “old-age patients” were reviewed.

Results: The information about ExD was extracted almost exclusively from reports on elderly patients with neurocognitive disorders. Tactile hallucinations, delusions of contamination, social isolation and focusing on own bodily sensations, and organic causes- dehydration, allergies, renal insufficiency, hepatic and pancreatic diseases, as well as toxic causes- e.g., adverse events of certain drugs should be investigated in elderly patients exhibiting signs of ExD. A differential diagnosis is very important in this population in order to find the most adequate treatment. Behavioral treatments, serotonergic antidepressants, and glutamatergic modulators have been explored in patients with ExD, although specific trials for

elderly patients with this disorder are still lacking. However, case reports support the utility of several serotonergic antidepressants in the elderly.

Conclusions: ExD is a less explored disorder in the elderly, where an extensive differential diagnosis and screening for somatic/psychiatric comorbidities are needed. Trials exploring the potential treatments for ExD in old-age patients are also required for evidence-based case management.

Illness-Related Domestic Violence Experiences of Individuals Diagnosed with Obsessive Compulsive Disorder: A Qualitative Study

Z. Bayram, M. C. Aktaş and H. Gundogdu*

Psychiatric and Mental Health Nursing, Van Yüzüncü Yıl University, Van, Türkiye

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1311

Introduction: Obsessions and compulsions often focus on routine life actions such as consuming, bathing and living in public, so the disorder interferes with the social, family and occupational functioning of both the individual and their caregiver. In OCD, caregivers are often involved in the ritual behaviors of the individual, either by providing avoidance or by assisting in ritual behaviors. Individuals with OCD are often exposed to aggression from family members because of these behaviors. Research has shown that individuals with OCD may experience illness-related domestic violence. In the literature review on the subject, there were no qualitative studies examining the experiences of individuals diagnosed with OCD towards domestic violence caused by the symptoms of the disease. A mix-method study conducted by aimed to explore the illness-related domestic violence experiences of individuals diagnosed with OCD. The study utilized both quantitative and qualitative methods to gather data from individuals with OCD. The findings of the study revealed that a significant number of individuals with OCD reported experiencing domestic violence related to their illness. This study highlights the importance of addressing the issue of domestic violence in individuals with OCD and the need for appropriate interventions and support.

Objectives: This study was planned to examine the experiences of individuals diagnosed with OCD regarding domestic violence caused by the symptoms of the disease in Turkey.

Methods: The sample of the study was determined by purposive sampling method. The study was conducted with individuals diagnosed with OCD who were being treated in the psychiatric clinics of two university hospitals. The study used mixed methods and was planned in two phases. In the first stage, Socio-Demographic Data Form and Yale-Brown Obsession Compulsion Scale were used. After reviewing the results of these scales, individual in-depth interviews were conducted with 20 patients who had a history of domestic violence and scored above 16 on the Yale Brown Obsessions and Compulsions Scale. Data saturation was deemed to have been reached and data collection was terminated.

Results: The analysis of the data is still ongoing in detail by the researchers. The findings and relational implications of the study will be presented.

Conclusions: It is thought that the results of the study will provide a basis for further research and intervention programs and contribute to the literature by determining the types of violence experienced by individuals diagnosed with OCD from family members due to the disease, how patients feel in the face of the problems they experience and how they cope with it. In addition, the results of the study are expected to help intervention programs to be developed for families to strengthen treatment adherence.

Alzheimer's and Parkinson's disease drugs side effects

J. Batistela¹, F. J. Ropero Pelaez², G. Hida³ and S. Taniguchi^{4*}

¹Albert Einstein Hospital, São Paulo; ²Mathematics, Computation and Cognition, University Federal of ABC, São Paulo; ³Big Data Analytics - Artificial Intelligence, Albert Einstein Hospital and ⁴São Paulo University, São Paulo, Brazil

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1312

Introduction: Alzheimer's and Parkinson's disease are neurodegenerative disorders with life limiting conditions. The symptomatic pharmacological therapeutic strategies unfortunately are also related to undesirable side effects. Acetylcholinesterase inhibitors administered to Alzheimer's disease patients increase cholinergic transmission in cortex and hippocampus.

Antiparkinsonian drugs increase dopaminergic system activity, to compensate for dopaminergic neurons' degeneration in *corpus striatum*, therefore supplying the imbalance of these neurotransmitters in these degenerative areas. But undesirable the increase of these neurotransmitters in other cerebral and peripheral areas brings us important side effects

Objectives: To study Alzheimer's cholinergic drugs and Parkinson's dopaminergic drugs' side effects

Methods: This retrospective study included 107 geriatric patients enrolled in a private long-term care institution. 79 patients with Alzheimer's disease had mean age of 88.11 ± 5.78 years old, mean weight of 61.62 ± 13.10 kg. 28 patients with Parkinson's disease had mean age of 84.93 ± 5.71 years old, weight mean 66.36 ± 2.83 kg.

Results: Alzheimer's disease patients 41.77% (33) received. Acetylcholinesterase inhibitors (Donepezil, galantamine and rivastigmine) Psychomotor agitation and aggressive behavior 63.666% and nausea (15%) were observed in the patients treated with these drugs. The association of L-DOPA and DOPA decarboxylase inhibitors (benserazide) were administered to 53%(15) of the Parkinson's disease patients in doses between 2.0-19.0 mg/kg/day. L-DOPA associated to catechol-O-methyltransferase inhibitor (entacapone) 3 mg/kg/day were given to 7.14% (2) patients. Bromocriptine 0.04 mg/kg/day was given to 3.57% (1) patients. Mental confusion and hallucination side effects were observed in 53.33% (8) patients treated with L-DOPA associated with the DOPA decarboxylase inhibitor (benserazide).

Conclusions: The increase of cholinergic activity due to the acetylcholinesterase inhibitors in the Nigro- striatal pathway could be

related to psychomotor agitation in Alzheimer's disease patients in a similar way to akathisia induced by neuroleptics. The increase of dopamine levels due to the administration of L-DOPA, in *corpus striatum* improved Parkinson's disease symptoms although the increase of dopaminergic activity at mesocortical pathways may be related to confusion and hallucination observed in these patients. Adjustments in dosage of these drugs could provide improvement in these patients' daily life conditions.

Integration of Geriatric Psychiatry and Geriatrics: Enhancing Mental Health Assessment in the Elderly

A. F. Borges* and V. Domingues

Serviço de Psiquiatria e Saúde Mental, Centro Hospitalar de Leiria, Leiria, Portugal

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1313

Introduction: The ageing population presents complex clinical challenges, particularly in the realm of mental health among the elderly. The intersection of geriatric psychiatry and geriatrics plays a critical role in providing a holistic and comprehensive approach to addressing psychiatric issues in older adults. This abstract explores the integration of these two disciplines and their significance in elderly mental health care.

Objectives: This study aims to underscore the benefits of collaboration between geriatric psychiatry and geriatrics while highlighting areas of intersection. These areas include the assessment of medical and psychiatric comorbidities, the management of neuropsychiatric disorders, and the promotion of healthy ageing, both physically and mentally.

Methods: We comprehensively reviewed the literature, encompassing research studies, case reports, clinical guidelines, and reports published in the last 10 years. The research was conducted on medical databases, including PubMed, Medline, and specialized sources in gerontology.

Results: Effective integration between geriatric psychiatry and geriatrics provides a more comprehensive and patient-centred approach to addressing the mental health needs of the elderly. This includes enhanced assessment and treatment of a wide range of psychiatric conditions commonly found in older adults, such as cognitive disorders (including dementia and mild cognitive impairment), mood disorders (including depression and bipolar disorder), anxiety disorders, psychotic disorders, and substance use disorders. Additionally, the collaboration ensures a better understanding of the complex interplay between physical and mental health in the ageing population. The integration approach also encompasses the management of neuropsychiatric symptoms associated with various medical conditions common in older adults, such as delirium and behavioural disturbances in dementia. This coordinated care extends to the judicious use of psychotropic medications, considering the unique pharmacokinetics and pharmacodynamics in the elderly population, with a focus on minimizing adverse effects and drug-drug

interactions. Furthermore, promoting emotional well-being and preventing mental illnesses emerge as critical areas of collaboration between these disciplines. Strategies for achieving this goal include psychoeducation, lifestyle interventions, and fostering a supportive environment for the elderly.

Conclusions: In summary, the collaboration between geriatric psychiatry and geriatrics is crucial for addressing the complex mental health needs of the elderly, providing patient-centred care, and optimizing resources. This integrated approach is essential in ensuring the well-being of older adults, emphasizing a holistic, multidisciplinary approach to mental health issues in this population.

EPV0662

Prevalence and Associations of geriatric depression in Sudur-Paschim Province of Nepal: A community-based cross-sectional study

D. Kunwar

psychiatry, kathmandu university school of medicine, kathmandu, Nepal

doi: 10.1192/j.eurpsy.2024.1314

Introduction: The elderly population is rapidly growing worldwide. Depression is an important public health concern among the elderly population in terms of its prevalence and the burdens of ill health in individual sufferers and families.

A considerable number of studies focusing on the prevalence, associated factors, and treatment of depression have been conducted in Western Europe and North America. However, this kind of research is relatively limited in Nepal.

Objectives: - To find out and prevalence and its associated factors of depression among the elderly in sudur paschim province Nepal.

Methods: This community-based, cross-sectional, door-to-door survey was conducted in the two representative districts of Sudur-paschim Province, Nepal. Eligible participants were assessed for geriatric depression and quality of life. the sample size was calculated at 945.

Results: Depression was found in 43.9% of the participants.

The association of different variables with WHOQOL-8 first question. Income was significantly associated with poor quality of life (p-value 0.04).

Furthermore, we have evaluated the association of different variables across four domains of the WHOQOL-8 scale and found statistically significant differences across age, sex, residence, occupation, income, history of smoking, history of alcohol use, comorbidities, and depression.

Conclusions: Depression is highly prevalent among the elderly in the Sudur-Paschim Province of Nepal. So policymakers should take this research outcome seriously and should keep the mental health of the elderly population a priority during the implementation of public health policies.

EPV0663

Is content of delusions in psychotic depression related to the risk of dementia?

J. T. Coelho^{1*}, B. Martins², A. Silva¹, C. Silveira¹ and A. S. Machado¹

¹Department of Psychiatry and Mental Health and ²Department of Neurology, University Hospital Center of São João, Porto, Portugal

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1315

Introduction: Some studies have shown that late-life depression is related to faster cognitive decline and may increase the risk of dementia.

Identifying risk and protective factors for dementia is essential to develop preventive interventions. Some literature has suggested that mood disorders (namely depression) are potential modifiable risk factors for dementia.

Thus, it is important to know clinical presentation of depression that is associated to dementia, as a manifestation of subclinical dementia or as a risk factor for neurocognitive disorders.

Objectives: We aim to identify clinical characteristics related to dementia of inpatients admitted for first time due to depressive episode after 55 years old.

Methods: Retrospective cohort study of inpatients admitted between January 1st 2010 and March 31st 2022 in a psychiatry inpatient unit of a tertiary hospital. Descriptive analysis of the results was performed using the SPSS software, version 26.0.

Results: Our sample included 57 inpatients, 15,8% (n=9) with the diagnosis of dementia 5,2 (SD 5,6) years after admission. All of these patients presented a depressive episode with psychotic symptoms, namely delusion activity. In those with hallucinatory activity, no one developed dementia.

Interestingly, 33,3% of patients with dementia (n=3) presented with delusion of ruin, 55,6% (n=5) with delusion of prejudice/persecutory delusion and 66,7% (n=6) manifested delusion of ruin and/or prejudice.

We also found that 42,9% (n=3) of patients with dementia manifested Cotard delusion while this type of delusion was observed in 13,6% of patients without dementia (p=0,095).

Conclusions: Our study has several limitations because is based on results of only one hospital, with a small sample size.

However, since depressive symptoms are potentially modifiable risk factors for dementia, future studies are essential to understand the mechanisms that link depression to cognitive decline as well as clinical characteristics that may constitute predictors of dementia.

EPV0665

The importance of non-pharmacological approach versus pharmacological treatment of behavioral and psychological symptoms (bpsd) in patients with Alzheimer's dementia (AD) in a geriatric institution

M. Spirova^{1,1,2,3*}

¹PHI Specialized Hospital for Geriatric and Palliative Medicine, Skopje; ²PHI General hospital, Kavadarci and ³PHI Health center Skopje, Skopje, North Macedonia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1316

Introduction: BPSDs in patients with AD are present up to 90% and can cause serious complications in their overall health. A non-pharmacological approach and cognitive enhancers should be a priority in treatment in order to reduce the use of antipsychotics. In the pharmacological treatment of bpsd, additional therapy is inevitable in many cases

Objectives: the need for adequate education of the medical staff in a geriatric center for the nonpharmacological approach in patients with bpsd in AD. Polypharmacy is common in pharmacological treatment.

Methods: A cross-sectional study of 180 patients hospitalized at geriatric unit in period of January till May 2023 was conducted. 61(33.9%) were patients with AD, 44 or 72.1% were females and 17 or 27.9% were males, with mean age 78.6±5.6 years. 50 patients (82.0%) had potentiated BPSD in the first days of hospitalization and needed additional therapy

Results: 19 of 61pts (31.1%) were on dual therapy, full doses of donepezil and memantine. 17 (89.5%) needed additional therapy for BPSD; 13 (68.4%) a short-term antipsychotic and 4 (21.1%) patients antidepressant therapy. 22 patients (36.1%) were admitted with donepezil only. 18 (81,8%) needed additional therapy. The remaining 20 (32,8%) were solely on memantine. 15 (75.0%) needed additional therapy

Conclusions: Vast majority of patients AD (82.0%) manifested BPSD and needed additional therapy. Number of scientific papers it is found that cognitive stimulation in persons with moderate dementia has a benefit more than any pharmacological treatment. Education of caregivers of people with AD is inevitable. Opening of day care centers that will enable continuous support as well as individual access which would help delay institutionalization of people with BPSD at AD the need

EPV0666

Late Onset Bipolar Disorder (LOBD): a case report

M. Martín De Argila Lorente^{1*}, B. Franco Lovaco¹, B. Rabinovici¹, C. Díaz Mayoral² and G. E. Toapanta Yanza³

¹Psychiatry, Hospital Dr. Rodríguez Lafora; ²Psychiatry, Hospital Universitario Príncipe de Asturias and ³Geriatric, Hospital Universitario La Paz, Madrid, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1317

Introduction: Bipolar disorder (BD) in the elderly patient may present as the evolution of illness initiated earlier in life or as a new-onset entity. Therefore, two groups of patients are distinguished: "late onset" (LOBD) when the first mania occurs in old age and "early onset" in elderly patients with long-standing history. BD in elderly patients (≥60 years) constitutes 25% of all BD cases. Specific aspects of older age bipolar disorder (OABD) are somatic and psychiatric comorbidity, impaired cognition and age-related psychosocial functioning. The management of BD in the elderly is complex given the high sensitivity of these patients to pharmacological side effects, particularly of psychotropic drugs.

Objectives: The case of a patient with LOBD is presented, followed by a theoretical review of the subject.

Methods: A case is presented with a bibliographic review.

Results: A 76-year-old woman who had no prior history of mental health issues until March 2023 when she was initially admitted to a geriatric hospitalization unit for manifesting manic symptoms. She was readmitted in July 2023 due to worsening depressive symptoms that included a declining mood, passive thoughts of death, deterioration in self-care, weight loss, insomnia, constipation, and dry mouth despite recent changes in her medications. She was on treatment with escitalopram (which was gradually discontinued and replaced with mirtazapine), quetiapine, lormetazepam, and lorazepam. Imaging tests showed chronic ischemic lesions in her brain and a small meningioma, the rest of the test were normal.

The initial diagnostic hypothesis was a bipolar depressive episode, and her treatment was adjusted accordingly. She was started on lithium, and her quetiapine dosage was increased, along with the anxiolytic lorazepam. Due to the persistence of depressive symptoms, including low mood, anhedonia, apathy, and negative thoughts, she was also prescribed antidepressant medication (venlafaxine and mirtazapine). Her condition gradually improved, with better eating and sleep patterns, increased participation in activities, and reduced somatic complaints and anxiety.

As she continued to experience somnolence and decreased morning energy, her antipsychotic medication was switched from quetiapine to lurasidone. The dose of lithium was decreased due to tremors in her extremities, although they remained within the therapeutic range. Despite these adjustments, her mood significantly improved, and she showed no signs of worsening or psychotic symptoms, leading to her discharge.

Conclusions: Summarizing different studies, LOBD who develop mania for the first time at an advanced age (≥ 50 years) constitute 5-10% of all BD. It is important to perform a thorough differential diagnosis, as an organic substrate and diverse etiologies may be present. Current guidelines recommend that first-line treatment of OABD should be similar to that of BD in young patients, with careful use of psychotropic drugs.

EPV0667

The modulation effect of cognition on the interpretation bias of mentalization in late-life depression (LLD): A study of eye gaze interpretation – a potential screening tool for high-risk group of LLD

P. W. Cheng

Psychiatry, the university of Hong Kong, Hong Kong, Hong Kong
doi: 10.1192/j.eurpsy.2024.1318

Introduction: Impairment in mentalization, interpreting and perceiving social relevant information has been found to play a part in the development and maintenance of depression. Major depressive disorders showed significant impairment in social cognition and such impairment appears to be positively associated with the severity of depression. Self-referential gaze perception, as a measurement of mentalization, was predominantly measured in patients with psychosis but rarely examined in late-life depression (LLD).

Objectives: To assess the effect of cognition on the interpretation bias of mentalization

Methods: This will be a cross-sectional case-controlled study on Chinese older adults with major depressive disorder recruited from outpatient departments of the public mental health service in Hong Kong. The same inclusion and exclusion criteria, with the exception of the history of major depressive disorder, will be used to recruit the control group. Assessments included sociodemographics, cognitive assessments and depressive symptoms. The primary experimental task was Gaze Perception Task using E-prime Professional 2.0. The stimuli of task are photographs of six Chinese models (3 men and 3 women) facing straight to camera with 13 different gaze directions (0° , 5° , 10° , 15° , 20° , 25° and 30° to the left and to the right, respectively). Participants shall be instructed to respond with a “yes” or a “no” to the question (for self-referential gaze): ‘Do you feel as if the person in the picture is looking at you?’.

Results: 41 patients and 41 healthy controls have been recruited. The group comparison in SRGP revealed that there was only significant difference in the unambiguous-SRGP ($U=561.000$, $Z=-2.62$, $N=82$, $p=0.009$). Patients had higher unambiguous self-referential gaze accuracy (Mean=0.16) than controls (Mean= 0.075). With a cut-off score of 22, patients with better HK-MoCA scores had better unambiguous SRGP scores than those with lower HK-MoCA scores ($p=0.024$). This difference was not observed in healthy controls. HK-MoCA could predict ambiguous SRGP rate $F(1,80)=14.85$, $p<.001$, $R^2=15.7\%$. and predict unambiguous SRGP rate $F(1,80)=14.85$, $p<.001$, $R^2=15.7\%$.

Conclusions: LLD subjects had a significant interpretation bias in the unambiguous averted gaze (20° , 25° and 30°) interpretation compared with healthy controls. LLD subjects tend to have more self-referential perception of the clear averted gaze. This misinterpretation of the eye gaze is probably due to the interpretation bias in processing external information, which is commonly reported as mentalization impairment in depression (Weightman et al., 2014).

EPV0668

Benzodiazepines and risk of dementia – Is there a reason for alarm?

R. P. L. Andrade*, N. Castro, R. Vaz, J. Martins, J. Abreu, E. Almeida, I. Santos, F. Cunha and H. Afonso

Centro Hospitalar Tondela-Viseu, Viseu, Portugal

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1319

Introduction: The population ageing is a reality associated with an increase in prevalence of Dementia. The use of benzodiazepines is often postulated as a risk factor in these syndromes.

Contrary to recommendations for its short-time use, long-term and chronic use are common, with an estimated 8,7% of elderly people in the US taking benzodiazepines.

Objectives: To clarify the most recent evidence on the use of benzodiazepines and the risk of developing dementia.

Methods: Non-systematic review of literature, using PubMed as database and filtering the results for meta-analysis.

Results: Four articles were included in this review.

Zhong G et al. concluded that risk of dementia increased in consumers of benzodiazepines and it was associated with higher doses. In turn, AlDawasari A et al., when trying to clarify the use of different sedative-hypnotic drugs, found and increased risk with the consumption of benzodiazepines. After exclusion of articles with confounders and adjustment for protopathic bias, the risk was not maintained.

Lucchetta RC et al. concluded that the risk exists but without inferring differences between doses or duration of action.

Finally, Penninkilampi R e Eslick GD investigated this association, after controlling for the protopathic bias, concluding, contrary to AlDawasari et al., that the association benzodiazepines consumption and dementia do not result from this bias.

Conclusions: We cannot draw robust and concrete conclusions between benzodiazepines consumption and the pathogenesis of dementia because not only is the literature limited, but results are also heterogeneous.

However, these prescriptions must be carried out cautiously, especially in the elderly, due to the known adverse effects associated with them.

EPV0669

Prevalence of Dementia, associated Co-morbidities, and Multidisciplinary Team Involvement in a Psychiatry of Old Age Service

S. Crowley* and E. Dunne

Psychiatry of Old Age, North Lee Mental Health Service, Cork, Ireland

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1320

Introduction: Dementia is a common diagnosis in service users seen by Psychiatry of Old Age (POA) Services. This clinical audit was conducted prior to the services engagement with a focus group, which aimed to explore the implementation of the “Appropriate prescribing of psychotropic medication for non-cognitive symptoms in people with dementia” (National Clinical Guideline No. 21) and identify additional resource requirements to be submitted for consideration by the HSE’s estimate process for 2023.

Objectives: Its aims were to evaluate:

- The prevalence of service users with a dementia diagnosis among those seen by the POA Service, from January 2018–June 2022
- The prevalence of co-morbid psychiatric diagnoses among those with a dementia diagnosis.
- The resources needed to manage currently active cases with a diagnosis of dementia, by evaluating MDT member involvement.

Methods: Data is routinely collected on service users treated by the POA service for service evaluation, including service users’ diagnoses, and current MDT member involvement. All service users seen by the POA service between Jan 2018 – June 2022 were included. The total number of service users, and service users with

dementia and mild Cognitive impairment were counted, in order to evaluate the prevalence of dementia. We then evaluated the proportion of those with dementia who had co-morbid psychiatric diagnoses. We then looked at currently active cases with dementia, and evaluated how many MDT members were involved in their ongoing care.

Results: 392 service users were treated by the service from Jan 2018–June 2022. Of these 104 cases were still active with the service. 152 (39%) of these service users had a diagnosis of dementia. Of those with dementia, 45% (68, n=152) also had another psychiatric co-morbidity. Psychosis was the most common psychiatric co-morbidity, seen in 22% of those with dementia (33, n=152). 12% of active service users with a dementia diagnosis were only seen in outpatients clinics only, 60% were seeing one MDT member, 28% were seeing multiple MDT members (n=25).

Conclusions: Dementia was the most common diagnosis among service users seen by the POA service. 45% of service users with dementia being seen by the POA service also had another psychiatric co-morbidity. Such patients require significant MDT input.

Underrated and Underestimated – Deprivation in Dementia. A Case Report

S. C. Steininger*, R. Frizi-Roser, S. Schneider, T.-V. Hoang and T. Zetzsche

Alterspsychiatrie, Clenia Schlössli, Oetwil am See, Switzerland

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1321

Introduction: Deprivation is widely known in children and adolescents and means a lack of social, emotional, or sensory stimuli, due to disabilities such as deafness, but also social isolation and reduced parental care. It may cause developmental disorders such as impaired language, motoric and social development. Little is known of the impact of social deprivation in demented patients. Stimulus shielding, which is a widespread option for psychiatric symptoms of dementia such as agitation, vocalization and aggressive behavior may – if frequently used- have similar effects on demented patients.

Objectives: We report the case of a 71-year-old patient with dementia caused by PSP (Progressive Supranuclear Palsy), who was in inpatient treatment due to continuous undirected vocalizations. She presented with inability to walk, dysarthria, aphasia, and hearing difficulties beside major mnemonic impairment. In a prior hospitalization and in her residency, she was frequently isolated from other patients due to loud screaming and vocalizations in terms of stimulus shielding by suspected overstimulation. In order to that, for four months, she developed progressive difficulties to speak, hear, understand, as well as gait disorders. In addition, the vocalizations increased.

Methods: We rated the symptoms due to deprivation, triggered by lack of mobilization, social experiences, visual, tactile and acoustic stimuli following a vicious circle of anxiety, vocalizations and recurrent isolations. Therefore, a multimodal therapy assessment was implemented, including daily physical therapy, mobilization, basal stimulation, social reintegration and basal conversation training.

Results: After a few days of high intensity treatment, speech reappeared in form of one- word sentences and proceeded to the ability to have short conversations. Mobility increased, starting from severe gait disorder, including the use of a wheelchair and emerged to the ability of walking up to 50 metres. Additionally, the undirected vocalizations improved and were reduced. In addition, hearing ability improved during the four-week treatment.

Conclusions: This case highlights the impact of deprivation in demented patients. Especially it shows that these symptoms can be reversible under a high intensity multimodal and multi- professional treatment within a few weeks. Therefore, stimulus shielding, should be carefully evaluated in order to prevent deprivation – and thus deterioration of the symptoms – in demented patients.

Practice recommendations to manage Alzheimer's disease based on the targeted behavioral and psychological symptoms

Y. Ouazzani Housni Touhami^{1,2,3*}, E. Layoussifi^{1,2,3} and R. Benjelloun^{1,2,3}

¹Faculty of Medicine, Mohammed VI University of Health and Sciences; ²Psychiatry Department, Cheikh Khalifa International University Hospital and ³Psychiatry Department, Mohammed VI International University Hospital, Casablanca, Morocco

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1322

Introduction: Behavioral and psychological symptoms (BPS) of Alzheimer's disease, known as neuropsychiatric symptoms, involve a range of symptoms that include agitation, psychosis (hallucinations, delusions), affective symptoms (depression and anxiety), apathy, and sleep disturbances. These behavioral and psychological symptoms harm the patients' daily lives and significantly burden their families. Managing BPS of Alzheimer's disease requires a targeted approach focused on each symptom to achieve a better therapeutic response.

Objectives: Providing practice pharmacological recommendations targeted to each of the behavioral and psychological symptoms of Alzheimer's disease.

Methods: A literature review was conducted using Medline via PubMed, Embase, PsycINFO, and Cochrane databases until September 2023.

Results: There is a consensus in the literature that non-pharmacological approaches should be recommended as the first-line treatment for most behavioral and psychological symptoms of Alzheimer's.

Second-generation antipsychotics (risperidone and olanzapine, with improved efficacy; aripiprazole and quetiapine, with better tolerance) are recommended for severe agitation states with a risk of self or hetero-aggression, as well as for persistent psychotic symptoms in Alzheimer's disease. The benefit-risk balance of these agents must be assessed, with close monitoring of heart arrhythmias, metabolic risk, orthostatic hypotension, and extrapyramidal symptoms. The recommendations suggest tapering antipsychotics within the first three months of their prescription. Selective

serotonin reuptake inhibitors (SSRIs) such as Escitalopram, Citalopram, and Sertraline can be considered a therapeutic option for persistent affective symptoms (depression and anxiety) with significant functional impairment or suicidal risk, severe apathy, or constant agitation. Minimum effective doses are recommended for Escitalopram and Citalopram due to the risk of QT interval prolongation. There is limited evidence regarding the effectiveness of benzodiazepines, mood stabilizers, cholinesterase inhibitors, and memantine for various behavioral and psychological symptoms; the benefit-risk ratio and therapeutic response do not support the prescription of these agents. Melatonin and Mirtazapine have limited benefits for sleep disturbances, while benzodiazepines, antihistamines, and antipsychotics should be avoided.

Conclusions: The pharmacological approach should target a thorough clinical assessment of the psychopathological dimensions of behavioral and psychological symptoms of Alzheimer's disease. The prescription should be based on evaluating the benefit-risk balance and adherence to literature recommendations for patient safety.

EPV0672

Mania and alzheimer disease, review and case report

M. Garcia Moreno^{1*}, A. De Cos Milas², L. Beatobe Carreño², P. Del Sol Calderón¹ and A. Izquierdo de la Puente¹

¹Psychiatry, Hospital Universitario Puerta de Hierro Majadahonda and

²Psychiatry, Hospital Universitario de Móstoles, Madrid, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1323

Introduction: There are numerous organic causes that can be related to affective symptoms such as neurological, metabolic, infectious and pharmacological. Neurological conditions associated to affective symptoms include vascular lesions, tumors, infections, seizures and dementia. Within cognitive impairment conditions, depressive symptoms are more frequent in vascular dementia and Alzheimer disease, and behavioral or manic symptoms in frontotemporal dementia although we cannot rule out less common associations.

Objectives: To review about organic mania due to dementia

Methods: We carry out a literature review about organic mania accompanied by a clinical description of one patient with manic symptoms and cognitive impairment.

Results: A 80-year-old male was admitted to the short-term hospitalization unit from the emergency department due to manifold symptoms. He had believed for weeks that he was millionaire and capable to cure all the diseases in the world, reason for which he had given away many of his belongings and had tried to register the patent for his invent. He also had future plans to invest all the money he earned from the patent in the construction of roads in Latin America. He had not previous history of mental illness. Neurological study concluded a diagnosis of Alzheimer disease. It was treated as a manic episode with a mood stabilizer and antipsychotic, with partial resolution of the condition.

Conclusions: It is common to find depressive symptoms in cognitive disorders. Although manic symptoms are much more frequent in frontotemporal dementia or other organic disorders, we can also

find them in patients with Alzheimer disease. Since there is no specific curative treatment for this disease, concomitant psychopharmacological treatment is recommended if manic symptoms appear.

Disclosure of Interest: None Declared

Differential diagnosis between frontotemporal dementia and bipolar disorder, review and case report

M. García Moreno^{1*}, A. De Cos Milas², L. Beatobe Carreño², P. Del Sol Calderón¹ and A. Izquierdo de la Puente¹

¹Psychiatry, Hospital Universitario Puerta de Hierro Majadahonda and

²Psychiatry, Hospital Universitario de Móstoles, Madrid, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1324

Introduction: Dementia can present with psychiatric symptoms even before the cognitive impairment, which makes difficult to establish an adequate diagnosis. There have described symptoms of this type in vascular dementia, frontotemporal dementia, Alzheimer disease and Lewy bodies dementia. Frontotemporal dementia has a prevalence of 9-20% and it's the third in frequency among degenerative dementia. It appears before the age of 65 years old and is more common in men. Two variants have been described, linguistic and behavioral. The behavioral one has usually an initial psychiatric presentation, with behavioral disorders, disinhibition and personality changes. Therefore it's important to make an adequate differential diagnosis with late onset bipolar disorder.

Objectives: To review about frontotemporal dementia and its differential diagnosis with late onset bipolar disorder.

Methods: We carry out a literature review about frontotemporal dementia and its differential diagnosis with late onset bipolar disorder, accompanied by a clinical description of one patient with behavioral disturbance and language disorder.

Results: A 59-year-old female was admitted to the short-term hospitalization unit from the emergency department due to behavior disorder. She had no relevant personal or familiar psychiatric history up to two years before when she received diagnosis of bipolar disorder. She presented behavioral disorganization, psychomotor restlessness, verbal aggressiveness, verbiage, insomnia and decreased intake. Psychopathological examination became difficult due to her language disorder since she presented an incoherent speech with paraphasias and loss of the common thread. Neurological study guided diagnosis to frontotemporal dementia even though they left the psychopharmacological treatment to our discretion. Olanzapine 5 mg twice a day was initiated, and behavioral improvement was observed. However, the patient maintained a significant functional impairment.

Conclusions: Psychiatric presentation is frequent in dementia, even before cognitive failures which makes essential an exhaustive differential diagnosis. It's important to consider the diagnosis of frontotemporal dementia in those patients who debut with behavioral disturbance in the 50s. Psychopharmacological treatment is only symptomatic so functional recovery should not be expected.

Disclosure of Interest: None Declared

doi: 10.1192/j.eurpsy.2024.1325

Introduction: Affective disorders are associated with cognitive deterioration, manifested by an increased risk of developing dementia. Late-onset bipolar disorder (BD) establishes a dynamic interaction between dementia and BD, considering its particular manifestations in old age.

Objectives: Provide a comprehensive overview of the clinical and epidemiological attributes specific to late-onset BD, elucidating its interplay with dementia.

Methods: We conducted a literature search on PubMed in August 2023, using the following terms: late-onset bipolar disorder AND dementia. Only systematic reviews and meta-analysis were included with no year or language restrictions. Three articles were eligible for this review: two systematic reviews and one meta-analysis.

Results: Late-onset BD can be defined as a secondary condition and may result from an expression of lower vulnerability to BD, when compared to early-onset BD. On the other hand, late-onset BD may be conceptualized as a subtype of pseudodementia, or even considered a risk factor for dementia. In fact, this particular association with dementia supports the existence of a specific class of BD, i.e. BD type VI. Such diagnostic overlap might be explained by common factors that have been associated with both BD and dementia, such as cardiovascular risk factors, systemic inflammation, stress and levels of baseline cognitive reserve. Despite the commonalities, other aspects, such as family history and prior history of a mood disorder, may help to make the differential diagnosis between late-onset BD and dementia.

Conclusions: There is a diagnostic challenge between dementia and the neurocognitive decline associated with BD, particularly in the case of a late-onset BD. Although the available evidence is limited, current evidence demonstrates that BD can indeed be seen as a risk factor for dementia. Therefore, cognitive impairment in individuals with BD should not be overlooked.

Factors associated with psychotropics adverse effects in elderly psychiatric inpatients

W. Abid, M. Turki, B. Ben jmeaa, A. Zribi, M. A. Megdiche*, S. Ellouze, N. Halouani and J. Aloulou

Psychiatry B department, Hedi chaker university hospital, sfax, Tunisia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1326

Introduction: Adverse effects (AEs) of psychotropic drugs are more frequent and potentially more dangerous in elderly subjects

(ES), probably due to a greater frequency of somatic comorbidities, as well as polymedication.

Objectives: The aims of this study were to determine the prevalence of AEs of psychotropic treatment among ES hospitalized in psychiatry, and to identify the associated sociodemographic and clinical factors.

Methods: We conducted a retrospective and descriptive study. It concerned male patients aged at least 60 years, hospitalized in the psychiatry B department at CHU Hedi Chaker (Sfax, Tunisia) between 2018 and 2022. We collected demographic and clinical data from their medical records using a pre-established form.

Results: We included 30 patients. The average age was 64 years. Addictive behaviors were reported in 60%, and somatic histories were noted in 53.3% of patients. The three most frequent psychiatric diagnoses were schizophrenia (43.3%), bipolar disorder (33.3%) and depressive disorder (13.3%). Among our patients, 10% experienced adverse psychotropic drug reactions: orthostatic hypotension 6.7%; neurological AEs 3.3%. Univariate analysis showed no significant relationship between sociodemographic variables and psychotropic drug AEs. Patients with bipolar disorder were more likely to develop AEs of psychotropic treatment ($p=0.04$).

Conclusions: Our results suggest that special attention should be paid to avoiding psychotropic medication AEs in psychiatric inpatients ES. Indeed, extra precautions need to be taken in this population due to their reduced ability to report their symptoms.

Meta-analysis of generalization reliability of the Montreal Cognitive Assessment (MoCA) questionnaire in cognitive impairment

R. Fernández Fernández^{1*}, Á. Izquierdo de la Puente², P. del Sol Calderón², M. Vizcaino da Silva² and A. Rodríguez Rodríguez³

¹Psychiatry, Hospital Universitario Infanta Cristina, Parla; ²Psychiatry, Hospital Universitario Puerta de Hierro Majadahonda, Majadahonda and ³Psychiatry, Hospital HM Puerta del Sur, Móstoles, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1327

Introduction: Dementia is a syndrome of high prevalence and health impact. The Montreal Cognitive Assessment (MoCA) questionnaire is a screening tool whose use has increased in recent years, especially in cases of mild cognitive impairment. Some studies suggest that its ability to detect cognitive impairment, especially in early or mild stages, seems to be greater than gold-standard instruments (Ciesielska et al., 2016).

Objectives: We have performed a meta-analysis of reliability generalization to see if different adaptations and use in different contexts show consistent results.

Methods: We performed a literature search in PscINFO and Medline with the terms "Cognitive impairment" AND "internal consistency" AND "Cronbach", using the following inclusion criteria:

1. Be a study in which the MoCA scale was applied to a population sample.
2. Studies published in the last 10 years.

3. Studies that provide the reliability coefficient or sufficient data to calculate them.
4. Be written in English or Spanish.

We have limited our study to the last 10 years and the English language has given us a total of 19 results in Medline and 132 results in PscINFO. Subsequently, we completed this search by snowball sampling.

A random effects model was assumed for the statistical calculations and the transformation of our values using the Hakstian and Whalen (1976) proposal. Statistical analysis was performed with the MAJOR package of the Janovi program, based on the R environment.

Results: We obtained a mean reliability for the transformed test scores of 0.42 (95% CI: 0.38 - 0.45), as well as high heterogeneity measured by Cochran's Q statistic and the I^2 index, which is attributed after analysis of moderating variables to the geographical adaptation of the questionnaire and the type of patient on whom it is applied. Our Funnel Plot graph indicates that we do not appear to have committed a publication bias.

Conclusions: Our meta-analysis shows high heterogeneity, mainly explained by the population of origin, both geographically (continent) and clinically (presence of primary cognitive impairment or not), with special incidence in those with impairment secondary to other pathologies, mainly neurological. However, we should consider the high probability that we have not included important variables in our analysis that could increase the explanatory power of our model.

Gender differences in the association of dementia and depression

R. Fernández Fernández^{1*}, P. del Sol Calderón² and Á. Izquierdo de la Puente²

¹Psychiatry, Hospital Universitario Infanta Cristina, Parla and ²Psychiatry, Hospital Universitario Puerta de Hierro Majadahonda, Majadahonda, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1328

Introduction: The evolution of depression and dementia has been shown to differ in some studies. For example, a history of recent depression has been found to be associated with an increased risk of Alzheimer's disease in women (Kim et al., 2021).

Objectives: We will use data collected from several dementia studies to analyze whether the presence of depression at diagnosis is more frequent in women.

Methods: We conducted a systematic search for articles analyzing the presence of depression in patients with a diagnosis of dementia. We analyzed by Student's t test the presence of depression according to sex, considering the alternative hypothesis that there is more depression in female than male patients.

Results: The mean age of the sample was 71 years. We obtained a statistically significant Student's t test ($p=0.02$).

Conclusions: The approach and approach to depression in the elderly as a risk factor could be different according to sex. For example, some studies have proposed the use of hormone replacement therapy (HRT) after menopause as a possible protective factor

for the subsequent development of dementia (Kim et al., 2022). Further studies are recommended in this regard.

Neuropsychiatric symptoms in frontotemporal dementia: a case report

A. Izquierdo De La Puente^{1*}, P. del Sol Calderón¹ and R. Fernandez Fernandez²

¹Psychiatry, Hospital Universitario Puerta de Hierro de Majadahonda, Majadahonda and ²Psychiatry, Hospital Universitario Infanta Cristina, Parla, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1329

Introduction: We present the case of a 70-year-old man who, after presenting atypical depressive symptoms, was diagnosed with incipient frontotemporal dementia.

Objectives: Through the presentation of the case, a brief review is made of the affective prodromes of frontotemporal dementia

Methods: The patient, who had no personal history of interest, suddenly began to present depressive symptoms consisting of marked irritability, dysphoric mood, anxious semiology with a subjective feeling of anguish, maintenance insomnia and a feeling of lack of self-control, with a tendency towards verbal heteroaggressiveness. The patient reported all these symptoms with great suffering. After one year of treatment with venlafaxine 300g DMD and quetiapine 400g DMD, with one admission to the short-stay inpatient unit for self-harm threats, the patient had not experienced any improvement. In addition, during this year, the patient's family began to observe small memory lapses that affected his daily functioning, making the patient progressively more dependent.

Results: In view of this clinical picture, it was decided to request an MRI and a brain PET scan, where deficits in the frontal and temporal regions were observed, and a diagnosis of incipient frontotemporal dementia was made.

Conclusions: Frontotemporal dementia is the third most common dementia in people over 65 years of age. About half of the patients debut with psychiatric symptoms, one of them being depressive symptoms. Treatment is focused on the use of psychotropic drugs with the aim of symptom management. Olanzapine or aripiprazole are effective for psychotic symptoms or acute agitation. For more subacute conditions, SSRIs or trazodone are recommended. The iACOs are not recommended, because they are ineffective and worsen neuropsychiatric symptoms.

Disclosure of Interest: None Declared

EPV0679

Major depressive episode in the elderly. Use of maintenance ECT: a case report.

A. Izquierdo De La Puente^{1*}, P. del Sol Calderón¹, R. Fernandez Fernandez² and M. Garcia Moreno¹

¹Psychiatry, Hospital Universitario Puerta de Hierro de Majadahonda, Majadahonda and ²Psychiatry, Hospital Universitario Infanta Cristina, Parla, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1330

Introduction: We present the case of an elderly patient with a severe depressive episode who, in order to maintain psychopathological stabilisation, receives ECT on an outpatient basis.

Objectives: The objective is to briefly review the use of ECT as a maintenance treatment for severe depression in the elderly.

Methods: Patient aged 76 years, multipathological, with a history of hypertension, DM and LBP. Femoral head fracture, myelodysplastic syndrome, severe osteoporosis with vertebral crushing, requiring rescue treatment with tramadol, and renal failure.

She came for consultation, reporting depressive symptoms of months' duration, together with delusions of ruin and nihilism. Despite antidepressant and stabilising treatment with duloxetine at daily doses of 120mg, extended-release quetiapine 600mg, lorazepam 2.5mg and mirtazapine 45mg, the patient began to show negative behaviour towards accepting food, clinophilic behaviour and abandonment, which led to her being admitted to the short-term hospitalisation unit.

Results: Due to the severity of the depressive symptomatology, it was decided to start ECT, administering a total of 12 sessions, which were effective, and outpatient follow-up was resumed. However, after a week, the patient again began to show marked apathy and abulia, as well as complete anorexia lasting more than 24 hours, which led to a new admission. It was then that it was decided to maintain the ECT treatment, on an outpatient basis, as maintenance treatment, together with pharmacological treatment.

Conclusions: ECT is indicated in severe depression, with or without psychotic symptoms, with malnutrition and organic pathology. According to studies, it has a beneficial response of more than 60%. However, the rate of receiving depressive symptomatology in a severe episode is high, despite ECT, so studies and clinical practice recommend maintenance ECT. It is usual to start with weekly sessions, and progressively space them out to maintain the minimum that guarantees stability.

EPV0680

Schizoaffective Disorder and Parkinson's Disease: a case report

A. Izquierdo De La Puente^{1*}, P. del Sol Calderón¹ and R. Fernandez Fernandez²

¹Psychiatry, Hospital Universitario Puerta de Hierro de Majadahonda, Majadahonda and ²Psychiatry, Hospital Universitario Infanta Cristina, Parla, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1331

Introduction: We present the case of a patient with schizoaffective disorder and Parkinson's disease (PD), requiring treatment adjustment, with the use of high doses of quetiapine for the treatment of psychotic symptomatology.

Objectives: The aim is to briefly review the treatment of dopaminergic psychosis in the elderly.

Methods: Patient aged 86 years, institutionalised, presenting severe episodes of behavioural alteration, high anxiety and delusions of harm, together with auditory and visual

hallucinations. As relevant physical history, the patient has AHT, aortic insufficiency, and bladder cancer operated on in 2012. As psychiatric history of interest, the patient has been diagnosed since his 30s with schizoaffective disorder, Parkinson's disease and moderate-severe cognitive impairment secondary to the previous two.

As usual treatment, in addition to anticoagulation and antihypertensive therapy, the patient has been receiving L-dopa for his PD for years, antidepressant treatment with escitalopram 10mg, haloperidol 80 drops a day, divided into three doses, and lormetazepam 2mg as a hypnotic.

In addition to the symptoms described above, the patient had episodes of confusional features, as well as marked stiffness in the cogwheel and significant gait disturbance, having suffered several falls without serious repercussions.

Results: Due to the comorbid neurological pathology, it was decided to progressively modify the treatment, withdrawing the benzodiazepine due to the risk of confusional disorder and replacing it with trazodone. Antipsychotic treatment was gradually replaced by extended-release quetiapine, reaching a maximum dose of 800mg. Likewise, escitalopram treatment is replaced by sertraline.

With this adjustment, there was an improvement in the psychotic symptoms, as well as in the anxious symptoms. Episodes of distress are NOT observed, and the patient's functionality improves, allowing him/her to participate in daily activities, both cognitive stimulation and physiotherapy.

Conclusions: The Spanish Society of Psychogeriatrics recommends that before using antipsychotics, it is advisable to first treat the underlying potentially treatable causes (pain, infections, toxic effects of drugs...), assess non-pharmacological interventions and always, if the use of antipsychotics is required, assess the risk-benefit ratio.

In relation to the above, it is not surprising that in the elderly, the use of second-generation antipsychotics is recommended in the first place, as opposed to the classical ones. The latter are only recommended in emergency situations where an almost immediate effect is required.

For dopaminergic psychosis, there are only controlled trials with clozapine. However, due to prescribing difficulties, aripiprazole or quetiapine is recommended in the first instance.

"Neuropsychiatric manifestation of hyponatremia: a case report"

N. El Moussaoui*, S. Bahetta, L. Tbatou, S. Belbachir and A. Ouanass

Arrazi University Psychiatric Hospital, Salé, Morocco

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1332

Introduction: "Electrolyte abnormalities are commonly encountered in daily clinical practice, and their diagnosis relies on routine laboratory results. Electrolyte disturbances can affect the brain among many other organs and tissues and must be promptly recognized, as they can lead to serious and potentially life-threatening complications if neglected or not appropriately

treated. Neurological manifestations reflect the severity of acute neuronal dysfunction and thus require urgent treatment. Acute and/or severe electrolyte imbalances can manifest with rapidly progressive neurological symptoms, seizures, and psychiatric manifestations. They are more frequently observed in patients with sodium disorders (especially hyponatremia), hypocalcemia, and hypomagnesemia.

Objectives: Were the psychiatric manifestations secondary to hyponatremia or epilepsy? Or is it a comorbidity? What are the risk factors? And what is the appropriate course of action for this type of patient?"

Methods: We present, through a clinical case, the situation of a 64-year-old patient who experienced status epilepticus secondary to hyponatremia, requiring hospitalization in the neurology department. Subsequently, she developed psychiatric manifestations with a marked change in behavior. She began experiencing symptoms of anxiety and depressive mood, headaches, somatic complaints, and social isolation. Her condition gradually worsened, necessitating hospitalization in the psychiatry department 3 years later.

Results: The patient was placed on Carbamazepine by her neurologist, and since then, she has not experienced epileptic seizures. Her follow-up electrolyte panel initially showed slight disturbances before normalizing. Psychiatric manifestations were concurrent with these somatic symptoms and worsened over time. During her psychiatric hospitalization three years later, after a thorough evaluation, she was prescribed Sertraline and Risperidone in combination with Carbamazepine, resulting in a significant improvement in her condition.

Conclusions: In summary, this case illustrates the critical impact of electrolyte abnormalities on both neurological and psychiatric health, especially in older patients. Understanding risk factors associated with electrolyte imbalances is crucial for effective diagnosis and management, particularly in the elderly. This underscores the importance of a multidisciplinary approach to address the potential serious consequences of electrolyte disturbances on overall patient well-being.

EPV0684

Cytoprotective mechanism of cerebro-cognitive reserve

A. Sidenkova*

Psychiatry, Ural State Medical University, Yekaterinburg, Russian Federation

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1333

Introduction: Consideration of the reserve problem would be incomplete without an analysis of the cytoprotective mechanism. The predominant molecular hallmark of aging and degeneration is the accumulation of altered gene products. Moreover, several conditions, including protein, lipid, or glucose oxidation, disrupt redox homeostasis and lead to the accumulation of unfolded or misfolded proteins in the aging brain in case of AD, and other neurodegenerative diseases that have as a common denominator abnormal protein production, mitochondrial dysfunction and oxidative stress. Some authors classify aging, pathological aging, and neurodegeneration as "protein conformational diseases".

Objectives: scientific publications

Methods: analytical review

Results: The central nervous system has evolved a conserved unfolded protein response mechanism to cope with the accumulation of misfolded proteins. As one of the main intracellular redox systems involved in neuroprotection, the vitagene system becomes a potential neurohormetic target for novel cytoprotective interventions. Vitagens encode the cytoprotective heat shock proteins (Hsp) Hsp70 and heme oxygenase-1, as well as thioredoxin reductase and sirtuins. The cellular stress response is the ability of a cell to withstand stressful conditions, including the heat shock response. The production of heat shock proteins, including protein chaperones, is necessary for the folding and repair of damaged proteins, which promotes cell survival to avoid apoptosis. «Molecular chaperone» are proteins that function as part of an ancient defense system in our cells. They promote cell survival by sequestering damaged proteins and preventing their aggregation. Chaperone complexes are involved in the regulation of mitochondrial functions, assembly of the cytoplasmic proteolytic system of brain cells. The cellular response to stress requires the activation of survival pathways that are under the control of protective genes called vitagens. Vitagens are involved in the production of heat-shock protein molecules, glutathione, and bilirubin. They have antioxidant and anti-apoptotic activity and provide protection against oxidative stress.

Conclusions: Studies have shown that the heat shock response contributes to the maintenance of cellular homeostasis, the establishment of a cytoprotective state in a wide range of human diseases, including inflammation, cancer, aging, and neurodegenerative disorders. Endogenous proteins can be manipulated by food or pharmacological compounds, which represents an innovative approach to therapeutic intervention in neurodegenerative disorders, actually influencing reserve mechanisms and adaptive capacity.

Platelet enzymatic activities in patients with late-onset schizophrenia spectrum disorders

T. Prokhorova*, I. Boksha, O. Savushkina, E. Tereshkina, E. Vorobyeva and G. Burbaeva

FSBSI "MENTAL HEALTH RESEARCH CENTRE", Moscow, Russian Federation

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1334

Introduction: Impairments in energy metabolism, glutamate neurotransmitter and antioxidant systems contribute substantially in development of schizophrenia spectrum disorders, especially in late-onset psychosis (LOP).

Objectives: Revealing subgroups of patients with LOP by determining activity of platelet enzymes of energy, glutamate, and glutathione metabolism.

Methods: 62 women of 52-89 years old were studied, with late onset schizophrenia spectrum disorders (F20.0, F25, F22.0, F06.2 by ICD-10). PANSS with its subscales was used to assess the severity of psychotic symptoms. Scores by PANSS and activity levels of

platelet cytochrome c-oxidase (COX), glutamate dehydrogenase (GDH), glutathione reductase (GR) and glutathione-S-transferase (GST) were evaluated twice: before and on the 28-th day of antipsychotic treatment. Activities of COX, GDH, GR, and GST were measured in 37 women of 50-84 years old comprising the control group.

Results: Clustering of patients by the enzymatic activities resulted in 2 clusters (C1 and C2) significantly different by COX and GST ($p < 0.001$). In C1 ($n=40$), as compared with control, reduced level of GDH activity before and after treatment ($p=0.049$ and $p=0.032$, respectively) and a reduced level of GR activity before treatment ($p=0.026$) were revealed. In C2 ($n=22$), as compared with the control, COX activity was increased before and after treatment ($p=0.0001$), GDH activity was decreased before and after treatment ($p=0.0002$ and $p=0.0001$, respectively), and GST activity was decreased before and after treatment ($p=0.029$ and $p=0.0029$, respectively). GR activity was not significantly changed in both clusters. Significant correlations were found between enzymatic activities and scores by psychometric scales: in C1, GR activity positively correlated with the score reduction (delta) by PANSS-Pos ($R=0.45$, $p=0.004$), by PANSS-Psy ($R=0.44$, $p=0.005$), and by PANSS ($R=0.47$, $p=0.002$), and GST activity – with the score reduction by PANSS-Psy ($R=0.315$, $p=0.048$). In C2 ($n=22$), GDH activity negatively correlated with the score reduction by PANSS-Pos ($R=-0.41$, $p=0.050$) and by PANSS ($R=-0.49$, $p=0.021$).

Conclusions: The different correlations revealed in two separated clusters between enzymatic activity levels and clinical measures characterizing the antipsychotic treatment efficacy will allow us to approach differentiated predicting the effectiveness of pharmacotherapy using the biochemical parameters.

Disclosure of Interest: None Declared

EPV0687

Clustering patients with late-life depression by blood glutathione-dependent enzymatic activities for stratification of a heterogeneous group

T. Prokhorova*, I. Boksha, O. Savushkina, E. Tereshkina, E. Vorobyeva and G. Burbaeva

FSBSI "MENTAL HEALTH RESEARCH CENTRE", Moscow, Russian Federation

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1335

Introduction: We have previously found significant alterations in activities of glutathione dependent enzymes in blood cells of patients with late-life depression (LLD) compared with age-matched controls.

Objectives: The revealing subgroups of LLD patients by glutathione-metabolism enzymes' activities in blood cells using cluster analysis.

Methods: LLD patients ($n=101$) of 60-86 age (69 patients with recurrent depression (RD), 23 with bipolar disorder (BD) and 9 patients with a single depressive episode (DE)) were assessed by Hamilton depression rating scale (HAMD-17), and Hamilton Anxiety Rating Scale (HARS). Activity levels of glutathione reductase (GR) and glutathione S-transferase (GST) were

determined in patients' platelets (-pl) and erythrocytes (-er). The control group consisted of 51 peoples 55-84 years old without mental pathology. Cluster analysis module of the STATISTICA software was used for clustering the patients by baseline blood parameters.

Results: Three clusters of patients were obtained: C1, $n=39$, C2, $n=31$, C3, $n=31$, differing significantly in all biochemical parameters (Kruskal-Wallis test, $p<0.001$), except GST. When compared with control group by Mann-Whitney test, GST-pl, GST-er, and GR-er were significantly decreased in C1; GST-er was significantly increased in C2; GST-pl, GR-pl, and GR-er were significantly decreased in C3. Several significant correlations were found between the measured parameters and scores by HDRS or HAMD-17. In C1, baseline activity of GST-er correlated with total scores by HAMD-17 ($R=0.335$, $p=0.043$) after treatment. In C2, baseline activity of GR-er correlated with total scores by HARS ($R=-0.376$, $p=0.037$) after treatment and GR-pl correlated with delta scores by HAMD-17 under the treatment ($R=0.484$, $p=0.006$). No significant correlations were found in C3. Patients with BD distributed significantly unevenly between C1, C2, and C3, with significantly more BD patients clustering in C1 (61%) compared with C2 and C3 (Yates-corrected Chi-square = 7.73, $p=0.0054$), whereas patients with RD and DE distributed evenly.

Conclusions: Patterns of activity levels for glutathione-dependent enzymes in patients with BD differ from those in patients with RD and DE. Significant correlations of the measured biochemical parameters with scores by HDRS or HAMD-17 assessed after the treatment and evidenced for the treatment efficacy seem to be promising biomarkers for further evaluation of the treatment efficacy in heterogeneous group of LLD patients using the proposed approach to their stratification into subgroups.

Aberrant Functional Connectivity Between Regions Involved in Belief Evaluation and Processing of Bodily Information in Patients with Somatic Delusions

Y. Panikratova¹, E. Abdullina¹, A. Dudina^{1*}, A. Andrushchenko², G. Kostyuk², D. Romanov^{3,4}, E. Ilina³, M. Magomedagaev³, P. Iuzbashian³ and I. Lebedeva¹

¹Laboratory of Neuroimaging and Multimodal Analysis, Mental Health Research Center; ²Mental-health Clinic No.1 named after N.A. Alexeev; ³Department of Psychiatry and Psychosomatics, I.M. Sechenov First Moscow State Medical University and ⁴Department of borderline mental pathology and psychosomatic disorders, Mental Health Research Center, Moscow, Russian Federation

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1336

Introduction: According to the two-factor theory of delusional belief (Coltheart. Ann N Y Acad Sci 2010; 1191 16-26), explaining the presence of a delusion requires a combination of two neuropsychological impairments. The first deficit initially prompts the delusional belief and defines its content, whereas the second deficit – aberrant belief evaluation – interrupts the

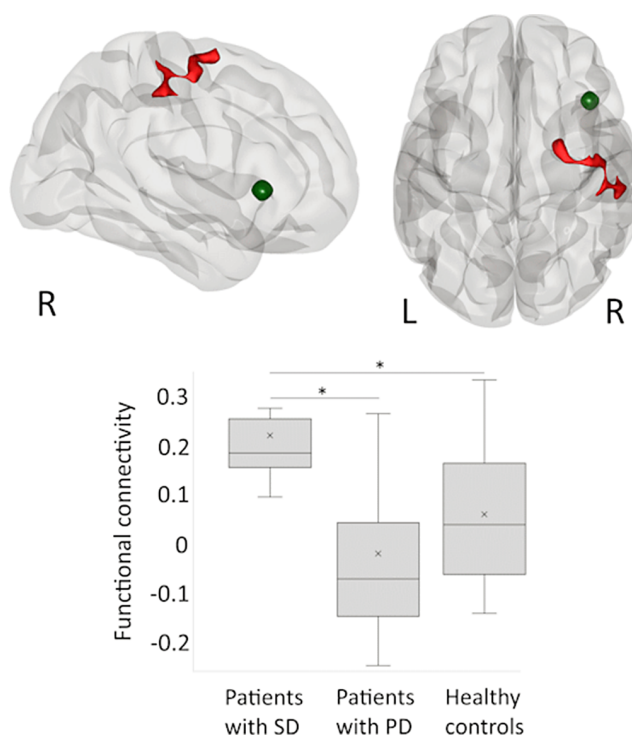

rejection of a delusional belief and is common for different types of delusions. The second deficit is associated with compromised functioning of the right ventral frontal/anterior insular cortex (r-VF/AI; Darby et al. Brain 2017; 140 497-507). However, neural correlates of the first deficit in different types of delusions remain obscure.

Objectives: The aim of the study was to search for regions whose functional connectivity with r-VF/AI is different between patients with somatic delusions (SD) and persecutory delusions (PD) and to further clarify the results by comparing clinical groups with healthy controls. We hypothesized that each clinical group is characterized by aberrant functional connectivity between a region, associated with poor belief evaluation (r-VF/AI), and a region, presumably associated with a neuropsychological impairment specific to the corresponding type of delusions.

Methods: Patients with delusional disorder or paranoid schizophrenia ($n = 23$) and healthy controls ($n = 9$; 5 females; mean age 36.2 ± 1.3) underwent resting-state fMRI (Philips Ingenia 3T). Nine patients had SD (5 females; mean age 40.3 ± 7.9) and fourteen patients had PD (3 females; mean age 35.6 ± 10.2). The clinical groups were compared in terms of whole-brain functional connectivity of r-VF/AI (ROI-to-voxel analysis in CONN; RRID: SCR_009550; www.nitrc.org/projects/conn). Statistical thresholds were $p < .005$ voxelwise, $p[\text{FDR}] < .05$ clusterwise. Each clinical group was compared with controls in terms of functional connectivity between r-VF/AI and previously identified regions with between-group differences in connectivity (ROI-to-ROI analysis). Age was a covariate of no interest in all analyses.

Results: Patients with SD compared to patients with PD and healthy individuals had higher functional connectivity between the r-VF/AI and a cluster in the right precentral and postcentral gyri extending to supramarginal and superior frontal gyri (Figure 1).

Image:

Conclusions: The regions whose functional connectivity with r-VF/AI was aberrant in patients with SD are involved in the processing of tactile, proprioceptive, and visceral information. Our results coincide with a suggestion that the evaluation of beliefs related to bodily sensations is disturbed in patients with SD.

Are antipsychotics carcinogenic?: A review of the literature

S. Walha, D. Mezri, K. Mahfoudh, S. Hamzaoui, A. Ouertani, U. Ouali, A. Aissa* and R. Jomli

"Psychiatry A", Razi Hospital, Manouba, Tunisia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1337

Introduction: Antipsychotics are currently widely prescribed for various mental disorders. A presumption of a potential carcinogenic effect of antipsychotics was raised by certain studies. There are few data in the literature on this subject.

Objectives: Study the relationship between the use of antipsychotics and the risk of cancer.

Methods: A systematic literature review was carried out on PubMed looking for articles in English, published during the last decade (2013-2023), using the keywords "Antipsychotics" and "Cancer". We included all articles studying the relationship between antipsychotics use and cancer risk.

Results: Nine articles were included in our study, the majority of which focused on breast cancer. The results regarding breast cancer were discordant: although three studies did not show an association between the administration of antipsychotics and breast cancer, more recent studies have proven the opposite. Indeed, chronic exposure to antipsychotics, particularly those raising prolactinemia, was significantly associated with an accumulated risk of breast cancer, especially with positive estrogen receptors, whereas prolactin-sparing antipsychotics were not associated with it. Regarding hematologic malignancies, unlike other antipsychotics, long-term use of clozapine was associated with a high risk of malignancy, and had a greater effect on mortality from lymphoma and leukemia than to agranulocytosis. On the other hand, it has been proven that the use of atypical antipsychotics is associated with a reduced risk of lung cancer.

Conclusions: Data from the literature regarding the carcinogenic potential of antipsychotics remain discordant and inconclusive. The most recent studies are worrying and highlight in particular an association between the use of antipsychotics and the increased risk of breast cancer. If these data are confirmed in future studies, this will undoubtedly impact the benefit-risk balance when making therapeutic decisions.

Exploratory study of a meditation intervention program on Portuguese breast cancer survivors

A. Torres^{1,2*}, C. Ribeiro³ and S. R. Costa³

¹Department of Psychology and Education, University of Beira Interior, Covilhã; ²Department of Education and Psychology of University of Aveiro, Center for Health Technology and Services Research (CINTESIS@RISE), Aveiro and ³Department of Education and Psychology, University of Trás-os-Montes e Alto Douro, Vila Real, Portugal

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1338

Introduction: Cancer patients, namely breast cancer survivors, are highly vulnerable to psychological morbidity. Noninvasive interventions are incentivized to promote the mental health and quality of life of cancer survivors. Recent studies provided evidence supporting the use of meditation as a promising adjuvant tool for improving the mental health and quality of life of cancer survivors.

Objectives: The present study aims to carry out a clinical trial to evaluate the effects of an online group of meditation program of Kundalini Yoga on breast cancer women, through a longitudinal and randomized research design, in the following variables: psychological morbidity, self-compassion, spirituality, and quality of life.

Methods: This study had the participation of 35 participants distributed randomly for 3 equivalent groups (N=11 EG, N=13 ACG, N=11 PCG), with the diagnosis of breast cancer, aged between 34 and 78 years.

The sample of women with breast cancer was randomly selected from a breast cancer support association.

The protocol was applied online individually on pre-test, post-test, and 1-month follow-up moments, in 3 comparison groups: 1) the Experimental Group(EG), who practiced yoga Kundalini meditation; 2) the Active Control Group(ACG) that practiced relaxation; 3) the waiting list Passive Control Group(PCG). Intervention sessions were carried out for the EG and the ACG, in an online format, lasting about 30 minutes, weekly, for 8 weeks. Statistical analyses were considered at a 0.05 significance level. All analyses were performed with IBM SPSS, version 27.

Results: The results showed that the group that did yoga kundalini meditation (EG) had benefits, unlike the control groups, in the variables of emotional functioning, global spiritual well-being, and personal well-being. There were statistically significant differences in the overall self-compassion score when comparing the 3-time points in all groups. The sub-scale of self-kindness and transcendental well-being shows an increase significantly between the 3 moments in the active control group. The passive control group performed significantly worse over time in the self-kindness.

Conclusions: Based on preliminary results, the Experimental Group (EG) exhibited improvements in Self-Compassion, Spirituality, and Emotional Functioning (as evaluated by the QLQ C-30) following eight consecutive weeks of online Kundalini Yoga Meditation practice. These findings contribute to the growing body of evidence supporting meditation's potential to enhance life quality and spiritual well-being in individuals with breast cancer. These preliminary findings suggest that further research in this promising field is warranted.

Network Analysis of the Relationships Between Symptoms, Functioning, and Sleep/Fatigue in Colorectal Cancer Patients

J. Sim^{1,2*}, J. Yu¹ and Y. Yun³

¹Department of AI convergence; ²Department of Psychiatry, College of Medicine, Hallym University, Chuncheon and ³Department of family medicine, Seoul National University, Seoul, Korea, Republic Of

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1339

Introduction: Among the various patient experiences, cancer-related fatigue and sleep disturbances emerge as pivotal aspects that can substantially impact individuals' quality of life. There exists a relative scarcity of research focusing on the intricate relationship between symptoms, functioning, fatigue, and sleep disturbances in colorectal cancer (CRC) patients.

Objectives: In this context, the current research endeavors to apply advanced statistical methodologies to elucidate the complex relationships between symptoms, functioning, fatigue, and sleep disturbances. By exploring the intricate web of patient characteristics, clinical factors, psychosocial elements, this study aims to construct a holistic model that not only captures the nuances of colorectal cancer patients' experiences but also uncovers potential avenues for intervention and support.

Methods: In our cross sectional study, we administered the European Organization for Research and Treatment of Cancer Quality of Life Questionnaire Core 30 (EORTC QLQ-C30), the Quality of Life Questionnaire Colorectal Cancer Module (QLQ-CR29) to 987 patients who were surgically-treated for CRC from the tertiary hospital from 2013 through 2018. To confirm the relationship between symptoms of CRC patients, univariable logistic regression was used to examine the potential relationship between independent variables and the occurrence of fatigue and sleep disorders. Least Absolute Shrinkage and Selection Operator (Lasso) was used for variable selection. The selected variables were then applied to a multivariate logistic regression analysis to examine the most influential predictors of fatigue and sleep disturbance. Finally, gaussian graphical models (GGM) were used to identify potential interactions between characteristics, symptoms, functioning, with fatigue, and sleep disturbances in CRC. In this study, Directed Acyclic Graph (DAG) was used to identify causal dependency and path of variables.

Results: About 10.4% of study participants reported experiencing fatigue. Sleep problems were reported by 15.8% of the study participants. Multivariable logistic regression analysis using Lasso showed that sleep problem (odds ratio [OR]=2.34; 95% CI, 1.03-5.31), physical, role, and emotional functioning, pain, dyspnoea, and appetite loss were significant predictors of fatigue, while emotional functioning, dyspnoea, and appetite loss were significant predictors of sleep problem. The variables that were directly linked to fatigue were role functioning, emotional functioning, dyspnoea, appetite loss, body image and trouble with taste. The variables that were directly linked to sleep problem were emotional functioning and appetite loss.

Conclusions: In conclusion, there were complex relationships between symptoms, functioning, fatigue, and sleep disturbances. The symptom network of CRC patients showed different patterns toward fatigue and sleep.

Case Report and Literature review. Neuropsychiatry Manifestation of Frontal Lobe Neoplasm- Meningioma. Prevalence, Presentation and Pathogenesis

U. Anyeji MD* and O. Alli-Balogun MD

Psychiatry, BronxCare Health System, Bronx, United States

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1340

Introduction: Meningiomas are the most frequent primary brain tumor. Although most Meningiomas are benign, their location in the central nervous system can predict symptomatology which could result in significant morbidity and mortality. However, due to the slow-growing nature, meningiomas are usually asymptomatic, and diagnosis is often made incidentally on neuroimaging or at an autopsy. The incidence rate is 1.2-fold higher in Black Americans than White Americans. Neuropsychiatry manifestation might be only initial presentation; thus, psychiatrists are often the first to see these patients, and the correct diagnosis may be made only when the tumor has grown to a considerable size and begun to displace the brain.

Objectives: The aim of this study is to understand the biological basis of psychiatry symptoms in patients with Frontal Lobe meningiomas.

Methods: A review of literature and individual patient data analysis was conducted. The literature review was conducted on PubMed, Medline, MeSH, Google Scholar, and Mount Sinai's Levy Library using the key words; meningioma, meningioma with psychiatric symptoms, psychosis, depression, neuropsychiatry manifestation of meningiomas.

Results: The review revealed that 88% of brain tumors and psychiatric symptoms are located in the frontal region. Meningiomas accounts for 13%-26% of intracranial tumors. There is a reported low incidence due to its slow growing nature and are usually asymptomatic. Incidence of meningiomas is predominant in females, and is attributed to hormonal factors, this is associated with estrogen and progesterone cycles. Reports shows that smoking has been linked to increase risk of meningiomas in men. Frontal lobe meningiomas may present with only psychological symptoms that resemble depression, anxiety states, hypomania and schizophrenia. Personality and mental status changes are also noted in Frontal lobe tumors. Left sided lesions are associated with inhibition of motor activity, impairment in motor and initiative aspect of speech, diminished generalization ability and general inertia of mental process.

Conclusions: Given the absence of frank neurological symptoms, to help localize the lesion, most meningiomas are missed due to diagnostic overshadowing of the primary psychiatric illness. Peritumoral edema indicates the underlying mechanism and location of the lesion predicts symptomatology. Like our patient who is an 81-year-old male with no past psychiatry history, presenting to our comprehensive psychiatry emergency program with psychiatric manifestation as the initial presentation and subsequently with MRI suggestive of Right Frontal extra-axial meningioma. This study shows that primitive frontal lobe tumors are likely to be misdiagnosed as patients with such tumors are often referred first to psychiatrist. High index of suspicion is needed.

Emotional meanings attributed to sexual experiences reported by Brazilian Men with Head and Neck Cancer seen at a Public University Oncologic Outpatient Service: A Qualitative Study

R. S. E. Sant'Ana, C. S. P. Lima and E. R. Turato*

Lab of Clinical-Qualitative Research, University of Campinas, Campinas, Brazil

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1341

Introduction: "What can and what cannot I do in a sexual relationship?" [In this way, a middle-aged man with HNC - Head and Neck Cancer, under chemotherapy or radiotherapy, asks. This doubt is raised to the oncologist, radiotherapist, nurse or psychotherapist. Apparently, his concern is objective, considering he has a severe diagnosis and important treatments. However, underlying the manifest doubt, there are symbolic constructions in his mind that generate anguish. The health professionals' response must go beyond information. They also must understand the symbolic emotional meanings associated with the patient's speech. This attitude will bring a psychotherapeutic effect to the ill man.

Objectives: To interpret symbolically sexual and emotional experiences reported by male patients diagnosed with HNC under outpatient treatment in a public specialized clinical unit.

Methods: We used the CQM - Clinical-Qualitative Method (Turato. Portuguese Psychos. J, 2000 2(1): 93-108). For data collection, the main researcher used the Semi-Directed Interview with Open-ended Questions In-Depth and Field Notes. The employ of the Seven Steps of the CQCA - Clinical-Qualitative Content Analysis (Faria-Schützer et al. Cien Saude Colet. 2021; 26(1): 265-274) brings us to discussion categories. The sample was closed with 12 patients according to the information saturation strategy (Fontanella et al. Cad Saude Publica. 2008; 24(1): 17-27). The interviews were conducted by the first author of this abstract, a male nurse, as part of his master's research at a postgraduate course in Oncology. The findings were validated by peer reviewers from the Lab of Clinical-Qualitative Research at the State University of Campinas.

Results: Two categories were chosen for this presentation: 'The dyad perceived in the felt body and the experienced body', and 'The body re-signified between the sexual and affective dimensions'. The body symbolized before and after the illness experiences a movement in phenomenological consciousness that leads to external changes in its attitudes. The patient needs now to ask himself and others what this body can - or cannot - do. The severely ill body imposes new meanings for life and sexuality. It does not cancel the wish but asks for a new channelling of your psychic/sexual energies.

Conclusions: These findings indicate that patients with HNC want to talk about sexuality and ask about the risks of sexual activity, contrary to what the common view supposes. Traditional Balint groups met with the multidisciplinary team can be beneficial for doctors and nurses to deal with their own emotional limitations. Furthermore, the Consultation-Liaison Psychiatry, under the approach of psychosomatic medicine, focuses on the care of patients with behavioural and emotional manifestations, together with the work of the oncologists.

Neuropsychiatric manifestations in oncological patients: A clinical case of manic syndrome in a patient with pancreatic adenocarcinoma

P. Herrero Ortega*, J. Garde González, A. Oliva Lozano and M. A. Morillas Romerosa

Psychiatry, La Paz University Hospital, Madrid, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1342

Introduction: Neuropsychiatric manifestations in the context of medical illnesses, particularly oncological conditions, pose unique challenges. Pancreatic carcinoma is known to present a high rate of psychiatric comorbidity, with its association with major depressive disorder documented in up to 75% of patients. This poster focuses on the case of a 51-year-old patient recently diagnosed with stage IV pancreatic adenocarcinoma, who exhibited manic symptoms without any prior psychiatric history.

Objectives: To describe the clinical presentation of a patient with previous diagnosis of advanced pancreatic cancer who is admitted in the ER with a maniform episode and review in literature its possible etiology and its clinical management.

Methods: Clinical case report and brief literature review.

Results: 51-year-old male was admitted at the emergency department with subacute behavioral changes in the previous weeks which included growing irritability, aggressive attitudes (which resulted in a restraining order from his mother), excessive spending, insomnia and inappropriate life plans. He had no psychiatric history, substance misuse of any kind or family history of mental disorders. Medical evaluations including a cranial CT scan, an MRI, blood and serological tests, were all within normal parameters. The patient had been recently diagnosed with pancreatic adenocarcinoma stage IV and was undergoing treatment that included corticosteroids, immunotherapy and chemotherapy (FOLFIRINOX).

During the hospitalization, the patient was assessed by the oncology team, who based on the normality of the imaging and laboratory findings, initially discounted an organic or metastatic cause for the symptoms. Pharmacological treatment with Sodium Valproate, up to 1000 mg/day and Quetiapine up to 450 mg/day was initiated, resulting in a progressive improvement in irritability and related symptoms. While the normality of medical tests initially suggested a non-organic cause, the atypical onset of psychiatric symptoms at this age in a patient with no prior psychiatric history raised the hypothesis of a potential link with his medical condition. The final diagnosis was mania secondary to pancreatic adenocarcinoma.

Conclusions: This case underscores the complexity of neuropsychiatric manifestations in oncological patients, particularly when presented without a prior psychiatric history. Upon reviewing the existing literature, it is clear that manic symptoms are relatively rare in patients with pancreatic adenocarcinoma. Furthermore, the underlying mechanisms behind these symptoms remain poorly studied. Potential contributors may include the effects of treatment modalities such as corticosteroids, immunotherapy and chemotherapy. Additionally, the manifestation of paraneoplastic syndromes and immunodysregulation could play a role in the context.

EPV0697

A cross-cultural analysis of the relationship between the level of depression and attitudes toward death in cancer patients

K. Kholmuradova

Psychology, Moscow State University, Tashkent, Uzbekistan
doi: 10.1192/j.eurpsy.2024.1343

Introduction: ♦Over the last 10 years, the number of cancer patients in the world has increased by almost 23%, and the number of cancer deaths has also increased by about 10%. Malignant neoplasms still remain as one of the main causes of mortality in the population. Patients with oncopathology are characterized by a high level of depression which leads to inadequate attitudes towards the disease and its treatment, and this may further act as a risk factor for disease susceptibility and aggravate its course (Schulz-Kindermann, 2021). It is relevant to search for variables that act as a personal resource in coping with cancer. It is hypothesized that one such personal resource is the specificity of attitudes towards death.

Objectives: To conduct a comparative analysis of the relationship between the level of depression and the peculiarities of the attitude to death in cancer patients in Russia and Germany.

Methods:

- Beck Depression Inventory to determine the level of depression severity.
- Death Attitude Profile-Revised to determine the type of attitude to death.

For statistical processing of data, the SPSS 23.0 statistical package was used with a preliminary check for normality of distribution using the Kolmogorov-Smirnov statistical criterion.

SELECTION: The sample consisted of a total number of 50 cancer patients with 25 each undergoing treatment in Russia (Moscow) and in Germany (Munich). The study was based on the sample obtained from the P. A. Herzen Moscow Research Oncological Institute and the Helios Munich-West Clinic. Overall, the sample was relatively gender-balanced.

Results: The following results were obtained from the study:

1. The mean value of depression level in cancer patients is higher in Russia than in Germany.
2. The level of depression in cancer patients in both the countries is correlated with:
 - marital status ($p=0.36$)
 - stage of disease ($p=0.001$)
 - type of treatment ($p=0.001$)
 - belief in God ($p=0.024$)
 - adherence to a particular religious denomination ($p=0.008$)
3. The level of depression was correlated with a certain type of attitude towards death: a higher level of depression was associated with scores on the "fear of death" scale ($p=0.000$), and a lower level (or lack of) with the "neutral acceptance of death" scale ($p=0.000$)
4. The fear of death is seen to be most common in the sample of patients from Russia, while the neutral acceptance of death is more prevalent in the sample from Germany.

Conclusions: The results suggest that a positive attitude to death (neutral as one of these types) is correlated, along with other factors,

with lower levels of depression, which may be a personal resource in coping with the disease.

This allows us to make the assumption that when providing psychological support to cancer patients, it is necessary to pay attention not only to the attitude to life and illness, but also to the attitude to death.

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1344

Introduction: Childhood cancer survivors have neurocognitive sequelae that in most survivor follow-up programs are underdiagnosed and for which there is usually no treatment plan.

Video games have demonstrated various psychological and neurocognitive benefits in different subpopulations, such as patients with organic neurological deficits or children with ADHD. However, few studies have been carried out using video games-based interventions in the paediatric oncology population.

Objectives: The aim of this work is to present the WINNERS study protocol, the objectives of which are to diagnose the neurological and cognitive sequelae in child cancer survivors, and to demonstrate the benefit in these areas of a training program based on video games.

Methods: A randomized controlled and unblinded trial is presented. Fifty-six patients aged 8 to 17 years stratified into two age groups (8-12 and 13-17) who had received any of the following treatments 1 to 6 years before the enrolment will be selected: high-dose chemotherapy with blood-brain barrier crossing, intrathecal or intraventricular chemotherapy, CNS radiotherapy or hematopoietic stem cell transplantation.

A neuropsychological evaluation will be performed consisting of a battery of neuropsychological tests to assess parameters such as attention, memory, visuospatial ability or speed of response, as well as a neuroimaging evaluation by structural and functional magnetic resonance imaging. The evaluation will be repeated 3 months and 6 months after the enrolment. Patients will be randomized to a treatment group or to a recycled waiting group. Intervention will consist on a 12-week training at home using 3 video games: a brain training game, an exergaming game and a skill training game.

Results: According to the hypotheses of this study, it is expected that the proposed program of videogame-based interventions will improve neurocognitive and other wellbeing parameters in the intervention group.

Conclusions: This study aims to improve the quality of care for patients who have survived a cancer disease by detecting sequelae that have so far been poorly attended, and by proposing a gamification-based intervention program that is effective and attractive for this population.

The winners project: neuropsychological changes after a video game-based training program in pediatric cancer survivors. a case report

C. Gonzalez-Perez¹, E. Moran², N. Malpica³, J. Alvarez-Linera⁴, H. Melero⁵, M. Alonso⁶, M. Esteban⁶, A. Perez-Martinez¹ and E. Fernández-Jiménez^{7*}

¹Department of Pediatric Hemato-Oncology, La Paz University Hospital; ²Children Psychology, Juegaterapia; ³Medical Image Analysis and Biometrics Laboratory (LAIMBIO), Rey Juan Carlos University; ⁴Department of Neuroradiology, Hospital Ruber Internacional; ⁵Psychobiology and Methodology in Behavioral Sciences, Complutense University; ⁶Juegaterapia and ⁷Department of Psychiatry, Clinical Psychology and Mental Health, La Paz University Hospital, Madrid, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1345

Introduction: Children who have undergone an oncological process and have received treatment with chemotherapy or radiotherapy on the central nervous system may have significant neurocognitive sequelae. Some video games have shown neurocognitive benefits in people with impairments in different areas, such as attention or memory.

Objectives: This work aims to demonstrate the benefit of a video game-based training program to improve the neurocognitive profile in a child survivor of cancer.

Methods: The patient is a 9-year-old female who was diagnosed with acute lymphoblastic leukemia at the age of 4 years. She received routine treatment of this disease by chemotherapy, including high-dose chemotherapy (with blood-brain barrier crossing) and intrathecal chemotherapy. She is currently 3 years after the end of treatment.

The Continuous Performance Test 3 (CPT-3) (sustained attention/vigilance) was administered before and after a multifaceted training program consisting of playing 3 video games for 12 weeks, as follows: a brain-training game (4 days per week, 7-12 minutes per day), a skill-training game (2 days per week, 10 minutes per day) and an exergaming game (2 days per week, 10 minutes per day).

Results: Prior to intervention, the patient had 3 atypical z-scores on the CPT-3 (z scores: mean = 0, S.D. = 1), with a pattern compatible with ADHD (omissions z = 1.2; hit reaction time z = 3.4; hit reaction time block change z = 1.2). After intervention, she had only an atypical z-score (hit reaction time z = 3.6), with a pattern compatible with slowing, without ADHD.

Conclusions: The neuropsychological evaluation of this patient showed an improvement in his attentional pattern on the CPT-3 after the video game-based training.

Disclosure of Interest: None Declared

EPV0700

Discrepancy between subjective perception and objective cognitive performance in attention assessment within the winners project for cancer survivors. a case report

C. Gonzalez-Perez¹, E. Moran², N. Malpica³, J. Alvarez-Linera⁴, H. Melero⁵, M. Alonso⁶, M. Esteban⁶, A. Perez-Martinez¹ and E. Fernández-Jiménez^{7*}

¹Department of Pediatric Hemato-Oncology, La Paz University Hospital; ²Children Psychology, Juegaterapia; ³Medical Image Analysis and Biometrics Laboratory (LAIMBIO), Rey Juan Carlos University; ⁴Department of Neuroradiology, Hospital Ruber Internacional; ⁵Psychobiology and Methodology in Behavioral Sciences, Complutense University; ⁶Juegaterapia and ⁷Department of Psychiatry, Clinical Psychology and Mental Health, La Paz University Hospital, Madrid, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1346

Introduction: Paediatric cancer survivors have a risk for neuropsychological impairment due to the disease and the treatment received. These affections have been neglected in the follow-up of these patients. It is important to identify the most valid outcomes in the evaluation of neurocognitive sequelae in childhood cancer survivors.

Objectives: This work aims to compare the results obtained between subjective perception of caregivers and objective cognitive performance based on validated attention tests.

Methods: In a randomized controlled and unblinded trial to demonstrate the benefit of video games on different neurocognitive areas in cancer survivors, we studied attention functioning before and after the intervention program. The attention deficit subscale from the Behavior Assessment System for Children 3rd edition (BASC-3), self- and parent-reported versions, and the Continuous Performance Test, 3rd edition (CPT 3) will be used as outcomes (z scores: mean = 0, S.D. = 1).

Results: We observed an improvement in attention after intervention using the CPT-3 (omissions z = 1.2; hit reaction time z = 3.4; hit reaction time block change z = 1.2 versus hit reaction time z = 3.6 without other atypical z scores after intervention), changing the attentional pattern from "ADHD" to "slowed". However, in the parent-reported version of the BASC-3, a worsening in the attention subscale is observed (z = 0.3 pre-intervention vs z = 1.0 post-intervention) while the self-reported version of the patient didn't show any significant changes (z = 1.4 pre-intervention vs z = 1.1 post-intervention).

Conclusions: It is essential to use objective tests to measure neurocognitive sequelae in these patients. Subjective surveys can provide additional information, but not substitute the above.

Emotional meanings reported by patients about their life experiences under the following in the Watch and Wait protocol: A qualitative study in a Brazilian surgery university specialized outpatient service

M. R. Suedt¹, S. A. Silva¹, A. C. O. Bispo¹, R. S. E. Sant'Ana¹,
L. M. Guerra¹, C. A. R. Martinez², J. B. C. Carvalheira¹,
C. S. P. Lima¹ and E. R. Turato^{1*}

¹Lab of Clinical-Qualitative Research and ²Departamento de Cirurgia, State University of Campinas, Campinas, Brazil

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1347

Introduction: Health Psychology is aggregated to clinical studies providing physicians, nurses, and psychotherapists with psychodynamics of sick persons, facilitating interpersonal relationships and greater adherence to treatments. How do people deal with illness and treatment from what they symbolize in experiences of becoming ill? Watch & Wait Protocol for patients with rectal cancer is an active surveillance as an alternative approach in surgical medical management. Patients are followed with physical examinations, endoscopy, and imaging. Observation carried out through periodic examinations aims to avoid surgery stage while rectal cancer is maintained.

Objectives: To interpret emotional meanings attributed by patients, after adhering to the W&W protocol for rectal cancer, to life experiences of watching and waiting for the disease course.

Methods: Clinical-Qualitative Method (Turato. Portuguese Psychos. J, 2000 2(1): 93-108). For data collection, the first author used Semi-Directed Interview with Open-ended Questions In-Depth and Field Notes, after acculturation. Sample closed by information saturation (Fontanella et al. Cad Saude Publica. 2008; 24(1): 17-27). Interviews conducted by the first author, a female psychologist. We employed the Seven Steps of the Clinical-Qualitative Content Analysis (Faria-Schützer et al. Cien Saude Colet. 2021; 26(1): 265-274) to construct categories. Theoretical framework was the Balintian Medical Psychology. Findings were validated by peer reviewers from Lab of Clinical-Qualitative Research.

Results: Sample had 10 patients, 3 female and 7 male, from 52 to 77 years. Interviews carried out from October 2022 to March 2023. We constructed 03 categories: 1) Fate out of hands - "I get sick just coming in here." There is an apprehension experienced in each medical evaluation to check the clinical condition because the symbol of waiting is not having the own destiny in the hands. 2) Psychic defence - "Sometimes I even thought if I had to live on a grant for the rest of my life or die!" Imagining the worst is a psychic defence because if this probability occurs, the mind has already begun its elaboration. 3) Life upside down - "I was going to have the surgery, use a bag, my life was going to be upside down." Anxiety generated by waiting is a mental disorganizing.

Conclusions: Attitudes of observing and waiting carry different symbolisms to those who work with scientific thinking and who experience the observation of their own disease and the wait for what conduct they will receive. Observing oneself in illness requires acceleration of changes in ego identity. Waiting in front of illness asks the ego to think the worst. It is not a volitional choice. Preparing for the worst is a defensive

necessity in the emotional sphere to avoid surprises that take to mental rupture.

EPV0702

Assessment of psychological impact and relationships interpersonal in women with malignant breast neoplasia

M. C. V. R. De Oliveira*, C. B. Soares de Oliveira, F. P. Vieira Silva, M. P. R. Camargo and N. Gonçalves de Sá

MEDICINE SCHOOL, UNOESTE, PRESIDENTE PRUDENTE, Brazil

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1348

Introduction: Cancer causes an impact in the face of its news, whether due to feelings of anguish, stress and suffering due to the presence of the disease, which can be shared between patients, family members and loved ones. The news regarding the diagnosis generates, in addition to the psychological impact, financial difficulties, as the patient himself can often be responsible for a large part of the family income. Other complications are the difficulties in understanding the disease by the family members and/or the patient, denial of the disease in order to spare the patient from suffering and other loved ones, family conflicts related to the need to adapt to the new routine of daily life that the family should carry out aiming at the well-being of the patient and his treatment.

Objectives: To evaluate the psychological impact and interpersonal relationships in patients with breast cancer treated in the city of Presidente PrudenteSP by a support association.

Methods: This is an observational, quantitative, analytical and cross-sectional study, in which 200 patients with malignant breast cancer will be invited.

Results: The sociodemographic results found were: 62.5% white women, 65.6% aged between 45-65 years, 56.3% married, 46.9% have completed higher education, 56.3% had no family history of cancer, predominance of stages II, III and IV when discovered, 93.5% did not drink, 84.4% did not smoke. On the anxiety scale, 53.1% and 43.8% report getting tired easily and feeling like crying, respectively. On the social adequacy scale, 72.5% continued working only with some limitation during treatment, despite this, 41.4% had minor financial difficulties, 34.5% had difficulties expressing feelings with family members, 40.7% had a relationship well with family members with small arguments and finally 34.8% felt affection for the partner all the time, despite this 36.4% did not have sexual intercourse with them in the last month.

Conclusions: It was concluded, therefore, that when a family member gets sick, they all feel impacted, and each family will deal with the experience in a particular way, therefore, it is worth highlighting the encouragement of family participation in therapy sessions.

Fibromyalgia: functional, autoimmune or both? Treatment options for drug-resistant fibromyalgia

C. P. Desport*, D. O. Martins, J. R. Freitas and L. C. de Castro

Psychiatry, Hospital de Magalhães Lemos, Centro Hospitalar e Universitário do Porto, Porto, Portugal

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1349

Introduction: fibromyalgia is a modern disease, with growing investigation concerning its etiology and treatment. It has become a very prevalent diagnosis and total remission of symptoms is the exception which is dramatic considering the socio-occupational impact of this highly debilitating disease.

Objectives: to review the updates in the pathophysiology and treatment of fibromyalgia, especially when it is refractory to treatment. The authors also intend to better understand where fibromyalgia belongs, is it in psychiatry as a functional disorder or in rheumatology as an auto-immune disease?

Methods: bibliographical search in PubMed database, using the key-words “fibromyalgia” and “psychiatry”, limited to works published in the last 10 years.

Results: from our search resulted 158 articles, from reading of abstracts 30 were chosen for further reading.

Conclusions: concerning the etiology of this disease, on the one hand psychological factors cannot be neglected since there are several studies finding a positive correlation between stressors like history of physical abuse and fibromyalgia in adulthood, on the other hand investigation and meta-analysis have found that the immune-inflammatory response system might be altered with dysregulation of pro and anti-inflammatory cytokines and cell-mediated immunity. Regarding treatment, symptom relief is often unsatisfactory with classical treatment and so adjunct treatment such as electrical neuromodulation and aerobic exercise might, respectively, be effective in reducing pain and depressive symptoms, thereby improving quality of life, and in improving fatigue and in a lesser degree sleep.

doi: 10.1192/j.eurpsy.2024.1350

Introduction: Among young medical practitioners, the exigencies of daily practice entail many challenges concerning both physical and mental dimensions. The study of the interplay between these two dimensions is crucial to provide the necessary care for this population.

Objectives: This study aims to evaluate the prevalence of back pain and its association with mental health issues in young medical practitioners.

Methods: A cross-sectional study (January to April 2023) was conducted in the university interns and residents from Sfax. The Nordic questionnaire was used to evaluate back pain. The Generalized-Anxiety-Disorder (GAD -7) and the Patient-Health-Questionnaire (PHQ-9) were used to assess signs of anxiety and depression respectively.

Results: Our population consisted of 404 young doctors. One-hundred and twenty were males with a sex-ratio of 0.42. Among them, 76 (18.8%) had surgical specialties. Mean age was 28.03 ± 2.89 , BMI's mean was 23.65 ± 3.98 . Medical history was reported by 29.2% and psychiatric history by 4.9%. The median of the PHQ-9 and GAD-7 score were 3.5 (IQ: [1;6]) and 2 (IQ: [0; 5]). Signs of depression were found in 11.1% of the population whereas anxiety was found in 8.4% of them. Sixty-seven residents (16.6%) reported having back pain in the previous year. Neck pain, upper-back pain and lower back pain were experienced by 8.7%, 6.4% and 10.1% respectively.

Bivariate analysis showed that back pain was associated with PHQ-9 score ($p=0.006$), GAD-7 score ($p=0.018$) and it was not associated with BMI ($p=0.769$) neither with surgical specialties ($p=0.824$). Lower Back pain was associated with GAD-7 score ($p=0.004$).

Conclusions: Our study highlights the link between back pain and mental health problems in young doctors. Interventions englobing a better understanding of these two facets are needed to ensure an optimal care for this young population.

Low back pain and perceived psychological workload among electricians

I. Sellami^{1,2*}, A. Feki^{2,3}, A. Abbes¹, S. Baklouti³, M. L. Masmoudi¹, K. Jmal Hammami¹ and M. Hajjaji¹

¹Occupational medicine, Hedi Chaker Hospital; ²Medicine univeristy and ³Rheumatology, Hedi Chaker Hospital, Sfax, Tunisia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1351

Introduction: Low back pain (LBP) is a serious threat to electricians. It is well known that LBP is associated with physical strain. But the impact of psychological workload on the occurrence of LBP needs further investigation.

Objectives: This study aimed to assess the link between LBP and perceived psychological workload among electricians.

Methods: The study was conducted with a sample of workers from a Tunisian Electricity society. Data were gathered between January-June 2022 using a self-administered questionnaire including socio-professional characteristics and the Nordic musculoskeletal questionnaire during the last 12 months and the last 7 days. To assess the perceived workload, we used the National Aeronautics and Space Administration Task Load Index (NASA-TLX). In this study, we evaluated raw NASA-TLX scores.

Results: Our study included 68 male electricians. The mean age was 39.2 ± 10.3 years. The average job tenure was 16 ± 11.4 years.

According to the Nordic musculoskeletal questionnaire, 32.4% of participants reported low back pain during the last 12 months. Thirty participants (19.1%) had low back pain during the last 7 days. The mean score of mental demand, physical demand, performance, effort, frustration level and temporal demand were respectively 88.2 ± 14.3 , 61.1 ± 24 , 84.8 ± 13.3 , 82.6 ± 14.5 , 35.8 ± 29.2 and 60.4 ± 28.8 . The frustration level was associated with the presence of LBP during the last 12 months and the last 7 days ($p < 0.05$).

Conclusions: From the results of this study, we conclude that LBP was associated with the perceived psychological workload. Hence, the prevention of LBP should go through the improvement of work conditions to enhance the mental health of the electricians.

Psychosocial risk factors for headache in medical students

E. L. Nikolaev¹, F. V. Orlov² and S. S. Fakhraei^{3*}

¹Department of Social and Clinical Psychology; ²Department of Psychiatry, Medical Psychology and Neurology and ³Medical Faculty, Ulianov Chuvash State University, Cheboksary, Russian Federation

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1352

Introduction: Headache is often considered as a symptom reflecting mental ill-being of a person. Taking into account heavy academic loads, we should study it in medical students in reference to its connections with various psychosocial risk factors

Objectives: To establish interrelations between the frequency of headaches in medical students and risk factors of psychosocial nature

Methods: We conducted the research based on the Faculty of Medicine of Ulianov Chuvash State University. It covered 546 students of both genders who had no complains of having mental problems. We surveyed the students by means of Sociocultural Health Questionnaire (E. Nikolaev)

Results: The research showed that two out of three students complained of headaches of various intensity and frequency. It was present with statistically equal frequency ($p > .05$) in domestic (68.85%) and foreign (63.90%) medical students. Females experience headache more often ($r = .20$), and it more often correlates with a high level of stress ($r = .25$), lesser satisfaction with studying ($r = -.14$), higher frequency of e-cigarette consumption ($r = .15$), higher anxiety due to phantom ringing syndrome ($r = .15$), lower self-esteem of health ($r = -.29$), confidence ($r = -.16$), successfulness ($r = -.12$), happiness ($r = -.18$), well-being ($r = -.11$), liveliness ($r = -.16$), higher frequency of medication consumption ($r = .27$), higher frequency of visits to a psychotherapist in the childhood ($r = .11$), higher current need in the help of a psychologist ($r = .21$), psychiatrist and psychotherapist ($r = .21$).

Conclusions: These psychosocial risk factors call for attention from mental health professionals, and we should take them into consideration while providing medical care to medical students and developing health programs in universities.

Impulsivity as a predictor factor of health-related risk-taking

A. Megías-Robles^{1*}, L. Moreno-Ríos¹, R. Megías-Robles², A. Martínez-Estrella² and M. A. Torres³

¹Department of Basic Psychology, University of Malaga, Málaga; ²Junta de Andalucía, Motril and ³Department of Experimental Psychology, University of Granada, Granada, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1353

Introduction: There is a broad consensus that risk taking is largely determined by risk perception. However, previous literature has shown numerous examples of situations associated with potential health risks where our decisions are not made in accordance with the level of perceived risk.

Objectives: The aim of the present research was to investigate the role of impulsivity in the explanation of the discordance observed between risk perception and risk-taking in health-related domains.

Methods: The sample consisted of 612 participants (Mage = 23.54, 73.2% women). All participants were assessed for levels impulsivity and levels of risk perception and risk-taking propensity in contexts related to health.

Results: Results revealed that higher levels of impulsivity were significantly related to a lower tendency to perceive and take risks in the health domain. Most important for our objectives, we observed that the relationship with impulsivity was significantly stronger for risk taking than for risk perception. Moreover, impulsivity significantly predicted risk taking propensity when controlling for risk perception.

Conclusions: These findings suggest that, in the health-related domains, impulsivity can differentially affect risk perception and risk taking, thus, offering a possible explanation for the inconsistencies observed in the previous literature.

From adjustment disorder to schizotypal personality disorder

C. De Andrés-Lobo¹, M. D. C. Vallecillo Adame¹, T. Jiménez Aparicio¹, A. Rodríguez Campos^{1*}, N. Navarro Barriga¹, M. J. Mateos Sexmero¹, B. Rodríguez Rodríguez¹, M. Fernández Lozano¹, M. Calvo Valcárcel¹, M. Andreo Vidal¹, P. Martínez Gimeno¹, M. P. Pando Fernández¹, L. Rojas Vázquez¹, G. Lorenzo Chapatte¹, M. Ríos Vaquero¹ and A. Monllor Lazarraga¹

¹Psychiatry, HCUV, Valladolid, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1354

Introduction: Individuals with schizotypal personality disorder are characterized by tendencies to magical thinking, unusual perceptions, discomfort in social situations, and restricted affect. It is

frequent that they have social anxiety and have difficulty in understanding the motivations and thoughts of others.

Objectives: Presentation of a case of a patient who was first diagnosed with adjustment disorder, but on a closer study, was discovered to have a schizotypal personality disorder.

Methods: We conducted a bibliographic review by searching for articles about schizotypal personality disorder and theory of mind in Pubmed.

Results: We present the case of a 39-year-old woman, diagnosed with adjustment disorder after a conflict at work with a colleague that caused her anxiety-depressive symptoms. In consultations, the patient shows verbiage without expansiveness or euphoria, with rambling speech. She expresses feelings of indignation and injustice, she is irritable, with contained anger. She refers that she prefers to be distrustful of others because she does not understand their intentions. Her thoughts are very rigid, which leads her to have avoidant and phobic attitudes, having no relationships of friendship throughout her life.

A neuropsychological evaluation is carried out, resulting in a surprising WAIS with a TIC of 128. However, the Mayer-Salovey-Caruso Emotional Intelligence Test (MSCEIT) shows difficulties in Perception, Comprehension and Emotional Management. Considering the patient's symptomatology as a whole, it is noteworthy:

- Sustained social isolation throughout their life history
- Superficiality of interpersonal relationships
- Distrust and slight self-referentiality. Deficit in inferring the feelings and thoughts of others
- Peculiar speech with ideas of magical content, superstitions and rituals...

Which together supported a diagnosis of schizotypal personality disorder and generalized anxiety disorder. From this point we started to work on her self-esteem, modification of irrational beliefs and cognitive distortions, interpersonal communication and meta-cognitive therapy, with good results.

Conclusions: The type of schizotypal patients who come to consultations most frequently are the actively isolated/timorous profile due to their intense social anxiety and difficulties in understanding and adapting to the social world around them. Initial therapy should be empathic support. The theory of mind is the ability to infer the other's mental states and therefore predict their behavior, this ability being diminished in the schizotypal patient. Mentalization tasks, metacognitive therapy, cognitive flexibility training, social skills training, and promoting self-worth are useful. On some occasions it may be necessary to start psychopharmacological treatment to control anxiety and unusual perceptions when they cause discomfort.

BUT WHO LOOKS AT ME? About a daily clinical case in treatment in a mental health center

B. Gamo Bravo^{1*}, M. E. Gonzalez Laynez²,
S. M. Bañon Gonzalez¹ and N. Ogando Portilla¹

¹psychiatry, University hospital infanta Sofia, San Sebastian de los Reyes and ²psychiatry, University hospital of Toledo, Toledo, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1355

Introduction: BUT WHO LOOKS AT ME?

Patient around thirty years old, teacher and with obsessive, anxious, paranoid, schizotypic semiology that affects his functionality to the point of isolation, and take sick leave, which with pharmacological treatment with antipsychotics such as aripiprazole and olanzapine and the antidepressant sertraline (at a final dose of 200 mg) and group psychotherapy in multifamily groups remits from these symptoms with functional and symptomatic improvement.

Objectives: Highlight the diagnostic difficulties due to the coexistence of symptoms that are part of personality imbalances or first-order diagnostic entities as in this case, depressive picture in a personality with obsessive and paranoid traits

Methods: Describe the evolution and psychiatric clinical decompensation of a patient with depression and anxiety and a personality of cluster A traits, paranoid type and obsessiveness

Results: CLINICAL DIAGNOSTIC TRIAL

ANXIOUS DEPRESSIVE SYNDROME (PREDOMINANCE OF SYMPTOMS OF OBSESSIVENESS AND DISTRUST)

MIXED CLUSTER A PERSONALITY DISORDER (PARANOID AND SCHIZOTYPIC TRAITS)

Conclusions: Discussions and conclusions: There is a gap difficult to separate in many cases between obsessiveness and paranoidism as communicating vessels, whose worsening of one worsens another and whose improvement of one leads to the improvement of the other, which at the pharmacological level respond to combined approach versus potentiated atypical antipsychotics and antidepressants such as sertraline that help us neutralize the discomfort

“Esketamine” in Borderline Personality Disorder: focus on suicide ideation

M. Olivola*, F. Mazzoni, V. Arienti, S. C. Civardi,
G. Carnevale Miacca, P. Leali, F. Santilli, A. Guffanti and
N. Brondino

Department of Brain and behavioral science, University of Pavia, Pavia, Italy

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1356

Introduction: Borderline personality disorder is often associated with comorbid conditions such as eating disorders, mood disorders, and substance use disorders. The prevalence of BPD and major depressive disorder (MDD) are about 5.9% and 8%, respectively, but up to 80% of patients with BPD experience one or more episodes of MDD in their lifetime. BPD is associated with suicidal behaviors and self-harm, they are also fifty times more likely than the general population to attempt or die by suicide. Up to 10% of BPD patients will die by suicide

Objectives: Our aim is to verify if Esketamine could be effectiveness in treating patterns of behavior that have proven to be socially disruptive like self harm, suicidal attempts in patients with BPD. Suicidal ideation is a major risk factor for suicide in patients with TRD and BPD. The interval between the onset of suicidal ideation and suicide attempt is often very short, highlighting the need for urgent intervention and the development of new rapid-onset antidepressant therapies.

Methods: We recruited 25 adult subjects referred to the outpatient clinics of Pavia suffering from TRD with current Moderate-Severe Depressive Episode (scoring ≥ 22 on the MADRS). Of them 9/25 patients has a BPD. Study duration was 8 weeks. The following evaluation scales were administered before the first drug administration (T0) and repeated after one week (T1), four weeks (T2) and eight weeks (T3) of treatment: Montgomery Asberg Depression Rating Scale (MADRS), Columbia-Suicide Severity Rating Scale (CSSRS), and The Zanarini Rating Scale for BPD subgroup patients. We also collected sociodemographic and clinical information. Doses and frequency of esketamine administration during the study period, adverse events and reasons for discontinuation were also recorded.

Results: A significant reduction of depressive symptoms was found at T1 and T2 compared to T0. Suicidal ideation disappeared as early as T1 and was maintained at T2, especially in the BPD group. In the subgroup with borderline disorder we saw more improvement in impulsive (Self-mutilation and/or suicidal efforts; two other forms of impulsivity) and affective categories (Inappropriate anger / frequent angry acts; chronic feelings of emptiness; mood instability) in Zanarini Rating Scale.

Conclusions: Our findings support the safety and tolerability of esketamine in TRD and BPD comorbidity sample. It is noteworthy that esketamine has an action on various pathways that are considered defective in borderline patients. Glutamate plays a key role in personality traits such as impulsivity, aggression, and suicidal behavior. Treatment with esketamine could reduce the number of suicide attempts and help reduce the self-harm of BPD.

EPV0714

The relationship between non-suicidal self-injury and suicidal ideation in patients with borderline personality disorder treated at the Arrazi psychiatric hospital in Salé

N. Ait Bensaid* and F. El Omari

Arrazi psychiatric hospital in Salé, Salé, Morocco

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1357

Introduction: Non-suicidal self-harm, i.e. the intentional self-infliction of bodily harm without apparent suicidal intent, is a powerful risk factor for suicidal ideation and behavior [1]. Although non-suicidal self-harm and suicidal behaviour are distinct concepts, the two forms of deliberate self-harm frequently coexist and share key instrumental functions, such as escaping aversive internal states, reducing dysphoria or communicating distress, especially in patients with personality disorders. [2] Some individuals also report using non-suicidal self-harm to ameliorate suicidal thoughts or urges [2].

Objectives: To assess the relationship between non-suicidal self-harm and suicidal ideation in patients with borderline personality disorder followed at the Arrazi psychiatric hospital in Salé.

Methods: This was a descriptive cross-sectional study using a questionnaire including sociodemographic criteria, clinical criteria and the Beck suicidal intentionality scale to assess the relationship between non-suicidal self-harm and suicidal ideation in patients

with borderline personality disorder followed and hospitalised at the Arrazi psychiatric hospital in Salé.

The inclusion criteria were as follows: both sexes with a diagnosis of borderline personality disorder according to DSM 5 criteria.

Exclusion criteria were current psychosis and severe intellectual disability.

Results: We collect 63 participants.

The average age of the participants was 23, and they were predominantly female (89%). About 85% were single and 97% had no occupation. The majority of participants had a substance use disorder.

All participants had a history of non-suicidal self-harm and 36% had a history of suicide attempts.

Suicidal intent was strong in 45% of participants who had already attempted suicide.

Approximately 46% of participants reported that non-suicidal self-harm was intended to alleviate suicidal ideation and approximately 27% of participants reported having experienced suicidal ideation shortly after non-suicidal self-harm.

Conclusions: Non-suicidal self-harm is very common in patients with borderline personality disorder often considered to have a mitigating effect on the internal stress of these patients and sometimes even neglected. The relationship between non-suicidal self-harm and suicidal ideation is an important one, and may reduce suicidal ideation in the short term but subsequently encourage further self-harm, thereby increasing the risk of suicide.

Particular attention must be paid to these patients and their self-harm, and specialised, comprehensive care is required.

A man stitches his mouth in the context of a personality disorder

A. Monllor Lazarraga^{1*}, P. Marques Cabezas¹, L. Rojas Vazquez¹, M. Rios Vaquero¹, G. Lorenzo Chapatte¹, T. Jimenez Aparicio¹, C. De Andres Lobo¹, C. Vallecillo Adame¹, M. J. Mateos Sexmero¹, N. Navarro Barriga¹, B. Rodriguez Rodriguez², M. Fernandez Lozano¹, M. A. Andreo Vidal¹, M. Calvo Valcarcel¹, M. P. Pando Fernandez¹, P. Martinez Gimeno¹ and G. Guerra Valera¹

¹Psiquiatria and ²SACYL-Hospital Clínico Universitario Valladolid, Valladolid, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1358

Introduction: A 28 year old patient will be presented. This paramilitary man was brought to the Emergency Room due to an autolytic attempt with Benzodiazepines, along with a mouth suture, in the context of a soon to be resolved problematic ankle osteosynthesis procedure. The patient claimed to be suffering pain, furthermore struggling due to the fact he could not be working due to his ankle issue. Language barrier was a problem during the interview.

Objectives: The objectives of this case is to try to explain the issues that may arise in patients with personality disorders in the context of an autolytic attempt

Methods: This patient will be presented, along with systematic bibliography review of the topic.

Results: The following results were extracted upon the attention given to this patient which was admitted to the Psychiatric Unit. First of all, the mouth stitches were removed, along with a petition for toxicological analysis. The results gave positive for cannabis and benzodiazepines. The patient was also brought previously this year with another autolytic attempt, this time on cocaine consumption too. Furthermore, a thorough review was made of the other autolytic attempts, including those which happened in his country of origin. The patient has hundreds of small cuts among his arms, from previous cuts made in the past. Furthermore, subcutaneous wounds were auto inflicted in the ER, with a small blade.

Among the whole interview, it was clear he had a personality disorder, with high impulsivity levels and lack of control once the situation overflows.

We also tried to understand the outcome of suturing his mouth. The patient referred his acts of impulsiveness due to his overwhelming situation of both having no job at this moment and the pain he was suffering due to his ankle procedure.

The patient was admitted to our Unit due to the high risk he could repeat this act. Upon arrival, the same day he was admitted, the patient asked if he had to stay at the unit. When explaining the following already told event, furthermore insisting in the possibility of been evaluated by the Traumatology team, he proceeded to try and hang himself with his medical-hospital clothing.

The patient was treated with antipsychotics. Along with Lormetazepam at night. At the end of the hospitalization, and after been evaluated by the Psychiatrist of this Unit, the patient was also treated with Lithium due to its effectiveness in the treatment of autolytic attempts.

Conclusions: Personality disorders are one of the psychiatric pathologies that prevail with greater frequency in autolytic attempts ¹. Additionally, it should be taken into account the possible ongoing consumption of psychoactive drugs that could also derive in psychopathological decompensation. On top of the following, the use of antipsychotic treatment is indicated for the managing of conduction altercations ², besides Lithium being a great option in managing suicidal temptations ³.

Personality disorders and addiction A study of 54 patients

Y. BENSALAH^{1*}, L. TBATOU¹, M. SABIR¹ and F. ELOMARI¹

¹Psychiatric hospital Ar Razi, salé, Morocco

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1359

Introduction: Personality disorders are very often comorbid with addictions and are known to have a negative impact on the development of substance use disorder.

Objectives: Evaluate the prevalence of personality disorder in patients with problematic use of psychoactive substances followed at Ar Razi hospital Determine the relationship between different personality disorders and the clinical aspects of psychoactive substance use

Methods: This is a descriptive and analytical cross-sectional study carried out among 54 patients followed at Ar-Razi hospital Salé in Morocco for problematic use of psychoactive substances from June 1 to September 15, 2023 (Diagnosis assessed by DSM 5) Data collection was done using a questionnaire including clinical and socio-demographic characteristics and data on addiction to psychoactive and behavioral substances. The psychometric scale used to assess personality disorder: Personality Disorder Questionnaire (PDQ-4+)

Results: We recruited 54 patients with age ranges from 18 to 45 years, with a male predominance. The average age at the start of psychoactive substance use was 15 years. Tobacco is the most used substance followed by cannabis Antisocial, histrionic and borderline personality disorders were the most common in our population. There was a statistically significant difference between specific personality disorder and the presence of severe psychoactive substance use disorder

Conclusions: The frequency of personality disorders is high among subjects with problematic use of psychoactive substances. It is necessary to take care of them simultaneously (integrated care) in order to improve the prognosis

EPV0718

Avoidant personality disorder through the lens of ICD 11

A. Bogdanovska Toskic^{1*} and S. Arsova Hadzi-Angjelkovska²

¹Psychiatry, General Hospital Kumanovo, Kumanovo and ²Psychiatry, University Clinic of Psychiatry, Skopje, North Macedonia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1360

Introduction: With the new dimensional diagnosis of personality disorders in ICD 11, the categorical model has been abandoned. The types of personality disorders in the new dimensional model should show certain common characteristics. According to the recognition of the common characteristics of individual types of personality disorders, as well as determining the severity, a transition from the categorical to the dimensional diagnostic system can be made.

Objectives: To analyze and present the trait domains specifiers in persons with avoidant personality disorder and to facilitate the adoption of the new diagnostic criteria.

Methods: An unsystematized literature review was made, with key words: avoidant personality disorder, ICD 11, ICD 10, traits; and a case was presented.

Results: This is the case of a 26-year-old student who has had no friends since his school days. During his secondary education, on the initiative of another person, he got together with several other people, but he was not fully accepted. During the studies, the communication with the colleagues took place only at the university and around the responsibilities. About a year ago, he had reduced willpower and suicidal thoughts, when he took antidepressant and adjuvant antipsychotic therapy for some time. He is now being examined due to severe tension, dissatisfaction, lack of friends, repeated suicidal ideation. According to researches, people with avoidant disorder have prominent trait domains – negative affectivity, detachment and

reduced dissociality (Bach *et al.* BMC Psychiatry 2018; 18:351), negative affectivity, detachment and anankastia (Simon *et al.*, Front. Psychiatry 2023, 14:1175425), negative affectivity and detachment (Bach *et al.* Borderline Personality Disorder and Emotion Dysregulation 2022, 9:12). In our case, assessments of trait domains were made with PSQ-11 and PiCD. On the PSQ-11, an increase in the negative affectivity, detachment and anankastia on critical score was obtained, while on the PiCD, an increase in negative affectivity, detachment, anankastia, and a decrease in dissociality was obtained. Mild personality disorder was scored on the Rating Scales for Severity of Disorder (SASPD, LPFS-BF 2.0).

Conclusions: The types of personality disorder can be represented by certain common trait domains specifiers, which will be useful in adopting the diagnostic criteria in ICD 11 for personality disorder. Assessment of the severity of the disorder provides additional information on treatment strategies and prognosis. The most significant features of avoidant personality disorder are negative affectivity and detachment, while anankastia is on the borderline score and has a reduction in dissociality.

Disclosure of Interest: None Declared

EPV0719

Level of personality functioning among outpatients with predominant anxiety symptoms

A. Bogdanovska Toskic^{1*} and S. Arsova Hadzi-Angjelkovska²

¹Psychiatry, General Hospital Kumanovo, Kumanovo and ²Psychiatry, University Clinic of Psychiatry, Skopje, North Macedonia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1361

Introduction: Dimensional diagnosis of personality disorders has as its main criterion the assessment of the level of functionality. And in patients with other diagnostic categories, there is a difference in the degree of functioning, as well as a difference in the course and prognosis of the disorder. The reason for such a different course may be the existence of a certain degree of personality dysfunctionality.

Objectives: The aim of the study is to determine the prevalence of personality disorder in patients with neurotic disorder and predominantly anxiety symptomatology.

Methods: A descriptive cross-sectional study was made to determine personality disorder in patients with neurotic disorder (F40-F48, excluding those where the disorder is related to stress F43) and predominantly anxiety symptomatology. The HAM-A scale was used to assess anxiety, and the LPFS-BF-2.0 was used to assess the level of personality functioning. The results were processed by descriptive statistical analysis.

Results: The study included 25 individuals (N 25, 64% women), aged between 18 and 65 years (mean age 44.16, SD 13.20) with a diagnosed neurotic disorder. All subjects had elevated anxiety symptomatology, mean HAM-A score was 35.36 (SD 7.76). The assessment of the level of personality functioning with the LPFS-BF-2.0 gave the following results: 20% of people have a personality difficulty, 12% have a mild personality disorder, 32% have a moderate and 4% have a severe personality disorder.

Conclusions: According to the obtained results, 68% of people with a neurotic disorder and a high degree of anxiety have a

certain degree of personality dysfunction. The prevalence of personality disorder in individuals with neurotic disorder is high (48%). These results lead to the conclusion that people with pronounced anxiety often have a disruption in personality. In people with a high level of anxiety, an assessment should be made for the level of functioning of the person, as well as for the existence of a personality disorder, and the treatment should be adjusted according to the results obtained. In addition to the treatment of the emerging symptoms, the personality dysfunctions should also be treated.

Disclosure of Interest: None Declared

EPV0720

Typology of hyperthymic personalities with affective phases

A. Barkhatova*, A. Churkina and S. Sorokin

Department of endogenous mental disorders and affective states, Mental health research center, Moscow, Russian Federation

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1362

Introduction: Modern authors characterize hyperthymic individuals as eloquent, humorous, self-confident, optimistic, energetic, liberated, sexually active, constantly planning and implementing their plans. Four or more of the listed characteristics indicate the individual's involvement in the circle of hyperthymic people. Statistical data on the prevalence of hyperthymic is scarce, which is due to rare requests for help and the diagnosis of this condition not as a disease, but within the framework of characterological traits. Attempts to classify hyperthymics have been made more than once, but previously none of the authors divided them according to the presence of side character traits in the personality structure.

Objectives: To establish psychopathological types of hyperthymic individuals in whom affective states were formed.

Methods: The sample consisted of 50 patients (42 women, 8 men) who were on inpatient or outpatient treatment at the clinic since 2019 to 2022. Patients were examined by clinical-psychopathological, clinical-anamnestic methods due to the presence of a phase affective state.

Results: Four types of hyperthymic personalities have been identified: anxious-hyperthymic, hysterical-hyperthymic, schizoid-hyperthymic and standard hyperthymic. *Anxious-hyperthymic type*, 20% (n=10) characterized by a combination of increased activity, sociability with such traits as suspiciousness, perfectionism, meticulousness, exactingness, concern for one's health and the desire to maintain a healthy lifestyle. *Hysterical-hyperthymic type*, 46% (n=23) includes both hyperthymic and hysterical traits in the form of increased emotionality, egocentrism, drama, and desire for recognition from others. In addition, patients in this group are characterized by increased concern about their appearance (bright clothes, makeup, tattoos). *Schizoid-hyperthymic type*, 10% (n=5). In addition to increased activity and emancipation, patients in this group are prone to fantasizing, overvalued hobbies, sthenicity, emotional poverty and rationalism. *Standard type*, 24% (n=12) are characterized by the presence of typical hyperthymic traits - optimism, energy, constant desire for productive

activity, success in the chosen profession, rapid career growth, sociability, openness.

Conclusions: Hyperthymic individuals with the development of affective phases are heterogeneous in their psychopathological structure and have features of the pathocharacterological structure that make it possible to distinguish anxious-hyperthymic, hysterical-hyperthymic, schizoid-hyperthymic and standard types. The developed classification of hyperthymia reveals the predominance of the hysterical-hyperthymic type (46%).

ADHD and BPD, two disorders for the same patient? Psychopathological dimensions and other cross-cutting factors in ADHD and BPD: a pragmatic review

M. D. P. Paz-Otero^{1*}, E. Lozano-Bori¹, S. Puyal-González¹, J. Sánchez-Rodríguez¹, F. Mayor-Sanabria¹, M. Fernández-Fariña¹ and Í. Alberdi-Páramo¹

¹Hospital Universitario Clínico San Carlos, Madrid, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1363

Introduction: The relationship between Borderline Personality Disorder and Attention Deficit Hyperactivity Disorder has been highlighted in different studies over the last few years, with an estimated prevalence of around 15-35% of ADHD in adult patients diagnosed with BPD and a 7.4 times higher risk of developing BPD in patients diagnosed with ADHD.

Objectives: To conduct a pragmatic review of the recent literature on the relationship between ADHD and BPD, so that it serves as a starting point for an in-depth study of the socio-demographic, clinical and cross-sectional dimensional factors of both disorders.

Methods: A bibliographic review of scientific articles published in recent years, in English and Spanish, extracted from the MEDLINE database, which delve into the relationship between BPD and ADHD, will be carried out. In addition, the common psychopathological dimensions, such as impulsivity or emotional dysregulation, as well as the weight of other dimensional factors related to both disorders, will be studied.

Results: The results of the selected articles will be grouped, for a better understanding, in the following sections:

- Clinical factors and shared comorbidities.
- Psychopathological dimensions: impulsivity and emotional dysregulation.
- Other common dimensional factors.

Conclusions: There are common symptoms and etiological or perpetuating factors, as well as comorbidities shared in both conditions, which in many cases make the correct diagnosis and, therefore, the appropriate therapeutic approach to these patients, quite difficult. Taking into account the differential characteristics of BPD and ADHD, it is possible to create different profiles that allow a precise approach to both disorders in those cases in which they coexist in the same patient.

Narcissistic predispositions of self-harm in young women with and without depression

O. U. Vorontsova, T. I. Medvedeva, O. M. Boyko*, S. N. Enikolopov and S. O. Kuznetsova

Clinical psychology, Federal State Budgetary Scientific Institution "Mental Health Research Center", Moscow, Russian Federation

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1364

Introduction: Diagnostic criteria for narcissistic personality disorder primarily focus on grandiosity and significance. In psychotherapeutic work, it is important to distinguish two subtypes of pathological narcissism: narcissistic grandiosity and narcissistic vulnerability. One of the manifestations of narcissistic traits is unstable or unformed self-esteem, manifested in attempts to conform to ideals. A part of modern society perceives the female body as an object that "needs to be looked at". Self-objectification refers to a learned pattern of self-assessment of the importance of one's body and appearance compared to other aspects of the self. Self-observation and comparison of oneself with others is one of the manifestations of self-objectification. With acts of auto aggression, the body becomes a tool or a means to solve psychological problems. In order for this to become possible, the ability to objectify your body "to look at it from the outside" plays an important role.

Objectives: Analysis of the relationship between non-suicidal self-injurious behavior and narcissistic personality traits in young women with depression and young women without a psychiatric diagnosis.

Methods: The study included 49 women divided into two groups. The first group included 24 patients with depression undergoing inpatient treatment (mean age 18.4). The second group included 25 healthy subjects (mean age 18 years). The methods: The answer to the question "Sometimes I purposely injure myself" was used as an indicator of self-harm (NSSI) (five-point Likert scale); "Ich structure test" (ISTA); "Physical Appearance Comparison Scale-Revised" (PACS-R).

Results: In the clinical group, a significant association of severity of NSSI with indicators of "deficit narcissism" was revealed (Spearman $r=,534^*$). Correlations were found between the severity of NSSI and PACS-R ($r=,344^{**}$). In the clinical group, there was no connection between "Comparison with others" and narcissistic traits. In a group of healthy subjects, significant associations of NSSI severity with "destructive narcissism" ($,572^{**}$) and PACS-R ($,576^{**}$) were revealed. In the clinical group, the severity of NSSI is associated with a more serious pathology - the lack of formation of "normal" narcissism, and in the healthy group it is more likely to be deformed narcissism. Self-objectification and comparison of oneself with others in the clinical group is not associated with manifestations of narcissistic traits, such connections are demonstrated in the group of healthy young women.

Conclusions: It is shown that in the clinical group of depressed young women, the severity of self-harming behavior is associated with "deficit narcissism", and in healthy young women, first of all, with "destructive narcissism" with an increased need to compare themselves with others.

Explanation of the personality factor with the Enneagram in the selection of the specialty branch of the intern doctors

B. Özen, E. Ilgin*, E. Akça, A. Özercan, P. Seçgin and Ö. Yanartaş
Psychiatry, Marmara University Research & Training Hospital, Istanbul, Türkiye

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1365

Introduction: Personality characteristics have an important place in the choices of interns who are at the stage of deciding how their profession will be shaped in the future. While the Big 5 personality model has been widely used in evaluating the personality traits factor in career planning, the Enneagram has increased in popularity in recent years. In this study, it was aimed to investigate how senior medical students evaluate their professional future between these choices and the students' personality types.

Objectives: Forms and scales were presented to 221 interns who agreed to participate in our study and were studying in their final year in the 2022-2023 period at three different faculties, two state universities and one private university in the Marmara Region in Turkey.

Methods: The sociodemographic data form, Enneagram Personality Types and Subtypes Inventory, and Positive Future Expectation Scale, prepared by the researchers and containing questions about the factors that may be effective in choosing medical specialization, obtained through a face-to-face pilot interview with ten students and literature review, were applied to the participants. Participants answered the forms and scales via 'Google forms'.

Results: 211 out of 221 participants, who did not constitute outliers, were included in the analysis. The mean age of the participants was 24.43 (S.E= 0.11)

In terms of Enneagram typologies, Type 2 (39.3%) exhibited the highest prevalence, followed by Type 1 (13.3%), Type 6 (11.8%), and Type 7 (8.5%).

Furthermore, a statistically significant relationship was found between specialization area and Enneagram types (Fisher exact <.001, p< .001). Post-hoc examinations highlighted specific associations, such as the relationship between Type 3 and Cardiovascular Surgery, Orthopedics and Traumatology; Type 4 and Pneumology, Psychiatry; Type 5 and PRC, Type 6 and Infectious Diseases, Neurology, Medical Microbiology; Type 7 and Cardiology; Type 8 and Pediatrics, Medical Biochemistry; and Type 9 and Family Medicine, Radiology, Psychiatry, Medical Pathology.

Conclusions: When the results are evaluated, the highest rate of type 2 and type 1 of the Enneagram typology in senior medical faculty students supports the fact that the medical profession consists of responsible and principled people who love helping others. It is compatible with the character traits of people with type 9 who avoid stress and conflict, preferring the department to have a low workload, and turning to family medicine, radiology, psychiatry and medical pathology departments, which are estimated to have relatively fewer working hours and emergency applications. Our study suggests that this scale be used more widely, as the Enneagram typology, which is used in many professional and career choices, shows results compatible with the participants' preferences in choosing a medical specialty.

From schizotypy to psychosis: is it a natural continuum?

M. A. Andreo Vidal, M. B. Arribas Simón*, M. Calvo Valcárcel, M. P. Pando Fernández, P. Martínez Gimeno, M. D. L. Á. Guillén Soto, B. Rodríguez Rodríguez, N. Navarro Barriga, M. Fernández Lozano, M. J. Mateos Sexmero, C. De Andrés Lobo, M. D. C. Vallecillo Adame, T. Jiménez Aparicio, Ó. Martín Santiago, A. Monllor Lazarraga, M. Ríos Vaquero, L. Rojas Vázquez, L. Sobrino Conde, A. Apario Parra and G. Lorenzo Chapatte

Psychiatry, Hospital Clínico Universitario de Valladolid, Valladolid, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1366

Introduction: Schizotypal personality is a condition suffered by 4% of the population. It is defined by presenting interpersonal, behavioral and perceptual features similar to the clinical features of psychotic disorders, such as schizophrenia, in less intensity and dysfunctionality, but at risk of reaching psychosis.

Objectives: Presentation of a clinical case about a patient with premorbid schizotypal personality traits presenting with an acute psychotic episode.

Methods: Literature review on association between schizotypal personality and psychosis.

Results: A 57-year-old woman with a history of adaptive disorder due to work problems 13 years ago, currently without psychopharmacological treatment, goes to the emergency room brought by the emergency services due to behavioral alteration. She reports that "her husband and son wanted to sexually abuse her", so she had to run away from home and has been running through the streets of the town without clothes and barefoot.

Her husband relates attitude alterations and extravagant behaviors of years of evolution, such as going on diets of eating only bread for 40 days or talking about exoteric and religious subjects, as believing that the devil got inside her husband through a dental implant. He reports that these behaviors have been accentuated during the last month. She has also created a tarot website, and has even had discussions with several users. She is increasingly suspicious of him, has stopped talking to him and stays in his room all day long, with unmotivated laughter and soliloquies.

It was decided to admit him to Psychiatry and risperidone 4 mg was started. At the beginning, she was suspicious and reticent in the interview. As the days went by, communication improved, she showed a relaxed gesture and distanced herself from the delirious ideation, criticizing the episode.

Conclusions: In recent years, there has been increasing interest in understanding the association between schizotypy and serious mental disorder. Several theories understand schizotypy as a natural continuum of personality that reveals genetic vulnerability and that can lead to psychotic disorder when added to precipitating factors. Other theories define schizotypy as a "latent schizophrenia" where symptoms are contained and expressed in less intensity.

Around 20% evolves to paranoid schizophrenia or other serious mental disorders. It is complex to distinguish between those individuals in whom schizotypy is a prodrome and those in whom it is a stable personality trait. To date, studies applying early psychotherapeutic or pharmacological interventions have had

insufficient and contradictory results, and the follow-up and treatment of these individuals could be a stress factor and a stigma. Some studies are looking for reliable markers of evolution to schizophrenia in order to establish adequate protocols for detention, follow-up and treatment.

Specifics of anticipatory competence of adolescents with speech pathology

A. Akhmetzyanova* and T. Artemyeva

Department of Psychology and Pedagogy of Special Education, Kazan Federal University, Kazan, Russian Federation

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1367

Introduction: Adolescents with speech pathology experience disturbances in sound pronunciation, phonemic processes, poor vocabulary, insufficiently formed grammatical structure, and disturbances in coherent speech. The specifics of the emotional-volitional sphere of adolescents in this group are anxiety, isolation and negativism prevent the establishment of full social contacts with peers and adults and complicate the formation of their anticipatory competence.

Objectives: Studying the specifics of the anticipatory competence of adolescents with speech pathology.

Methods: The study involved 56 adolescent children aged 11-15, attending an educational institution for children with disabilities, diagnosed with general speech impairment level 2. The study was carried out using the following methods: "Achenbach Questionnaire", "Test of Anticipatory Consistency" by V.D. Mendelevich, "Anticipation of the outcome of a situation with a violation of the norm" by V.P. Ulyanova and the author's methodology "Studying the anticipatory competence of adolescents" by Akhmetzyanova A.I., Artemyeva T.V.

Results: It was revealed that adolescents with speech pathology experience difficulties in mastering the material, it is difficult for them to concentrate their attention on the task and bring the work they have started to the end. Adolescents of this nosological group face difficulties in predicting the outcome of situations and the consequences of their own behavior in a situation of social interaction, find it difficult to control time in the process of doing homework and organizing leisure time, make a forecast of various situations that may arise at school and family, make new acquaintances, and communicate freely with parents, teachers and peers.

Conclusions: The level of speech development influences the formation of personal-situational, speech-communicative anticipatory competence of adolescents, and the ability to predict speech situations. Teenagers with speech pathology need help from adults. This paper has been supported by the Kazan Federal University Strategic Academic Leadership Program.

Specifics of socialization of children with autism spectrum disorders

A. Akhmetzyanova*, T. Artemyeva and A. Minullina

Department of Psychology and Pedagogy of Special Education, Kazan Federal University, Kazan, Russian Federation

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1368

Introduction: One of the important tasks of modern education is the adaptation of children with autism spectrum disorders to the social space, which allows them to ensure their personal development and self-realization.

Objectives: Study of the specifics of the socialization of children of preschool age with autism spectrum disorders.

Methods: The study involved 27 preschool children with autism spectrum disorders attending an educational institution for children with disabilities; 6 were girls and 21 were boys; 20 children with intact speech and 7 children with speech disorders. The following methods were used: "Map of manifestations of activity by A.M. Shchetinina, N.A. Abramova; "Map of observations of the manifestations of communicative abilities in preschool children" A.M. Shchetinina, M.A. Nikiforova; "Emotional faces" N.Y. Semago.

Results: It was found that children with autism spectrum disorders have the greatest severity of such activity indicators as "is in a good mood" (1.67), "shows stubbornness" (1.56) and "shows great mobility" (1.56). Among the manifestations of communicative abilities in preschool children, the most developed parameter is: "sincere in his statements, in the manifestation of his feelings" (2.07). At the same time, the lowest expression of communication skills (0.96) in children with autism spectrum disorders is observed in terms of: "has organizational skills", "the child seeks to understand the other, his thoughts, feelings"; "observant, sees and realizes the characteristics of other children and adults". The least pronounced indicator is observed in the indicator of initiative; children do not show initiative in communication, have difficulty understanding and supporting the initiative of another child in an interaction situation. Children have a low level of operational communicative actions and skills: children are not expressive in communication, do not master verbal means of communication and are not able to maintain contact with communication partners.

Conclusions: The results obtained in the study confirm the need to develop and implement psychological and pedagogical programs aimed at developing social skills in preschool children with autism spectrum disorders. This paper has been supported by the Kazan Federal University Strategic Academic Leadership Program.

EPV0727

Anticipatory competence of adolescents with movement disorders in the prevention of deviations

A. Akhmetzyanova* and T. Artemyeva

Department of Psychology and Pedagogy of Special Education, Kazan Federal University, Kazan, Russian Federation

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1369

Introduction: Anticipation is the most valuable component of the regulatory side of human behavior. Adolescence is a sensitive period in relation to the formation of an anticipatory and prognostic system, which in turn provides an opportunity to assess causal relationships and evaluate the consequences of actions taken.

Objectives: Study of the anticipatory viability of adolescents with long-term disorders in the prevention of deviations.

Methods: The study involved 46 adolescents aged 11-15 studying at a specialized boarding school for children with disabilities. The observational method was used as well as the author's methodology "Studying the anticipatory solvency of adolescents" Akhmetzyanova A.I., Artemyeva T.V.; "Diagnostic questionnaire for identifying propensity to various forms of deviant behavior for students of educational institutions" developed by the Department of Psychiatry of the Military Medical Academy named after S.M. Kirov.

Results: The subjects had difficulty predicting the passage of time, with its adequate and rational distribution, including planning their own activities. Adolescents with musculoskeletal disorders had difficulty making a pragmatic and realistic forecast of possible events in communication with other people, as well as predicting the emotional states of interaction participants. Adolescents with movement disorders were characterized by an inadequate assessment of themselves as a subject of professional activity, fixation on the movement disorder, and high levels of anxiety and neuroticism. The subjects showed a tendency to suicidal behavior due to risk factors such as high levels of anxiety associated with self-esteem and anxiety in interpersonal relationships, high affectivity and demonstrativeness, social pessimism and negative prediction of the future. During the correlation analysis, the relationship between spatio-temporal and speech-communicative anticipatory consistency with indicators of deviant behavior - delinquent behavior and deviant behavior was revealed.

Conclusions: The data obtained in the study will allow specialists to timely identify and prevent the development of deviant behavior, as well as build a route for correctional classes with each child. This paper has been supported by the Kazan Federal University Strategic Academic Leadership Program.

Mental disorders: exploring normality models to distinguish what is normal from what is illness

A. Fernandes^{1*} and M. Gomes²

¹Hospital de Braga, Braga, Portugal and ²Psychiatry Department, Hospital de Braga, Braga, Portugal

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1370

Introduction: When reading about psychopathology what we find described are experiences similar to our own. Psychiatry deals with anguish, fear, motivation, choice, and many other aspects that makes us human. However, even though psychopathology is rooted in common human experience, mental disorders are often outside the experience of those who don't suffer from it. Therefore, the distinction between normality and disease is central to psychiatry.

The DSM proposes that mental disorders are necessarily linked to distress and/or impairment. However, it adds that the syndrome or pattern must not be an expectable response to an event - it excludes "normal" experiences and responses from the realm of mental illness. But how do we distinguish normal distress from illness? This review investigates how different meanings of normality can help us discern the fine line between mental illness and ordinary human experience.

Objectives: We intend to critically examine and compare different models of normality. Additionally, we seek to discern the implications of these models for distinguishing mental disorders from normal mental experiences.

Methods: Review of the literature.

Results: We analyzed definitions and models of normality throughout the literature and selected the most relevant ones according to their popularity and/or strength of argument. Different models of normality (e.g. Biostatistical, Process, Health, Ideal, Biological advantage, etc.) were examined and compared, and the conceptualization of mental disorder was examined through the lens of each of these frameworks. Our investigation reveals the multifaceted nature of normality, with different models offering unique perspectives on mental health. From statistical approaches to cultural considerations, each model contributes distinct criteria for distinguishing what is normal from what is illness. By synthesizing these results, we gain a comprehensive view of the factors influencing the conceptualization of normality in the context of mental health.

Conclusions: This review emphasizes the importance of adopting a nuanced, cautious and multifactorial approach when discerning mental disorders from normal experiences. Rather than relying on a singular definition, our analysis suggests that a comprehensive understanding of normality can help us to better discern what is normal and what is illness.

EPV0729

Phenomenology or constructivism in psychopathology

G. Dzhanupov

State psychiatric hospital for treatment of drug addiction and alcoholism, Sofia, Bulgaria

doi: 10.1192/j.eurpsy.2024.1371

Introduction: Phenomenology is historically fundamental for psychopathology. In recent decades constructivist approaches occur as an alternative. Some consider them quite compatible, others take the reverse stance, arguing for advances of one or the other. This has parallel in discussions and contradictions in philosophy of mind.

Objectives: As Dennett points, there is no science free of philosophy, so it is recommendable to make clear and bear in mind on what kind of philosophy is based contemporary psychopathology.

Methods: Brief review and comparison between phenomenological and constructivist approaches.

Results: There is no doubt, that culture influences self and experience. Culture and social environment shape abnormal experiences as well. In an extreme variant a constructivist statement would sound as "Someone suffers from a disorder because a violation of social norms." The self is considered as socially constructed entirely, in the spirit of Mead. Psychopathological theories are

function of societal development as well. Phenomenological approach pays attention to constitution and structure of subjective experience. The self has a multilayer structure with a pre-reflexive experiential level of self. Elements of subjective reality do exist, that are not result from social influence, these include abnormal experiences. Especially some experiences in severe mental illness originate from profound disturbance of intentionality based on dysfunction of pre-reflexive self-awareness as it shown by T. Fuchs.

Conclusions: Phenomenology offers more broad and satisfying framework for psychopathology and psychiatry. Contribution of constructivism is not to be ignored, but seems to be one-sided. Further research and deeper education in phenomenological psychopathology of trainees would be valuable.

Disclosure of Interest: None Declared

The Reductions in Phenomenology - A Comparison Across Main Authors

N. D. Ramalho^{1*}, I. Lopes¹, T. Rocha¹, G. Santos¹, J. Leal¹, J. F. Cunha¹, D. Seabra¹, D. Santos¹ and J. C. Moura¹

¹Psychiatry and Mental Health Department, Centro Hospitalar Barreiro Montijo, Lisbon, Portugal

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1372

Introduction: Phenomenology is one of the fundamental tools in the clinical practice of psychiatrists, constituting one of the touchstones regarding the diagnostic framework in which clinicians navigate.

For Husserl, Phenomenology provided access to the structure of pure consciousness, experience and existence. These are conditions of possibility for the object of Psychiatry, ontologically prior to it. Thus, clarification of the object and method of Phenomenology is preliminary to understanding the object of Psychiatry.

Phenomenology, being a direct tributary of Philosophy, evolves dialectically, constantly dialoguing with its predecessors. While it is taken as a philosophical current, it is also considered a method. It is precisely as a method that we can see how the methodology changes in different phenomenological traditions.

Objectives: To compare how the main phenomenological traditions operate.

Methods: Comparative analysis between the phenomenological reductions in key figures of the phenomenological tradition, resorting to the corpus of the *Husserliana*, *Being and Time*, *Phenomenology of Perception* and *General Psychopathology*. Additionally, a non-systematic literature review of papers on the database Philpapers, using the keywords “critical phenomenology”, “eidetic reduction”, “phenomenological reduction”.

Results: While there is a multiplicity of ways of taxonomizing phenomenological currents, we divide it in: pure, existential, embodied, jasperian, psychopathological, and critical.

Husserl's pure phenomenology uses the free variation in phantasy and *epoché* as operators, starting from the natural attitude.

Heidegger's existential phenomenology makes no reference to a reduction of any kind. For him, it is necessary to take a step back, to a more primordial mode of being through which we can access Being, where the world is given and constituted.

Embodied phenomenology, of Merleau-Pontian provenance, recognizes the reduction, but cannot be fully achieve it.

Jasperian phenomenology uses empathy and co-experience as its operators, through which it gains access to the subjective states of the other, with the aim of systematizing and taxonomizing subjective phenomena.

Phenomenological psychopathology tentatively uses Husserlian reductions to identify the a priori structures of the human, be it Biswanger's forms of manifestation of failed human existence or Blakenburg's anthropological disproportions.

Critical phenomenology uses a historical-transcendental analysis of experience as its operator, through which it accesses transcendental intersubjectivity.

Conclusions: At a time when the DSM and ICD are increasingly seen as inadequate, limited and dogmatic, the resurgence of interest in Phenomenology is evident. It is important to avoid falling back on new presuppositions without constant revision and questioning, at the risk of simply mutating dogmas and missing the original legacy of pure phenomenology, the suspension of presuppositions.

Achieving self-awareness through film screening “Twin Peaks” By D. Lynch as an example of mindfulness meditation

J. K. Nowocień* and N. Szejkó

Department of Medical Ethics and Palliative Medicine, Medical University of Warsaw, Warsaw, Poland

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1373

Introduction: Transcendental cinema, distinguished from slow cinema by Paul Schreder, draws on the philosophy of existentialism and depicts the complexity of the human psyche using psychoanalytic tools. We claim that through the use of special procedures, the projection of transcendental cinema essentially becomes a meditation session in the spirit of mindfulness, which has been proven to alleviate and cure more than just neuropsychiatric ailments.

Objectives: The purpose of this work is to demonstrate the similarity between mindfulness philosophy and transcendental cinema. We believe that the assumptions of both currents are so similar that we can treat the film screening in the category of a meditation session. Thus, we arrive at a situation in which we not only watch the protagonist developing his own consciousness in accordance with the mindfulness philosophy (also following the path of psychoanalysis), but also we, as viewers, develop self-awareness.

Methods: We analyze D. Lynch's Twin Peaks series in accordance with Paul Schrader's understanding of ‘transcendental cinema’. In addition, we use the scientific achievements of classical psychoanalysts, analyzing the metaphysical world of the characters in accordance with this trend. Using J. Kabat Zinn's scientific publications, we analyze cinema in terms of a meditation session.

Results: Participation is crucial; in meditation and in the transcendental cinema. Mindfulness means focusing on the emotions and feelings experienced at a given moment, on what comes to us, what we experience. Transcendental cinema using specific formal and

narrative tools (e.g. extended scenes, no cuts, etc.) forces us to actively participate. Transcendental cinema fulfills the tenets of mindfulness, and during the screening we undergo a meditation session. What's more, this style in cinema allows an in-depth exploration of the psyche, it brings us closer to the metaphysical, emotional dimension of humanity what develops in us the ability to understand the psyche of others, as well as our own.

Conclusions: We claim that the similarity between the philosophy of mindfulness and transcendental cinema allows us to treat a film screening as a meditation session. Cinema enriches us not only with knowledge about disorders and the therapeutic process, but is in itself a supportive tool - screening can allow viewers to deepen their awareness and improve their health. What is more, David Lynch's work brings us closer to exploring the human psyche and the individualization of inner experiences, while also showing us what influence transcendental meditation has on characters and what happens when they undergo a kind of therapy; in the spirit of psychoanalysis or mindfulness philosophy.

EPV0733

Philosophy of transcendental cinema and its applications in psychiatry. The case of lost highway by david lynch

J. K. Nowocień* and N. Szejko

Department of Medical Ethics and Palliative Medicine, Medical University of Warsaw, Warsaw, Poland

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1374

Introduction: Thanks to Paul Schrader, transcendental cinema was distinguished from the slow cinema trend. What distinguishes it from it are the precise psychological portraits of the characters and the aptly reproduced world of internal experiences. Transcendental cinema draws from the philosophy of existentialism, presenting the assumptions of the human psyche. In D. Lynch's cinematography, we can find faithful representations of mental disorders, such as dissociative fugue, depersonalization, mania or psychosis. Based on the "Lost Highway" (1997), we will prove that D. Lynch, with his cinematography, not only provides knowledge about mental disorders, but also gives patients humanity and dignity. The series also resembles a meditation session in the style of mindfulness, which, when practiced, helps a person affected by mental illness in his recovery process.

Objectives: The aim of this work is to indicate the accurate record of the inner characters' experiences in D. Lynch's cinematography, which provides us with knowledge about mental disorders of an individual. By creating a visual image that affects many senses, transcendental cinema sensitizes us and makes us aware of the suffering of a patient affected by mental disorders. The session, while drawing on the philosophy of mindfulness, becomes a meditative session, therapeutic for both us and the protagonist.

Methods: In this research we use the approach proposed by Paul Schrader and David Lynch to analyze transcendental cinema as an art that combines philosophy, cinematography and psychiatry. As a representation of the experiences of a person outgoing the therapy basen on psychoanalysis.

Results: Many studies indicate the positive impact of mindfulness meditation on physical and mental health. Through long scenes, transcendental cinema draws attention to individual stimuli reaching our body, non-judgmental noticing them, focusing on one thought and one sensation, draws from the philosophy of mindfulness, becoming a meditative session in itself. Therefore, a film screening provides us with knowledge about the internal experiences of a psychiatric patient, indicates the form of therapy and at the same time leads us through a therapeutic meditation session.

Conclusions: We believe that the transcendental cinema represented by David Lynch can be treated not only as a representation of mental disorders and the suffering associated with them, but also as a meditative, healing and liberating session. Not only for the person affected by the disorder, but also for us as viewers.

EPV0734

Mental health support through transcendental cinema. "Mulholland Drive" By D. Lynch as an example of a mindfulness meditation session

J. K. Nowocień* and N. Szejko

Department of Medical Ethics and Palliative Medicine, Medical University of Warsaw, Warsaw, Poland

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1375

Introduction: Regular practice of mindfulness has proven effectiveness in the treatment of affective disorders (Cash and Whittingham, 2010), increases the level of satisfaction in life (Brown and Ryan, 2003), as well as the level of self-esteem (Rasmussen & Pidgeon, 2010). Using "Mulholland Drive" (2001) by David Lynch as an example, we will prove that transcendental cinema, through the unique slow character, the means of expression used and the emphasis placed on the metaphysical experiences of the characters, in which D. Lynch forces us to participate, makes the screening similar to a meditation session.

Objectives: The aim of this work is to indicate a new direction of research, linking cinema with psychoanalysis, philosophy and psychiatry and proving that a screening of transcendental cinema can be treated as a mindfulness meditation session.

Methods: This work is based on the film "Mulholland Drive" by D. Lynch and the understanding of transcendental cinema according to Paul Schrader. Using J. Kabat Zinn's scientific publications, we analyze cinema in terms of a meditation session and using the approach of first generation analysts (S. Freud, C. Gustav Jung, S. Spielrein) in terms of a therapeutic process based on psychoanalysis.

Results: "Mulholland Drive" subjects the protagonist to a therapy session: the woman lives guided by the unconscious, a dream that seems real and finally at the end she reaches her own true self. On screen, she undergoes successfully the therapeutic process. The transcendental cinema focuses on metaphysical sensations, has elongated scenes, creates *dead time*, viewer remains in the frame even when the character comes out of it, and strives for *kenosis* - the reduction of sensory experience. All of these qualities are crucial in mindfulness: focusing on emotions and feelings experienced in the moment, non-judgmental and calmly concentrating on single

stimuli. This similarity allows us to treat a transcendental film show in the category of a meditation session.

Conclusions: Recognizing the similarity between the philosophy of mindfulness and transcendental cinema allows us to conclude that a film screening enriches us not only with knowledge about disorders and the therapeutic process, but is in itself a supportive element for mental health. Our work is the first to analyze cinema in the context of mindfulness meditation. In our opinion, culture should be more widely analyzed as a tool to support mental health and the development of one's own identity.

Person-centered approach to suicide ideation in posttraumatic stress disorder in veterans: a latent profile analysis

M. Vilibić^{1,2*}, S. Nadalin^{2,3}, B. Aukst Marčetić^{1,2}, Ž. Šurina Osmak⁴, V. Peitl^{1,2} and D. Karlović^{1,2}

¹Department of Psychiatry, University Hospital Centre Sestre milosrdnice; ²School of Medicine, Catholic University of Croatia, Zagreb; ³Department of Psychiatry, General Hospital "Dr Josip Benčević", Slavonski Brod and ⁴Department of Health, Ministry of Defence of the Republic Croatia, Zagreb, Croatia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1376

Introduction: While most research on suicidal ideation (SI) in veterans adopts a variable-oriented perspective, this approach often fails to capture the complex interplay of symptoms and comorbid disorders. We hypothesised that a person-centred approach can identify distinct subpopulations of veterans with varying profiles of SI, PTSD symptoms, depression, and agitation.

Objectives: To examine whether distinct subpopulations of veterans exist, characterized by different profiles of PTSD severity, depression and agitation, and intensity of SI.

Methods: We conducted a cross-sectional study in one big University Hospital Centre in Croatia on the sample of men, war veterans aged 30-65 years, undergoing treatment for chronic PTSD. Latent profiles indicators included the Clinician-Administered PTSD Scale (CAPS), Beck Scale for Suicide Ideation (SSI), Hamilton Depression Rating Scale-17 (HDRS-17) and Corrigan Agitated Behaviour Scale (CABS).

Results: We included 203 male participants with a median age of 47 (IQR 43-45) years. The optimal model, allowing variances of indicators to vary between profiles while constraining covariances to zero, yielded five distinct latent profiles. Notably, the highest SI was found in a subpopulation with elevated CABS scores, but moderate PTSD and depression symptoms (13% of participants). Next in SI intensity were 11% of veterans with severe symptoms across all assessed disorders. Next in SI severity were 21% of veterans with low levels of agitation but high levels of depression. The last two profiles, one with mild symptoms of all assessed disorders (43%) and the other with high agitation (12%), have low SI severity.

Conclusions: Our findings affirm the utility of a person-centred approach in identifying nuanced subpopulations of veterans with

diverse symptom profiles related to SI. This stratification can inform targeted interventions, thereby enhancing the efficacy of suicide prevention strategies.

Analyze the factors that influence the therapeutic response to psychic trauma

B. Serván Rendón-Luna*, G. Strada Herrera, F. Mayor Sanabria, I. López Claramunt and L. Reyes Molón

Hospital Clínico San Carlos, Madrid, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1377

Introduction: Psychic trauma profoundly affects a person's confidence in himself and others. There is a sudden experience of helplessness, loss of control, fear for one's own life, and the humiliation of having been violated. The victim may run out of internal and external reference elements.

Objectives: Describe the factors that influence the development of Post-traumatic stress disorder after experiencing traumatic experiences.

Methods: Review in the literature of the different factors that influence the subject's response to the traumatic experience.

Results:

1) Predisposing and precipitating factors:

- characteristics of the traumatic event: severity of the stressor agent: dose-dependent, Characteristics of the same: sudden, prolonged, repetitive, intentional; decrease the ability to control the situation and develop effective coping strategies; they question basic cognitive schemas; the symbolic meaning of the traumatic event.
- characteristics of the person (predisposing factors of vulnerability): genetic-constitutional vulnerability, adverse experiences in childhood, previous traumatic events: increased vulnerability, personality characteristics, recent stressors or life changes, inadequate support system, use of alcohol, perception locus control more external than internal, pre-existing psychiatric symptoms: neuroticism, anxiety, depression, critical ages of development: time of greatest vulnerability (11-16 years).

2) Perpetuating and empowering factors: sharing traumatic events, seeking the logic of the facts, rupture of affective ties.

3) Elements of Resistance: tendency to selectively remember the positive elements in autobiographical memory, acceptance of a certain dose of uncertainty in life, perceiving themselves as survivors, perception of the stressful stimulus as less threatening, Less physiological reactivity to stress, use of humor, positive emotions counteracting during the traumatic process.

4) Elements of Resilience: ability to extract and assimilate positive elements from negative situations.

Conclusions: Trauma threatens 3 basic assumptions of life: the world is good, the world has meaning, the self has value. The knowledge of these mentioned factors allow a better psychotherapeutic approach to Psychic Trauma.

Comparative study of the effectiveness of EMDR G-TAP and CBT group protocols for the treatment of trauma in children exposed to a conflict context

E. Dozio^{1*}, C. Bizouerne² and V. Wamba³

¹Action contre la Faim; ²Indipendent, Paris, France and ³Action contre la Faim, Bangui, Central African Republic

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1378

Introduction: 357 million children live in conflict zones. Children's mental health is a major but complex issue as needs and interventions depend on the age of the child, caregivers, daily safety and protection, etc. EMDR and CBT are the recommended therapies to treat PTSD according to the WHO, but there is not enough standardized evidence-based protocol for children. Testing and evaluating trauma management systems for children is essential for trauma treatment interventions to be implemented in emergency contexts, such as war and conflict situations.

Objectives: This research compares two intervention protocols for children aged 6 to 17 years suffering from Post Traumatic Stress Disorder after exposure to conflict traumatic events in the Central African Republic: the protocol "Kôno" developed by Action contre la Faim, based on a CBT and narrative approaches and the EMDR/G-TAP (Group Traumatic Events Protocol). After a psychoeducation session, the children were assigned to the ACF-KONO or EMDR/G-TAP groups for 5 sessions. The Child Psychosocial Distress Screener (CPDS) to measure general well-being and functioning and the Child Revised Impact of Events Scale (CRIES) to assess trauma, were administered before and after treatment.

Methods: 793 children participated in the research, 391 were included in the ACF-KONO protocol and 402 in the EMDR/G-TAP protocol. Both protocols have been shown to be equally effective in improving well-being and reducing traumatic symptoms. 185 children (90 ACF-KONO and 95 EMDR/G-TAP) were also re-evaluated after 5 months. The CPDS and CRIES-8 measurements reveal that the results are stable over time, with the use of both protocols. Detailed results will be presented.

Results: This research contributes to the discussion on a framework for group protocols for children in mental health and psychosocial support interventions in humanitarian programs. The two protocols tested showed very good results in reducing symptoms of PTSD in children. How to choose between EMDR/G-TAP and CBT? What contextual and cultural adaptations are to be expected? Are there differences in children's appreciation? And in that of mental health practitioners? Ideas for reflection will be shared.

Conclusions: It is possible to widen access to therapeutic treatment of PTSD for children in emergency situations such as war and conflict. Further research in other contexts is needed. These studies should explore qualitative elements, such as children's appreciations, but also the impact of these different protocols on the vicarious trauma of professionals involved in the treatment of children's trauma.

Post-traumatic stress disorder after childbirth: A Tunisian study

N. Sghaier^{1*}, R. Ben Soussia¹, H. Bouchahda², I. Belhadj², H. Ben Garouia³ and H. Khiari³

¹Psychiatry Departement; ²Gynecology and obstetrics Department, Taher Sfar Hospital, Mahdia and ³Psychiatry Departement, Ibn Jazzar Hospital, Kairouan, Tunisia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1379

Introduction: Childbirth is a special time for every woman, bringing pregnancy to an end and marking the birth of a new baby. This transitional event presents countless physical and psychological changes. Post-traumatic stress disorder (PTSD), the result of particularly intense stress, is often linked to the perception of childbirth as a traumatic event, requiring optimized follow-up and screening.

Objectives: The aim of this current study is to estimate the prevalence of post-partum post-traumatic stress disorder in a sample group of Tunisian women and to determine factors associated with childbirth-related post-traumatic stress disorder.

Methods: This is a longitudinal prospective descriptive study conducted among women hospitalized for childbirth in the obstetrics and gynecology department and those who consulted the prenatal outpatient clinic at Taher Sfar Mahdia Hospital. The duration of the study is 7 months, from March 15, 2020 to September 15, 2020. Data collection was based on a pre-established questionnaire determining the various socio-demographic and clinical characteristics. Psychometric assessment was carried out using the Posttraumatic Stress Disorder Checklist Scale (PCL-S).

Results: We enrolled 120 women with a mean age of 28.2 ± 5.3 years. Few women had a psychiatric history of depression (1.2%) or anxiety (3%), and 29% had a pathological obstetric history. Nevertheless, 12.5% of patients were hospitalized during pregnancy. Eighty-seven patients expressed anticipatory fear of childbirth, and 102 women had good marital and social support. Almost half of deliveries (48.3%) were vaginal, and almost a third (27.5%) were emergency caesarean sections. Level 3 pain was reported in 73.3% of cases. Psychometric assessment revealed a prevalence of PTSD of 5.8%, with PTSD symptomatology in 18.4% of women. PTSD was statistically associated with low level of education ($p=0.02$), postpartum complications ($p=0.05$) and gender of newborn ($p=0.01$).

Conclusions: Postpartum PTSD is a major public health problem affecting the healthy development of the newborn, the overall mental and physical recovery and well-being of the mother. Our findings suggest several intervention points for healthcare practitioners, including careful prenatal screening of past trauma history, social support, pain management and expectations about the birth, within a multidisciplinary approach.

Post-traumatic stress disorder in parents of schizophrenic patients at the Arrazi Psychiatric Hospital in Salé following familial violence

N. Ait Bensaid* and F. El Omari

Arrazi psychiatric hospital in salé, Salé, Morocco

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1380

Introduction: Parents whose adult child has a serious mental illness are at risk of serious violence from their child. One of the reasons for the high risk of PTSD is violence in the home [1,2]. The high risk of PTSD in parents of patients with schizophrenia is an issue of great concern because parents are likely to fear repeated violence and, therefore, to object to patients being discharged from hospital.

Objectives: To assess the existence of post-traumatic stress disorder in relatives of patients with schizophrenia treated at the Arrazi University Psychiatric Hospital in Salé following familial violence.

Methods: This was a descriptive cross-sectional study using a questionnaire including sociodemographic criteria, clinical criteria, questions about domestic violence and an "IES-R" post-traumatic stress symptom assessment questionnaire to investigate the existence of post-traumatic stress disorder in relatives of patients with schizophrenia followed up at Arrazi University Psychiatric Hospital in Salé following familial violence.

Results: The response of 72 relatives of schizophrenic patients was collected. About 70% of the participants were mothers. The average age of the participants was 58. All lived with children who had been treated for schizophrenia for more than 18 years (57% of participants). Around 20% of these children were in hospital at the time of completing this questionnaire.

About 80% of the children with schizophrenia spent all their time at home, and about 89% of the participants had already been victims of violence from their sick children. 90% had been sworn at and insulted, the majority blamed themselves for the illness, about 56% had already been kicked or punched, and 36% had already received death threats and 12% serious injuries/.

For all items, parents with a high IES-R score had significantly more experiences of violence than parents with a low IES-R score. The percentage of parents with a high IES-R score was 45%.

Conclusions: The experience of severe violence and hospitalisation of a patient was related to a high risk of post-traumatic stress disorder in parents. These two factors can be considered as traumatic events arising from crisis situations and can have harmful consequences for parents and their schizophrenic children, who are sometimes rejected. There seems to be a need to create crisis intervention programmes that offer a multidisciplinary approach capable of rapidly detecting the exacerbation of a serious mental illness and providing rapid and intensive treatment as quickly as possible. Finally, the provision of support, education or treatment for parents during their child's hospitalisation is essential.

Uncovering the Connection: PTSD and Road Accidents

S. Bellafqih*, Y. El Fatmaoui, S. Belbachir and A. Ouanas

Hôpital Arrazi, CHU Ibn Sina, Salé, Morocco

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1381

Introduction: Post-Traumatic Stress Disorder (PTSD) is a psychiatric disorder that can occur after a traumatic event. It results in mental suffering and physical complications that profoundly alter personal, social, and professional life.

One can develop PTSD after experiencing a frightening event, for example: rape, the death of a loved one, war veterans, or following a car accident. In Morocco, traffic accidents cause, on average, nearly 3,500 deaths and 12,000 serious injuries per year.

Objectives: Our main purpose is to evaluate the incidence of post-traumatic stress disorder in patients who are victims of traffic accidents and to identify key risk factors in the general population.

Methods: This is a descriptive cross-sectional study through a questionnaire shared on social networks including a socio-demographic description, a clinical description, and the "Peritraumatic Distress Inventory (PDI)" Scale to evaluate the risk of developing PTSD.

Results: This study is based on 48 participants with 82.8% of females and 17.2% of men. The average age was 27.6. Most of the participants lived in urban areas (93%), a majority had higher education (93.1%), and 41.4% of the candidates had a physical impact of the accident.

According to PDI scale, 65% showed PTSD and the average score was 20.3. A score of 15 and above indicates significant distress.

Conclusions: Our results confirm the presence of PTSD in victims of accidents. We propose a clinical reflection on the possible improvement of the care of people suffering from PTSD following a public road accident.

Prevalence and patterns of post-traumatic stress disorder in victims of intimate partner violence

F. Tabib*, F. Guermazi, R. Masmoudi, D. Mnif, I. Feki, I. Baati and J. Masmoudi

Department of psychiatry A, UHC Hedi Chaker, Sfax, Tunisia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1382

Introduction: It's a well-known fact that violence, particularly repetitive violence or violence lasting several years, as is often the case with intimate partner violence (IPV), has a severe psycho-traumatic impact. Although not all women are affected to the same degree or in the same way, post-traumatic stress disorder (PTSD) is the most common mental health consequence of IPV.

Objectives: To assess the psycho-traumatic impact of IPV on female victims. To study the factors associated with PTSD among these women.

Methods: We conducted a descriptive and analytical cross-sectional observational study, carried out over a 10-month period from March 2021 to December 2021, among female victims of IPV

consulting psychiatric emergencies at UHC Hédi Chaker, Sfax, Tunisia for medical expertise at the request of the court. We studied the PTSD in these women using the Post Traumatic Stress Disorder Checklist Scale (PCLS).

Results: The total number of participants was 120 with an average age of 37.27 years. The majority had secondary education or less (62.5%), were professionally active (53.3%), and were financially dependent on their partners (26.7%). As for the women's clinical characteristics, 19.2% were under psychiatric care, 15% had attempted suicide and 10% had a history of childhood abuse. Regarding the couple's profile, marriage was arranged in 58.3% of cases, and the average duration of marriage was 12.34 years, exceeding 10 years in 44.2% of cases.

The impact reported by our women was 100% psychological and 96.7% familial. As a result, 75.8% had sought help from family and friends, and 55.8% had decided to separate from their partners. According to the PCLS scale, 78.3% of female victims showed PTSD with a positive score > 44. It was associated with a higher number of suicide attempts ($p=0.04$), a marriage duration exceeding 10 years ($p=0.02$), help-seeking ($p=0.001$), and divorce ($p=0.014$).

Conclusions: PTSD is a particularly serious psychiatric condition. However, its impact remains insufficiently understood and taken into account in medical, psychological, social, and legal care. Knowing the psycho-traumatic consequences of violence is absolutely essential to better protect, support, and care for victims.

Secondary Trauma by Internet Content Moderation: a Case Report

L. Martinez-Sadurni*, F. Casanovas, C. Llimona, D. Garcia, R. Rodriguez-Seoane and J. I. Castro

Institut de Neuropsiquiatria i Addiccions (INAD), Hospital del Mar, Barcelona, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1383

Introduction: In recent years, a global debate has emerged regarding the protection of Internet users from exposure to harmful content. Content moderation is defined as the organized practice of filtering user-generated content posted on internet, social networks, and media to determine the appropriateness of the content for a site, locality, or jurisdiction. The growing volume of this content along with the psychological impact of this activity have promoted the application of automated approaches based on artificial intelligence and machine-learning. However, the changing characteristics of content, as well as the cultural differences that influence its appropriateness, mean that human moderation of Internet content currently continues to exist. Psychological effects of this activity such as symptoms of post-traumatic stress disorder (PTSD) could represent an example of secondary trauma.

Objectives: Our aim is to describe a clinical case of post-traumatic stress disorder presenting with specific traumatic exposure idiosyncrasy that could lead to a better consequence characterization of a recent social phenomena such as internet content moderation.

Methods: We expose the clinical case of a woman with emotional distress who was referred to our outpatient psychiatric unit in

Barcelona in 2022 after five years working as an internet content moderator.

Results: We describe the case of a 35-year-old woman without relevant medical, toxicologic or psychiatric record that presents to our out-patient psychiatric clinic with post-traumatic stress disorder after five years of working as an internet content moderator and being exposed to visual traumatic content such as sexual assault and paedophilia. The clinical presentation consisted with one year of recurrent daily panic attacks, intrusive images about the traumatic exposure, intrusive thoughts, insomnia, vivid nightmares, avoidance of exposure to her son, distrust of the environment and intense fear for her son security. The disorder interfered in her capacity to work. The patient received psychological treatment and ISRS (Sertraline) was prescribed, however only partial response was reached with persistence of the majority of symptoms.

Conclusions: The presented case suggests a temporal and symptom content relationship between the described work exposure and the appearance of emotional distress in a patient without PTSD history. Although previous evidence of secondary trauma in people exposed to indirect traumatic experiences has been reported, for example in healthcare professionals, the exposure to alien trauma through digital exposure as a work activity is yet to be specifically examined. It is necessary to expand knowledge on the clinical expression of this phenomenon due to the observed recurrence of anxious and depressive symptomatology related to repeated exposure to traumatic content.

Post-traumatic stress in healthcare workers during the COVID-19 pandemic: a cross-sectional study

Z. Athimni¹, N. Belhadj Chabbeh², S. Chatti¹, F. Chelly², L. Ben Afia¹, M. Bouhoula¹, A. Chouchane¹, A. Aloui¹, I. Kacem^{1*}, M. Maoua¹, A. Brahem¹, H. Kalboussi¹ and O. El Maalel¹

¹Occupational Medicine and Professional Pathologies Department, Farhat Hached Teaching Hospital, Avenue Ibn El Jazzar, Sousse, 4000, Tunisia and ²Occupational Medicine and Professional Pathologies Department, Sahloul Teaching Hospital, Tunisia, Sousse, Tunisia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1384

Introduction: During the COVID-19 pandemic, healthcare professionals worked under critical care conditions and had to adapt quickly to extreme work situations. They were confronted with several occupational stressors.

Objectives: To determine the prevalence and factors associated with post-traumatic stress symptoms among healthcare personnel at Farhat Hached Hospital in Sousse during the COVID-19 pandemic.

Methods: This was a descriptive cross-sectional study conducted among care staff at the Farhat Hached University Hospital in Sousse over a 3-month period during the 4th wave of COVID-19. Data were collected using a questionnaire covering socio-professional and medical data. Post-traumatic stress symptoms were assessed using the Impact of Event Scale-Revised (IES-R). Statistical analysis was performed using SPSS.23 software.

Results: Our study included 326 health professionals from the CHU Farhat Hached. The mean age of our population was 36.38 ± 10.19 years. The sex ratio was 0.23. Most healthcare staff were married (61.3%) and had dependent children (60.4%). Nurses were the most represented at 32.2%, followed by health technicians (22.7%) and medical residents (18.4%). Average job tenure was 10.62 ± 10.69 years, with extremes ranging from 1 to 39 years. The prevalence of post-traumatic stress disorder was 32.5%. Paramedics were more likely to develop post-traumatic stress symptoms ($OR=2.3$ (IC95%: 1.4-3.8), $p=0.001$). Leisure activities were protective factors against post-traumatic stress symptoms ($OR=0.4$ (IC95%: 0.2-0.8), $p=0.018$). The multivariate analytical study revealed that being a paramedic and having a personal history of COVID19 infection were independently associated with post-traumatic stress symptoms.

Conclusions: Our results demonstrated the significant impact of the COVID-19 pandemic on the mental health of healthcare personnel. Lessons learned from this pandemic should help in the development of context-specific strategies to support healthcare workers and promote the protection of their mental health.

A randomized controlled trial comparing trauma-focused treatment with and without concurrent personality disorder treatment in patients with posttraumatic stress disorder and comorbid borderline personality disorder

A. Snoek^{1*}, J. Dekker², A. Beekman³, A. Beekman³, I. Aarts¹, I. Aarts¹, A. van den End⁴, M. Blankers², C. Vriend³, O. van den Heuvel³ and K. Thomaes⁴

¹Sinai Centrum, Arkin, Amstelveen; ²Arkin; ³Psychiatry, Amsterdam UMC and ⁴Sinai Centrum, Arkin, Amsterdam, Netherlands

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1385

Introduction: Posttraumatic stress disorder (PTSD) and borderline personality disorder (BPD) often co-occur. There is growing motivation among clinicians to offer trauma-focused treatments, such as Eye Movement Desensitization and Reprocessing (EMDR), to patients with PTSD and comorbid BPD. However, a large subgroup of these patients does not sufficiently respond to trauma-focused treatment and is more likely to be excluded or dropout from treatment. Dialectical Behaviour Therapy (DBT) for BPD is well established and although there is some evidence that DBT combined with prolonged exposure is twice as effective in reducing PTSD symptoms than DBT alone, the comparative efficacy of trauma-focused treatment with and without concurrent PD treatment has not been investigated yet.

Objectives: The current study will therefore evaluate the comparative clinical efficacy of EMDR with and without concurrent DBT in patients with PTSD and comorbid BPD.

Methods: Adult patients were randomly assigned to EMDR with ($n = 63$) or without concurrent DBT ($n = 63$). A wide range of clinician-administered and self-report assessments were conducted

before, during and up to six months after treatment. The longitudinal change in PTSD severity as the primary outcome was measured using multilevel mixed regression in SPSS. The present study is part of the overarching Prediction and Outcome Study in comorbid PTSD and Personality Disorders (PROSPER), which consists of a second RCT comparing trauma-focused treatment with and without concurrent PD treatment in patients with PTSD and cluster C PD.

Results: Results, available in January 2024, will reveal which treatment works best for this difficult-to-treat group of patients.

Conclusions: This is the first study to compare the clinical efficacy of EMDR with and without concurrent DBT in patients with PTSD and comorbid BPD. Results will reveal which treatment works best for this difficult-to-treat group of patients.

Reactivation of trauma in an inadequately structured person

V. V. Jovanovska

Psychiatry, PHI General Hospital Kumanovo, Kumanovo, North Macedonia

doi: 10.1192/j.eurpsy.2024.1386

Introduction: The person is constantly exposed to various types of psychosocial stress, and what will be the course and outcome of the reaction, in addition to other factors, primarily depends on the structure of the person (cognitive, conative, affective and somatic characteristics).

Objectives: Presentation of a case of an inadequately structured person (a 29-year-old girl) who experiences an emotional loss, thus reactivating a trauma experienced many years ago (content-like emotional loss). The activation of traumatic memory as a center for generating a complex of pathological symptoms is provoked due to the personal structural inability of a person to legally reorganize, reintegrate and absorb stress.

Methods: For a complete psychological exploration of an organization, personality dynamics, symptoms, defenses, motives, goals, values, interpersonal relationships, etc. I have applied: MMPI-202, NEO PI-R, Millon's test, PIE, ZS and Azinger aggression scale.

Results: The result is an inadequately structured person of the avoidant type: introverted, vulnerable, disturbingly self-centered, constantly alert to prevent his impulses and affectional compunctions from leading to a repetition of pain and suffering experienced in the past, denying his feelings to maintain interpersonal distance, sensitive, helpless in an aggressive environment, low self-esteem and self-confidence, with weak capacities to overcome stress, etc. Anxiety and depressive symptoms are dominant. Manifest symptomatology is elaborated.

Conclusions: In a person with an inadequate structure, there is an increased vulnerability, therefore applying an exploratory approach to people with a stressful condition in daily professional practice is a necessary need in order to more effectively, comprehensively treat the current and previously memorized stressful reactions with an emphasis on the highly personalized response to stress.

The Contribution of Maladaptive Personality Traits to Psychological Distress Among Israeli Women Veterans

G. Zerach^{1*}, E. Shem Tov² and S. Shati²

¹Ariel University, Ariel, Israel and ²Psychology, Ariel University, Ariel, Israel

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1387

Introduction: Exposure to potentially traumatic events (PTEs) during military service is associated with mental health problems such as posttraumatic stress disorder (PTSD) and depression symptoms. However, knowledge regarding the implications of maladaptive personality traits in psychopathology among female veterans is sparse.

Objectives: The present study aims to use the *Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition* (DSM-5) -- an alternative model of personality disorder, to examine associations between maladaptive personality traits, PTSD and depression symptoms, among female Israeli veterans.

Methods: A volunteer sample of female Israeli combat veterans ($n=616$) and non-combat veterans ($n=484$) responded to self-report questionnaires in a cross-sectional study.

Results: Combat veterans reported higher levels of combat exposure and PTSD symptoms, but not depressive symptoms, than non-combat veterans. Combat veterans also reported lower levels of negative affectivity but higher levels of disinhibition than non-combat veterans. All five traits were positive predictors of psychological distress, with psychoticism constituting the strongest predictor. A moderated-mediation analysis indicated four traits (negative affectivity, detachment, disinhibition, and psychoticism) that had a moderating effect on the relationship between combat exposure and PTSD symptoms, and two of the traits (antagonism and disinhibition) that had a moderate effect on the relationship between combat exposure and depressive symptoms.

Conclusions: Maladaptive personality traits play an important role in psychological distress following female veterans' combat service. Future prospective research is necessary to determine the temporal associations between pre-enlistment maladaptive personality traits and post-deployment mental health of veterans.

Impact of excessive interest in news related to the war on mental health in conditions of big invasion and information war: experience of Ukraine

M. Markova^{1*}, T. Aliieva¹, T. Abdriakhimova², H. Prib³ and A. Markov³

¹Kharkiv National Medical University, Kharkiv; ²Bogomolets National Medical University and ³Academy of Labour, Social Relations and Tourism, Kyiv, Ukraine

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1388

Introduction: An important component of the russian-Ukrainian war is information war. Russia conducts psychological diversions the purpose of which is harming and disorganization the

population's mental health by reducing the ability of criticality thinking and formation of various stress-associated, anxiety-depressive, phobic, etc. disorders.

Objectives: To study the impact of information about the war on the mental health of Ukrainian population.

Methods: 186 Ukrainian people voluntarily completed the questionnaire in Google format. It contains tools for assessing the level of stress PTCL, anxiety response GAD-7, depression PHQ-9, the intolerance to the uncertainty (IUS-12 in G.Gromova's adaptation) and developed by us "Test for the detection of disorders related to the obsession with news about the Russian-Ukrainian war" (M. Markova et al, 2022).

Results: Most of the civilian population of Ukraine demonstrate excessive fascination with news associated with the war, with almost 50% have all the signs of clinically formed addiction. Psychopathological anxiety and depressive manifestations of varying intensity are characterized by more than 30% of the population. Almost 80% suffer from the effects of psycho-traumatic factors, of which 45% are observed by post-stress maladaptation, 25% - by signs of PTSD (23%) or PTSD (2%).

The presence of anxiety-depressive response does not depend on the level of obsession with the news: among persons with signs and/or clinical psychopathological symptoms, there are persons both excessively passionate about information and with a safe level of use.

Any high level of interest in news (addiction/dangerous/risky) has a close direct correlation with the intensity of pathological stressful response and the level of tolerance to uncertainty.

All persons with anxiety-depressive and pathological stressful response symptoms, and 58% of people with excessive fascination with news are characterized by low tolerance to uncertainty. This can serve as a prognostic marker of development of maladaptation and testify to the leading role of a lack of tolerance to uncertainty in its development in wartime.

42% of people who have an excessive interest in news, haven't signs of maladaptive response. They use the interest of information as a stress management's resource, which has a positive effect on the mental state and increases the ability to successfully function in uncertainty.

Conclusions: The development of information and psychological stability by increasing tolerance to uncertainty is a perspective area of research in the field of mental protection of the population of Ukraine.

The new paradigm of psychiatry precision medicine and its emerging clinical framework

B. Abdelmoula^{1*} and N. Bouayed Abdelmoula¹

¹Genomics of Signalopathies at the service of Precision Medicine - LR23ES07, Medical University of Sfax, Sfax, Tunisia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1389

Introduction: Precision medicine is a promising approach to improving the prevention, prediction and treatment of disease,

based on individual characteristics and biomarkers/genetic variants shared by specific subgroups of patients.

Objectives: This study aims to address the new paradigm of precision medicine in psychiatry and to discuss, through the literature, its emerging clinical framework.

Methods: We conducted an exhaustive review of the scientific literature using PubMed database and Google Scholar, with “Precision Medicine in Psychiatry” as keywords.

Results: Our review revealed that while psychiatrists have long practiced a personalized therapeutic approach with, for example, treatment choices guided by individual criteria, the methods for achieving this objectively have until now been largely lacking. This dilemma has begun to be resolved with the implementation of data analysis methods such as machine learning and large-scale genomic analysis studies. The goals of precision psychiatry involved the delineation of genetic risk factors using GWAS, the redefinition of the functional domains involved in mental disorders and pharmacological repositioning. The highly polygenic nature of mental disorders and the failure of GWAS to confirm the role of candidate genes have suggested that a systems genetic approach that considers function at the network level would provide a better approach to the problem of linking heterogeneous genetic risk factors and brain mechanisms. In addition, the growing evidence that certain disorders such as psychotic disorders are syndromes rather than diseases in their own right suggests that many conditions currently recognized as such may have similar underlying patterns of cognitive dysfunction and neurobiological abnormalities that will need to be reclassified.

Conclusions: The application of precision medicine in psychiatry is still in its infancy. Numerous research programs creating large multimodal databases with multiple data on brain imaging, genetics, etc. will soon support the clinical deployment of precision medicine in psychiatry.

doi: 10.1192/j.eurpsy.2024.1390

Introduction: The global burden associated with common mental disorders is high, especially for people living in low resource settings. Although psychosocial interventions delivered by locally available lay or community health workers are effective, mechanisms of intervention response are poorly understood. One of the greatest barriers is that psychosocial interventions are administered as complex, multi-component “packages of care”.

Objectives: Our aim is to systematically review all the randomized controlled trials (RCTs) that have tested the efficacy of psychosocial interventions delivered through the task shifting modality to treat

people suffering from common mental disorders (depression, anxiety, and related somatic complaints) in low resource settings, dismantle the intervention protocols creating a taxonomy of active intervention components, and re-evaluate their efficacy.

Methods: We will use the component network meta-analysis (cNMA) methodology. The major benefit of cNMA is the possibility to disentangle intervention components and explore their effectiveness separately or in various combinations (even in disconnected networks). cNMA increases statistical power by combining direct and indirect comparisons while fully respecting the randomized structure of the evidence. According to the additive cNMA model which we will implement, adding a component “c” to a composite intervention “X” will lead to an increase (or decrease) of the effect size by an amount only dependent on “c”, and not on “X”. We will denote the corresponding component specific incremental standard mean difference (iSMD) so that $iSMD_c = SMD(X+c) - SMD(X)$. Combining these component-specific iSMDs will allow the estimation of SMD between any two composite interventions.

Results: A network of comparisons and a hierarchy that includes all intervention components expressed as iSMD, indicating the added benefit of adding a component to an intervention, will be presented. By selecting the most effective components it will be possible to outline a novel task shifting psychosocial intervention to be tested in future RCTs.

Conclusions: These findings will set the basis for further investigations in the field of precision medicine. This project is funded by the European Union’s HORIZON EUROPE research programme under grant agreement No 101061648.

Pharmaco-EEG of antipsychotics’ response: a systematic review

M. De Pieri^{1*}, V. Rochas², M. Sabe¹, C. Michel² and S. Kaiser¹

¹HUG and ²University of Geneva, Geneva, Switzerland

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1391

Introduction: Response to antipsychotic medications (AP) is subjected to a wide and unpredictable variability and efforts were directed to discover predictive biomarkers to personalize treatment. Electroencephalography abnormalities in subjects with schizophrenia were reported, as well as a pattern of EEG changes induced by APs

Objectives: The aim of this review is to provide a synthesis of the EEG features that are related to APs efficacy, including both pre-treatment signatures and changes induced by APs during treatment.

Methods: A systematic review of English articles using PubMed, PsychINFO and the Cochrane database of systematic reviews was undertaken in april 2023. Additional studies were added by hand-search. Studies having as an endpoint the relationship between AP-related clinical improvement and electroencephalographic features were included. Heterogeneity prevented a quantitative synthesis.

Results: Out of 1232 records screened, 22 studies were included in a final qualitative synthesis. Included studies evaluated resting-state

and task-related power spectra, functional connectivity, microstates and epileptic abnormalities. At pre-treatment EEG, the most relevant predictors of a poor response were a change in theta power compared to healthy control, a high alpha power and connectivity, a diminished beta power in resting-state. Considering EEG during treatment, an increased theta power, a reduced beta-band activity, an increased alpha activity, a decreased coherence in theta, alpha and beta-band were related to a favorable outcome.

Conclusions: EEG is promising as a method to create a predictive biomarker for response to APs; further investigations are warranted to harmonize and generalize the contradictory results of reviewed studies.

Multidimensional assessment of personality disorders using different theoretical models: a comparison of the Young Schema Questionnaire, the SCID-5-AMPD structured diagnostic interview, and the PDS-ICD-11 self-report questionnaire

V. Pribula¹, J. Biliczki², L. Király¹, F. Pongracz³, P. Ruscsak¹, N. B. Vadon^{4,5}, T. A. Renko^{4,5}, B. Erdelyi-Hamza⁴, H. Szocs³, G. Vizin¹ and X. Gonda^{4*}

¹Institute of Psychology, Eotvos Lorand University; ²Department of Crisis Intervention and Psychiatry, Peterfy Sandor Street Hospital and Clinic; ³Institute of Psychology, Eotvos Loránd University; ⁴Department of Psychiatry and Psychotherapy and ⁵Department of Clinical Psychology, Semmelweis University, Budapest, Hungary

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1392

Introduction: There has been a recent shift in the conceptualisation of personality disorders in diagnostic systems such as DSM-5 or ICD-11, from a categorical approach towards a dimensional approach reflecting severity in general or severity of dysfunction and related pathological traits. In addition, several psychotherapeutic approaches work with their own model of personality pathology, which similarly capture symptoms of personality disorders and their underlying processes in a more subtle way from multiple aspects, and along different constructs.

Objectives: The aim of our study was to investigate similarities and differences between conceptualisations of personality disorder and instruments used for evaluation based on the BNO-11 Personality Disorders Severity Questionnaire (PDS-ICD-11), Module I. of the Structured Diagnostic Interview for the DSM-5 Alternative Personality Model (SCID-5-AMPD) measuring level of personality function, and the Young Schema Questionnaire assessing early maladaptive schemas.

Methods: Hospitalized borderline patients were assessed using the Young Schema Questionnaire, the PDS-ICD-11, and Module I. of the SCID-5-AMPD assessing personality function level. Data are analysed using correlation and linear regression models.

Results: Only part of the results are shown. The PDS-ICD-11 Severity Index and Self-function Index showed significant ($p < 0.05$) and strong correlations with the Abandonment ($r = 0.98$, $r = 0.94$), Vulnerability to harm and illness ($r = 0.92$, $r = 0.98$),

Insufficient Self-Control ($r = 0.91$, $r = 0.88$) and Negativism/Pessimism ($r = 0.95$, $r = 0.90$) schemas. The mean score and all domains of the SCID-5-AMPD Module I (level of personality function) showed significant strong correlations with the Vulnerability to harm and illness schema (AMPD-Average $r = 0.87$; AMPD-Identity $r = 0.86$, AMPD-Objectivity $r = 0.81$, AMPD-Empathy $r = 0.77$, AMPD-Intimacy $r = 0.80$, $p < 0.05$); moreover, a strong significant correlation was found between the Abandonment schema and AMPD-Average ($r = 0.81$, $p < 0.05$), AMPD-Identity ($r = 0.98$, $p < 0.05$), and AMPD-Intimacy domains ($r = 0.77$, $p < 0.05$).

Conclusions: The main indicators of measures that operationalise a dimensional approach to personality disorders show distinct patterns of strong overlap with some of the maladaptive schemas but cover only a part of the schema domains. For a careful diagnosis and psychotherapeutic plan, the combined use of these measures can provide in-depth and multifaceted information.

The Role of Alcohol Use Disorders in the Development and Progression of Dementia

A. H. I. Abu Shehab^{1*}, T. Simona², A. B. Ciubară³, D. C. Voinescu⁴, C.-F. Buciu⁵ and A. Ciubară⁶

¹Psychiatry Department, "Elisabeta Doamna" Psychiatric Hospital, Galati; ²Psychiatry Department, Carol Davila University of Medicine and Pharmacy, Bucharest; ³Orthopedics and traumatology Department; ⁴Rheumatology department, "Dunărea de Jos" University - Faculty of Medicine and Pharmacy, Galati; ⁵public health and management, University of Medicine, Pharmacy, Science and Technology of Târgu Mureş, Târgu Mureş and ⁶Psychiatry Department, "Dunărea de Jos" University - Faculty of Medicine and Pharmacy, Galati, Romania

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1393

Introduction: In recent years, there has been an increase in interest and research into the link between alcohol use disorders (AUD) and dementia. Alcohol use disorders, which are characterised by excessive and problematic alcohol consumption, have been associated to a variety of detrimental health effects, including liver disease, cardiovascular difficulties, and cognitive impairments.

Objectives: To explore the link between alcohol use disorders and dementia onset and progression, explaining probable causes and emphasising preventive approaches.

Methods: The present study involved a thorough examination of relevant research papers, with a specific emphasis on longitudinal cohort studies, neuropathological observations, and biochemical interactions pertaining to the effects of alcohol on the brain. In addition to the aforementioned criteria, the review also took into account other complicating factors, including choices regarding lifestyle, genetic predisposition, and coexisting medical conditions.

Results: The results indicate a strong association between prolonged and excessive alcohol consumption and a heightened susceptibility to the early onset of dementia. The mechanisms underlying alcohol-related neurological damage encompass direct neurotoxic effects of

alcohol, thiamine shortage, and alcohol-related cerebrovascular illness. Moreover, it is worth noting that alcohol use disorder (AUD) has the potential to worsen the advancement of neurodegenerative processes in individuals already diagnosed with dementia.

Conclusions: The association between AUD (Alcohol Use Disorder) and dementia is complex and involves multiple factors, presenting considerable difficulties in terms of clinical intervention and treatment. The use of early intervention strategies and public health initiatives focused on addressing alcohol use disorder (AUD) could have a significant impact on preventing or reducing the development of dementia.

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1394

Introduction: The aim of this study was to identify low-risk traits of schizophrenia among healthy undergraduate student volunteers, and the investigation of these traits with regards to their specificity in contrast to individuals with a latent disposition towards bipolar disorder. Self-agency, as a phenomenon closely related to psychomotor functioning, provides a unique opportunity for the investigation of subjective self-perception.

Objectives: The implicit self-agency performances that are considered illness- (or risk state-) specific were compared between groups to find early markers of a specific schizotypic developmental path.

Methods: In a sample of 710 healthy university students, with the help of screening questionnaires, we were able to successfully form two risk groups, in one of them the emphasis on cyclothymia (CTF: Cyclothymia factor group, N=25), and in the other (PSF: Positive schizotypy factor group, N=26) the tendency to unusual experiences and paranoid thinking emphasis was typical. We assigned a properly matched control group (N=29) displaying both features on average. We focused on the implicit aspect of self-agency, using the well-known paradigm of intentional binding, as well as the self-developed device that exclusively tests the pre-reflexive feeling of movement initiation, the sense of self-agency.

Results: During the examination of intentional binding, although the specific predictive and retrospective component indicators did not show any significant difference for either group, the association of the sound alone could induce a binding effect in the control group. In the predictable frequency condition, there was a strong significant effect ($W = 65.00$, $p = .007$, $r_{rb} = -.60$), and in the non-predictable condition a trend-level effect. Remarkably, this binding

effect did not develop in either the CTF or PSF groups, indicating an implicit agency impairment in both risk groups. However, during the examination of sense of self-agency, we observed a disturbance specifically among healthy college students with positive schizotypal traits, in the form of falsely attributing their movement initiation to external influences. The percentage of this 'miss'-type answering differed between groups, $H(2) = 7.68$, $p = .021$, $\epsilon^2 = .10$. The Dwass-Steel-Critchlow-Fligner pairwise comparisons showed that this difference was due to the PSF Group showing a significant difference from the Control Group ($W = -3.83$, $p = .019$), but not from the CTF group, and the CTF Group also did not differ from the Control Group.

Conclusions: Thus, in premorbid conditions, in at-risk groups of non-help-seeking individuals, or in cases of early detection of prodromal abnormalities, objective confirmation of suspected susceptibility to schizophrenia may be aided by, among other things, instrumental assessment of self-agency.

Chronotype and health related quality of life among undergraduate university students

E. L. Nikolaev¹, I. Poverinov² and M. Alhasan^{3*}

¹Department of Social and Clinical Psychology; ²Philosophy, Sociology and Pedagogy Department and ³Medical Faculty, Ulianov Chuvash State University, Cheboksary, Russian Federation

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1395

Introduction: Chronotype represents genetically determined behavioral characteristics of a person's twenty-four-hour activity. Research shows that a person's chronotype is interrelated with their mental health. Are there similar connections with general health and health related quality of life?

Objectives: To establish how various chronotypes are represented in university students and if there are any interrelations between chronotypes and health-related quality of life

Methods: We used SF-12 Health Survey и Morningness–Eveningness Questionnaire (MEQ) by Horne and Ostberg to survey 305 university students of both genders.

Results: The results showed that the majority of the students (71.2%) have an intermediate chronotype. The second goes a moderate morning chronotype (17.7%), the third – a moderate evening chronotype (9.8%). Definite morning and definite evening chronotypes were revealed in less than 1% of the students. SF-12 Health Survey scale indicators that assess quality of life corresponded to standard scores for the given group of the respondents. We have revealed valid relations in correlational interconnections of the achieved parameters. Thus, the morning chronotype is most consistently associated ($p < 0.01$) in undergraduate university students with higher indicators of health related quality of life including General Health ($r = .23$), Vitality ($r = .21$), Role Physical ($r = .18$), Role Emotional ($r = .17$), Physical Functioning ($r = .16$), Social Functioning ($r = .13$). Mental Health and Bodily Pain in university students are not connected with the chronotype ($p > .05$).

Conclusions: Therefore, this research establishes that the majority of the students are related to the intermediate chronotype, and the

morning chronotype corresponds to higher levels of most indicators of health related quality of life excluding the level of mental health.

Assessment of the relationship between psychotic-like experiences and traumatic life events: a cross-sectional study

S. Boudriga^{1*}, M. Methni¹, S. Ben Nasr², A. Larnaout¹, U. Ouali², A. Aissa² and J. Ventura³

¹Razi, Manouba, Tunisia; ²Psychiatry A, Razi, Manouba, Tunisia and

³Department of Psychiatry and Biobehavioral Sciences, Semel Institute for Neuroscience and Human Behavior, Los Angeles, United States

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1396

Introduction: Traumatic life events (TLEs) have been associated with the entire spectrum of psychosis outcomes, including risk and severity of psychotic disorders and psychotic-like experiences (PLEs). In a non-clinical setting, understanding the relationship could help improve prevention services.

Objectives: The aim of this study is to establish the relationship between TLEs and PLEs.

Methods: A cross-sectional study was conducted in a Tunisian business and engineering school from March 2022 to June 2022. Participants completed the Tunisian dialect version of the Prodromal Questionnaire-Brief (PQ-B), a validated self-report instrument designed to evaluate prodromal symptoms. TLEs such as physical, sexual, and emotional abuse, as well as neglect experiences, lived or witnessed have been assessed along with bullying experiences.

Results: The final sample size consisted of 358 participants, with a median age of 22 ± 2.22 years, with a sex ratio (M/F) of 1.41. More than half of the participants (58.6%) reported having experienced TLEs (49% in the preceding 6 months) while 31% had experienced bullying or abuse in school (27.9% in the preceding 6 months). The mean total score of the PQ-B for the study population was 7.27 ± 4.387 , 36.3% reached the threshold and were defined as PQ-B-positive subjects. Those with a lifetime history of major life events were more likely to screen positive on the total score PQ-B ($p = 0.000$), as were those with a lifetime history of bullying or abuse ($p = 0.000$).

Conclusions: Understanding the factors that interact in the significant association between PLEs and TLEs may provide useful information for prevention programs and the improvement of mental health.

Urban planning, noise pollution and mental health outcomes

E. Abdelmoula^{1*}, B. Abdelmoula² and N. Bouayed Abdelmoula²

¹LR AMC, Ecole Doctorale Sciences et Ingénierie Architecturales (ED-SIA), Tunis and ²Genomics of Signalopathies at the service of Precision Medicine - LR23ES07, Medical University of Sfax, Sfax, Tunisia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1397

Introduction: In large cities around the world, many sources of noise including traffic, domestic, construction, and industrial activities, contribute to urban noise pollution, which is now, a major concern in public health as declared by the WHO, for more than a decade (in 2011).

Objectives: The aim of this study was to try to find potential recommendations and references in terms of urban planning, particularly with the emergence of smart cities, to combat the problem of noise pollution and related mental health hazards.

Methods: We conducted a comprehensive review of the scientific literature using the following keywords: cities, smart cities, noise, pollution and mental health.

Results: Our research found that the continuous exposure to high noise levels could lead to psychological and physiological problems, such as hearing disorders, high blood pressure, heart disease, inconvenience and sleep disorders. While recent evidence indicates that road traffic noise has a negative impact on mental health and that aircraft noise significantly increases the risk of depression, there are not enough studies to date to properly assess the relationship between urban noise pollution and mental health hazards such as anxiety, mood disorders, sexual disturbance, cognitive impairment, learning disabilities, dementia, etc. In the field of urban planning, there is also a lack of reliable data on individual exposure to environmental noise in space and time, and on its effects on mental health.

Conclusions: Various noise mitigation strategies in urban renewal plans are proposed, such as the implementation of noise mapping to provide the detailed spatial distribution of noise levels in urban areas, their sources and time intervals, noise barriers along traffic arteries, vegetation and landscaping. New infrastructure projects involving new expressways and high-speed trains as well as the widening of major roads in their central areas are also suggested.

The impact of eating habits on mood disorders (A prospective study to show the importance of food on preventing mental health disorders)

N. Baabouchi

psychiatry, arrazi hospital, rabat, Morocco

doi: 10.1192/j.eurpsy.2024.1398

Introduction: Adopting a traditional healthy eating pattern is strongly associated with a more stable, adaptive, and serene mood. In contrast, adopting a modern and industrialized diet is linked to a higher incidence of anxiety and depressive disorders.

To prevent mood disorders, a varied diet rich in colorful fruits and vegetables is recommended. Studies show that the consumption of vegetables, whole grains, and fruits can help prevent the risk of major depression and anxiety disorders by more than 35%. A well-rounded plate, rich in micronutrients (trace elements, vitamins, minerals), is essential for the proper functioning of our brain and its emotional areas.

Our brain requires significant amounts of iron, zinc, magnesium, and vitamins B, E, D, and K. Unfortunately, our modern diet often lacks sufficient intake of these essential micronutrients. A deficiency in iron or zinc is associated with a significantly higher risk

of major depression, and a lack of magnesium is a potential source of anxiety disorders.

Choosing a diet rich in micronutrients (whole grains, cereals, fresh fruits, and vegetables) can address potential deficiencies and contribute to a more adaptive and balanced mood. Similarly, carefully selected dietary supplements can prove to be effective.

Objectives: it shows the importance of alimentation and her role on Primary and secondary prevention in depressive disorders.

Methods: This poster is a prospective study done on 100 random people via a multi choice quizz, to see the impact of their food on their mental health .

Results: in the making

Conclusions: Food should today be universally considered as a potential risk factor or protective factor in depressive disorders. Since the recent decades, nutritional psychiatry has developed a field of research promising The International Society For Nutritional Psychiatry Research (ISNPR) who is a collective of doctors and researchers with the common objective of advance research and communication of nutritional medicine in the field of psychiatry. Cross-sectional epidemiological studies finding an association between diet quality and mental health in longitudinal studies, a step has been taken. The observational data have been widely replicated and documented in several meta-analyses and are supported by prospective studies studying the effectiveness of improving nutritional quality in the treatment of depression. It now appears necessary that in the near future psychiatrists must receive training on the impact of diet in psychiatric disorders including depression, and get into the habit of taking an interest in the eating habits of their patients, as well as their microbiota .

EPV0766

Vitamin D, vitamin B12, folate, homocysteine, and major haemato-chemical parameters in patients with mood disorders

D. Marazziti^{1*}, R. Gurrieri² and F. Mucci¹

¹Department of Clinical and Experimental Medicine, Section of Psychiatry and ²Department of Surgical-Medical and Molecular Pathology and Critical Care Medicine, University of Pisa, Pisa, Italy

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1399

Introduction: The potential involvement of the immune and inflammatory systems has been extensively studied in mood disorders (MDs). Despite these findings and despite the fact that the pathogenetic role of altered immunologic and metabolic profiles in MDs is being confirmed in many current studies, there is still a lack of consensus about it, due to controversial results.

Objectives: The present study aimed to appraise peripheral metabolic parameters (blood glucose, lipoproteins, triglycerides, uric acid, blood urea nitroge [BUN], transaminases and others⁹ and plasma/serum levels of essential nutrients (vitamin D, B12, folate and homocysteine) in a group of inpatients affected by MDs, as compared with healthy controls.

Methods: Methods. Ten ml of venous blood was drawn from fasting subjects. The metabolic parameters and vitamins were measured according to common clinical-chemistry methods. Comparisons for continuous variables were performed by the Student's

t-test for variables that follow a normal distribution, and by the Wilcoxon-Mann-Whitney test for variables not normally distributed. The correlations between biological markers were explored by calculating the Pearson's correlation coefficient or Spearman rank correlation.

Results: Most patients showed loer circulating vitamin D levels, in respect to both control subjects ($P < .0001$) and the normative cut-off values. This finding was paralleled by increased serum homocysteine concentrations i ($P < .0001$), indicating an imbalance in their methionine metabolism. Homocysteine levels were negatively correlated with vitamin D, vitamin B12 and folate in control subjects, but not in patients. In addition, patients displayed higher blood glucose and lower BUN than controls, indicating an impaired protein-to-carbohydrate metabolism and/or altered nutritional/dietary status.

Conclusions: We provide herein further support to the notion that MD patients are a population where vitamin deficits, dysmetabolism and/or dietary defects are common feature, and, s such, they might be more vulnerable to a variety of somatic illnesses than the general population. This cross-sectional investigation, albeit preliminary, might contribute to improve the characterization and the monitoring of the clinical status of mood disorder patients, as well as to identify new molecular targets for more tailored treatments ad of more pointed health-care intervention,

Quality of life in children and adolescents with beta thalassemia

A. Tsagkou¹, E. Evangelou², E. Vlachou², A. Zartaloudi^{2*}, E. Dousis², C. Dafogianni², M. Polikandrioti² and I. Koutelekos²

¹Greek Health System and ²University of West Attica, Athens, Greece

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1400

Introduction: Children and adolescents with thalassemia suffer from chronicity of the disease and its treatment, including transfusion dependence and complications of iron overload.

Objectives: To investigate the quality of life of children and adolescents with Beta Thalassaemia.

Methods: This study is a cross-sectional study conducted at the Greek public Children's Hospital. PedsQL™ 4.0 Generic Core Scale (Greek version) was used to evaluate HRQOL in 41 thalassemia patients aged between 5 and 18 years and in 41 healthy controls of the same age range. For the analysis, the Statistic Package (SPSS ver.24) was used. Using Spearman's correlation coefficient, t-test and MannWhitney tests were used, while for variables with three or more levels the Anova and Kruskal-Wallis. In order to investigate the relationship between two quantitative variables, Spearman's correlation coefficient was used, while the relationship between two qualitative variables was used to control x2. As a statistical significance level, $\alpha = 5\%$ was defined.

Results: Of the 41 children with beta Thalassemia who participated in the study, 48.8% (n = 20) were boys and 51.2% (n = 21) girls. The mean age of children was 10.02 ± 4.10 years. For healthy children who participated in the study 51.2% (n = 21) were boys

while 48.8% (n = 20) were girls. The mean age of the children was 9.63 ± 3.77 years. Children with Beta Thalassaemia have a lower quality of life in Physical Health and Activity(<0,001), Emotional Health(0,031), School Activities(0,008), Psychosocial Health (0,014), and the overall PedsQL 4.0 (<0,001)questionnaire compared to healthy children. Children between the ages of 5 and 7 have higher levels of quality of life in physical health and activity than older children(<0,001). In addition, children aged 5 to 7 have higher quality of life and overall PedsQL 4.0 score than older children(0,033) Children receiving combination therapy show better quality of life than children receiving subcutaneous therapy (total PedsQL 4.0 <0,001).

Conclusions: Children and adolescents in all five categories had a better quality of life, after improved iron chelating methods and other psychosocial interventions.

Parents' needs during a child's hospitalisation in a paediatric intensive care unit (PICU): a systematic review

A. Boroklinioti², A. Sarantaki¹, E. Dousis¹, A. Zartaloudi^{1*}, E. Evangelou¹, C. Dafogianni¹, M. Polikandrioti¹, E. Vlachou¹ and I. Koutelekos¹

¹University of West Attica and ²Greek Health System, Athens, Greece

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1401

Introduction: The admission of children to PICU is a painful experience for parents. Regularly, they are asked to make important decisions about treatment options in collaboration with the care team, which causes them stress, uncertainty and trauma.

Objectives: To investigate the needs of parents during the child's hospitalization in a pediatric intensive care unit (PICU).

Methods: A systematic review of the literature and a search of articles in the international databases PubMed, Cinahl, Google Scholar, Cochrane Library and Greek scientific journals was performed with a peer review process during the period between April and July 2022. A time limit was set regarding the date of publication of the articles (articles published in the last 15 years).

Results: Nine studies were found that met the criteria for inclusion in the review. The thematic analysis of the results deduced the following sections A: Need for information from health professionals regarding the child's health status and the possible treatment options available, B: Need for psychological support from health professionals (psychologists, nurses, doctors) in order to be able to manage the difficult situation they are experiencing due to the hospitalization of their child, but also to be able to manage their grief and sorrow in case of loss of the child. C: Need for safe hospitalisation of the child.

Conclusions: Parents have needs during their child's hospitalization in the PICU, which if put in boundaries-frames and guided by health professionals (who possess knowledge and composure in difficult moments) can bring about a smooth course of the child's health during hospitalization.

Disclosure of Interest: None Declared

EPV0770

Parents' psychosocial needs during the child's hospitalization in pediatric intensive care units (PICU): a systematic review

I. Kalogerogianni², A. Zartaloudi^{1*}, E. Dousis¹, E. Evangelou¹, C. Dafogianni¹, E. Vlachou¹, M. Polikandrioti¹ and I. Koutelekos¹

¹University of West Attica and ²Greek Health System, Athens, Greece

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1402

Introduction: The admission and hospitalization of a child in a Pediatric Intensive Care Unit (PICU) creates stress and anxiety in the family. The family is called upon to make important decisions about the child's treatment, while roles within the family environment are disrupted.

Objectives: The investigation of the psychosocial needs of the relatives of hospitalized children in the NICU.

Methods: We conducted a systematic review of studies published until the end of 2022 in the Greek and English languages in the databases "Pubmed", "Scopus" and "Iatrotec" with the following keywords: "Pediatric Intensive Care Unit", "Socio-psychological Needs" and "Parents".

Results: Of the 26 studies found, 5 studies met the inclusion-exclusion criteria and were included in the review. The most frequently mentioned psychosocial needs of the parents were: (1) the need for complete, immediate and honest information regarding the health status of their hospitalized child and the changes in their condition, (2) the need to provide comfort to the parents during duration of their child's hospitalization, (3) the parents' need for psychological support and guidance regarding the care of their hospitalized child, (4) the feeling of security regarding the care provided, and (5) the need for frequent contact with the hospitalized child. Also, it was observed that the medical and nursing staff underestimated some needs of the parents, such as the need for closeness, while there were others that we underestimated, such as the religious needs.

Conclusions: Parents present increased psychosocial needs during their child's hospitalization in the PICU. Nursing staff play an important role in supporting relatives by providing family-centered care.

Evaluation of adherence to treatment in patients with anxious-depressive syndrome.

T. Jiménez Aparicio¹, M. Fernández Lozano¹, M. Merizalde Torres¹ and A. Rodríguez Campos^{1*}

¹Psiquiatría, Hospital Clínico Universitario Valladolid, Valladolid, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1403

Introduction: Treatment-resistant depression can pose a major challenge to mental health professionals, both in identifying cases and in devising consequent therapeutic strategies (1). However, it is not uncommon that the lack of response to antidepressant treatment is actually due to non-adherence to it in many cases (2).

Objectives: In this context, it would be interesting to know the rate of abandonment of antidepressant treatment in patients with anxious-depressive symptomatology, since the patient's evolution may depend entirely on this.

Methods: To this end, the psychiatry service of the Hospital Clínico Universitario de Valladolid has collected data on adult patients who come for a first consultation in the mental health team, referred for presenting symptoms of anxiety and depression.

These data have been recorded over the last 2 years, including different socio-demographic and clinical variables. Subsequently, a descriptive analysis was carried out, the preliminary results of which are presented below.

Results: We started from a sample of 222 patients at the present time: 69 men and 153 women, which is in accordance with previous data on the prevalence of anxiety disorders and depression by gender (3). Antidepressant treatment was prescribed (from psychiatry or primary care) in 80% of them. A review 6 months later showed that up to 1/3 of these patients (34%) had abandoned treatment on their own before completing this period, as can be seen in the first graph (image 1), which is contemplated in several guidelines and recommendations in the scientific literature (4). No major differences were observed between genders for treatment indication or treatment abandonment.

On the other hand, 61% of the patients in the sample had been treated with benzodiazepines. Among them, up to 74% were still taking these drugs 6 months later (image 2). This result is striking, since in reality, the duration of treatment with benzodiazepines should be much shorter, according to the latest reviews (5).

Finally, cross-checking these data, it was observed that for 116 patients (52% of the total) the initial treatment included antidepressants and benzodiazepines. At 6 months, 18 of these patients (16%) had voluntarily discontinued the antidepressant, but continued with benzodiazepines.

Image:

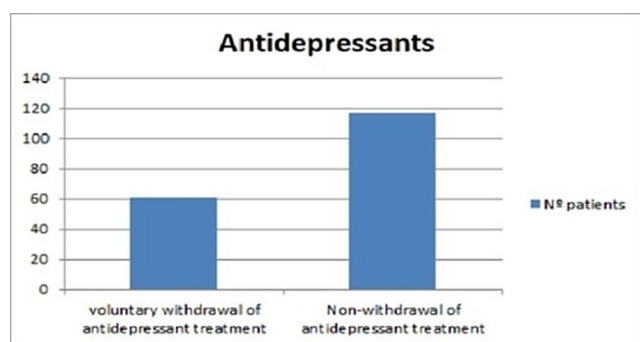

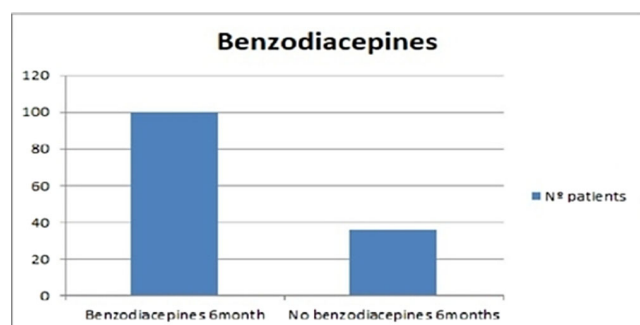

Image 2:

Conclusions: It is very important to review adherence to treatment in all patients, especially in those cases in which the persistence of symptoms makes us think of a possible resistant depression. For this reason, it would be advisable to try to establish an adequate doctor-patient relationship that allows trust in the therapist and communication between both and leads to a favorable evolution.

EPV0772

Dimensions of Psychological Resilience Among Mental Health Professionals in Greece: A Postdoctoral-based Literature Review

A. Kalmanti¹, N. Smyrnis¹, I. Michopoulos¹, V. Yotsidi², V. Moraiti^{3*} and G. N. Porfyri⁴

¹2nd Department of Psychiatry, Medical School, National and Kapodistrian University of Athens, "Attikon" University Hospital;

²Psychology Department, Panteion University of Social and Political Sciences; ³Early Intervention in Psychosis (EIP), Ikelos NGO (Collab. "Attikon" University Hospital), Athens and ⁴Psychiatric Department, General Hospital of Papanikolaou, Thessaloniki, Greece

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1404

Introduction: Resilience is defined as the process and outcome of successfully adapting to difficult or challenging life experiences, and adjustment to external and internal demands, including challenges in family or relationship dynamics, serious health concerns, financial pressure or work-related stress. Employees' creative self-sufficiency, work environment, as well as the interpersonal relationships developing in the workplace which constitute basic parameters of professional satisfaction can potentially affect both psychosomatic resilience of the employees as well as their performance at work. Exploring the available bibliography, it was revealed that the mental health professionals' community has not been sufficiently examined in terms of emotional resilience.

Objectives: To examine the dimensions of psychological resilience among mental health professionals.

Methods: In the context of a postdoctoral research which is conducted on a sample of the Greek population- personnel working in mental health hospital and community-based settings -a review of 35 articles from 1985 to 2023 on PubMed and Google Scholar was proceeded regarding psychological resilience among mental health professionals.

Results: Creative self-sufficiency and professional satisfaction were found to be positively correlated with resilience among mental health professionals. Additional factors have been found to influence mental resilience among mental health professionals, such as individual personality traits, coping style, perceived social support, a sense of security, and organizational support.

Conclusions: This review contributes to the evolving understanding of resilience, particularly regarding mental health providers. The positive correlation between creative self-sufficiency and professional satisfaction highlights the importance of fostering these dimensions to enhance mental resilience through implementing emotional capacity-building practices, social skills counseling, as well as mindfulness-based interventions.

Attitudes and knowledge toward mental disorders among healthcare providers in psychiatric departments

F. Askri*, M. Lagha, K. Ben Younes, I. Ben Romdhane, H. Wided and R. Labbane

PSYCHIATRY C, RAZI HOSPITAL, MANOUBA, Tunisia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1405

Introduction: Stigma towards mental health disorders is an issue standing in the way of healing and integrating the patient into the social life. Stigmatising does not only come from the general population but also from health care providers. Studies found out that lack of knowledge and skills among health care professionals is associated with stigmatization, which affects the attitudes and the patient's treatment process.

Objectives: The main aims of this study were to evaluate the attitudes and knowledge about mental health among nurses and psychiatry residents working in psychiatric departments, to explore the relationship between knowledge and attitude toward mental health and to find out the possible link with sociodemographic and work characteristics

Methods: A cross-sectional questionnaire was conducted in two departments of psychiatry at RAZI hospital focusing on nurses and psychiatrist trainees. The sociodemographic informations, duration and choice of working in psychiatric field, personal experience with mental illness were collected.

The Mental Health Knowledge Questionnaire (MHKQ) and the mental illness clinicians attitude scale (MICA-4) were used to evaluate the participants mental health knowledge and attitude towards psychiatry and people with mental disorders.

Results: A total of 30 health care providers finished the questionnaire. Their median (\pm interquartile range) age was 29 (\pm 9) years within a range of 25 to 60 years old. Our participants were predominantly female (N = 26; 86.7%). The overall median of MHKQ scale was 10 (\pm 6) with a higher score in psychiatrist trainees than nurses but no significant difference was found (p= 0.066) However there was a significant difference between the two groups regarding the MICA scale (p=0.02) with a negative attitude found in the group of nurses. Participants with no personal experience with mental illness along with those who were obliged to work in psychiatric facilities tend to have higher score on the MICA scale with significant statistically relationships, respectively, p =0.18 and p=0.09 We didn't find any statistically significant relationship between the total scores of the MICA and MHKQ scales (ρ = -0.206, p = 0.275)

Conclusions: In our study negative attitude toward mental disorders were found in the group of nurses. Education about mental health disorders as well as addressing the importance of mental health outcomes must be included in the first year training of every healthcare provider. New strategies Focusing on improving the knowledge and skills among healthcare professionals are important to make due to their positive effect on the recovery.

Teaching stress reduction techniques including biofeedback for managing stress in medical students

R. Krishnan^{1,2*} and K. Kósa¹

¹Department of Behavioural Sciences, University of Debrecen, Debrecen, Hungary and ²Greenwich Mental Health Liaison Team, Oxleas NHS Foundation Trust, London, United Kingdom

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1406

Introduction: Medical students have been under immense pressure throughout their studies, impacting their mental health and academic performance. Stress reduction is a fundamental skill that all students require to manage their studies and lives efficiently. Biofeedback devices providing information about physiological states have been shown to aid stress reduction. Methods to reduce stress should be taught to medical students to help them tackle the challenges of medical school.

Objectives: Our goal was to teach stress reduction methods such as extracurricular activities and paced breathing aided by biofeedback training and its application in simulated healthcare situations to medical students.

Methods: 15 medical students who completed medical physiology were recruited for an elective course of 7 sessions on practical techniques in stress management. One credit was offered to those who completed the course requirements consisting of participation in sessions and individual biofeedback training.

Sessions (classes) consisted of presentations on good sleeping and eating patterns, group simulations of stressful hospital environments, visiting a science centre with interactive displays, an orchestra performance, and nature walks. Before biofeedback training, heart and respiration rates were taken individually by a biofeedback device during the first week of the course. Data was processed using a code created in statistical software. Heartbeats per minute and heart rate variability (HRV) for every 10 seconds were calculated and plotted on a graph. Two measurements were taken with each student: a baseline measurement for 10 minutes and another measurement during controlled breathing paced at 6 breaths per minute for 15 minutes, of which the first 10 minutes were used for calculation and plotting. Students provided narrative feedback in an essay submitted after the course was completed.

Results: 5 males and 10 females from years 2-5 registered for the elective, and 12 participated in individually scheduled sessions. Heart beats per minute decreased, whereas HRV increased during paced breathing sessions in 83% of them. Most students reported feeling calm and drowsy during the sessions, and 2 students fell asleep by the end.

Feedback from 11 students showed that the music session and the science centre visit were the highlights throughout the elective. Improvements recommended were to have a consistent time slot for all sessions and fewer simulations.

Conclusions: In concert with the literature, biofeedback training seems to be a feasible and effective method for relaxation in medical students. This method could be offered as part of mental health services for students. Data could be used to follow students' progress and identify those requiring extra support. Providing them with avenues to de-stress while emphasizing activities outside medicine could boost their confidence and improve their coping skills.

EPV0778

Measuring CO in an anti-smoking campaign in Virovitičko-podravka County in Croatia

S. Mihaljević*, M. Beneš and M. Venus

Institute of Public Health “Sveti Rok” Virovitičko - podravka County, Virovitica, Croatia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1407

Introduction: Measuring carbon monoxide (CO) in exhaled breath with a visual representation can aid in smoking cessation by increasing smokers' awareness of how smoking negatively affects their health and how many harmful substances they introduce into their bodies. Individuals attempting to quit smoking can regularly measure CO levels to monitor their progress in reducing this gas in their system. The national „Smoke Out Day” is a day aimed at encouraging smokers to quit smoking in the Republic of Croatia. It is celebrated on the first day of Lent, as it is a period when most people contemplate giving up something they enjoy throughout the year. The Institute of Public Health of Virovitičko-podravka County sets up a booth in one of the cities in County on that day. There we offer pamphlets to passersby with information about the harmful effects of smoking and provide them with the opportunity to measure carbon monoxide in their exhaled breath.

Objectives: The aim of this study was to explore relationship between smoking status, smoke exposure and the levels of exhaled carbon monoxide.

Methods: For measuring CO we used piCO simple Smokerlyzer. From April 2015 till May 2023, 462 individuals have participated in this measurement. The data were processed using the Python programming language version 3.9 and the statistical library Pingouin version 0.5.3. Data visualization was performed using the Seaborn library version 0.12.2. The statistical analyses employed in this study are partial correlations. The Spearman method was used for partial correlations because it can identify nonlinear relationships and is more accurate and robust when the assumptions for Pearson correlation are not met.

Results: Partial correlation analysis indicates that there is a statistically significant relationship between the level of carbon monoxide and the following parameters:

- Non-smoking status in years ($\rho = -0.526$, $p < 0.001$, two-tailed test).
- Number of cigarettes smoked per day ($\rho = 0.369$, $p < 0.001$, two-tailed test).
- Testing time after 3 PM ($\rho = 0.234$, $p < 0.001$, two-tailed test).
- Number of years as a smoker ($\rho = 0.230$, $p < 0.001$, two-tailed test).
- Age in years ($\rho = -0.179$, $p < 0.001$, two-tailed test).
- Time spent in a smoky area ($\rho = 0.114$, $p < 0.016$, two-tailed test).

Conclusions: In summary, these results provide valuable insights into the factors associated with carbon monoxide levels in humans, with smoking-related variables, age, and testing time showing notable partial correlations. It is important to consider these relationships when assessing and managing carbon monoxide exposure and its potential health implications.

The Nefashot Initiative's Journey: Transforming from Local Activism into a Diverse Community Promoting Mental Health through Arts and Culture

S. Regev^{1,2*} and R. Diller²¹Department of Health Policy and Management, Ben-Gurion University of the Negev, Be'er Sheva and ²Nefashot, Jerusalem, Israel

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1408

Introduction: *Nefashot*, meaning ‘Souls’ and ‘People’ in Hebrew, emerged from a local group of impassioned activists. Our core mission is to promote mental health awareness through cultural and artistic expressions, bridging gaps in open and inclusive conversations.

Objectives: In our early years, our primary goal was to infuse MH discussions into public spaces through art. However, as our community has evolved, so too have our objectives. Today, we recognize the profound impact of these connections and discussions, both within and beyond our dynamic community. We've come to understand that belonging to this community is, in itself, a catalyst for change. This shift in perspective has allowed us to fully embrace the transformative potential of community engagement and direct our activities.

Methods: At the heart of our approach is the nurturing of a profound sense of belonging within our diverse community. We achieve this through two vital activities: (1) Ongoing Community Communication: Within our dynamic community, which includes individuals dealing with mental health challenges, professionals, family members, friends, and allies, communication is paramount to our unity. We maintain an open and continuous dialogue through a dedicated WhatsApp group. This platform facilitates connection, sharing of experiences, and mutual support, strengthening the bonds that unite us in our shared mission. (2) Community-Driven Event Production: Beyond our annual ‘Osim Nefashot’ week, held around World Mental Health Day, we seize opportunities throughout the year to organize events or collaborate with larger events like International Women's Day in March or Book Week in June. Encouraging active participation in event planning and execution not only amplifies the voices of our members but also deepens their sense of belonging within our ever-evolving community.

Results: Our hallmark is a sustainable process, welcoming new creators, forging connections, and expanding our influence while retaining core members. This renewal and continuity enable us to reach new audiences and expand mental health awareness through art and culture. Our growth is showcased, with 90 events organized last year.

Conclusions: Nefashot's transformation from activists to a diverse community is an ongoing journey requiring commitment and deliberate steps. Our allocated resources and activities ensure each participant, from creators to venues to attendees, plays a vital role in advancing mental health awareness. We remain dedicated to nurturing inclusivity and promoting mental well-being through art and culture.

Variables Predicting Psychological Help Seeking Attitudes: Self-Stigma, Mental Health Literacy, and Depression/Anxiety

H. Gündoğdu, K. Aslan, H. C. AYHAN and C. M. AKTAŞ
 psychiatric and mental health nursing, Van Yüzüncü Yıl University,
 van, Türkiye
 *Corresponding author.
 doi: 10.1192/j.eurpsy.2024.1409

Introduction: Psychological help-seeking attitudes are influenced by various factors, including self-stigma, mental health literacy, and levels of depression and anxiety. Several studies have examined the relationships between these variables and help-seeking attitudes, shedding light on the predictors of seeking psychological help. Self-stigma, or the internalization of negative attitudes towards seeking psychological help, has been found to significantly impact help-seeking attitudes. Individuals who experience higher levels of self-stigma are more likely to hold negative attitudes towards seeking help. Additionally, mental health literacy, which refers to knowledge and understanding of mental health issues, has been identified as another important predictor of help-seeking attitudes. Individuals with higher mental health literacy are more likely to have positive attitudes towards seeking psychological help. Depression and anxiety, two common mental health concerns, have also been found to influence help-seeking attitudes. Research has shown that individuals with higher levels of depression and anxiety symptoms are more likely to express intentions to seek counseling for psychological and interpersonal concerns. These mental health concerns can serve as motivators for individuals to seek professional help. Furthermore, cultural and demographic factors can also play a role in shaping help-seeking attitudes.

Objectives: This study was planned to examine the variables predicting psychological help seeking attitudes: self-stigma, mental health literacy, and depression/anxiety

Methods: The sample of the study was determined by purposive sampling method. The study was conducted with individuals who willing to participate the study and above 18 years age. Individuals who saw the online advertisement and click on the study's link were brought to the study's home page on Online Surveys. Should they wish to proceed, they will be brought to an information page detailing the purpose of the study, how their confidentiality and anonymity will be preserved and how their data will be treated.

Socio-Demographic Data Form, Mental Health Literacy Scale, Self-Stigma of Seeking Psychological Help Scale and Attitudes Towards Seeking Psychological Help Scale were used. Data analyses was planned to run via Statistical Package for the Social Sciences version, 27.0.

Results: The analysis of the data is still ongoing in detail by the researchers. The findings and relational implications of the study will be presented.

Conclusions: In conclusion, self-stigma, mental health literacy, and levels of depression and anxiety are important variables that predict psychological help-seeking attitudes. Understanding these factors can inform the development of interventions and strategies to promote help-seeking behaviors and reduce barriers to seeking psychological help.

Teacher well-being: Perceived stress, psychosocial risks, and burnout in Morocco

H. Guider^{1*}, F. Hadrya², M. A. Lafraxo¹, Z. Boumaaize¹,
 Y. El Madhi³, A. Soulaymani¹, A. Mokhtari¹ and H. Hami¹

¹Laboratory of Biology and Health, Faculty of Sciences, Ibn Tofail University, Kenitra; ²University Hassan First of Settat, Higher Institute of Health Sciences, Health Sciences and Technologies Laboratory, Settat and ³Regional Center for Education and Training Professions, Rabat, Morocco

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1410

Introduction: Teachers encounter various challenges that can significantly affect their professional well-being. This issue stands as of paramount importance, for it not only wields influence over job satisfaction but also carries weighty implications for the quality of education provided.

Objectives: This study aims to investigate the factors that affect teachers' well-being, specifically examining the relationship between perceived stress, psychosocial risks, and burnout among public high school teachers in Tetouan, Morocco.

Methods: A questionnaire survey was conducted among 258 teachers, resulting in a response rate of 57%. Three distinct instruments were used to collect data: The Perceived Stress Scale (PSS) to evaluate perceived stress levels, the Job Content Questionnaire (JCQ) to assess psychosocial risks at work, and the Maslach Burnout Inventory (MBI) for burnout measurement. We examined the bivariate correlations among these three concepts.

Results: The results demonstrate significant associations among the studied factors. Perceived stress has a positive correlation with emotional exhaustion ($r=0.51$; $p<0.01$) and depersonalization ($r=0.56$; $p<0.01$), and a negative correlation with personal accomplishment ($r=-0.31$; $p<0.01$). Additionally, emotional exhaustion has a positive correlation with psychological demand ($r=0.38$; $p<0.01$). Depersonalization shows a positive correlation with psychological demand ($r=0.18$; $p<0.05$), but a negative correlation with decision latitude ($r=-0.30$; $p<0.01$) and social assistance ($r=-0.24$; $p<0.01$). Conversely, personal accomplishment presents a positive correlation with decision latitude ($r=0.58$; $p<0.01$) and social assistance ($r=0.50$; $p<0.01$).

Conclusions: This study underscores the importance of decision latitude and social assistance in promoting personal accomplishment and mitigating burnout among teachers. Nonetheless, further research is required to substantiate these results and determine the fundamental cause and effect relationships.

EPV0782

The relationship between bornout, somatic symptoms and work stress among hospital medic staff.

I. A. Török¹, K. Németh-Rácz¹, E. Kelemen¹,
 E. Szabóné Frank¹ and I. Szendi^{2*}

¹Psychiatry Departmentt, Semmelweis Hospital Kiskunhalas, Kiskunhalas and ²-, -, Hungary

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1411

Introduction: The mental health for workers in the healthcare industry have been put through challenges. The first evaluation happened during the first wave of the pandemic, the second one, with grater sample size, have been conducted in Spring 2022. The healthcare system makes it less plausible to release stress adequately. The attitude of repression by the people makes the rise in stress-levels less knowledgeable. This time the somatic symptoms makes the stress-levels steady shown. Our goal, to make visible, to categorise and recognise the somatic symptoms and the psychological symptoms, thus predicting the burn-out phase.

Objectives: The attitude of repression by the people makes the rise in stress-levels less knowledgeable. This time the somatic symptoms makes the stress-levels steady shown. Our goal, to make visible, to categorise and recognise the somatic symptoms and the psychological symptoms, thus predicting the burn-out phase.

Methods: Methods:

Participants: 497 medic workers

- PPS - Perceived Stress Scale - Type d personality scale -
- Workplace Stress Questionnaire and Symptom List (Hungarian Hypertonia Society)
- Beck Depression Questionnaire (9-item)
- Oldenburg Burn-Out Questionnaire Results: From the questionnaire answers we counted
- WHO Well-being Scale (5-item)

Results: 12% of the people reached levels above the significant stress-level and 26% reached the mild-depression level. The burn-out levels have been significantly higher in the region of disappointment. Regarding the results of the somatic symptoms, depression and stress levels it had a leading factor, which was exhaustion.

The most frequent co-occurrences of the 20 somatic and psychological symptoms of the Hungarian Hypertension Society Symptom List were also used in this study to refine the analysis. The factor analysis highlighted 3 symptom clusters out of the 20 symptoms with the following co-occurrences (fatigue, concentration disturbance, headache, feeling of tension, palpitation, dizziness, inner tremor, distressing thoughts, sweating and nausea) The symptoms formed a total of 6 factors, of which 2 were found to be predictive of burnout and depression. The factors of muscle tension, fatigue, lack of concentration, feeling tense showed the strongest correlation with the measured variables (burnout $r=0,447$, depression $r=0,343$, D-scale, negative mood $r=0,369$, $p=0,000$ at significance levels.)

Conclusions: The attention for the somatic complaints have a high attention between the workers, it's part of the work culture to give more and more sacrifices, to hide the psychological effects, and deem them as weaknesses. Regarding the health of the worker it's necessary to be more informative, to show more bearable physical symptoms to define and prevent the burn-out periods.

Physical activity and self-esteem in domestic and foreign medical students

E. Nikolaev¹, A. Zakharova², G. Dulina², D. Hartfelder², S. Petunova², N. Grigorieva², E. Lazareva², N. Maksimova², E. Litvinova², E. Vasilieva² and S. S. Fakhraci^{3*}

¹Department of Psychiatry, Medical Psychology and Neurology;

²Department of Social and Clinical Psychology and ³Medical Faculty, Ulianov Chuvash State University, Cheboksary, Russian Federation

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1412

Introduction: It is a well-known fact that regular physical activity (PA) has a positive effect on a person's somatic health. Does PA have similar correlations with self-esteem in medical students of different cultural backgrounds?

Objectives: To determine the intensity and correlations of PA and self-esteem in domestic and foreign undergraduate medical students

Methods: We carried out a survey of 305 domestic and 241 international medical students of both genders at Ulianov Chuvash State University. For this aim we used the Sociocultural Health Questionnaire (E. Nikolaev)

Results: We have established that with the same duration of the sessions the average frequency of physical activity (PA) of foreign medical students is higher than that of domestic students ($p=.001$). The latter more often exercise in gyms ($p=.001$) and consume bodybuilding supplements ($p=.01$). Foreign medical students' self-assessment of their health ($p=.001$) and sportiness ($p=.001$) is higher than that of domestic students (7.90 vs 6.98 и 6.72 vs 5.82 correspondingly). Higher frequency of PA correlates in domestic medical students with higher self-assessment of their successfulness ($r=.47$), attractiveness ($r=.46$), and confidence ($r=.43$); while in foreign students – of their sportiness ($r=.49$), confidence ($r=.25$), sociability ($r=.23$). Longer sessions of PA by domestic medical students are interrelated with higher self-assessment of their intellect ($r=.35$), confidence ($r=.34$), happiness ($r=.34$); while in foreign students – of sportiness ($r=.47$), health ($r=.36$), and successfulness ($r=.36$).

Conclusions: The revealed data testify to the fact that PA of both domestic and foreign medical students closely correlates with positive assessment of their own personality.

Assessment of the methylome and the cognition in urban dwellers

E. Abdelmoula^{1*}, N. Bouayed Abdelmoula² and B. Abdelmoula²

¹LR AMC, Ecole Doctorale Sciences et Ingénierie Architecturales (ED-SIA), Tunis and ²Genomics of Signalopathies at the service of Precision Medicine- LR23ES07, Medical University of Sfax, Sfax, Tunisia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1413

Introduction: The epigenome involving chemical modifications of DNA and chromatin that modulates gene expression in response to external and environmental conditions is characterized by great plasticity and reacts by epigenetic marks such as methylation signatures that can be inherited across generations.

Objectives: Urban dwellers likely adapt to the level and growth of urbanization and resulting environmental changes through epigenetic changes. The aim of this study is to present what is currently known about the DNA methylome (the information of DNA methylation of all cytosines in a genome) and cognition when humans are exposed to changing urban environments.

Methods: We conducted a comprehensive review of the scientific literature using PubMed database with the following keywords: DNA methylation, brain and urbanity.

Results: Our search revealed a scarcity of scientific articles reporting methylome studies with assessment of correlations between methylome, cognitive status and urban environment. Among these papers, a Chinese study (2021) found a significant correlation between childhood urbanicity and better cognitive performance by measuring genome-wide methylation profile using more than 850,000 genome-wide CpG sites. In this study, the authors suggested that the impact of childhood urbanicity on cognition is partially mediated by the methylome and brain structure/function in humans whose childhood urbanicity differed. Other studies using other research approaches, suggested that the impact of living in an urban area is linked to better performance in terms of working memory, processing speed and verbal learning. We also found that the vast majority of studies investigating DNA methylation involved in rapid adaptation to new environments, including urban environments, focused on plant and animal species.

Conclusions: The effects of urbanization on human beings are a topic of ongoing debate. Some studies suggest that urbanization can have beneficial effects on cognition, while others find that it can have harmful effects. Quantitative studies of methylation and the correlations between methylome, cognition, and urbanicity offer new opportunities to measure these effects and gain a better understanding of their mechanisms.

Natural soundscapes, urban design and psychological well-being

E. Abdelmoula^{1*}, B. Abdelmoula² and N. Bouayed Abdelmoula²

¹LR AMC, Ecole Doctorale Sciences et Ingénierie Architecturales (ED-SIA), Tunis and ²Genomics of Signalopathies at the service of Precision Medicine - LR23ES07, Medical University of Sfax, Sfax, Tunisia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1414

Introduction: While the acoustic environment in the cities correlates with various health-related problems, health benefits of natural sounds are proven. These positive effects of the sounds of nature should probably be taken seriously in urban design and urban renewal projects.

Objectives: The aim of this study was to review the paradigm of natural soundscapes in the cities, psychological effects of natural soundscapes and the potential urban recommendations for such architecture design.

Methods: We conducted a comprehensive review of the scientific literature using Web databases with the following keywords: natural soundscapes, natural sound, urban design, and mental health.

Results: Our research found that improving the urban environment soundscape for the well-being of city dwellers has become one of the most pressing challenges of modern times. In a growing number of published studies, positive psychological effects of natural soundscapes are explored using various methods such as questionnaires, biofeedback sensors coupled with virtual reality

experiences in laboratories, and quantification of the prevalence of restorative acoustic environments in parks. In a recent study (2023), Jian Kang from the United Kingdom, reported that “by taking psycho-acoustical, neural and physiological, and contextual factors into account, the European Research Council Soundscape Indices project will adequately reflect levels of human comfort, to integrate side-by-side with (and eventually replace) decibel-based metrics into existing (international) regulations”. The same paper highlighted how the transition from fighting noise pollution to creating soundscapes is key.

Conclusions: Architects should develop mandatory guidelines regarding the spatial planning focusing on managing natural soundscapes in cities. Various sites such as green urban public spaces that offers exposure to natural sounds should be an integral part of the urban environment. These areas must be with a high abundance of natural sound (geophony and bio phony) and a low anthropogenic sound to enhance human physical and psychological health.

The Impact of Climate Change on Mental Health: A General Population Study

R. Uçak^{1*}, C. H. AYHAN¹, M. C. AKTAŞ¹ and N. KAYNAR DEMİREL²

¹psychiatric nursing, Van Yuzuncu yıl university, van and ²Psychiatric nursing, Van Yuzuncu yıl university, -, Türkiye

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1415

Introduction: Climate change and its impact on mental health is a growing area of research. Several studies have explored the relationship between climate change and mental health, highlighting the various ways in which climate change can affect individuals' psychological well-being. Incorporating mental health indicators into climate change and health vulnerability and adaptation assessments is another important aspect of research in this area (Hayes & Poland, 2018). The study suggests that standardized methods to measure and predict the psychosocial outcomes of climate change should be implemented to better understand the mental health impacts. While the physical health consequences of climate change have received more attention, the mental health impacts are often overlooked (Nicholas et al., 2020).

Objectives: This study was planned to examine the impact of climate change the impact of climate change on mental health

Methods: This descriptive and cross-sectional study was conducted with individuals who willing to participate the study and above 18 years age. Individuals who saw the online advertisement and click on the study's link were brought to the study's home page on Online Surveys. Should they wish to proceed, they will be brought to an information page detailing the purpose of the study, how their confidentiality and anonymity will be preserved and how their data will be treated.

Socio-Demographic Data Form, Climate Change Worry Scale, Eysenck Personality Questionnaire Revised- Abbreviated, general health questioner and Depression, Anxiety, Stress scale were used

for collecting data. Data analyses was planned to run via Statistical Package for the Social Sciences version, 27.0.

Results: The analysis of the data is still ongoing in detail by the researchers. The findings and relational implications of the study will be presented.

Conclusions: In conclusion, this study highlight the importance of understanding the mental health impacts of climate change and developing strategies to address them. Climate change can have direct and indirect consequences on mental health, and vulnerable populations such as children and adolescents may be particularly at risk. Reducing psychological distance and incorporating mental health indicators into assessments can help in understanding and addressing the mental health consequences of climate change.

The short- and long-term effects of yoga on relaxation states measured by the Smith Relaxation States Inventory 3

T. A. Renkó^{1,2*} and Á. Schmelowszky³

¹Department of Psychiatry and Psychotherapy; ²Clinical Psychology Department, Semmelweis University and ³Institute of Psychology, ELTE PPK, Budapest, Hungary

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1416

Introduction: The beneficial effects of yoga have been researched for decades, and in some countries it is also used in health care to maintain physical and mental health. Its effectiveness in the treatment of stress and anxiety, as well as in achieving a relaxed state, is supported by numerous studies.

Objectives: In the present research, our aim was to investigate the direct and subclinical effects of yoga, where the subjects did at least 10 minutes of yoga a day for two weeks. Our hypotheses are that the participants experience relaxation, mindfulness and positive emotions significantly (1) more often and (2) more intensely as a result of yoga.

Methods: We included 25 average population, healthy people between the ages of 18 and 30, who exercised at least 10 minutes of yoga a day for two weeks with the help of a mobile app. We used the Smith Relaxation States Inventory (SRSI3) and its disposition-measuring version (SRSI3d), which examine 19 relaxation states (R-states) presumably related to relaxation, divided into 4 categories: basic relaxation, mindfulness, positive energy and transcendence. During the statistical analyses, the values taken at the beginning of the research, before practice, were compared with the values taken directly after the last practice using the Wilcoxon test. Bonferroni correction was used to correct the first-order error that increases when testing several hypotheses simultaneously.

Results: Immediately after practicing yoga, the participants had significantly higher basic relaxation ($M_0=2.74$, $M_1=4.24$, $p<0.0001$), awareness ($M_0=2.71$, $M_1=2.89$, $p<0.0001$) and positive energy ($M_0=3.88$, $M_1=4.81$, $p<0.0001$) and in the long term they experienced significantly more relaxation ($M_0=3.12$, $M_1=3.94$, $p<0.0001$), awareness ($M_0=3.41$, $M_1=4.40$, $p<0.0001$), positive

energy ($M_0=4.39$, $M_1=5.14$, $p<0.001$) and transcendence ($M_0=3.23$, $M_1=4.05$, $p=0.001$).

Conclusions: Based on our results, yoga can be an effective additional tool in maintaining and improving health, but also in improving the condition and quality of life of mental and somatic patients.

Cerebral-cognitive reserve: concept and functions of the cerebral-cognitive reserve

A. Sidenkova

Psychiatry, Ural State Medical University, Yekaterinburg, Russian Federation

doi: 10.1192/j.eurpsy.2024.1417

Introduction: The modern understanding of AD allows us to consider it through the constructs of “vulnerability” and “stability” of the brain as a dynamic system of dialectical interaction between the pathogenic process and the protective process that prevents neurodegeneration. The concept of cognitive reserve (CR) is based on observations of discrepancy between the degree of brain pathology and the severity of clinical manifestations. The concept of “reserve” was proposed to describe the resistance of the brain to a developing damage caused by a pathological process. Stern (2002) considered CR as a protective factor that modifies the impact of brain pathology on cognitive function. The researchers have defined CR as an ability to optimize cognitive function through differential involvement of structures or neural networks of the brain into brain activity.

Objectives: A systematic review of scientific studies has been conducted

Methods: The review includes an analysis of full-text literature sources.

Results: Several possible directions of CR influence on cognitive functions have been described:

- 1) CR may reduce the risk of MCI or dementia through mechanisms, which do not depend on the level of neurodegenerative pathological changes in the brain.
- 2) CR can interact with the markers of brain pathology or healthaffectingthe future cognitive decline or risk of progression. It has been found that smaller volumes or thickness in some AD vulnerable areas of the brain represent a stronger risk factor for cognitive impairment in people with low CR than in people with higher CR. CR protective effects on clinical outcomes reduce as the number of damaged neurons increases.
- 3) The protective effect of CR increasesduring late AD onset and at a low rate of the damaged substrate accumulation.
- 4) CR changes the relationship between genetic factors and aging withclinical and cognitive outcomes. The relationship between age and AD pathology level or age-related structural changes in the brain may weaken in people with higher CR

Conclusions: The concept of cerebral-cognitive reserve actualizes the problem of the search for compensatory mechanisms of cognitive deficit in AD, the assessmentof the structure of the reserve, the development and implementationof programs to maintain the

reserve, the prevention of its depletion, starting from the preclinical stage of the disease, which can prevent the transformation of preclinical manifestations of AD into cognitive disorders

Psychological meanings reported on access to guidance on love life and sexuality in prenatal consultations at a public primary health care service in a Brazilian metropolitan city: a qualitative study with pregnant adolescents

P. E. Ortolan¹, M. P. P. Lipi², M. Borges², L. S. Valladão¹, R. A. Bastos¹, L. M. Guerra¹, D. B. A. P. Vale¹ and E. R. Turato^{1*}

¹Lab of Clinical-Qualitative Research and ²gynecology and obstetrics, State University of Campinas, Campinas, Brazil

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1418

Introduction: What topics from their personal lives do patients bring to talk to the clinical team, in addition to reporting their health-illness complaints, being examined, and receiving medical and nursing guidance? Knowing the symbolic aspects of the professional-patient relationship allows for care with more empathy and greater adherence to outpatient service follow-ups. The sociocultural contexts of vulnerable adolescents amplify the importance of reproductive health care and understanding perceptions about romantic relationships and sexuality. During adolescence, risky behaviours can interfere with life opportunities and the future. The lack of care for adolescents' reproductive health is associated with irreparable physical and psychosocial consequences. In Brazil, the Unified Health System functions as an important support for the community.

Objectives: To interpret the symbolic meanings attributed by pregnant teenagers regarding the possible experience of talking and receiving guidance about romantic relations and sexuality from the clinical team of public primary attention (in the EPA-2023, we presented the work "on family relationships", another branch belonging to the same PhD research).

Methods: We used the Clinical-Qualitative Method (Turato. Portuguese Psychos. J, 2000 2(1): 93-108). For data collection, the main researcher used the Semi-Directed Interview with Open-ended Questions In-Depth and Field Notes, fully transcript. The employ of the Seven Steps of the Clinical-Qualitative Content Analysis (Faria-Schützer et al. Cien Saude Colet. 2021; 26(1): 265-274) permits the solid discussion categories. Sample closed by saturation information criterion (Fontanella et al. Cad Saude Publica. 2008; 24(1): 17-27).

Results: Sample of 10 adolescents, from 15 to 19 years. Interviewed by the first author, a female psychologist, online from September 2020 to June 2022. Findings validated by peer reviewers from Lab of Clinical-Qualitative Research. Categories to this congress: 1) maternal figure referred to as the axis of orientations on sexuality. This seems to empty the opportunity or the need to discuss these aspects in clinical consultations; 2) interviewees do not cite teenage pregnancy in its new emotional status as present in the prenatal consultation protocol; 3) there is a discourse of the re-signification of relationship with a loving partner by assuming also symbolically the pregnancy by both.

Conclusions: Professionals that the teenagers access in clinical consultations at primary attention are not perceived psychoanalytically as transferential figures for conversations about romantic relationships and/or sexuality. It is opportune to rediscuss the expected and/or desired roles of the clinical team in that studied context from the psychic and cultural symbolic universe.

Interleukine-6 and Interleukine-1 β levels in post-traumatic stress disorder, depression and healthy controls: a preliminary report

V. Dell'oste¹, S. Fantasia¹, D. Andreoli¹, V. Pedrinelli¹, L. Palego¹, L. Betti², G. Giannaccini² and C. Carmassi^{1*}

¹Department of Clinical and Experimental Medicine and ²Department of Pharmacy, University of Pisa, Pisa, Italy

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1419

Introduction: Patients with Post-traumatic stress disorder (PTSD) or mood disorders, as depression, often showed dysregulation of the hypothalamic-pituitary-adrenal axis and autonomic nervous system, resulting in increased levels of pro-inflammatory cytokines and heightened activity of the immune system that may cause alterations in the structure and function of brain regions through direct neurotoxic effects, oxidative stress, changes in levels of neurotransmitters and decreasing some neurotrophins. Among the most studied pro-inflammatory cytokines in this field there are Interleukine-6 (IL-6) and Interleukine-1 β (IL-1 β); however, scant and conflicting data are currently available in the literature about their use as potential biomarkers, and even less on possible comparisons in PTSD and depression.

Objectives: The aim of the present study was to evaluate circulating levels of IL-6 and IL-1 β in patients with PTSD and to compare them with those of subjects with depression and healthy controls.

Methods: A sample of 45 subjects, including 15 subjects diagnosed with PTSD (PTSD group), 15 with depression (DEP group), and 15 healthy controls (HC group) were recruited at the Psychiatric Clinic of the Department of Clinical and Experimental Medicine, University of Pisa. HC group included subjects recruited on a voluntary basis. The psychiatric diagnosis was assessed by the Structured Clinical Interview for DSM-5-Clinician Version (SCID-5-CV), the Impact of Event Scale-Revised (IES-R) and the Trauma and Loss Spectrum-Self Report lifetime version (TALS-SR). A peripheral venous blood sample was collected to perform the biochemical assays. The analyses of IL-6 and IL-1 β were performed with a dedicated enzyme-linked immunosorbent assay (ELISAs) achieved at the Laboratory of Biochemistry of the Department of Pharmacy, University of Pisa.

Results: No statistically significant gender or age differences emerged in the three groups. There were no statistically significant differences in IL-1 β levels among the three groups. Conversely, the PTSD group showed higher levels of IL-6 compared to the DEP and to the HC ones, with a statistically significant difference in the post-

hoc analysis among the PTSD and DEP groups with respect to the HC one ($p < 0.05$).

Conclusions: Our results suggest the key role of a chronic low-grade inflammatory state in PTSD and in depression, probably related to a dysregulation in HPA axis and cortisol release, with an increase in proinflammatory cytokines including IL-6 that seemed to be more pronounced in PTSD.

Psychoneuroimmunomodulating effect of lymphocytes with ortho-fluoro-benzonal modulated activity in syngeneic long-term alcoholized recipients

E. Markova*, I. Savkin, E. Serenko, A. Smyk and M. Knyazheva

Neuroimmunology Lab, State Research Institute of Fundamental and Clinical Immunology, Novosibirsk, Russian Federation

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1420

Introduction: Lymphocytes are dysfunctional during long-term ethanol consumption and may contribute the progression from healthy to problem drinking. GABAA receptors are molecular targets of ethanol on lymphocytes, potentiating the effects of alcohol.

Objectives: We first demonstrated that original compound *ortho*-fluoro-benzonal, artificial GABA receptor ligand, has immunostimulating properties and is able to restored long-term alcoholized mice lymphocytes activity *in vitro* through GABAA receptors. Based on the previous results we investigated effects of the *ex vivo ortho*-fluoro-benzonal modulated lymphocytes in recipients with experimental alcoholism.

Methods: Male (CBAXC57Bl/6)F1 mice with 6-month 10% ethanol exposure were undergoing the transplantation of syngeneic long-term alcoholized mice lymphocytes, pretreated *in vitro* with *ortho*-fluoro-benzonal. Recipient's ethanol consumption, parameters of the nervous and immune systems functional activities were estimated.

Results: It was shown that lymphocytes modulated *ex vivo* with *ortho*-fluoro-benzonal after intravenous injection caused in syngeneic long-term alcoholized recipients ethanol consumption decrease and stimulation of behavioral activity in the "open field" test against the background of changes in the level of a number of cytokines in pathogenetically significant brain structures. Stimulation of humoral immune response, estimated by the relative number of antibody-forming spleen cells was also detected in recipients after lymphocytes transplantation. The injected immune cells were recorded in the parenchyma of the spleen and brain of recipients, which suggests, in particular, their direct influence on these functions.

Conclusions: Results demonstrated that transplantation of *ortho*-fluoro-benzonal-modulated lymphocytes caused positive psychoneuroimmunomodulating effect in long-term alcoholized recipients, which makes it possible to consider adoptive immunotherapy as a promising method in the treatment of alcoholism.

EPV0793

Central effects of peripherally administrated immune cells modulated by a psychoactive substance in aggression

E. Markova^{1*}, E. Serenko¹, M. Knyazheva¹, A. Akopyan², M. Tikhonova² and T. Amstislavskaya²

¹Neuroimmunology Lab, State Research Institute of Fundamental and Clinical Immunology and ²State Research Institute of Neurosciences and Medicine, Novosibirsk, Russian Federation

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1421

Introduction: It is known that the formation of aggressive behavior is accompanied by neurodegenerative and neuroinflammatory changes. Immune cells have a regulatory effect on the central nervous system functions, including regulation of behavior.

Objectives: We first demonstrated that *ex vivo* chlorpromazine - modulated immune cells have a positive aggressive behavior editing effect. The aim of the study was to investigate the influence of the indicated cells on some central mechanisms underlying the development of aggressive reactions.

Methods: (CBAXC57Bl/6) F1 aggressive male mice, developed in conditions of chronic social stress, were undergoing the transplantation of syngeneic spleen lymphocytes with *ex vivo* chlorpromazine-modulated functional activity. In recipients the immunohistochemical analysis was performed assessing the expression of the microglial marker Iba1. The levels of brain-derived neurotrophic factor (Bdnf) and cytokines was assessed by ELISA. For histological examination Nissl staining was applied.

Results: Aggressive behavior editing after the chlorpromazine-modulated immune cells transplantation registered against the background of some structural and functional changes in the brain. It was found an increase in the density of pyramidal neurons in CA1 and CA3 hippocampal regions and augmented level of Bdnf. The decreased expression of microglial activation marker Iba1, accompanied with decreased levels of pro-inflammatory cytokines (IL-1 β , IL-2, IL-6, INF- γ) and increased anti-inflammatory (IL-4) cytokine was found. Visualization of functionally active lymphocytes pre-treated with chlorpromazine in the brain parenchyma of aggressive recipients suggests a direct effect of injected lymphocytes on CNS.

Conclusions: The effect of chlorpromazine - modulated immune cells that edits aggressive behavior is realized by stimulating neurogenesis, neuroplasticity and reducing neuroinflammation.

Psoriasis and Schizophrenia: An immunological link

B. Fonseca Silva*, P. Felgueiras, Â. Pinto and A. Oliveira

Centro Hospitalar Vila Nova de Gaia Espinho, Vila Nova de Gaia, Portugal

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1422

Introduction: Schizophrenia has progressively been seen as a multifactorial disease, with its pathogenesis including immune dysfunction. Studies have leaned into the activation of brain inflammation, influencing the development of schizophrenia in certain subgroups of patients. Additionally, the role of the T helper (Th17) cells and neuromediators associated are implicated in the pathophysiology of psoriasis, a chronic immune-mediated dermatological condition. A significantly elevated risk was found with 41% increased odds of schizophrenia compared with subjects without psoriasis. The concomitant diagnosis of both illnesses has motivated further investigation into their shared pathways.

Objectives: Characterize the prevalence of psoriasis in patients with schizophrenia and mutual involved mechanisms.

Methods: Retrospective analysis of inpatients of a Portuguese Psychiatry department with the established diagnosis of Schizophrenia, between 2018 and 2022. Additionally a literature review on the topic was conducted.

Results: A sample of 94 patients admitted was obtained. The majority of patients were male (80,1%). The prevalence of the diagnosis of Psoriasis was 6,4% (n=6). A previous epidemiological study conducted in the Portuguese general population concluded that the prevalence of psoriasis is on average 4,4%, which is inferior to the value obtained in our sample. Other studies that measured the relationship between both diagnoses corroborated our results, documenting higher prevalences of psoriasis in patients with schizophrenia than the general population.

Conclusions: The relationship between psoriasis and schizophrenia seems to be bidirectional, with schizophrenia patients having higher risk of psoriasis and psoriasis patients having higher risk of schizophrenia. This could be explained by multiple mechanisms, mainly the activation of Th17 cells but also the fact that there may be a genetic susceptibility due to proximal chromosome loci associated with both diseases (chromosome 6p21.3). This information is essential in providing care to patients because treatment must be carefully adapted. It has been demonstrated that atypical antipsychotics might worsen psoriatic manifestations and immunosuppressive agents are linked to psychotic episodes and worse mental health. Thus, there should be increased alertness for the detection of these conditions in patients with either one of them.

A study on the complex interplay between inflammation and severe mental disorders (SMInflam)

B. Della Rocca*, M. Luciano, G. De Felice, M. Di Vincenzo, C. Toni, E. Arsenio, G. Sampogna and A. Fiorillo

Università della Campania "L. Vanvitelli", Naples, Italy

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1423

Introduction: An alteration of inflammatory indices has been reported in several major mental disorders. This alteration seems to be related to disease severity and treatment resistance, but its pathophysiological meaning remains to be established. Patients with severe mental disorders tend to have increased levels of circulating cytokines and increased microglial activity in the central nervous system, suggesting that inflammation may contribute to

the onset, or chronicity, of mental disorders. Detecting inflammation-relevant symptom clusters across mental disorders may represent an important step towards precision medicine in psychiatry.

Objectives: The SMInflam project is a longitudinal, observational, real-world study which aims to: assess a set of inflammatory indices at baseline in a sample of patients with the diagnosis of a major mental disorder; identify inflammatory profiles of these patients using a latent class analysis approach; assess the response to pharmacological treatments of patients with different inflammatory profiles; re-assess the inflammatory indices and profiles at several times during follow-up and test their correlation with the evolution of psychopathology.

Methods: The sample will consist of 50 patients with a diagnosis of a major mental disorders consecutively enrolled at the outpatient unit of the Department of Psychiatry of University of Campania. All enrolled patients will be administered a set of reliable and validated psychopathological assessment tools. We will perform a complete physical evaluation, and a battery of laboratory tests. Peripheral markers of chronic inflammation will be assessed. Clinical and biological assessments will be performed at baseline (T0) and after 3 and 6 months (respectively, T1 and T2).

Results: Expected results include the evaluation of the levels of inflammatory indices in a varied sample of patients with severe mental disorders. According to the pre-post design, these aspects will be evaluated before the start and at the follow-up. We will also take into consideration the role of confounding factors such as age and gender, which represent a critical biological variable influencing such inflammatory pathways.

Conclusions: Collected data will be used for having a more informative, reliable and valid characterization of psychopathology in a vast sample of patients with severe mental disorders. Our study may represent the first of a new wave of methodologically-sound studies on the role of inflammation and psychopathology in patients with severe mental disorders.

Limbic encephalitis – A case report of atypical dementia syndrome with potentially therapeutic consequence

F. Xepapadakis^{1,2*} and W. Kawohl^{1,2}

¹Psychiatry, Clenia Schlössli AG, Oetwil am See/Zurich, Switzerland and ²Department of Basic and Clinical Sciences, University of Nicosia Medical School, Nicosia, Cyprus

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1424

Introduction: Limbic encephalitis (LE) is a subacute or chronic, non-infectious inflammation of the brain, usually occurring in adulthood, with predominant involvement of mesiotemporal structures and a clinical manifestation consisting mainly of new memory impairment, affective disorder, temporal lobe epilepsy, psychoses, etc.

Objectives: To point out the importance of knowledge of potentially treatable dementia syndromes such as atypical manifestation of probably LE.

Methods: We present a clinical case of a 47-years-old woman with an atypical dementia syndrome and typical radiological findings

corresponding to a LE, among others, but without the previously known immunological antibodies.

Results: According to the literature, the diverse subsyndromes of LE can be subsumed under the two main categories of “paraneoplastic” and “non-paraneoplastic”. In addition to the acute and subacute courses, there is increasing evidence for chronic, slowly progressive courses, which expand the spectrum of potentially treatable dementia syndromes. Understanding and knowledge of the broad, clinical syndrome of LE have increased dramatically in recent years. Both nosological classification through differentiated diagnosis and specific therapeutic protocols have become increasingly developed and established. Nevertheless, there are rare clinical cases with a clinical phenotype and radiological findings that correspond to LE, but are both non-paraneoplastic in origin and seronegative with respect to the previously known immunological typing by autoantibodies. This gray area of nosological entity represents a diagnostic and therapeutic challenge.

Conclusions: The authors would like to point out the importance of an adequate diagnosis of the forms of LE that have been nosologically classified so far and are partly well treatable. Limbic encephalitis is an important differential diagnosis in dementia, especially in young patients with atypical courses. There is a need for further research regarding better diagnosis and therapy of the so far immunologically unidentifiable forms of clinical LE.

Investigation of cytokine imbalance in schizophrenia, assessment of the possible role of serum cytokine levels in predicting treatment response, prognosis and psychotic relapses

K. Bodnár*, L. Hermán, R. I. Zsigmond and J. Réthelyi

Department of Psychiatry and Psychotherapy, Semmelweis University, 1085, Hungary

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1425

Introduction: Schizophrenia, a multisystem chronic psychiatric disorder of unknown etiology, is associated with several immune dysfunctions, including abnormal levels of circulating cytokines. Existing evidence shows a potential causative role for cytokines in schizophrenia symptom development. Furthermore, disease duration, symptom severity, aggressive behavior, and cognitive deficits are correlated with levels of certain cytokines. Despite the development of new antipsychotics, the negative and cognitive symptoms of schizophrenia often do not respond adequately to pharmacotherapy.

Objectives: Research questions and hypotheses: 1. Can there be a cytokine or cytokines among the different cytokine levels detected in schizophrenia that can be used as biomarkers of treatment response? 2. Can changes in cytokine levels indicate the occurrence of psychotic relapse? 3. Can changes in the cytokine level play a role

in predicting the prognosis of the disease? The secondary objectives of the planned research, in addition to the above, are to clarify the knowledge gathered so far about the relationship between cytokine level changes and the clinical symptoms associated with them.

Methods: We investigate cytokine levels, blood samples are taken on hospital admission. Based on the publications, we mainly focus on the IL-2, IL-4, IL-6 and IL-10 levels, which can serve as possible predictive biomarkers relating to treatment response. We will also assess the possible role of abnormal cytokine levels and their association with symptoms severity and their potential clinical implications. The severity of the symptoms is monitored with the PANSS.

Results: 15 schizophrenic patients who were hospitalized due to a psychotic relapse have been included. Blood samples were taken to measure cytokine levels, the PANSS scale was recorded during a psychotic relapse. We have included 9 healthy, age- and gender-matched healthy controls in the study, from whom blood samples were taken to measure cytokine levels. Preparation for measurement of cytokine levels is underway. Patient involvement is ongoing.

Conclusions: A better understanding of cytokine imbalance in schizophrenia patients can potentially help in early diagnosis, novel therapeutic target identification and development, patient stratification for choosing the best therapeutic protocol, and predicting prognosis, relapse and treatment response.

Spirituality is Associated with Immune Parameters and Disease Activity in Primary Sjögren's Syndrome: A Cross-Sectional Study

L. Módos^{1,2*}, Z. Aradi³, F. I. Horváth³, P. Piko^{4,5}, A. Szántó³ and A. Bugán¹

¹Faculty of Medicine, Department of Behavioural Sciences, University of Debrecen, Debrecen; ²Sántha Kálmán Member Hospital, Szabolcs Szatmár Bereg County Teaching Hospital, Nagykaló; ³Faculty of Medicine, Department of Internal Medicine, Division of Clinical Immunology; ⁴Faculty of Medicine, Department of Public Health and Epidemiology, University of Debrecen, Debrecen and ⁵National Laboratory for Health Security, Center for Epidemiology and Surveillance, Semmelweis University, Budapest, Hungary

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1426

Introduction: The role of spirituality in health and disease is a complex and emerging area of research. Incorporating spirituality into the bio-psycho-social model of health and disease leading to the bio-psycho-social-spiritual model provides a more comprehensive framework. In this context, chronic disorders like primary Sjögren's syndrome (pSS) are of interest due to their intricate interactions between biological, psychological, and spiritual factors.

Objectives: To study possible relationships between spirituality, immune parameters, and disease activity in pSS patients.

Methods: Patient recruitment for the study took place at the Autoimmune Sjögren specialty clinic, University of Debrecen, resulting in 112 patients. Assessing spirituality of the patients happened through 4 direct questions and the Spirituality

Transcendence Scale (24 items). Besides, clinical data of the patients were involved in the study including blood cell counts, rheumatoid factor, immunoglobulin G, Sjögren-specific autoantibodies and disease activity scores (semi-objective and patient reported.). The statistical analysis was conducted applying group comparisons between spiritual and non-spiritual groups, and linear and logistic regression analyses adjusted for sex, age, disease duration, settlement type, education, living in partnership and smoking. Out of the 112 patients 4 gave incomplete response, and therefore got excluded from the analysis, resulting in a total sample size of 108.

Results: Semi-objective disease activity score (ESSDAI) and perceived vaginal dryness was significantly lower in the non-spiritual group. Spirituality was proven as a significant predictor of anti-SSB autoantibody serum activity and ESSDAI, while engaging in prayer/meditation and its duration predicted significantly anti-SSA autoantibody serum activity, perceived skin and tracheal dryness. Concerning logistic regression analysis, we found that an increase of one unit in spirituality reduces the probability with 81.6% of having a detectable, semi-objective disease activity at all. Significant associations were found between the duration of prayer/meditation and both semi-objective and patient reported disease activity scores and autoantibody anti-SSB with an inverse ratio based on logistic regression model.

Conclusions: Spirituality is associated with immune parameters and disease activity in pSS. Patients with spiritual attitude are less likely to have increased disease activity. Besides being spiritual, engagement in individual spiritual activities, such as prayer/meditation has beneficial disease modifying effect. These changes are supposedly due to psychoneuroimmunological pathways. In addition to the biologically measurable variables, the alleviation and aggravation of perceived symptoms (e.g. dryness) are important outcomes of spiritual engagement and practice.

Case-series of patients treated with anti-NMDAR encephalitis at Semmelweis University

L. Herman^{1*}, J. M. Réthelyi¹, I. Sipos² and R. I. Zsigmond¹

¹Department of Psychiatry and Psychotherapy and ²Department of Neurology, Semmelweis University, Budapest, Hungary

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1427

Introduction: Anti-NMDAR encephalitis is an autoimmune disorder, characterized by neuropsychiatric symptoms, such as mood instability, psychosis, catatonia, dyskinesia, seizures and vegetative lability. Psychiatric symptoms usually occur in the initial phase, therefore almost half of the patients are first observed at a psychiatric unit, however in later phases the patients' condition often show progression with the characteristic neurological symptoms, such as perioral dyskinesia and seizures. Although, early recognition and treatment is essential to reach good outcomes, delay in the diagnostic process often happens due to the unspecific early symptoms and the lack of knowledge of this disorder amongst psychiatrists.

Moreover, there are cases, where neurological symptoms do not appear, which can lead to diagnostic failure and mismanagement of these patients. Since anti-NMDAR encephalitis is a rare

condition, it is important to treat such cases in specific centres, where sufficient knowledge and multidisciplinary approaches are available.

Objectives: Our aim was to gather all patients' data treated with anti-NMDAR encephalitis at two departments (Neurology and Psychiatry) of Semmelweis University. We wanted to analyse psychiatric manifestations of the disorder in details and follow these symptoms long term, with special interest on the cognitive symptoms.

One of our aims was to follow-up these patients and measure antibody titres in their serum, to be able to assess, whether there was any association between prolonged serum positivity and cognitive impairment.

Methods: We have retrospectively analysed data of previous cases and prospectively followed up recently hospitalised patients.

Neurocognitive assessment had been conducted by the same psychologist, all the patients were followed up by the same interdisciplinary team, including a neurologist and two psychiatrists. Laboratory tests (autoimmune antibody essays) were conducted by the Immunological Laboratory at Semmelweis University.

Results: Altogether, 13 female patients were treated with anti-NMDAR encephalitis in the past ten years at Semmelweis University. All of them received plasma exchange, iv. steroids and azathioprine. 8 out of the 13 needed ventilation and intensive care treatment. 2 of these patients have mild psychiatric symptoms as residual symptoms, and 1 of them is still in the recovery stage, currently experiencing mild cognitive symptoms.

Only two patient had ovarian teratomas out of the 13, which is a lower number than expected from previous studies.

4 out of 12 had positive antibody titre at follow up, one patient is still at recovery stage, however her antibody titres are still very high.

Conclusions: Semmelweis University is one of the largest centre treating patients with anti-NMDAR encephalitis in Hungary. We had altogether 13 patients in the last ten years, with very good outcome, since all of them recovered, although 2 have residual symptoms.

Interleukin-15: a possible link between anorexia nervosa and schizophrenia

P. Lederer*, A. Mihaljević-Peš, I. Begovac and M. Tripković

Department of Psychiatry and Psychological Medicine, University hospital Centre Zagreb, Zagreb, Croatia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1428

Introduction: Interleukin-15 is a cytokine that induces or enhances differentiation, maintenance, or activation of several T-cell subsets (including NK, NKT, Th17, Treg, and CD8+ memory cells) and also plays an important role in regulating visceral (intra-abdominal or interstitial) fat breakdown and myofibrillar protein synthesis (hypertrophy). It is also involved in modulating serotonergic activity in the brain by modulating the transmission of GABA and serotonin, which may be the basis for mood and memory disorders, as well as activity levels, sleep, and thermoregulation. Both anorexia nervosa (AN) and schizophrenia (SCH) represent two distinct and serious psychiatric disorders in which

some of these symptoms may overlap and where neuroinflammation plays an important role which is yet to be precisely determined.

Objectives: This article summarizes recent findings and highlights interleukin-15 as a possible link between anorexia nervosa and schizophrenia.

Methods: A review of the current literature in the field of psychoneuroimmunology.

Results: In recent years, research has shown elevated levels of IL -15 in the serum of patients suffering from anorexia nervosa and schizophrenia. It is also interesting to note that IL -15 has structural similarities to IL -2, which previous studies have also shown to be elevated in patients with schizophrenia.

Conclusions: These associations, so far suggesting an important role of inflammation and its mediators, need further investigation in light of possible genetic overlap between anorexia nervosa and schizophrenia identified in genome-wide association studies (GWAS).

Clinical and immunological features of prolonged and chronic endogenous manic and manic-delusional states in the structure of endogenous diseases

S. A. Zozulya*, E. B. Rumyantseva, S. V. Sizov, I. V. Oleichik and T. P. Klyushnik

Mental Health Research Centre, Moscow, Russian Federation

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1429

Introduction: The relevance of studying the clinical and immunological characteristics of prolonged and chronic endogenous manic and manic-delusional states is conditioned by their high prevalence, insufficient understanding of pathogenetic mechanisms, and the need to develop adequate therapeutic approaches.

Objectives: To study the clinical and biological correlations between inflammatory markers of blood plasma, the severity of manic symptoms and psychopathological characteristics of patients with prolonged and chronic endogenous manic and manic-delusional states.

Methods: 70 female patients aged 18 to 55 years (mean age 33.6 \pm 5.9 years) with prolonged and chronic endogenous manic and manic-delusional states within different nosologies (F31.1-2, F25.01, F25) were examined. Psychometric assessment was performed using the PANSS, YMRS, and GAF scales. The control group consisted of 55 mentally and somatically healthy women of the corresponding age.

Leukocyte elastase (LE) activity, α 1-proteinase inhibitor (α 1-PI) activity, and the autoantibody levels to astrocytic protein S-100B and myelin basic protein (MBP) were determined in blood plasma.

Results: The increase in the level of immune system activation of different degrees (according to the complex of inflammatory and autoimmune markers) associated with the severity of the patient's condition within the examined nosologies was revealed.

The highest level of immune activation, characterized by an increase in the activity of both LE and α 1-PI ($p < 0.01$), and the level of autoantibodies to S-100B and MBP ($p < 0.05$), was characteristic of patients with chronic endogenous manic and manic-delusional states in the framework of schizophrenia. Manic symptoms within different

nosologies had clinical features, however, no differences in the severity of these symptoms on the YMRS scale were revealed ($p > 0.05$).

Positive correlations were found between LE activity and the PANSS subscale of general psychopathological symptoms ($R = 0.3$, $p = 0.006$) and the PANSS total score ($R = 0.3$, $p = 0.03$). The level of antibodies to S-100B correlated with the PANSS negative subscale score ($R = 0.3$, $p = 0.04$). A negative correlation was found between LE activity and the level of social functioning of patients according to the GAF scale ($R = -0.3$, $p = 0.02$).

Conclusions: The immune profile of patients with prolonged and chronic manic and manic delusional states within endogenous psychiatric disorders is determined mainly by nosologic affiliation, which is also related to the clinical features of manic states.

You are what you eat: diet, microbiota and mental health

A. M. Matas Ochoa*, S. Rubio Corgo and I. Durán Cristóbal

Psychiatry, Infanta Leonor University Hospital, Madrid, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1430

Introduction: In recent years, there is a growing interest in microbiota and how certain dietary patterns affect our brain.

We know that diet has an important impact in physical and mental health. The mechanism that underlies is already unknown, but there is emerging evidence that diet modulates brain gut microbiota and has implications in mental problems.

Objectives: The aim of this poster is highlight the importance of diet in mental health and the link with microbiota.

Methods: Review of recent literature about diet, microbiota and psychiatry. The studies were collected of the electronic databases PubMed.

Results: New researches highlight the importance of adequate nutrition for mental health. Several studies link healthy diet with a minor risk of mental illnesses or with the improvement of depressive symptoms. Likewise, poor dietary habits could aggravate cognitive decline and increased risk of developing anxiety, depression or other mental illnesses.

It has been shown that a diet rich in fiber, polyphenols and micronutrients improve gut microbial composition and can reduce metabolic endotoxemia and neuroinflammation, and this has been associated with improvements in brain health. Also, prebiotic and probiotics have positive effects.

Therefore, dietary interventions could be a complementary therapeutic approach for patients with mental problems. This is what nutritional psychiatry focuses on.

Conclusions: Microbiota as a potential therapeutic target for mental illness is a hot topic in psychiatry, but also, its interaction with dietary change or the use of probiotics and prebiotics. This action is easy to implement in our clinical practice and could be part of a biopsychosocial treatment to improve or prevent some psychiatric disorders. Nutritional psychiatry is a new field that needs to be developed and the knowledge in microbiota, diet and mental health could help. Hopefully, the research about this topic continues expanding.

EPV0803

The activity of platelet enzymes and subpopulation composition of monocytes in schizophrenia

T. Prokhorova*, I. Boksha, Z. Sarmanova, O. Savushkina and E. Tereshkina

FSBSI "MENTAL HEALTH RESEARCH CENTRE", Moscow, Russian Federation

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1431

Introduction: The studies on various groups of patients with schizophrenia revealed impairments in immune system, glutamatergic, and antioxidant systems contributing substantially in schizophrenia pathogenesis.

Objectives: To search for links between the activities of platelet enzymes involved in glutamate and glutathione metabolism and monocytes' subpopulation compositions in patients with schizophrenia and to identify possible correlations of the biomarkers with clinical data. Research objectives: determination of subpopulation ratio of monocytes; measurement of the activity levels of glutamate dehydrogenase (GDH), phosphate-activated glutaminase (PAG), glutathione reductase (GR) and glutathione S-transferase (GST) in blood platelets; search for correlations between these parameters and the scores by psychometric scales.

Methods: The study included 36 women aged 16-45 years with acute schizophrenia hospitalized in the Mental Health Research Centre with their current condition assessed as depressive-delusional. The control group consisted of 17 women 18-45 years old without somatic or mental pathology. GDH, PAG, GR and GST activities were measured by spectrophotometric methods, and numbers of monocyte subpopulations - "classical", "intermediate", "non-classical" - by flow cytometry. The Hamilton Depression Rating Scale (HAMD-17) was used to assess depression severity. The data was processed using the Statistica 8.0 software.

Results: The detected changes in monocyte subpopulations' composition towards the increase in the proportion of cells having a pro-inflammatory phenotype (CD14++CD16+ "intermediate") indicated the activation of inflammatory reactions. Also, the activities of platelet enzymes of glutathione metabolism (GR and GST) were significantly decreased ($p < 0.05$). Moreover, GDH and GST activities significantly correlated with the scores by HAMD-17 ($r = 0.40$, $p = 0.022$ and $r = 0.45$, $p = 0.030$, respectively). The results indicate the presence of pathological inflammatory process, the decrease in activities of glutathione antioxidant metabolism enzymes and a link to glutamate metabolism involvement (GDH) in the studied patient group.

Conclusions: The identified redistribution in the monocyte subpopulations' composition and decrease in the activity of enzymes involved in glutamate metabolism and antioxidant system indicate the involvement of the immune, glutamate and antioxidant systems in the pathogenesis of schizophrenia and may reflect a functional interaction between these systems.

Psychopathology

EPV0805

Unitarity or multiplicity of the psychosis: neverending question in psychopathology.

J. J. Martínez Jambrina

Psychiatry, Hospital San Agustín, Aviles, Spain

doi: 10.1192/j.eurpsy.2024.1432

Introduction:

- Introduce the topic of the continuity of psychoses and its relevance in contemporary psychiatry.
- Present authors as Henry EY, Jim van Os and Germán Berrios as key figures in the discussion on this topic, highlighting Ey, Dr. Jim van Os's significant contributions to the understanding of the continuum of psychosis, Germán Berrios's historical and cultural perspectives, and the importance of Bartolomé Llopis's critical viewpoint. We also review the evolutionary approach about mental disorders as a keypoint in this discussion.

Objectives: Analyzing and comparing the theses of Jim van Os, Ey, Germán Berrios, and Bartolomé Llopis's critical perspective. about the continuum of the psychosis and the importance of this never-ending question for its use in the clinical practice.

Methods: I will present a detailed literature review and a textual analysis of their writings.

Results:

- Provide a brief description of Jim van Os's theses highlighting his key ideas:
- **Dimensional Approach:** promotes a dimensional approach to understanding psychosis, viewing psychotic experiences as continuous variables rather than categorical entities. This challenges the traditional diagnostic system.
- **Psychotic-Like Experiences:** His research focuses on "psychotic-like experiences" (PLEs) in non-clinical populations, including mild hallucinations or paranoid thoughts.
- **Transdiagnostic Perspective:** His work contributes to a transdiagnostic perspective, suggesting flexibility in diagnostic boundaries in psychiatry.
- Next, introduce Germán Berrios's theses on the same topic, emphasizing his historical and cultural perspectives and recognition of individual variability.
- Finally, introduce Bartolomé Llopis's critical perspective:
- Llopis criticizes simplistic models of psychosis, arguing that they fail to capture the complexity of individual experiences.
- He advocates for comprehensive assessments that consider not only symptomatology but also the unique contexts and histories of individuals.
- While Ramón y Cajal is best known for his contributions to neuroscience and neuroanatomy, he did not directly apply Darwinian principles to his work in those fields. However He believed that an understanding of the evolutionary history of

the brain and nervous system could provide valuable insights into their structure and function.

Conclusions:

- Highlight the potential for a more comprehensive and holistic approach to understanding and addressing psychotic experiences within an evolutionary context.
- The relationship between the continuum of psychosis and evolutionism is a complex and multifaceted topic. It involves exploring how the concept of the continuum of psychosis, which suggests that psychotic experiences exist on a spectrum in the general population, may relate to evolutionary theories and perspectives on mental health. We will explain some key points to consider about this and the main psychiatrists which dealt with this question.

Examining Challenges and Evaluating Supportive Counseling Approaches for Students with Attention Deficit Hyperactivity Disorder (ADHD)”

I. Farmakopoulou¹, A. Metaxa¹ and M. Theodoratou^{2,3*}

¹social work and educational sciences, University of Patras; ²Social Sciences, Hellenic Open University, Patras, Greece and ³Health Sciences, Neapolis University Pafos, Pafos, Cyprus

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1433

Introduction: Introduction: Research indicates that 2-8% of students exhibit ADHD symptoms, a condition impacting personal, social, and academic functionality (Kwon et al., 2018). A significant proportion encounter educational and socio-emotional challenges, often leading to academic disruptions; indeed, 11-21% of such students defer enrollment for two consecutive years (DuPaul et al., 2021). Studies have highlighted pronounced issues related to academic performance within this demographic (Henning et al., 2022). These findings emphasize the critical need for innovative interventions and a deeper understanding of ADHD’s impact on young adults in academic contexts.

Objectives: To investigate challenges and evaluate supportive counseling approaches for students with Attention Deficit Hyperactivity Disorder (ADHD)”

Methods: This study utilized a qualitative approach, employing semi-structured interviews to understand the experiences and perspectives of university students with ADHD from across the country. The diverse sample comprised students from various academic disciplines and levels. Data were collected, ensuring participants’ comfort, and were analyzed using content analysis method, revealing insightful themes and patterns about ADHD’s impact in students’ quality of life and academic issues. The findings aim to contribute to a better understanding of ADHD

Results: The results of the study highlight the significant academic and organisational difficulties faced by participants with ADHD. Many struggled intensely to maintain concentration in class, with distractions causing significant attentional lapses and increased anxiety. Procrastination was a recurring problem, leading to last-minute submissions and increased stress. Forgetting to complete academic tasks, such as course registration, had a cumulative negative impact

on participants’ academic journeys. These findings highlight the complex challenges faced by people with ADHD in educational settings, and the need for comprehensive interventions. Addressing these multifaceted issues goes beyond academic accommodations and requires inclusive learning environments, counselling, peer support, and specialised faculty training to create a supportive ecosystem conducive to the success of individuals with ADHD.

Conclusions: This study highlights the multifaceted challenges, notably in concentration and task management, faced by individuals, presumably with ADHD, within academic settings. The reported struggles emphasize the urgent need for specialized interventions and support structures, focused on fostering concentration, effective task management, and administrative diligence. The insights provided are instrumental, guiding future research and intervention strategies aimed at addressing the identified needs and fostering an inclusive and supportive learning environment.

EPV0809

Emotionally charged events as a trigger for the acute development of psychotic symptomatology. A case report

P. Del Sol Calderon^{1,1*}, A. Izquierdo de la Puente¹, R. Fernández², M. García Moreno¹ and C. Delgado¹

¹Psychiatry, Hospital Puerta de Hierro and ²Psychiatry, Hospital Universitario Infanta Cristina, Madrid, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1434

Introduction: A 21-year-old male presented to the emergency room due to strange behavior

Objectives: Show how emotionally intense events can be a stress factor leading to dissociative or psychotic symptoms.

Methods: Case report and literature review

Results: The patient is in Spain after having attended the meeting with the Pope at the World Youth Day in Portugal. He is an engineering student who, in the week prior to the trip, had high levels of stress related to exam time. He also explained that he had recently had conflicts with his partner. In the psychopathological examination of the patient, a global insomnia of 3 days of duration stands out. In addition, a disorganized and disjointed speech focused on high concern that something bad could happen to his family and partner. In the interview he appears restless, nervous, with a perplexed contact. The patient’s companion says that he has been very worried and obsessed about his relationship with his partner, with constant doubts about asking her to marry him. It is decided to start olanzapine, receiving up to 15 mg per day. In the following interviews he shows better contact and a more organized speech.

Conclusions: It is known that emotionally intense situations can be a trigger for the development of psychotic symptoms. There are different manifestations of these stressful situations such as physical symptoms like fainting or but mental symptoms are also described such as dissociative amnesias, or less frequent as in this case psychotic symptoms. They are usually of sudden onset and early remission with good response to anxiolytics or antipsychotics.

Going through the adolescence with disabled sibling: resilience as a protective factor for the occurrence of internalizing and externalizing disorders in adolescents

M. Lipowska^{1*}, A. Łada-Maśko¹, K. Lipowska²,
U. Sajewicz-Radtke³ and B. M. Radtke³

¹Institute of Psychology, University of Gdańsk, Gdańsk, Poland;

²Department of Psychology, University of Amsterdam, Amsterdam, Netherlands and ³Laboratory of Psychological and Educational, Gdańsk, Poland

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1435

Introduction: Presence of the disabled child in the family poses many challenges for their siblings, especially in adolescence. Children with disabled siblings often receive less attention from family and friends, experience a sense of injustice and anger towards sick siblings, as well as they are more likely to experience various somatic complaints and higher levels of depression and anxiety. However, research shows that resiliency could be a protective factor associated with the functioning of children and adolescents in certain life events, such as sibling's disability, referring to good adaptation despite facing emerging adversities.

Objectives: Therefore, the aim of the current study was to examine the role of resilience as a possible protective factor for the occurrence of internalizing and externalizing disorders in adolescents having disabled sibling.

Methods: 175 diads of a healthy adolescent and one of its parents ($N = 350$) participated in the study. Participants were divided into two groups - 119 diads in the group with disabled sibling ($M_{\text{adolescent's age}} = 16.70$; $SD = .66$) and 56 diads in the group with a healthy sibling ($M_{\text{adolescent's age}} = 16.64$; $SD = .75$). The following measures were used in the study: Resilience Measurement Scale (SPP-18) and Child Behavior Checklist for Ages 6-18 (CBCL/6-18).

Results: The results showed no statistically significant differences in any of the measured resilience factors (optimistic attitude and energy, persistence and determination in action, sense of humor and openness to new experiences, personal competences and a tolerance for negative affect), in adolescents with disabled sibling, comparing to the control group. However, adolescents with disabled sibling were found to have a significantly higher risk of the occurrence of both, externalizing and internalizing disorders compared to adolescents with healthy siblings. Furthermore, findings of the study also confirmed that personal competences and a tolerance for negative affect predicts lower risk of the occurrence of internalizing disorders in adolescents having disabled sibling.

Conclusions: Our findings highlights that resilience may have important role in reducing the risk of the clinical problems occurrence in adolescents having disabled sibling. Therefore, comprehensive psychological support enhancing their personal growth and competence should be provided in the above group.

The Application of Pharmacogenetic Testing in Psychiatry for Treatment-Resistant Disorders: Optimal Timing and Implementation, a literature review

M. Pjevac

Clinical Psychiatry Center, university Psychiatric Hospital Ljubljana, Ljubljana, Slovenia

doi: 10.1192/j.eurpsy.2024.1436

Introduction: Treatment-resistant psychiatric disorders present a significant clinical challenge, often requiring trial-and-error approaches to find effective therapeutic interventions. Pharmacogenetic testing has emerged as a promising tool to guide medication selection and dosing, potentially reducing the time to achieve remission and alleviating the burden of persistent symptoms. However, the optimal timing and integration of pharmacogenetic testing into psychiatric practice remain underexplored.

Objectives: Pharmacogenetic tests can identify individuals with genetic variants that may predict their response to psychotropic drugs, thus enabling a more personalized approach to treatment. Evidence suggests that early application of pharmacogenetic testing, particularly after the first failed medication trial, can substantially improve outcomes for patients with treatment-resistant disorders. Such timely intervention can inform drug choice and dosing, averting protracted periods of ineffective treatment and minimizing exposure to unnecessary side effects.

Methods: This review synthesizes current literature on pharmacogenetic testing in psychiatry, with a focus on its application in treatment-resistant mood disorders, schizophrenia, and other non-responsive psychiatric conditions. We examine the genetic polymorphisms that influence drug metabolism, efficacy, and the risk of adverse effects, particularly considering cytochrome P450 enzymes and receptor gene variations.

Results: Pharmacogenetic testing holds significant promise in psychiatry, especially for treatment-resistant disorders, by aligning genetic profiles with medication selection to enhance therapeutic efficacy. While cost and access remain barriers, the benefits of early testing support its integration into standard care protocols. Further research is needed to establish clear guidelines and to expand the genetic targets relevant to psychiatric pharmacotherapy.

Conclusions: Adoption of pharmacogenetic testing after the initial treatment failure offers a pragmatic balance between the practical limitations of universal screening and the clinical imperative to alleviate the substantial morbidity associated with treatment-resistant psychiatric conditions.

EPV0812

Successful treatment of Premenstrual dysphoric disorder with irritable bowel syndrome using sulpiride

A. A. Alageel

College of medicine, Imam Mohammad Ibn Saud Islamic University (IMSIU), Riyadh, Saudi Arabia

doi: 10.1192/j.eurpsy.2024.1437

Introduction: Premenstrual dysphoric disorder (PMDD) is prevalent, more severe than premenstrual syndrome (PMS), and a challenging disorder. The first line of treatment is pharmacotherapy. Non-pharmacological therapy includes aerobic exercise, consumption of complex carbohydrates and frequent meals, relaxation training, light therapy, sleep deprivation, and cognitive-behavioral therapy could be helpful

Objectives: To our knowledge, there have not yet been any studies on this treatment option for PMDD with IBS

Methods: a case report

Results: A lady suffering from PMDD and irritable bowel syndrome (IBS) did not respond to antidepressants, painkillers, and melatonin. She used to sit at home and in her room these days, waiting for the PMDD severity to decrease. Her condition reached remission after taking a small dosage of sulpiride and stopped on the last day of the period. The patient is satisfied with the result since concerns about antidepressants are addressed and avoided. This case provides a new approach to using low-dosage sulpiride temporarily every month in patients with both PMDD and IBS

Conclusions: Premenstrual dysphoric disorder is a challenging condition. The symptoms of PMDD are not continuous, and somatic symptoms are a significant component of both the diagnosis and the patient's suffering. Choosing a suitable medication based on pros and cons contributes to successful treatment and patient satisfaction. This case provides a new approach to using low-dosage sulpiride in patients with both PMDD and IBS, but more studies are needed to confirm its efficacy and safety.

Neuroscience-based Nomenclature (NbN) and Early Career Psychiatrists: A Cross-Sectional Study on Views, Attainment and NeedsA. Seker^{1*}, D. Cavaleri², F. Santos Martins³, S. Bianchi⁴, D. Zani⁵, S. Zemach⁶, J. Zohar⁷ and A. Young⁸

¹Child and Adolescent Psychiatry, Institute of Psychiatry, Psychology & Neuroscience, London, United Kingdom; ²Medicine and Surgery, University of Milano-Bicocca, Monza, Italy; ³Psychiatry, Centro Hospitalar Universitário S. João, Porto, Portugal; ⁴Psychiatry, University of Perugia, Perugia, Italy; ⁵Psychiatry, Psychiatric Services Grisons, Chur, Switzerland; ⁶Psychiatry, The Jerusalem Mental Health Center, Jerusalem; ⁷Chaim Sheba Medical Center, Tel Hashomer, Israel and ⁸Mood disorders, Institute of Psychiatry, Psychology & Neuroscience, London, United Kingdom

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1438

Introduction: Anatomical Therapeutic Chemical (ATC) indication-based classification system is the World Health Organization (WHO) drug classification system and it is widely used in clinical and research practice, however there has been questions around the scientific base of this (1, 2). Neuroscience-based Nomenclature (NbN) has been developed by representatives from 5 international organizations, with specific expertise in psychopharmacology, to address the issues around neuropsychopharmacological drug classification and improve the focus on pharmacological domains and mode of action:

ECNP – European College of Neuropsychopharmacology

ACNP – American College of Neuropsychopharmacology

AsCNP – Asian College of Neuropsychopharmacology

CINP – International College of Neuropsychopharmacology

IUPHAR – International Union of Basic and Clinical Pharmacology

References:

1. Nutt DJ. Beyond psychoanaleptics - can we improve antidepressant drug nomenclature? [published correction appears in *J Psychopharmacol.* 2009 Sept;23(7):861]. *J Psychopharmacol.* 2009;23(4):343-345. doi:10.1177/0269881109105498

2. Zohar J, Stahl S, Moller HJ, et al. A review of the current nomenclature for psychotropic agents and an introduction to the Neuroscience-based Nomenclature. *Eur Neuropsychopharmacol.* 2015;25(12):2318-2325. doi:10.1016/j.euroneuro.2015.08.019

Objectives: As NbN is a novel classification system that can be used as a teaching tool as well as for other purposes, we aimed to understand the experience, views and needs of the psychiatric trainees and early career psychiatrists who will shape the future of psychiatry, around drug classification systems.

Methods: The ethical clearance of the study was obtained from King's College London. We prepared an online survey (<https://forms.gle/FCSdVTFH4U5QNn5t8>) with a multinational group of early career psychiatrists who met through the CINP and EFPT, and test-run the survey with a small group of psychiatric trainees. The online survey was then disseminated via emailing lists and groups of early career psychiatrists as well as through social media.

Results: At the time of this abstract submission, the data collection is ongoing. Results will include analyses of the experience with different drug classifications systems, awareness, views and attainment of NbN, stratified according to the demographic data (country, careers status, main work setting).

Conclusions: The findings from this study will shed light on the views and needs of early career psychiatrists on the topic from clinical and academic aspects, a previously unexplored perspective on drug classification systems. The findings can inform the planning of various strategies to address areas to improve the use and teaching of these tools.

Haematological alterations in the context of olanzapine treatment

B. Serra*, D. Ramis, R. Catalán and V. Llorca

Institut Clínic de Neurociències, Hospital Clínic de Barcelona, Barcelona, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1439

Introduction: Haematological alterations, especially in the red blood cell series, are a rare adverse effect of olanzapine treatment. A 64-year-old female patient with a diagnosis of long-standing schizophrenia was admitted to the psychiatric room for psychotic decompensation and leukopenia in control laboratory tests. She had a history of mild psoriasis, allergy to sulphonamides and infectious bursitis nine years earlier secondary to neutropenia due to clozapine. On previous admission, episodes of anaemia and neutropenia related to increased doses of olanzapine were observed. On current admission, a new episode of anaemia and neutropenia occurred with doses of up to 20 mg/day of olanzapine, hemoglobin levels of 63g/L and neutrophil count of $0,8 \times 10^9$ neutrophils/l were detected.

Objectives: Report a very rare but serious adverse effect in patients treated with olanzapine.

Methods: Haematological analysis were periodically carried out from 2009 to 2023.

A complete study was carried out with parameters of haemolysis, autoimmunity, a pharmacogenetic study and a myelogram.

Results: The autoimmunity and haemolysis study excluded an autoimmune or haematological illness that could justify the haematological alterations.

The myelogram showed normal cellularity.

The pharmacogenetic study showed no relevant alterations.

Image:

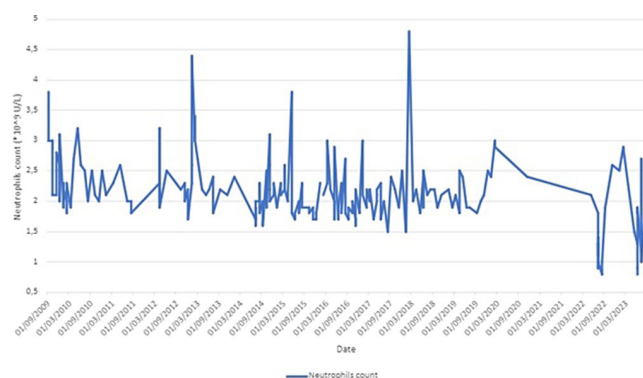

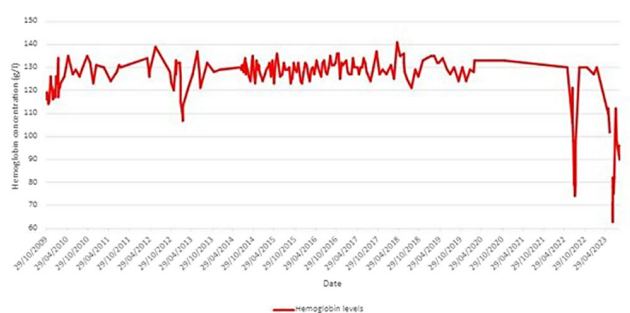

Image 2:

Conclusions: The case was classified as a non-immune haemolytic anaemia secondary to olanzapine and improved with withdrawal of the drug.

Disclosure of Interest: None Declared

Intranasal esketamine efficacy as a treatment for treatment-resistant depression, case series

C. Delgado Marmisa¹, I. Álvarez Correa¹, H. Vizcaino Herrezuelo¹, L. Egüen Recuero¹, E. Garrido Dobrito¹, L. Gayubo Moreo¹, B. Sanz-Aranguez¹, L. Delgado Tellez², L. Caballero Martínez¹, R. De Arce Cerdón¹ and B. Jiménez-Fernández^{3*}

¹Psychiatry; ²Pharmacology, Hospital Universitario Puerta de Hierro Majadahonda, Majadahonda and ³Department of Psychiatry, Hospital Universitari Germans Trias i Pujol, Barcelona, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1440

Introduction: Intranasal esketamine has been approved as a treatment for patients with treatment-resistant depression. We analyzed the results of its efficacy in 15 patients.

Objectives: To evaluate the efficacy of intranasal Esketamine as a treatment in patients with treatment-resistant depression

Methods: Case series

Results: For the last 8 months, since the treatment with intranasal esketamine was approved for resistant depression, we have treated 14 patients with this drug. Through this process, we followed a standardized method consisting in the following steps:

On the first esketamine session (DAY 1) the patient has to fill a CGI and a MADRS scale.

On the second esketamine session (DAY 7) the patient has to fill a CGI, a MADRS scale, a form about the level of satisfaction with the drug and a last form in which they can include the secondary effects. On week 6 since the start of the treatment, the patient has to fill again a CGI, a MADRS scale, a form about the level of satisfaction with the drug and a last form in which they can include the secondary effects.

In the 6th month since the start of the treatment, the patient has to fill again a CGI, a MADRS scale, a form about the level of satisfaction with the drug and a last form in which they can include the secondary effects they have perceived.

We analyzed and compared all of the previous data and obtained the following results:

At day 7: 64% of the patients had a response in the form of improvement, of which 66% were feeling "slightly better" and 33% were feeling "better".

At week 6: 71% of the patients had a response in the form of improvement, of which 50% were feeling "slightly better" and the other 50% were feeling "better".

At month 6: only 28% of the patients completed the treatment; of which 100% had a response in the form of improvement: 50% were feeling "slightly better", 25% were feeling "better" and 25% were feeling "far better".

Conclusions: Although our data suggests that intranasal esketamine has been effective in short term depressive symptoms, we have yet no information about its medium and long-term efficacy or secondary effects. Nevertheless, other potential factors should be evaluated as they could affect the results in the long-term such as the difficulty in maintaining the treatment for more than 6 weeks. In addition, the patients who experienced the most improvement according to our data were patients with a TAB diagnosis, so this could be an interesting research focus.

EPV0816

Sodium Oxybate-Induced secondary mania with psychotic symptoms: a case report and literature review

C. Cárdenes Moreno^{1*}, S. Yelmo-Cruz¹,
I. Pérez Sagaseta de Ilurdoz¹, J. J. Tascón-Cervera²,
G. P. González-Rodríguez¹ and M. Gallego-Restrepo²

¹Psiquiatría, Hospital Universitario de Canarias, San Cristóbal de La Laguna and ²Psiquiatría, Hospital Universitario de Gran Canaria Doctor Negrín, Las Palmas de Gran Canaria, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1441

Introduction: Sodium oxybate, an effective treatment for narcolepsy-associated daytime sleepiness and cataplexy, has been extensively. Despite its therapeutic benefits, sodium oxybate is not without its risks, and adverse psychiatric effects have been documented. This case report highlights a rare manifestation of sodium oxybate-related secondary mania with psychotic symptoms in a patient with narcolepsy, emphasizing the importance of recognizing and managing such adverse events. Additionally, we provide a brief review of similar cases reported in the literature.

Objectives: This report aims to describe the presentation, evaluation, and management of sodium oxybate-induced secondary mania with psychotic symptoms in a patient with narcolepsy. We also discuss the potential mechanisms underlying this adverse reaction and its clinical implications. Furthermore, we summarize findings from previous studies that have reported cases of secondary mania associated with sodium oxybate use.

Methods: We present the case of Mr. X, a 48-year-old male diagnosed with “Narcolepsy with cataplexy,” who had been receiving sodium oxybate treatment for 11 years. He was admitted to the hospital following a mild head injury and the emergence of a manic episode with psychotic features. Comprehensive clinical evaluation, including medical history, toxicology screening, and neuroimaging, was conducted.

Results: Upon evaluation, Mr. X exhibited hyperactivity, restlessness, grandiose delusions, paranoid delusions related to hospital staff, and decreased need for sleep. Notably, he had been consuming sodium oxybate excessively. Sodium oxybate was discontinued, and low-dose olanzapine was initiated. Within 24 hours, his manic and psychotic symptoms resolved. He admitted to overusing his medication, and his family reported a recent increase in his activity level. A review of the literature revealed similar cases of sodium oxybate-induced secondary mania with psychotic symptoms.

Conclusions: This case underscores the importance of vigilance for psychiatric side effects of sodium oxybate, particularly in patients with a history of substance abuse or potential overuse. Secondary mania associated with medications is a rare but significant clinical entity. Prompt recognition and intervention are crucial for patient safety and well-being. Further research is needed to elucidate the mechanisms underlying such reactions and to establish guidelines for their prevention and management.

EPV0817

Brief psychotic disorder treatment with Olanzapine in a patient with Phelan-McDermid syndrome

I. Retsou¹ and D. Antoniadis^{2*}

¹4th Department of PICU, Psychiatric Hospital of Thessaloniki and ²Psychiatry Department, Aristotle University of Thessaloniki, Thessaloniki, Greece

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1442

Introduction: The patient is a 50-year-old female, with multiple admissions in the PICU. At her first admission, at the age of 30 she presented the following main symptoms :mutism, negativism, crying and loss of bladder and bowel control. After collecting her complete family history, it was determined that her mother and one of her brothers were diagnosed with mild intellectual disability. Concerning her childhood history, she presented with late milestones as an infant and toddler and difficulties throughout primary education. Little information concerning her adult life was given, since the patient remained mute during the entirety of her first hospitalization.

Objectives: Determination of the efficacy of olanzapine in a patient with Phelan-McDermid syndrome with mild intellectual disability and psychotic symptoms such as auditory hallucinations, delusional ideas and disrupted behavior.

Methods: PANSS Test, intellectual capacity test, genetic testing.

Results: PANSS Scale Score at the 1st day of admission:100

PANSS Scale Score at the last day: 79

Intellectual capacity test: mild intellectual disability

Genetic testing results: Phelan-McDermid syndrome

Conclusions: After 20 days, symptoms showed mild recession in response to 20mg of olanzapine. In a period of 12 months, the patient showed no signs of relapse and she was not readmitted in the PICU.

Disclosure of Interest: None Declared

Urinary retention induced by psychotropics: A case report

E. Smaoui^{1*}, D. Mnif¹, N. Reguaieg¹, F. Guerhazi¹, S. Sakka²,
I. Baati¹ and J. Masmoudi¹

¹Psychiatry, CHU Hédi Chaker and ²Neurology, CHU Habib Bourguiba, Sfax, Tunisia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1443

Introduction: Neurological bladder is considered a functional disability that has a significant impact on the quality of life and psychological state of patients. Psychotropic drugs, in turn, can worsen the urinary dysfunction caused by this disease.

Objectives: Our objective is to illustrate, through the case of a patient suffering from a neurological bladder decompensated by the treatment of a characterized depressive episode, the link between these two pathologies.

Methods: We report the case of Ms. M.W., aged 51, with a history of high blood pressure stabilized under nebivolol and a neurological bladder diagnosed 10 years ago with episodic pollakiuria, admitted to the psychiatric department for repeated suicide attempts. She had never used psychoactive substances and had no family psychiatric history. The patient presented depressive symptoms evolving for 5 months. The diagnosis of a characterized depressive episode with melancholic features was made and the patient was treated with sertraline. From the first intake of the drug, the patient presented acute urinary retention (UR) requiring the placement of a permanent bladder catheter. The urinary symptoms improved upon stopping the treatment. Sertraline was changed to olanzapine and escitalopram. The patient stopped the treatment after one month because of the worsening of urinary symptoms requiring the installation of a suprapubic catheter. The urinary problem, together with the cessation of treatment, were responsible for a worsening of psychiatric symptoms leading to multiple suicide attempts. Given the advanced stage of the neurological bladder demonstrated by the urodynamic tests, our patient was treated with paroxetine, quetiapine and oxazepam along with psychotherapeutic education. The evolution was characterized by improvement in psychiatric symptoms and the urinary symptoms were stable.

Results: The lack of improvement after treatment discontinuation could be explained by an underlying neurological bladder manifesting with pollakiuria. The current literature on UR induced by psychotropic treatments is quite rare limited in case reports. This effect occurs especially when selective serotonin reuptake inhibitors (SSRIs) are prescribed in combination with other antipsychotics. Unlike first generation antipsychotics, atypical antipsychotics have muscarinic receptor antagonist properties which can induce UR. Among atypical antipsychotics, olanzapine has been shown to have the greatest antimuscarinic effects. Regarding SSRIs, they are associated with a lower risk of UR than other antidepressants and sertraline had the highest risk of UR.

Conclusions: SSRIs can induce UR particularly in combination with atypical antipsychotics. Coordination of care across multiple specialties and understanding the side effects of psychotropic medications can enable faster diagnoses and adequate management.

False-Positive Urine Drug Screening in a Patient on Quetiapine

J. Ying* and M. Y. G. Tan

East Region, Institute of Mental Health, Singapore, Singapore

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1444

Introduction: Urine drug tests are commonly used in psychiatry settings, mainly for the purpose of screening for substance abuse and excluding drug-induced psychiatric disorders. When carefully interpreted, these tests offer critical information for clinical judgement. However, certain psychotropic medications can trigger false-positive results in common urine drug screenings. For example, aripiprazole has been reported to cause false-positive urine amphetamine test results, and haloperidol has been associated with false-

positive urine drug tests for lysergic acid diethylamide (LSD). It is clinically significant to recognize some false-positive urine drug results and interpret certain results cautiously in clinical settings.

Objectives: We present a case of false-positive urine drug screening for tricyclic antidepressant (TCA) in a patient on quetiapine and aim to highlight the importance of accurate result interpretation in urine drug tests.

Methods: Details of the case were described. Information was gathered based on medical records.

Results: Mr. A, a 25-year-old construction worker, first presented at our hospital's emergency room on a Saturday in January 2023. He was brought by the police because he was aggressive and mentioned his colleagues were monitoring him. Being a foreigner, he did not have any prior medical records in our hospital. Urgent blood tests were performed, and organic causes were ruled out. He was started on quetiapine and lorazepam in the emergency room and was then admitted to our hospital.

A urine drug test was ordered on the following Monday, the third day of his admission. Surprisingly his urine drug screening revealed positive results for TCA and benzodiazepines. Initially as the patient was psychotic and could not give reliable history, we considered a few differential diagnoses, such as schizoaffective disorder and major depressive disorder with psychotic features, based on the presumption that TCA had been prescribed by the psychiatrist in Mr. A's home country. After further treatment, Mr. A became less psychotic and was able to share that he had a past psychiatric history of schizophrenia, but he had stopped antipsychotic medications four months ago.

Conclusions: This case report described a false-positive urine drug test for TCA while the patient was taking quetiapine. In this case, initially other diagnoses, such as schizoaffective disorder, were considered based on the incorrect assumption that patient was taking TCA.

False positive urine drug results can be confusing and misleading for clinicians. This report underscores the possibility of such false positives arising from quetiapine and emphasizes the critical importance of careful result interpretation.

Syndrome of Irreversible Lithium-Effectuated Neurotoxicity: Silent, but not innocent

M. S. Bicho*, J. M. Coelho, B. Peixoto, C. Cruz, P. Baião and I. Ferreira

Psychiatry, Hospital do Divino Espírito Santo de Ponta Delgada, Ponta Delgada, Portugal

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1445

Introduction: Lithium is one of the main drugs used in Bipolar Affective Disorder. However, it has a narrow therapeutic window, which requires close monitoring and progressive dose adjustment, according to serum levels, clinical response and the appearance of side effects. The term 'SILENT' explains descriptively persistent neurological sequelae related to lithium salt intoxication when symptoms persist for more than 2 months after stopping treatment. SILENT Syndrome is more common in females, at ages ranging

from 21 to 77 years and is characterized mainly by avermian-type cerebellar disorder, persistent extrapyramidal syndrome, brainstem dysfunction and dementia of varying severity. It can also result in apraxia of the body, changes in the coordination and balance, dysarthria, as well as intentional and kinetic cerebellar tremor, involuntary movements of orofacial dyskinesias or resting tremor.

Objectives: The authors intend to review the relevant and current literature in order to extend the knowledge about this condition and find the best conducts for clinical practice.

Methods: Non-systematic literature review.

Results: Complications from the use of lithium known in the medical literature include mainly nephrotoxicity, endocrine alterations and neurotoxicity. The neurotoxic effects of lithium usually occur at high serum concentrations. However, they can also occur with lithium in the therapeutic range, and memory, attention and ataxia impairment may be some of the permanent sequelae. The etiopathogenesis is unclear, but demyelination has been detected in multiple brain regions, mainly in the cerebellum. The mechanism of lithium-induced cerebellar injury is believed to be mediated by the entry of calcium into the cells of this organ. The main factors that predispose to greater side effects and risk of toxicity are patients with decreased renal function, advanced age, use of diuretics, dementia, pregnancy, low sodium intake and physical illness with vomiting and/or diarrhea.

Conclusions: Lithium is a drug used mostly in affective disorders and given the narrow therapeutic window, it requires close monitoring in order to avoid side effects that can be permanent. In this way, it is important to review the factors that increase the lithium toxicity and make recommendations about it.

Abilify Maintena 400 mg (aripiprazole once-monthly), two-injection start (TIS) regimen: the experience of the Psychiatric Unit (SPDC) of Rimini

M. P. Rapagnani*, L. Veronesi, M. Magnani and F. Sartini

Psychiatric Unit, AUSL della Romagna, Rimini, Italy

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1446

Introduction: The single-injection start regimen for aripiprazole once-monthly 400 mg (AOM 400) in patients with schizophrenia requires a single intramuscular injection in the gluteal or deltoid site and 14 days of concurrent oral therapy. Based on a population-pharmacokinetic model, the European Medicines Agency and Canada has recently approved a simplified starting strategy of aripiprazole once a month with single-day regimen of two injections at separate gluteal and deltoid injection sites, together with a single 20 mg dose of oral aripiprazole on the 1st day.

Objectives: The aim of the study is to evaluate the two injection start (TIS) regimen in inpatients in the Psychiatric Unit (SPDC) of the Hospital of Rimini.

Methods: We retrospectively reviewed medical records of patients, from February 2021 to April 2023, that have more than 18 years, who received the newly approved 2-injection start regimen as part of their standard care, evaluating if exist changes in clinical indicators, safety and tolerability of this regimen.

We valued retrospectively the days of hospitalization after the aripiprazole 400 mg TIS and the number of emergency room access, analyzing the “repository of AUSL della Romagna” and discharge letters and the “CURE” program of the Psychiatric Service of Rimini.

Results: We evaluated 24 patients from February 2021 to April 2023, 11 male (45,8%), 13 female (54,2%); average age 37,95, average length of stay in hospital was 11,75 days. 10 patients with diagnosis of psychosis/schizophrenia (41,7%), 6 patients with bipolar disorder (25%), 4 patients with personality disorder (16,6%), 2 patients with substance induced psychosis (8,3%), 1 patients with delusional disorder (4,2%), 1 patient with schizoaffective disorder (4,2%). 6 patients had the two-injection start regimen in 2021 (25%), 13 patients in 2022 (54,2), 5 patients in 2023 (20,8%); 20 patients did not have admission in hospital after the TIS (83,3%), 4 patients had 1 or more admission after the injection (16,7%). 3 patients (12,5%) had accesses in emergency-room after Abilify Maintena. 15 patients (62,5%) continue therapy; 9 patients (37,5%) had suspended the injection for drop-out or because of change of therapy not correlated at adverse effects (1 female patient had suspended treatment after the two-injections due to pregnancy). Just 1 patient that continue Abilify Maintena 400 mg had 2 accesses in the emergency-room.

Conclusions: The coadministration of 2 injections of 400 mg aripiprazole was not associated with safety concerns beyond those expected with a single-injection start regimen. From the study it appears that the long-acting therapy with Abilify Maintena 400 mg once-monthly helps to stabilize the patient to prevent hospitalization and accesses in emergency-room.

Evaluating the Efficacy of Prucalopride, a 5-HT₄ Agonist, in Managing Antipsychotic-Induced Constipation: A Prospective Randomized Controlled Trial Conducted at Chronic Psychiatric Rehabilitation Facilities on Corfu Island

P. Argitis¹, M. Peyioti^{1*}, O. Pikou², M. Demetriou¹, A. Karampas¹, S. Karavia¹ and Z. Chaviras¹

¹Psychiatric and ²Dermatology, General Hospital of Corfu, Corfu, Greece

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1447

Introduction: Achieving successful stabilization in patients with mental disorders often requires the administration of multiple antipsychotic medications, with the increasing prevalence of clozapine in cases resistant to other treatments. Constipation emerges as a particularly troublesome side effect, gradually progressing into a chronic state of gastrointestinal dysfunction, often accompanied by recurrent episodes of paralytic ileus of varying severity. Prucalopride, a 5-HT₄ agonist, selectively targets receptors within the intestinal system. This interaction induces muscular contractions and promotes chloride secretion. Literature suggest its potential efficacy in managing constipation induced by clozapine. In light of these observations, we designed and will conduct a randomized controlled trial to evaluate the effectiveness of prucalopride in alleviating constipation in patients who had

shown limited responsiveness to conventional laxatives or other conservative treatments

Objectives: The primary objective of this article is to present the methodology of a randomized control trial assessing the efficacy of prucalopride in the treatment of constipation among patients with mental disorders

Methods: The study will enroll 60 adult patients with mental disorders who will require more than two antipsychotic medications, including clozapine, for stabilization, and who will be experiencing constipation as a side effect

To ensure the validity of the study, the following additional inclusion criteria will be applied:

- Patients will have no severe acute medical conditions
- Patients will have no history of malignancy
- Patients will have no severe respiratory or cardiac diseases
- Patients will have negative results from an endoscopic evaluation of the large bowel, ruling out conditions such as irritable bowel syndrome, ischemic colitis, inflammatory bowel disease, or malignant neoplastic disease

Following the screening process, the patients will be randomly assigned to one of two treatment groups:

Prucalopride Group: Patients in this group will receive prucalopride for the treatment of refractory constipation

Conservative Treatment Group: Patients in this group will continue with conservative treatments. The treatment's success will be determined based on specific endpoints:

- Normalization of bowel movements, characterized by having more than five bowel movements per week
- Resolution of symptoms related to gastrointestinal dysfunction, including pain, bloating, defecation difficulties, and paralytic ileus

Results: Following the conclusion of the study, data from both groups will be meticulously collected and subjected to rigorous statistical analysis to identify differences in treatment outcomes between these two therapeutic approaches

Conclusions: The detailed findings will be presented in a forthcoming article

Disclosure of Interest: None Declared

EPV0823

A case of delirium following treatment with low dose mirtazapine and pregabalin

T. A. Manolis, D. Argyropoulos, N. Kokras* and A. M. Politis

First Department of Psychiatry, National and Kapodistrian University of Athens, Athens, Greece

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1448

Introduction: Pregabalin is a gamma-aminobutyric acid analogue used for the treatment of neuropathic pain, partial-onset-seizures, fibromyalgia, and anxiety disorders. Mirtazapine is an atypical antidepressant used in major depression and often prescribed off-label for insomnia. Delirium, an acute confusional state, is a very rare adverse reaction of both medications.

Objectives: We report a case of an elderly patient treated with low dose pregabalin and mirtazapine who developed drug-induced delirium which resolved rapidly upon withdrawal of both drugs

Methods: A 75-year-old woman was admitted for symptoms of anxiety, various bodily complaints (dysphagia, headache, tinnitus, weakness) and sleep-onset insomnia over the preceding 2 months. On admission, examination revealed an apparently anxious, uneasy and emotional looking patient. Mini mental state examination, as well as clock drawing and copying were normal, suggesting absence of cognitive impairment. Physical examination was unrevealing except for high blood pressure recordings (150/90 mmHg). Laboratory testing indicated creatinine at 1.19 mg/dl, with a creatinine clearance moderately decreased at 38 ml/min. Upon admission, she was placed on pregabalin 25 mg bid and mirtazapine 30 mg ¼ tablet qd.

Results: Three days after admission, pregabalin was increased to 25 mg tid. On the same day and about 2 hours after the night dose, the patient acutely developed delirium: she presented confusion, disorientation, incoherence, restlessness and deterioration of her anxiety. On physical examination she was afebrile with no hypertension or ataxia. An urgent brain magnetic resonance imaging was grossly unrevealing. Pregabalin and mirtazapine were discontinued, as a drug-induced delirium was suspected. She received as a symptomatic treatment lorazepam progressively up to 4 mg qd. Symptoms of delirium resolved rapidly, and she was discharged days later with full functional recovery

Conclusions: Cases of delirium have been described following treatment with pregabalin, but in significantly higher doses. Pregabalin relies heavily on renal clearance for its excretion and the dose should be adjusted in patients with creatine clearance below 60 ml/min. As our patient had a moderate decrease in renal clearance, we prescribed a dose within suggested limits, but in combination with mirtazapine led to the appearance of a drug-induced delirium. In conclusion, combined therapy with low-dose pregabalin and mirtazapine seems to account for the development of delirium in our patient as based on its temporal association with the initiation of this drug combination and its prompt resolution upon withdrawal of these two agents

EPV0824

Hyperammonemic encephalopathy in a 46 year old patient treated with valproic acid as treatment for borderline personality disorder: a case report.

P. Setién Preciados*, E. Arroyo Sánchez, C. Díaz Mayoral and J. Gimillo Bonaque

Servicio de Psiquiatría, Hospital Universitario Príncipe de Asturias, Alcalá de Henares, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1449

Introduction: Valproic acid (VPA) has been used in clinical practice since the 60's, with a relatively favourable safety and efficacy profile. Pancreatitis, hepatotoxicity and teratogenicity are the most significant adverse drug reactions. VPA is also known for causing hyperammonemia, which may be asymptomatic or can present with encephalopathy. VPA-induced hyperammonemic encephalopathy (VHE) is a serious but reversible condition, which requires high clinical suspicion for diagnosis. It may occur acutely or after chronic use of VPA.

Objectives: Review how frequent is for valproic acid to cause hyperammonemic encephalopathy, signs to watch out for and how it can be treated.

Methods: Presentation of a patient's case and review of existing literature, in regards to encephalopathy caused by valproic acid as a result of ammonia elevation.

Results: In the case displayed here, the patient is diagnosed of hyperammonemic encephalopathy after being treated with valproic acid as treatment for borderline personality disorder.

Reviewing literature, cases of hyperammonemia are rarely reported as VPA-induced, probably because this increased level of ammonia in blood can vary between asymptomatic, and clinically relevant levels. Symptomatology due to VPA-induced hyperammonemia include: lethargy, impaired consciousness, focal neurological signs and symptoms and increased seizure frequency. More rare described symptoms are: aggression, ataxia, asterixis, vomiting and coma.

There are multiple treatment modalities for patients diagnosed with VHE, the primary treatment being the discontinuation of VPA. Other treatments frequently used are Lactulose and Carnitine.

Conclusions: VHE is a rare occurrence, however can have fatal outcomes if not recognized and managed in time. Physicians should be vigilant while initiating Valproate therapy to patients. Clinicians should consider the possibility of VHE in patients with unexplained altered mental status, regardless of the duration of VPA therapy. A timely diagnosis is essential to prompt effective treatment, thus ensuring the patient's safety and decreasing the length of hospitalisation and the cost of care in hospitals.

EPV0827

A case report of Paliperidone palmitate-induced anaphylaxis

S. Pereira* and J. Pais

Department of Psychiatry and Mental Health, Centro Hospitalar do Tâmega e Sousa, Penafiel, Portugal

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1450

Introduction: Paliperidone Palmitate (PP) is an atypical antipsychotic, approved by the FDA for acute and maintenance treatment of schizophrenia and schizoaffective disorder.

It has a relatively safety profile, and reported cases of paliperidone palmitate-induced angioedema or anaphylaxis are uncommon.

Objectives: We intend to present a case of paliperidone palmitate-induced anaphylaxis to alert clinicians regarding this rare, but possible complication.

Methods: Non-systematic review of the literature and report of a case study.

Results: Long-acting injectable Paliperidone Palmitate (LAIPP) is a safe and effective alternative to oral Paliperidone, with less incidence of disease relapse related to medication non-compliance.

Substance use disorder (SUD) is highly prevalent in first-episode psychosis (FEP), and it is associated to decreased treatment compliance, which impairs the outcomes of these patients. Therefore, several authors have been recommended long-acting injectable antipsychotics (LAI-AP), such the LAIPP, as a first line for treatment of FEP-SUD patients.

The most common side effects associated with LAIPP are injection site reactions, extrapyramidal symptoms, hyperprolactinemia, sedation, hypersalivation, orthostatic hypotension, tachycardia, and

weight gain. Hypersensitivity reactions have rarely been reported and may be dose-dependent.

We report a case of a 20-year-old female, without medical history and no history of allergies, who was medicated with once-monthly LAIPP at dose 100 mg for the maintenance treatment of a first psychotic episode associated with cannabis abuse.

Approximately 24 hours after the first monthly injection dose, she was admitted in the emergency room (ER) presenting an increasing angioedema associated with stridor, requiring endotracheal intubation and administration of adrenaline, clemastine and hydrocortisone during the assessment in the ER.

After clinical stabilization, she was transferred to the internal medicine ward, and following a full recovery, she was discharged 6 days later while being medicated with Olanzapine 15 mg/day, Lorazepam 3 mg/day and Sertraline 50 mg/day. LAIPP was suspected as the etiology of the anaphylaxis reaction due to temporal relationship of its onset with therapy administration and by the exclusion of other potential causes. Consequently, LAIPP was discontinued at discharge.

Conclusions: This report shows the possibility of a late and potentially life-threatening anaphylactic reaction to LAIPP. So, all physicians should be aware of this potential complication, which requires timely recognition and management.

Disclosure of Interest: None Declared

EPV0828

Guanfacine in the Treatment of a Child Diagnosed with Tourette Syndrome: A Case Report

L. T. Durán Sandoval^{1*}, M. D. C. Blasco Fresco¹ and E. de la Fuente Ruiz^{1,2}

¹Psychiatry, Hospital Universitario Miguel Servet and ²Departamento de Medicina, Psiquiatría y Dermatología, Universidad Zaragoza, Zaragoza, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1451

Introduction: Tourette syndrome (TS) is a neurodevelopmental disorder characterized by the development of persistent and changing motor and phonic tics over time. The presence of at least two motor tics and one vocal tic that have persisted for at least a period of 1 year is required, and which developed before the age of 18. The most commonly used pharmacological treatment are antipsychotics, with a preference for atypical antipsychotics such as aripiprazole or risperidone. Clonidine and guanfacine have shown effectiveness in suppressing tics, and although generally less effective than antipsychotics, some authors are considering them as first-line treatments. The treatment is also influenced by any comorbidities the patient may present.

Objectives: To enumerate in a clinical case the pharmacological alternatives for TS, which vary according to the patient's comorbidities and the intensity of the tic symptoms.

Methods: Case study. Anamnesis of the patient and their family.

Results: A 12-year-old boy presenting simple motor and vocal tics for over a year. At the same time that a valuation is requested by child psychiatry, the mother also requests follow-up by neuropediatrics. Other causes are ruled out, an EEG is performed, and a TS diagnosis is made. The initial treatment was low-dose aripiprazole with partial effectiveness. After 3 months, he presents an

exacerbation of the tics, interfering with his social and academic life, making it impossible to attend classes. The mother takes him to emergency services, and he is admitted to pediatrics. During the stay in pediatrics, he is diagnosed with Attention Deficit Hyperactivity Disorder, in addition to confirming the TS diagnosis. Extended-release methylphenidate is initiated (neuropsychiatry). After starting methylphenidate, the patient's tics worsen, also presenting insomnia and hyporexia. Due to the diagnosis of ADHD, school failure, and affective symptoms (hypothymia), atomoxetine is initiated. The tics become constant and incapacitating. As the dose of aripiprazole is increased, the child presents extrapyramidal effects. As a therapeutic alternative, guanfacine is initiated, progressively discontinuing aripiprazole. Currently, the child is stable from motor and vocal tics, allowing him to lead a normalized life.

Conclusions: Although guanfacine is not as effective in reducing tics as antipsychotics, since the latter produce more side effects, it is justifiable to use it. This drug is capable of enhancing the therapeutic effect and reducing the adverse effects that antipsychotics could produce. Guanfacine may be a good alternative as a first line in the treatment of Tourette Syndrome with or without attention deficit disorder and hyperactivity.

Disclosure of Interest: None Declared

EPV0830

Asenapine versus other atypical antipsychotics for schizoaffective disorder Case study

E. Shaska

Acute Services, Psychiatric Hospital, Vlora, Albania
doi: 10.1192/j.eurpsy.2024.1452

Introduction: Antipsychotics are psychotropic medications that are indicated for the treatment of psychosis and mood disorders. Due to minimal side effects and their efficacy (affecting many receptors) compared to standard antipsychotics, today atypical antipsychotics are being used more and more as first-line treatment.

The aim of this study is to show the efficacy of asenapine and its tolerability as opposed to other atypical antipsychotics.

Objectives:

1. What are the side effects identified?
2. Side effects and efficacy of asenapine vs other atypical antipsychotics?

Methods: It is a comparative, regular, clinical study, an examination case of a 53-year old female diagnosed with Schizoaffective Disorder 27 years ago and treated outside of hospital with atypical antipsychotics, such as: risperidone, olanzapine, quetiapine, aripiprazole, amisulpride. The study covers the timespan of 2010-2022.

Results: The results showed that asenapine sublingual 15 mg had fewer side effects than other atypical antipsychotics. They were mouth dryness, headache, fatigue.

The other atypical antipsychotics caused: metabolic disorders, like considerable weight gain, cholesterol and glycaemia increase, extrapyramidal side effects, hyperprolactinemia.

Asenapine sublingual 15 mg was not as effective in treating Schizoaffective Disorder as risperidone 5mg, olanzapine 15 mg, aripiprazole 20 mg, amisulpride 600 mg.

The efficacy of asenapine sublingual 15mg was the same as quetiapine 400 mg.

Conclusions: This study showed that asenapine has minimal side effects but its efficacy in treating Schizoaffective Disorder as monotherapy is lower than other atypical antipsychotics.

Key words: antipsychotics, schizoaffective disorder, side effects, efficacy

Disclosure of Interest: None Declared

Importance of the type of pharmacological treatment in patients with severe mental disorder

M. Lucas, P. Romero*, N. Sirvent, R. Roig, J. Bajén, M. Aliño, C. Escobar and C. López

PSYCHIATRIC, SESCAM, ALBACETE, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1453

Introduction: The use of long-acting treatments is a common clinical practice in psychiatry. No disease insight and the risk of treatment discontinuation in a significant portion of our patients, increase the demand for psychiatric emergency and hospital admissions. Treatment adherence must be facilitated, taking into account possible side effects and patient's subjective satisfaction.

Objectives: -Evaluate the type of long-acting intramuscular treatment in selected patients. -Evaluate the differences in treatment satisfaction between different types of long-acting intramuscular treatments as well as frequency of psychiatric emergency and hospital admissions in the last year.

Methods: We select patients with different severe mental disorders who stay in a Medium Stay Unit, Sociosanitary Community Residence, Supervise house and Residence for the elderly in Albacete (Spain); all of them, with intramuscular neuroleptic treatment (zuclopenthixol dihydrochloride, aripiprazole long acting, palmitate paliperidone monthly, 3-monthly and 6-monthly) at least 1 year.

We evaluate their sociodemographic characteristics, the satisfaction questionnaire with the treatment (TSQM-9) and the rate of psychiatric emergencies and admissions after current intramuscular treatment in last year.

Results: We have selected 57 patients with an average age of 45.86. 78.94% with a diagnosis of schizophrenia, 12.28% with schizoaffective disorder, 5.26% bipolar disorder and 3.5% unspecified psychotic disorder.

We can see in the graphics below that the longer duration of the intramuscular treatment, the greater satisfaction in all the items of the TSQM-9 questionnaire.

31% of the patients with zuclopenthixol dihydrochloride treatment, have gone to psychiatric emergencies and 28% of psychiatric admissions in the last year. 18% of the patients with aripiprazole long acting, 17% with paliperidone palmitate long acting-monthly and 12% de 3-monthly have gone to psychiatric emergencies and 15%, 12% and 12% needed psychiatric admissions respectively. Patients with palmitate long acting-monthly have not emergencies or psychiatric admissions in the last year.

Image:

	Prevent	Relieves your symptoms	Time to start working	Easy or difficult to use	Easy or difficult is it to plan	Convenient or inconvenient to take	Good thing for you	Good treatment outweigh bad things	Global satisfaction
ZPX (2-4 M)	4,1	4,1	4,7	4	4,31	3,02	3,5	3,4	4,4
ARP 1M	5,9	6,2	5,2	4,7	6,2	6,2	4,12	4,05	5,34
PPLP1M	4,69	5,94	5	4,56	6,3	5,87	4,82	5,2	5,32
PPLP3M	5,8	6,1	5,8	5,12	6,5	6,3	5,15	5,8	6,01
PPLP6M	7,03	6,88	6,4	8,13	7,1	7,2	6,4	7,26	8,17

Image 2:

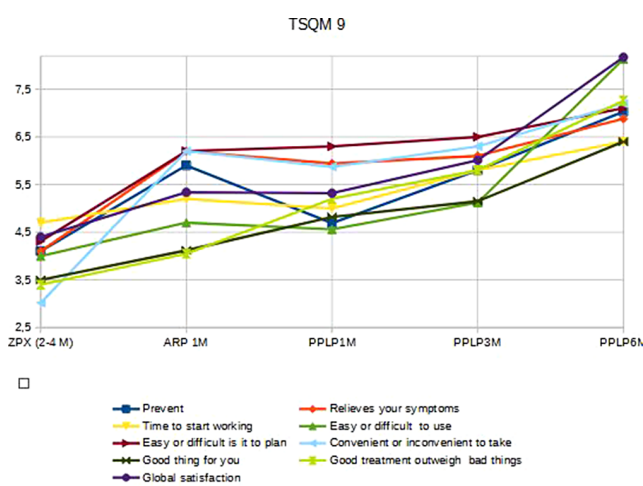

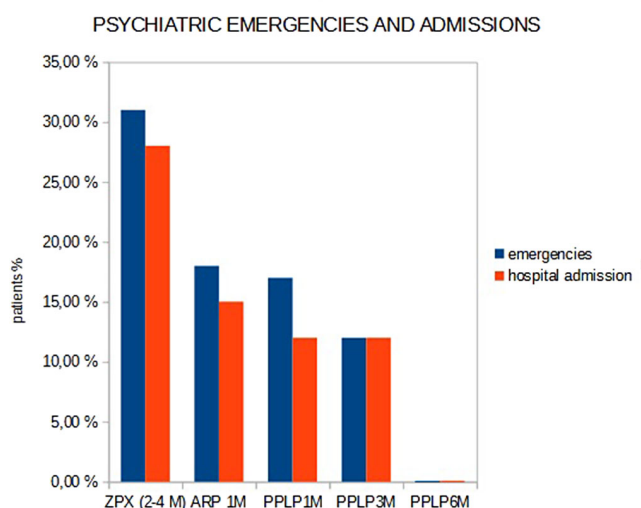

Image 3:

Conclusions:

- The longer long acting of the intramuscular treatments, the better patient satisfaction.
- With the longer duration treatment (Palmitate paliperidone LD 6 month), we have lower psychiatric emergencies and hospital admissions.

EPV0832

Aripiprazole induced reversible ptosis and oromandibular dystonia

S. E. Ilgin^{1*}, Ö. Yanartaş¹ and Ç. I. Özgenç Biçer²¹Psychiatry and ²Neurology, Marmara University Research & Training Hospital, Istanbul, Türkiye

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1454

Introduction: Aripiprazole is an atypical antipsychotic orally indicated for the treatment of schizophrenia, bipolar I, major depressive disorder. It is also indicated as an injection for agitation associated with schizophrenia or bipolar mania. Aripiprazole exerts its effects through agonism of dopaminergic and 5-HT_{1A} receptors and antagonism of alpha-adrenergic and 5-HT_{2A} receptors (Cosi et al., 2006). Ptosis is known as the drooping of the upper eyelid, and the patient usually presents with the complaint of the defect in vision and cosmesis (Shahzad & Siccardi, 2023). Oromandibular dystonia is uncommon neurological disorders with involuntary, mainly choreic (dance-like) movements, or excessive, involuntary and sustained or repetitive muscle contractions that may involve the face, lips, tongue, and/or jaw (Bakke, 2016).

Objectives: The aim of this study is to present a case of ptosis and orofacial spasm, which are neurological side effects that may be very rare side effects of aripiprazole.

Methods: The 22-year-old woman was referred to the psychiatric service via the emergency service, due to thoughts of harming herself and irritability. The patient was planned to be hospitalized due to decreased sleep, increased speech, and persecution delusions for the last days. After the patient stayed in the service for 25 days, the patient was prescribed olanzapine 10 mg for discharge. At the follow-up appointment, it was learned that the patient had gained weight due to olanzapine and was switched to aripiprazole on 4th of July. The patient's aripiprazole dose was gradually increased to 10 mg/day. The patient's relatives gradually noticed drooping eyelids, involuntary oral movements, and impaired speech due to aripiprazole. Cranial MRI and cranial MRI angiography performed to rule out organic pathologies resulted normal. Accordingly, the aripiprazole dose was reduced to 5 mg/day by his mother, and at the last follow-up appointment on August 4, aripiprazole was stopped and paliperidone was started, and the neurological symptoms completely resolved 4 days later.

Results: Since aripiprazole is frequently used in the field of psychiatry, its side effects are often wondered about. Extrapyramidal system side effects of antipsychotics are more common than ptosis. And In terms of the incidence of various extrapyramidal side effects, overall, no significant effects of age, sex, mean dose, study duration, or measuring method could be demonstrated. It is very important to distinguish between organic pathology and drug side effects, especially since ptosis accompanies neuromuscular diseases, ischemic, demyelinating brain lesions and intracranial aneurysms.

Conclusions: As a result, patients who are started on antipsychotics should be closely watched for side effects to increase patient comfort and drug compliance. Also organic pathologies must be excluded before making a final decision that it is a drug side effect.

Risperidone Induced DRESS Syndrome: A case reportS. E. Ilgin^{1,2*}, Ö. Yanartaş¹ and E. Akça²¹Psychiatry, Marmara University Research & Training Hospital and²Psychiatry, Marmara University Research & Training Hospital, Istanbul, Türkiye

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1455

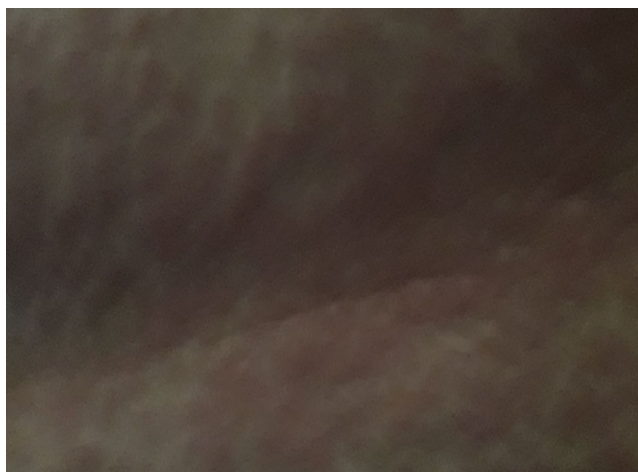

Introduction: DRESS (Drug Reaction with Eosinophilia and Systemic Symptoms) syndrome, also called DIHS (Drug-Induced Hypersensitivity Syndrome) is a rare drug-induced systemic hypersensitivity reaction that can be potentially life-threatening (Choudhary et al. J Clin Aesthet Dermatol 2013; 6 -7). Risperidone is an antipsychotic drug with significant antagonist activity at the 5-HT₂ and the D₂ receptors. It has been reported that risperidone may be effective in controlling agitation, delusion, hallucination, and withdrawal behavior in geriatric patients (Yunusa & El Helou. Front Pharmacol 2020;11:596).

Objectives: The aim of this study is to demonstrate the case of developed DRESS syndrome following the use of risperidone.

Methods: The 81-year-old female patient was admitted to the Dermatology Clinic due to skin rash, high fever and leukocytosis following the use of risperidone. The patient was consulted to Psychiatry.

Results: In her history it was determined that risperidone 0.5 mg/d was started to the patient with depression due to agitative symptom. On the 4th day of treatment, targetoid lesions, starting from the back and spreading first to the trunk and then to the extremities, were observed. Further laboratory examinations revealed that the fever was measured at 39.5 C°, liver enzymes were elevated (ALT= 119 IU/l, AST= 124 IU/l), and significant leukocytosis (WBC=12.000) was present along with the lesions. The patient was planned to be hospitalized to Dermatology Clinic on the 5th day and risperidone was stopped. The patient's agitation increased and following the risperidone discontinuation thereupon the lesions tended to fade and desquamation began. After the treatment of the DRESS syndrome, aripiprazole was given to the patient for agitative symptom. The level of agitation symptoms decreased, and the patient tolerated aripiprazole well without any observed side effects.

Image:

Conclusions: When initiating medication for the elderly population to address agitation, considering such rare side effects can prevent the patient from being hospitalized due to DRESS syndrome. To the best of our knowledge, this is the first case report associated with DRESS syndrome and risperidone treatment thus, it is necessary to be very careful when starting psychotropic medication for elderly patients.

Clinical Insights into Antipsychotics and Rifampicin Interaction: A Case Report

P. Abreu*, C. Ferreira dos Santos, M. Pereira, M. Vieira Lisboa, M. Cameira and M. Rebelo Soares

Centro Hospitalar Psiquiátrico de Lisboa, Lisbon, Portugal

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1456

Introduction: Antipsychotics are the primary class of drugs used to manage schizophrenia. These medications help control and reduce the severity of these symptoms, allowing individuals with schizophrenia to better function. On the other hand, rifampicin, used as treatment for tuberculosis, is a powerful inducer of several drug-metabolizing enzymes which have the potential to decrease the plasma levels of antipsychotics. Therefore, the presence of multiple pharmacokinetic interactions can alter how antipsychotics are metabolized, leading to a notable clinical impact when these medications are administered concurrently.

Objectives: The objective is to share valuable clinical experiences and insights to aid healthcare providers in making informed decisions when faced with the challenge of co-administering antipsychotics with rifampicin, ultimately ensuring the safety and efficacy of treatment for their patients.

Methods: It will be discussed a case of a 41-year-old woman with the diagnosis of schizophrenia under treatment with paliperidone palmitate and clozapine who had a sudden relapse after starting treatment for latent tuberculosis with rifampicin as a framework for a literature review based off Pubmed.

Results: The antituberculosis drug rifampicin induces drug-metabolizing enzymes in the liver, having the greatest effects on the expression of cytochrome P450 (CYP3A4) and therefore can lead to a decrease in the plasma levels of antipsychotic medications that also rely on these pathways for clearance. In this particular case, although specific data on clozapine and paliperidone concentrations were not reported, fluctuations in symptomatology following rifampicin introduction were probably explained by an inducing effect of this drug on their metabolism. So, when initiating rifampicin treatment and when discontinuing it, clinicians should carefully assess the dosages of any concomitant medications that may potentially interact with rifampicin. To ensure effective therapy during rifampicin treatment, it is crucial to monitor both the patient's clinical response and their blood drug concentrations, making dosage adjustments as necessary.

Conclusions: This case report offers valuable guidance to clinicians on safely and effectively managing drug interactions between antipsychotic medications and rifampicin, ensuring the well-being of

their patients during treatment. The co-administration of these medications lacks robust clinical evidence, and notably, there is insufficient data regarding its impact on plasma antipsychotic levels, a crucial factor in determining clinical effectiveness.

A Comparison of medication management with separate psychotherapy to medication prescribing with psychotherapy

L. Mehl-Madrona^{1*} and B. Mainguy²

¹Native Studies and ²Intermedia, University of Maine, Orono, United States

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1457

Introduction: Little research has been conducted on outcomes in mental health care by intensity of level of service. Mental health care has evolved in the United States to psychiatrists or psychiatric nurse-practitioners overseeing medications in 15-minute appointments while non-physicians provide the psychotherapy.

Objectives: We wished to compare these two models when one psychiatrist worked in two settings, providing the medication management alone model in one setting and the medication + psychotherapy model in the second setting.

Methods: All patients were seen by the same psychiatrist at (1) a community mental health center (CMHC) and (2) a private practice (PP) providing services to the same type of patients over 2 years. Patients were assessed with the My Medical Outcomes Profile (MYMOP2) and the Brief Psychiatric Rating Scale (BPRS). In the CMHC, patients were seen for a 15 – minute visits every 1 to 3 months. Patients were offered psychotherapy, ranging from 1/2 hour monthly to 1 hour every other week. Some patients received weekly psychotherapy due to an interest by the clinician. In the PP, patients were seen every 1 to 4 weeks by the psychiatrist who also provided psychotherapy when that was desired. Visits ranged from 15 to 75 minutes. Other practitioners could have also provided psychotherapy. Analysis was conducted for patients who completed at least four outcome ratings. Multi-level modeling techniques as implemented in SPSS were used to determine if patients improved over time.

Results: There were no differences in age, socioeconomic status, type of insurance, and type of diagnosis among the two groups. Follow-up occurred for two years. On average, no improvement occurred in outcome measurements in the CMHC setting while statistically significant improvement occurred in the PP setting. The cost of care was statistically significantly greater in the CMHC setting, due to the facility fees billed and collected for each patient (and approved by the government) of \$176 additional per visit.

Conclusions: Further work can be done on establishing minimal levels of service delivery that can produce improvement for large populations in community settings. Since it is unlikely that we can generate control groups of no treatment, perhaps analyses like this one, comparing treatment models, can establish a benchmark from which we can understand the necessary level of treatment. The PP setting may have afforded more attention for patients than the CMHC setting, though at a lower cost to the government. The

psychiatrist believed that he wanted patients to improve equally in both settings, but he could have been more enthusiastic in the setting in which he also did psychotherapy and therefore had better relationships with patients. On the other hand, this may be the point – better relationships with patients may be associated with better outcomes.

Psychological vulnerability and problematic psychotropic drug use among medical residents: exploring the relationship

H. Ktari, S. Sellami*, J. Ben Thabet, S. Omri, R. Feki, I. Gassara, N. Smaoui, L. Zouari, M. Maalej, M. Maalej Bouali and N. Charfi

Psychiatry C, University Hospital Hedi Chaker, Sfax, Tunisia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1458

Introduction: Psychological vulnerability and problematic psychotropic drug use among medical residents are critical and intricate areas of study in the field of healthcare and mental well-being. This topic looks into the potential links between the psychological vulnerabilities experienced by medical residents, which are frequently associated with the demanding nature of their profession, and their use of psychotropic drugs in a way that poses problems or risks. Exploring this relationship is critical for understanding the mental health challenges that medical residents face and developing effective strategies to support their psychological well-being.

Objectives: to identify the psychological factors linked to problematic psychotropic drug use in medical residents.

Methods: We conducted a cross-sectional descriptive and analytical study among Tunisian medical residents between August and September 2022. We used a self-administered questionnaire with a data collection form, the DAST-10 (Drug Abuse Screening Test) scale, and the DASS-21 (Depression, Anxiety, and Stress Scale) in an online survey. Data was analyzed using the 20th version of the SPSS software.

Results: The sample consisted of 80 medical residents. Among them, 23.8% (n=19) had reported a previous use of psychotropic drugs, and 15% (n=12) a misuse (without a prescription and/or without following the prescription). The DAST-10 revealed that 6 residents (31.6%) had problematic use of psychotropic drugs.

A high level of stress on the DASS-21 scale was associated with a problematic use (p=0.01) and a misuse (p=0.01) of psychotropic drugs. Furthermore, residents with high stress levels were more likely to demonstrate problematic use of psychotropic drugs (p=0.004). Such problematic use was correlated with personal history of anxiety disorders (p=0.01).

Furthermore, residents with problematic psychotropic drug use had higher anxiety and depression scores on the DASS-21 scale (p>0.05).

Conclusions: Our findings revealed a concerning prevalence of psychotropic drug use among medical residents and an association with high stress levels. This result emphasizes the need for targeted interventions to support young doctors' mental health.

doi: 10.1192/j.eurpsy.2024.1459

Introduction: The U.S. Food & Drug Administration (FDA) has cleared SNT (Stanford Neuromodulation Therapy) for treatment of major depressive disorder (MDD) in adults who have failed to achieve improvement from at least two prior trials of antidepressants. SNT protocol requires both structural and functional connectivity MRIs which is limited by high cost and lack of availability, its use without neuronavigation is still considered an off label use and need more investigation.

Objectives: 1-To investigate efficacy of SNT like accelerated off-label protocol without Neuronavigation in treating patients with TRD and suicidality.

2-To investigate durability (up to one month) of SNT like accelerated off-label protocol without Neuronavigation in treating patients with TRD and suicidality

Methods: Two cases diagnosed as treatment resistant unipolar depression with suicidal ideations received accelerated intermittent theta burst stimulation (a iTBS); with figure of eight coil administered to the left dorsolateral prefrontal cortex (DL-PFC) determined using Beam method. Stimulation was at 90% MT for 1800 pulses with an intersession interval of fifty minutes. Patients received ten sessions every day for five consecutive days for a total of fifty sessions (90,000 pulses). The following scales were applied at the baseline and at the end of each day of five treatment days: The Montgomery and Asberg Depression Rating Scale (MADRS) The Beck Depression Inventory, Columbia Suicide Severity Rating Scale (C-SSRS) and Young Mania Rating Scale (YMRS).

Results: The two cases at the end of the fifth day were completely improved regarding both suicidal ideations and depression without emerging of hypomania. Follow up was done weekly for one month with durable results.

Conclusions: SNT protocol without neuronavigation needs to be well investigated in suppressing both suicidality and depression in patients with TRD.

EPV0844

Non-Invasive Brain Stimulation for Perinatal Depressive Disorder: A Literature Review

C. Pinheiro Ramos*, M. Alves, D. Durães, S. Mendes and A. Gamito Setúbal Hospital Center, Setúbal, Portugal

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1460

Introduction: Peripartum Depressive Disorder (PPD) is a Peripartum Mental Disorder (PMD) characterized as a Major Depressive Disorder (MDD), wherein the manifestation of depressive symptoms initiates either during pregnancy or within the first 12 months following childbirth.

PPD impacts both maternal well-being and infant health, resulting in unfavorable outcomes during pregnancy and the postpartum period.

Non-Invasive Brain Stimulation (NIBS) is one of the rapidly expanding fields in medicine, using a range of techniques to modulate the brain.

Objectives: This study aimed to summarize the latest evidence about the impact of NIBS (efficacy, tolerance, and safety) in PPD.

Methods: A review was conducted, drawing on reputable (PubMed and Web of Science databases).

Key brain stimulation modalities, such as Transcranial Magnetic Stimulation (TMS), Transcranial Electrical Stimulation (TES), and Electroconvulsive therapy (ECT) were analyzed in the context of PPD.

Results: Preliminary findings indicate promising positive effect of NIBS in reducing symptoms associated with PPD.

In the postpartum, the favorable outlook on the effectiveness of NIBS implies that, when feasible, women diagnosed with mild to moderate PPD, especially those reluctant to initiate pharmacological interventions, should be presented with TMS or TES as an alternative therapeutic approach.

However, some doubts persist about the safety of NIBS regarding fetus and preterm birth.

Conclusions: NIBS constitutes a viable option for pharmacological and psychotherapeutic interventions, and it can also be integrated into comprehensive treatment regimens.

Future research include large-scale clinical trials and longitudinal studies is needed to address the efficacy, security, and long-term effects of NIBS.

The perception of Romanian mental health professionals on electroconvulsive therapy

C. E. Anghel^{1,2*} and C. Băcilă^{1,2}

¹Faculty of Medicine, The "Lucian Blaga" University and ²Scientific Research Collective in Neurosciences - The "Dr. Gheorghe Preda" Clinical Hospital of Psychiatry, Sibiu, Romania

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1461

Introduction: The journey for the electroconvulsive therapy began in 1938, when convulsive seizures induced by electrical stimulus were used, for the first time, in the therapy of patients diagnosed with Schizophrenia. Over the time, this therapy remains an important one, due to its applicability and necessity in the therapeutic management of patients with psychiatric pathology.

Objectives: Electroconvulsive therapy has evolved as a technique, nowadays being applied under induced intravenous anesthesia with the administration of oxygen on the mask, and from 2001, the sinus electrical stimulus has been replaced by the one in the form of a short pulse, upon the recommendation of professional organizations, in order to increase its therapeutic effectiveness. However, this form of therapy continues to be stigmatized, largely due to the

way it is presented in the mass media. The objective of this work was to analyze how mental health professionals perceive electroconvulsive therapy.

Methods: We conducted a study in which we used a questionnaire applied to the Romanian professionals in the field of mental health.

Results: The results were analyzed in accordance with the objective of the study.

Conclusions: Through this analysis we wanted to understand how electroconvulsive therapy is seen through the eyes of mental health professionals and to identify those aspects that can help us in carrying out information programs, with a major impact on mental health, in order to reduce stigma forasmuch the therapeutic benefits of electroconvulsive therapy outweigh the possible risks.

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1462

Introduction: Electroconvulsive therapy (ECT) is a psychiatric intervention that has proven effectiveness and safety in various psychiatric conditions, such as major depressive disorder, prolonged or severe manic episodes and catatonia. Despite positive scientific evidence, ECT was always seen as controversial by patients, caregivers, and even some psychiatrists, which lead to a decrease in its use over the years.

Objectives: To investigate the way young psychiatrists view the place of ECT in modern psychiatry by assessing their knowledge, attitude and access to training opportunities in ECT.

Methods: An anonymous survey was disseminated online among early career psychiatrists and psychiatric trainees. The questionnaire consisted of 36 multiple-choice and Likert scale questions.

Results: Most of our respondents consider ECT both an effective and a safe treatment option and would recommend ECT to their patients when indicated. Early career psychiatrists who had access to ECT training are more knowledgeable about the indications,

precautions and side effects of this method, but more than half of the participants mentioned ECT training was unavailable during their residency programme. Almost all respondents stated that they are interested in enhancing their theoretical and practical competencies in ECT.

Conclusions: Early career psychiatrists have a positive attitude towards ECT but express the need of targeted education aimed at improving levels of knowledge about ECT.

Disclosure of Interest: None Declared

Vagus nerve stimulation (VNS) as a long-term adjunctive treatment option in patients with difficult-to-treat depression (DTD)

E. Kavakbasi^{1*}, H. Bauermeister¹, L. Lemcke² and B. T. Baune^{1,3,4}

¹Department of Psychiatry; ²Department of Neurosurgery, University Hospital Münster, University of Münster, Münster, Germany; ³Department of Psychiatry, Melbourne Medical School, The University of Melbourne, Melbourne and ⁴The Florey Institute of Neuroscience and Mental Health, The University of Melbourne, Parkville, Australia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1463

Introduction: VNS is a long-term adjunctive treatment option in patients with DTD. It has been shown that patients with VNS as add-on to treatment-as-usual (TAU) have higher response and remission rates than TAU alone. Data on the impact of VNS on the other complex concomitant treatments are limited.

Objectives: In this study we evaluated changes in drug load from baseline to 12 months as well as the impact of previous ECT response status at baseline on changes in mean depression severity after 12 months of VNS.

Methods: We included n=20 DTD patients (mean age 52.6 years) in the prospective, observational, naturalistic Restore-Life study, who have been treated with adjunctive VNS as add-on to treatment as usual. The RESTORE-Life study is a multi-center study. In this analysis, we report on exploratory results from a single tertiary center. An index has been calculated for each drug by comparing the actual dose with the standard dose of the drug. The drug load for each patient has been constructed by summing up the indices of all agents prescribed for the patient.

Results: We observed a slight decrease in mean drug load from 4.5 at baseline to 4.4 at 12 months (p=0.594). The drug load was lower in previous ECT-responders than in ECT-non-responders at both time-points. There was a significant decrease in mean MADRS score from 27.3 at baseline to 15.3 at 12 months (p=0.001). Patients with a history of ECT response at baseline have experienced significantly greater improvement in mean MADRS score at 12 months (p=0.013). Number of maintenance electroconvulsive therapy (ECT) and esketamine sessions decreased from 37 ECT and 58 esketamine sessions in the first six months to 17 ECT (-54%) and 29 esketamine (-50%) sessions between months 6 and 12. VNS-related adverse events were present in 50 % of patients at 12 months (voice alteration/hoarseness 45%, dyspnea and pain during stimulation each 5%). There was no discontinuation of VNS due to adverse events.

Conclusions: Overall, VNS was associated with significant decrease in mean MADRS score at 12 months, whereas we did not detect any

significant change in medication load. A more extended observation period might be necessary to observe changes in medication load. There was a reduction in the need of maintenance treatment sessions of ECT and esketamine. History of ECT response may be predictive for greater improvement of depression severity in VNS patients.

Disclosure of Interest: E. Kavakbasi Grant / Research support from: The Sponsor of the Restore-Life study is LivaNova. Our institution received fees from LivaNova for study visits of the Restore-Life study. LivaNova had no influence on the content of this work., H. Bauermeister: None Declared, L. EPV0848

Synchronization of accelerated intermittent Theta-Burst-Stimulation (aiTBS) with VNS in difficult-to-treat depression (DTD)

E. Kavakbasi^{1*}, S. B. Klass¹ and B. T. Baune^{1,2,3}

¹Department of Psychiatry, University Hospital Münster, University of Münster, Münster, Germany; ²Department of Psychiatry, Melbourne Medical School, The University of Melbourne, Melbourne and ³The Florey Institute of Neuroscience and Mental Health, The University of Melbourne, Parkville, Australia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1464

Introduction: Patients with difficult-to-treat depression (DTD) need multimodal treatment with combination of psychotherapy, pharmacotherapy and neuromodulation. In severe cases, combination of neuromodulatory techniques may be considered to achieve symptom relief.

Objectives: To describe a novel treatment approach, which combines VNS in synchronization with accelerated intermittent Theta-Burst-Stimulation (aiTBS) over three weeks in two cases with difficult-to-treat depression.

Methods: In this presentation we describe two cases of DTD, which have been implanted with VNS and did not respond to aiTBS previously. Patients then were offered a synchronized treatment regimen, where each stimulus train of aiTBS was synchronized with ON-time of VNS. To start each train simultaneously with VNS ON-time, we set treatment cycle of each aiTBS and VNS to 19 sec. Patients received 2400-3000 TBS pulses daily for 3 weeks over left dorsolateral prefrontal cortex (DLPFC) at 100% of resting motor threshold.

Results: In the first patient the MADRS score decreased from 37 to 26 (-30%) and in the other patient there was a decrease of MADRS score from 20 to 9 (-55%), which corresponded to remission after 3 weeks of treatment. The synchronized treatment procedure was well-tolerated in both cases. As both patients experienced significant improvement, we planned maintenance treatment in both cases.

Conclusions: Synchronization of aiTBS with VNS is a novel treatment approach in patients with DTD, which can lead to improvement even if patients previously did not respond to aiTBS without synchronization with VNS.

EPV0851

The Effectiveness of High-frequency Repetitive Transcranial Magnetic Stimulation in Persistent Somatic symptoms Disorder: A Case report study

M. K. Albalushi

Psychiatry, Oman medical specialty board, Muscat, Oman

doi: 10.1192/j.eurpsy.2024.1342

Introduction: Background:

Somatic symptoms disorders are usually comorbid with depressive disorders despite that there is little evidence for effective treatment for it. Repetitive transcranial magnetic stimulation (rTMS) have been approved by FDA for mildly resistance depression. From this point we hypothesized that rTMS delivered over the prefrontal cortex (PFC) may be useful in somatic symptoms disorder. Therefore, in our case report we want to shed light on the potential effectiveness of rTMS in somatic symptoms disorder.

Objectives: case report

Methods: case report

Results: Case Report:

A 65-year-old Omani female with multiple medical comorbidities on multiple medications. She presented complaining of multiple somatic complains in the last 2 years after visiting multiple clinics and underwent several specialists' examinations, investigations and procedure for somatic treatments, all of them where normal. Then patient was seen by different psychiatric clinic multiple antidepressant and adjuvant anti-psychotic medication were try, patient still not improve.

Patient get admitted to hospital for observation and management. Initially she was preoccupying by her somatic complain kept on Fluoxetine and Olanzapine along with that topiramate was added, but still with minimal improvement. Then rTMS was added to her management plan following Intermittent theta burst (iTBS) rTMS protocol. After complete all sessions of rTMS patient was recovering from her all symptoms, no complain report from her.

Conclusions: Conclusion: our case highlights the important of investigated more thoroughly in rTMS as treatment option for Persistent Somatic symptoms Disorder.

EPV0852

Transient Febrile reaction after Electroconvulsive Therapy : A case report in an adult man with Ultra-Resistant Schizophrenia

K. Abdessattar, A. Hkiri, H. khiari*, O. Youssef and R. Ghachem

psychiatry department Pinel, Razi Hospital, Manouba, Tunisia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1466

Introduction: Electroconvulsive therapy (ECT) is a therapeutic method that induces artificial seizure by electrical stimulation to resolve various psychiatric symptoms. ECT is particularly effective in resistant schizophrenia and may improve response to medication despite the presence of potential adverse side effects. Post-ECT delirium and Headaches are some of the most frequent side effects presented in literature. Fever is yet another unexplained reaction,

however there are a few case reports and retrospective studies that report on it.

Objectives: We aim to illustrate through a clinical case and a review of literature the prevalence of post ECT fever as well as the possible explanatory mechanisms.

Methods: In this study we report the case of a man with ultra-resistant schizophrenia who was treated successfully with ECT despite the development of transient febrile reaction and we present a review of literature on pubmed using the following key words : ECT, fever, resistant psychosis, mechanisms.

Results: Our patient is a 48-year-old man with a psychiatric history of schizophrenia evolving since the age of 34. He has a history of matricide in 2021 resulting in his hospitalisation in a forensic psychiatric ward. He underwent trials of classic and atypical antipsychotics that weren't efficacious thus he was diagnosed with resistant schizophrenia in 2022. He was treated initially with clozapine 500 mg per day and then with the association (clozapine + amisulpride) yet it wasn't effective on his persecutory delirium and fraticide ideas. Plus, there was no reduction in his PANSS (Positive and Negative Syndrome Scale) scores. The diagnosis of ultra-resistant schizophrenia was established. The staff indicated the adjunction of ECT to Clozapine. In the inpatient unit, hours after his fourth ECT session he developed a fever (40°C), his blood pressure (120/80 mm Hg), pulse (85 beats per minute), and respiratory rate (20 breaths per minute) were normal. Blood samples, including cultures, were drawn, which showed normal blood cell count and CPK (140 U/L) but CRP was elevated (31 U/L), a chest x-ray showed no acute pulmonary disease, and his urinalysis result and Covid test were negative. His fever resolved then spontaneously after two hours. The same transient febrile reaction occurred again 3 times. It was postulated in literature that fever may be due to inadequate muscle reaction. Data also suggested the potential influence of ECT on the hypothalamus that is a key region in regulating body temperature.

Conclusions: Further studies are required in order to establish the real prevalence of this side effect and its possible causes.

Disclosure of Interest: None Declared

EPV0853

The current status of recommendations for non-invasive neuromodulation therapy in severe mental disorders

O. Vasiliu

Psychiatry, Dr. Carol Davila University Emergency Central Military Hospital, Bucharest, Romania
doi: 10.1192/j.eurpsy.2024.1467

Introduction: There is an increasing rate of treatment resistance in severe psychiatric disorders (SPDs), which indicates the necessity for finding new therapeutic interventions, because of the significant negative impact these disorders have on the patient's quality of life, functionality, and other important parameters. In clinical practice, SPDs are estimated to represent up to 30-60% of all diagnosed cases. Schizophrenia spectrum disorders (SSD), major depressive disorder (MDD), and bipolar disorders (BDs) are associated with lower response to a large variety of therapeutic approaches. In this context, new technologies should be considered for SPDs, and non-invasive

neuromodulation techniques can be explored as add-ons to ongoing therapeutic interventions.

Objectives: A literature review was conducted to detect the available evidence to support recommendations for neuromodulation techniques in SPDs.

Methods: Three electronic databases (PubMed, Cochrane, Google Scholar) were searched for papers corresponding to the keywords "treatment-resistant psychiatric disorders" and "neuromodulation" or "electroconvulsive therapy" (ECT) or "transcranial magnetic stimulation" (TMS) or "transcranial direct current stimulation" (tDCS), published from the beginning of the respective databases up to July 2023.

Results: After the initial search, 1258 papers surfaced, but only 72 remained to be included in the analysis, after filtering them according to the inclusion and exclusion criteria. TMS may improve both depressive and manic symptoms, but also reports of polarity changes were found, indicating the need for careful monitoring of treatment-emergent affective switches (TEAS). TMS may also improve cognitive functions, although not sufficient evidence was found to support this observation clearly. The efficacy of temporoparietal TMS in schizophrenia has not been proven with certainty, although this intervention may improve positive symptoms. ECT was an effective and well-tolerated intervention for severe mood episodes, SSD, and BDs. Depressive symptoms responded to tDCS in bipolar/monopolar patients, but reports of TEAS in the BDs population have been reported.

Conclusions: Non-invasive neuromodulation techniques may represent an efficient option in patients with SPD, but more good-quality trials are needed before this recommendation is formulated in clinical guidelines.

Attitudes and Perceptions of Early-Career Psychiatrists Towards Electroconvulsive Therapy (ECT) in Poland: A Call for Enhanced Training and Guidelines

M. E. Gołębiewska^{1*}, A. Wilkowska², W. J. Cubala² and M. Pinto da Costa^{3,4}

¹Department of Developmental, Psychotic, and Geriatric Psychiatry; ²Department of Psychiatry, Medical University of Gdansk, Gdansk, Poland; ³Institute of Psychiatry, Psychology & Neuroscience, King's College London, London, United Kingdom and ⁴Institute of Biomedical Sciences Abel Salazar, University of Porto, Porto, Portugal
*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1468

Introduction: In Poland, the therapeutic modality of Electroconvulsive Therapy (ECT) boasts a history spanning over seven decades. Despite its documented therapeutic efficacy and safety profile, its integration into clinical practice remains suboptimal. Recent data elucidates a marked paucity in the utilization rate of ECT in Poland. Therefore, it is imperative to discern the barriers impeding its broader adoption of this potentially life-saving treatment.

Objectives: The aim of this study is to investigate the attitude of early career psychiatrists towards ECT and its place in clinical practice in Poland.

Methods: A web-based, anonymous survey was conducted, targeting early career psychiatrists in Poland. The questionnaire, part of

an international study, consisted of 36 multiple-choice and Likert scale questions.

Results: The majority of respondents emphasised the importance of further educational opportunities related to ECT, seeing it as a safe, effective, and possibly lifesaving procedure. Most of them benefited from ECT training during their residency, however less than a half had the opportunity to administer ECT themselves. They exhibited an interest to introduce ECT into their therapeutic repertoire, depending on the provision of requisite financial and infrastructural support.

Conclusions: There is a palpable eagerness among early career psychiatrists in Poland to enhance their proficiency in ECT. A robust curriculum, encompassing both theoretical discourse and hands-on ECT training, is paramount for all psychiatry trainees. Concurrently, there is a pressing need to formulate national ECT guidelines within Poland, which could potentially ameliorate apprehensions surrounding this procedure.

Exploring the Landscape of Psychosurgery in Low and Middle-Income Countries: A Scoping Review Protocol

S. Murthy^{1*}, J. Wellington² and R. Suvarna³

¹University of Bari Aldo Moro, Bari, Italy; ²Bradford Teaching Hospitals NHS Foundation Trust, Bradford and ³University of Leeds, Leeds, United Kingdom

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1469

Introduction: Psychosurgical procedures gained an infamous reputation during the 20th century with the implementation of the lobotomy as treatment for several psychiatric illnesses. However, modern-day psychosurgery is a flourishing field that provides valid treatment alternatives to neuropsychiatric patients thanks to increasingly accurate and safe stereotactic procedures. As more than 80% of people with mental disorders reside in Low and Middle Income Countries (LMICs), investigating the impact of psychosurgical procedures has a global relevance. People living in LMICs are exposed to a variety of stressors which could facilitate the development of psychiatric and neurological diseases. The immense gap that still exists between the population of LMICs and adequate medical and surgical care is an important obstacle to the reduction of global mental health burden. A scoping review will be conducted to investigate the extent of the existing literature and identify key themes, challenges and research gaps on the implementation and outcomes of psychosurgery in LMIC settings.

Objectives:

- **To comprehensively map the existing literature:** Provide an extensive overview of the literature on the use of psychosurgery in low and middle-income countries.
- **To identify key themes:** Recognize recurring themes and topics within the literature related to psychosurgery in these settings.
- **To assess challenges:** Analyze the challenges and barriers associated with the implementation of psychosurgery in resource-constrained contexts.
- **To identify research gaps:** Highlight areas within the existing literature where further research is needed to enhance our understanding of psychosurgery in low and middle-income countries.

Methods: The methodology consists of five stages, consistent with Arksey and O'Malley's framework. Using the PICO model, the Research Question, Inclusion/Exclusion Criteria and search methods were developed. Electronic Medical Databases (Medline OVID, Cochrane Library, Embase, PubMed, Scopus) will be searched for relevant studies. The PRISMA-ScR framework is used to guide the reporting process. Quantitative and Qualitative data will be extracted, including key information such as study type, demographics and methods used to assess the outcomes of psychosurgical interventions. Data will be presented discursively, supported with statistics and graphs where appropriate. No ethical approval is required.

Results: /

Conclusions: The results will be useful to healthcare professionals in LMICs involved in neuropsychiatric care, evaluating the current uses of psychosurgery and their potential benefit for the affected population whilst highlighting gaps in knowledge with the aim of propelling further research.

Transcranial Magnetic Stimulation-induced Mania: A Risk Worth Taking?

M. Pereira*, P. Abreu, M. P. Cameira and M. R. Soares

Lisbon Psychiatric Hospital Center, Lisbon, Portugal

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1470

Introduction: In the context of treatment-resistant bipolar depression, the use of neuromodulation techniques, notably transcranial magnetic stimulation (TMS), has been on the rise, particularly in the treatment of mood disorders. TMS involves the generation of a strong pulsed magnetic field through an electromagnet placed near the skull, thereby inducing an electrical field capable of depolarizing nerve cell membranes (Dolberg et al., 2001). The magnetic nature of TMS carries advantages compared to direct electric stimulation, such as fewer side effects, reduced invasiveness, and precise targeting. Nevertheless, it is not without its risks. Reported concerns include the induction of manic or hypomanic states, particularly in individuals with bipolar disorder, as well as unipolar depression (Sakkas et al., 2003; Ozten et al., 2013; Knox et al., 2021).

Objectives: This review aims to assess the safety and viability of TMS as a therapeutic option and how to best optimize its clinical use.

Methods: A comprehensive literature review was conducted utilizing resources from Pubmed, Researchgate, and Google Scholar.

Results: Despite some inconsistencies and potential confounding factors, our findings suggest that TMS may not significantly elevate the risk of manic switching, especially when compared to conventional treatments like antidepressants. However, it may potentially induce manic episodes, particularly when used as monotherapy or in combination with other treatments. Variables such as treatment protocol and prior response to medication may contribute to mood switching risk. Proposed safety measures include personalized protocol design, close patient monitoring and the combination with mood-stabilizing medication.

Conclusions: Transcranial magnetic stimulation has been associated with manic and hypomanic episodes in mood disorder patients. While the evidence remains limited, it appears that certain

individuals may be more susceptible to mood switching. Nevertheless, further research is needed to better elucidate variables influencing mood switching during TMS treatment and to develop effective preventative measures, especially for patients already predisposed to manic switching.

Multifamily group evaluation with Score 15 questionnaire

B. Gamo Bravo^{1*}, M. E. Gonzalez Laynez²,
S. M. Bañon Gonzalez¹ and N. Ogando Portilla¹

¹psychiatry, University hospital infanta Sofia, San Sebastian de los Reyes and ²psychiatry, University hospital of Toledo, Toledo, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1471

Introduction: The multifamily group that has been underway since April 2019 in Alcobendas, Madrid is described. A group that serves people diagnosed with mental disorder and their families, with the aim of improving their health and quality of life. It is about facilitating and improving the basic communication of relational aspects and healthy bonds. It is intended to offer a space where you can think together about the experiences lived in your own family with the rest of the group

Objectives: Assess the evolution and improvement of the patient and family members with the Score 15 questionnaire, The Score is a way of giving users a voice about the therapy process, not about the contents of their problems, but about their perception of the effectiveness of therapeutic work and for professionals it is an opportunity to obtain important feedback from their work.

Methods: Using the Score 15 questionnaire on all participants in the group at time zero and after 12 sessions

Results: Improvement in the family description items, and in the quantitative improvement in scoring of the following questions: What degree of severity would indicate? Do you think therapy will be helpful/has it been helpful to you?

Conclusions: Family therapy in the modality of Multifamily Groups provides an improvement in intrafamily communication, its links and therefore in the rest of social communication, facilitating the exit from loneliness and misunderstanding and in turn broadens the understanding and understanding by therapists

Virtual Reality as Exposure Therapy in the Treatment of Blood-Injection-Injury Phobias

N. Halouani, N. Boussaid, M. Turki, M. Barkallah*, S. Ellouze and J. Aloulou

psychiatrie B, Hedi Chaker university hospital, Sfax, Tunisia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1472

Introduction: Virtual Reality (VR) is a transformative technology that facilitates the development of immersive virtual environments. Its application is steadily growing within Cognitive Behavioral Therapy (CBT) techniques, notably in virtual exposure therapy. This is particularly evident in the treatment of specific phobias, with a specific focus on addressing blood-injection-injury phobias.

Objectives: The objective of our study is to design a treatment protocol for patients suffering from blood phobia based on VR.

Methods: We used the following scales:

- Fear Survey Schedule-III (FSS-III) and the Injection Phobia Scale (IPS) for psychometric evaluation of the intensity of avoidance fear.
- Questionnaire on cybersickness: to identify potential adverse effects of exposure to virtual reality.

To conduct a functional analysis of phobias, we used the SECCA grid and the SORC grid.

Results: The therapeutic protocol stages of VR for a patient suffering from Blood-Injection-Injury Phobia (BIIP) are as follows:

1. Collection of sociodemographic and clinical data.
2. Functional analysis to identify triggering factors, contributing factors, and consequences of behavior. The SECCA or SORC grid can help in conducting this functional analysis.
3. Psychometric evaluation of the intensity of avoidance fear using the three scales: FSS-III, IPS, and the cybersickness scale.
4. Patient education on the mechanisms of the phobia.
5. Setting of objectives.
6. Therapeutic contract.
7. The Protocol :
8. Cognitive approach: identification of automatic thoughts and replacement with more rational thoughts.
9. Behavioral approach: Progressive exposure, controlled immersion of the patient in virtual environments corresponding to situations that trigger their phobia. This exposure is coupled with relaxation.

The treatment continues with regular follow-up to ensure the consolidation of progress and to adjust strategies.

For relapse prevention, simple measures, like personalized exercises to be done by the patient, can favor the long-term maintenance of the acquired skills.

Conclusions: Virtual reality exposure therapies (in virtual) are as effective as in-vivo therapies. Besides, they offer a significant advantage over the latter as they facilitate access to stimuli or anxiety-provoking situations that are difficult to access or control in the real world.

Optimizing Outpatient Mental Health Services: A REBT-Infused Approach to Empowerment and Well-being

M. Milutinovic*, S. Mitrovska and L. Novotni

University Clinic of Psychiatry, Skopje, North Macedonia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1473

Introduction: Rational Emotive Behavior Therapy (REBT) fundamentally posits that our thoughts, beliefs, and interpretations exert substantial influence over how we perceive and react to life's occurrences. Central to REBT is the process of recognizing and disputing irrational, self-defeating beliefs, in favor of adopting rational and constructive perspectives.

Objectives: This presentation endeavors to introduce the foundational principles of REBT, elucidate its applied techniques, demonstrate its efficacy through compelling case studies, and delineate its spheres of applicability.

Methods: Case Studies:

1. Overcoming Social Anxiety: Illustrating the transformation from debilitating social anxiety to enhanced social functioning.
2. Managing Work-related Stress: Exemplifying the alleviation of chronic stress in a high-pressure work environment.
3. Overcoming Depression: Demonstrating the journey from persistent despondency to restored vitality and engagement.

Results: In total, REBT furnishes a methodical and pragmatic approach to therapy, affording individuals agency in steering their emotional well-being towards positive and enduring transformation. It is imperative to acknowledge that the suitability of REBT hinges on the idiosyncratic needs, inclinations, and circumstances of each patient.

Conclusions: By internalizing and applying these foundational principles, REBT empowers individuals to identify and dispute irrational beliefs, paving the way for more adaptive emotional responses and an enhanced overall state of mental well-being. It equips individuals with tangible tools to navigate life's challenges with heightened resilience and emotional equilibrium.

Family systemic therapy in patients with eating disorders

P. Setién Preciados*, C. Díaz Mayoral and E. Arroyo Sánchez

Servicio de Psiquiatría, Hospital Universitario Príncipe de Asturias, Alcalá de Henares, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1474

Introduction: Eating disorders are a group of pathologies in which negative beliefs about food, body type and weight are associated with conducts that include food restriction, binge eating, excessive exercise, induced vomiting and the use of laxatives. They can be really severe, affecting quality of life and lead to multiple physical and psychiatric complications, even with a deadly fate.

Objectives: Presentation of a patient's case with an eating disorder and the intervention with her family, as well as, doing a review of the family interventions in these kinds of patients.

Methods: Presentation of a patient's case and review of existing literature, in regards to the use of family therapy in patients with eating disorders and its effects.

Results: As in the patient's case, there are a lot of studies that support the evidence of improvement using family therapy in patients with eating disorders. However, the difficulty to isolate

the necessary variables in order to do studies about psychological treatments, complicates finding scientific evidence that supports the clinical evidence that we see in our patients day by day with these types of interventions.

Conclusions: There are studies that support the efficacy of these types of family interventions. However, there needs to be a more thorough investigation with the objective of finding the more precise optimal family intervention, and specifically, determining for who and under what conditions, certain types of family interventions would be more effective.

The association between trajectory of change in social functioning and psychological treatment outcome in university students: a growth mixture model analysis

P. Barnett^{1,2,*}, R. Saunders¹, J. E. Buckman^{1,3}, S. A. Naqvi⁴, S. Singh⁴, J. Stott¹, J. Wheatley⁵ and S. Pilling^{1,2,3}

¹Psychology and Language Sciences, UCL; ²National Collaborating Centre for Mental Health, Royal College of Psychiatrists; ³Camden and Islington Foundation trust; ⁴North East London NHS Foundation Trust and ⁵Homerton University Hospital NHS Foundation Trust, London, United Kingdom

*Corresponding author.

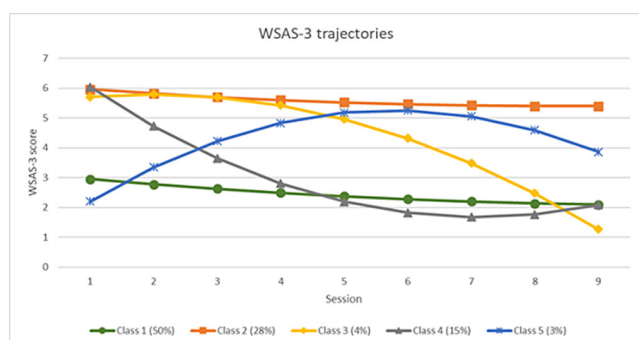

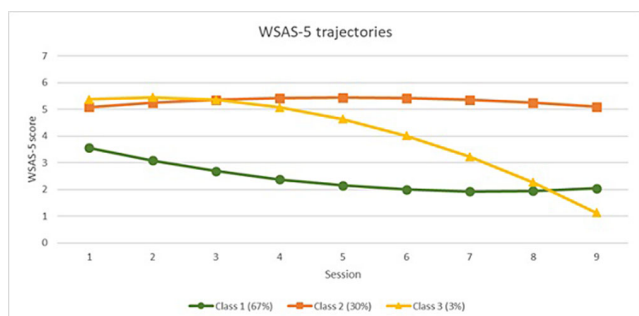

doi: 10.1192/j.eurpsy.2024.1475

Introduction: Attendance at university can result in social support network disruption. This can have a negative impact on the mental health of young people. Demand for mental health support continues to increase in universities, making identification of factors associated with poorer outcomes a priority. Although social functioning has a bi-directional relationship with mental health, its association with effectiveness of psychological treatments has yet to be explored.

Objectives: To explore whether students showing different trajectories of change in social function over the course of treatment differed in eventual treatment outcome.

Methods: Growth mixture models were estimated on a sample of 5221 students treated in routine mental health services. Different trajectories of change in self-rated impairment in social leisure activities and close relationships (Work and Social Adjustment Scale (WSAS) items 3 and 5) during the course of treatment were identified. Associations between trajectory classes and treatment outcomes were explored through multinomial regression.

Results: Five trajectory classes were identified for social leisure activity impairment (Figure 1), and three classes were identified for close relationship impairment (Figure 2). For both measures the majority of students remained mildly impaired (Class 1). Other trajectories included severe impairment with limited improvement (Class 2), severe impairment with delayed improvement (Class 3), and, in social leisure activities only, rapid improvement (Class 4), and deterioration (Class 5). There was an association between trajectories of improvement in social functioning over time and positive treatment outcomes. Trajectories of worsening or stable severe impairment were associated with negative treatment outcomes.

Image:**Image 2:**

Conclusions: Changes in social functioning impairment are associated with psychological treatment outcomes in students, suggesting that these changes may be associated with treatment effectiveness or recovery experiences. Future research should look to establish whether a causal link exists to understand if additional benefit for students can be gained through integrating social support within psychological treatment.

EPV0864**Case Analysis of a Patient with Functional Pathological Crying**

T. S. A. Tay

Psychological Medicine, Changi General Hospital, Singapore, Singapore

doi: 10.1192/j.eurpsy.2024.1476

Introduction: Functional pathological crying is a complex psychic phenomenon which poses both diagnostic and management challenges to the psychiatrist and psychotherapist. Apart from treatment with medications when clinically indicated, psychodynamic psychotherapy can be useful to understand the aetiology and to address these psychological issues faced by patients.

Objectives: In this case report, psychodynamic psychotherapeutic techniques are employed to examine and manage functional pathological crying.

Ms L was a 33-year-old Chinese single woman who presented with mixed depressive and anxiety symptoms associated with frequent severe bouts of wailing. She had a history of parental neglect and childhood sexual abuse. Following psychiatric assessment, she was diagnosed with Mixed Depressive and Anxiety Disorder, and Borderline Personality Disorder. She was treated with Sertraline 50mg every morning and was referred for psychodynamic therapy.

Methods: Building trust and rapport with Ms L was crucial so that the therapeutic relationship could be utilized as a vehicle for change through earned attachments. Helping her appreciate how present experiences reflect conflicts from her past and addressing her defence mechanisms with the aims of expression of emotions, exploring her wishes and fantasies to access unconscious conflicts were important. These build greater self-awareness which helped her to develop the capacity for emotional self-regulation, bringing about an increase in her level of adaptation to stressors.

Results: During the early phase of therapy, Ms L would be wailing throughout most of the therapy hour. As therapeutic rapport and trust were established, she began to open up about her abuse for us to explore her conflicts and complex emotions associated with it. The key themes that emerged were her chronic low self-esteem with fears of authorities and abandonment, the tendency to take up a defended regressive helpless child-like position whenever feelings related to the abuse were rekindled, as well as the manifestation of these complicated psychic experiences in the form of a complex wailing phenomenon.

The functional pathological crying was a mixture of an expression of her challenging conflictual painful feelings, symbolic expression of her cry for help, repressive and regressive child-like emotional states as well as having a defensive function to avoid coming in touch with painful feelings.

Through therapy, Ms L was able to make better sense of her wailing, develop the capacity for emotional self-regulation by adopting a healthier adult position in responding to difficult feelings when triggered, learning to forgive herself and others, assume better self-care and improved relationships with others.

Conclusions: Through psychodynamic psychotherapy, complex functional pathological crying can be better understood and managed to bring about intra-psychic and interpersonal functional improvements.

Disclosure of Interest: None Declared

EPV0865**Family intervention in schizophrenia: A case report**

E. Arroyo Sánchez*, C. Díaz Mayoral and P. Setién Preciados

Hospital Universitario Príncipe de Asturias, Madrid, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1477

Introduction: Schizophrenia is a chronic mental illness that has a lifetime prevalence worldwide of about 1% regardless of culture, social class and race. This implies that it affects a large number of

families. Family therapy has been used for years as a promising approach to intervene with people suffering from such pathology. It has been shown that families with a high level of hostility, critical comments and over-involvement are related to a higher number of relapses in the family member diagnosed with schizophrenia.

Objectives: The objectives are to examine whether systemic interventions could help to decrease the emotion expressed in these family members and thus decrease the number of relapses of patients as an alternative to pharmacological treatment.

Methods: A case report and a literature review on the impact of family therapy in patients with a diagnosis of schizophrenia. The search strategy included keywords such as “family intervention”, “schizophrenia” and “systemic therapy”. Selection criteria included randomized controlled trials (RCTs) and meta-analyses published between 2010 and 2021. Studies focused on the impact of family intervention on symptom management, relapse prevention and general functioning were included.

Results: The findings consistently demonstrated the effectiveness of family intervention in improving outcomes for people with schizophrenia. These interventions generally involved psychoeducation, communication skills training, problem-solving techniques, and emotional support for family members. Results showed significant reductions in symptom severity, decreased relapse rates, improved adherence to pharmacological treatment, and better overall functioning among people who received family intervention compared with those who received only standard care. In addition, family intervention was associated with reduced caregiver burden, improved family communication, as well as increased knowledge about schizophrenia and its management.

Conclusions: Family intervention has become a valuable adjunctive treatment for people with schizophrenia. The findings of this review highlight its positive impact on symptom management, relapse prevention, and overall functioning. Family intervention offers a holistic approach that recognizes the importance of involving and supporting the family system in the treatment process. This intervention provides families with the tools and resources necessary to effectively cope with the challenges associated with schizophrenia and promotes a supportive and nurturing environment for the individual. Future research should focus on long-term outcomes and implementation of the family intervention in routine clinical practice.

EPV0867

Combination of CBT and rTMS: what are the advantages?

M. Kiss-Leizer*, A. Á. Horváth, B. Kabella, L. Pogány and J. Lazáry
Psychiatry, National Institute of Mental Health, Neurology and Neurosurgery - Nyíró Gyula Center, Budapest, Hungary
*Corresponding author.
doi: 10.1192/j.eurpsy.2024.1478

Introduction: Obsessive-Compulsive Disorder (OCD) and Major Depressive Disorder (MDD) are among the ten most disabling disorders, yet only 30-40% of people with the condition seek

specialist care (WHO). Considered a relatively new tool in the treatment of OCD and MDD, repetitive transcranial magnetic stimulation (rTMS) was first used by our team 1 year ago. Based on current literature cognitive behavioural therapy (CBT) is effective in 60% of OCD cases, with MDD also having a good response rate of 50-60%. The efficacy of SSRI's has been demonstrated, but side effects can have a negative impact on adherence in the long term. Prolonged use of certain drugs has adverse reactions that lead specifically to memory impairment, which compromises suitability for psychotherapy. The same problem applies to the use of electroconvulsive therapy (ECT) in a major depressive episode.

Objectives: Our aim was to study the efficacy of combining rTMS with CBT, to gather clinical experience on how these two different methods work in practice when combined.

Methods: Patients diagnosed with therapy resistant MDD received rTMS treatment using 50Hz theta burst over 10 sessions. Therapy resistant OCD patients were treated by a 15 sessions rTMS using 1Hz single pulse. These rTMS sessions were combined with CBT, of which we would like to highlight two cases: one of them is a 34 years old woman, who has wide range of sexual, checking and contamination-related OCD symptoms and only received SSRI treatment so far. The other one is a 29 years old man, who suffers from religious obsessions, cleaning compulsions and other repetitive behaviours.

Results: The positive effects of rTMS treatment on working memory functions, attentional capacity and cooperative skills without significant additive effects suggest exciting possibilities for combining the two treatments, thus the combined treatment has been tested in clinical practice. In our own patient care, an important experience was that patients were committed to the therapy, felt safe and, unlike with medications, did not have to worry about side effects. While medication and ECT can make psychotherapy more difficult in the long term - mainly because of memory problems - rTMS facilitates it. Patients appreciate that we approach their problems in a complex way, and they perceive that the combination of the two very different methods reflects professionalism. Our poster attempts to present the experience of combining rTMS and CBT from the therapist's perspective through two case studies.

Conclusions: Based on our experiences it is an effective approach to combine rTMS with CBT in therapy resistant MDD and OCD patients. In the light of these results the revision of the existing guidelines are considerable.

EPV0868

Family systemic therapy: intervention in autism spectrum disorder

C. Díaz Mayoral*, P. Setién Preciados, E. Arroyo Sánchez and J. Gimillo Bonaque

Psiquiatría, Hospital Universitario Príncipe de Asturias, Madrid, Spain
*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1479

Introduction: Autism spectrum disorder (ASD) is a neurodevelopmental disorder characterized by communication impairments and difficulties in social interaction. These impairments can affect relationships with family members, increase stress and frustration for both the patient and family members, and contribute to behavioral disturbances in these patients. They are frequently associated with high rates of psychiatric comorbidity.

Objectives: Given the impact of this disorder on the family unit, we set out to assess the clinical effectiveness of systemic family therapy, its influence on improving communication and coping with this disorder, strengthening relationships and mental health in these patients and their families.

Methods: A literature review was performed by searching for articles in Pubmed on May 24, 2023, focusing the terminology used on “Autism Spectrum Disorder” and “Systemic Family Therapy”. The search was limited to full text articles in English and Spanish, published in the last 10 years.

Results: Several authors have stated that systemic family therapy could be beneficial:

- Providing education.
- Reporting additional educational resources.
- Focusing sessions on improving social and communication skills, mood and coping behaviors.
- Providing therapy to all family members to cope with this disorder and what it implies. It will be very important that the patient with ASD understands his condition and can receive support from his family, working with siblings on the bonding and coping with this condition.
- Contributing to facilitate mourning the loss of the condition of “neurotypical” person, exploring emotions, feelings and belief systems, valuing the social and cultural context of the family.

Conclusions: Reviewing a variety of literature on this therapeutic approach, the authors concluded that “strategic, narrative and structural interventions can be applied from multiple approaches, especially suited to the challenges often faced by patients with ASD and their families”. Therapeutic work needs to involve different family members at different times. Therapeutic conversations will consider the child, the family and the family unit in context. Studies so far have not been able to establish whether particular systemic approaches have more favorable outcomes than others, which warrants further research.

The effect of music type in ketamine-assisted group therapy on treatment-resistant mental health conditions: a prospective observational study

K. E. Sattler^{1*}, T. Walia² and V. Tsang¹

¹University of British Columbia, Vancouver and ²McMaster University, Hamilton, Canada

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1480

Introduction: Currently, Ketamine is the only safe, effective, and widely used psychedelic-like medicine in Canada. It has demonstrated notably efficacy in providing relief to those experiencing

treatment resistant mental health conditions. Pairing Ketamine treatment with psychotherapy, known as Ketamine Assisted Therapy (KAT), has been shown to yield more enduring outcomes. Work by Greenway et al. has demonstrated that playing music following ketamine administration for patients with bipolar disorder can help the patient feel more in control and reduce discomfort (Greenway et al. International Clinical Psychopharmacology 2021; 36 218-220).

Objectives: The primary objective is to evaluate and compare the subjective clinical efficacy of two different types of music during ketamine-assisted group therapy. This will be explored through various validated psychiatric questionnaires, including the PHQ-9, GAD-7, and PCL-5. The secondary objective is to compare the objective changes in brain activity between the two music types. This will be evaluated using EEG data collected from MUSE headband before and after each ketamine-assisted therapy session.

Methods: This study is a crossover trial of 32 participants undergoing ketamine-assisted therapy for treatment-resistant mental health conditions. Half of participants will undergo a KAT session with a “weightless” music playlist followed by a session with a “grounding” music playlist. The other half will do the same, in reverse order. All participants will complete several psychiatric questionnaires within 7 days of each session over email. Before and after each session, participants will play a simple game to test executive function while wearing a headband to measure EEG activity.

Results: The absolute and relative changes to the scores of the questionnaires will be examined between participants and music conditions. The change in brain activity from pre-session to post-session will be compared between the different music conditions as well. As this is a crossover trial, any changes in outcomes due to order effects will be controlled for. Relevant demographic and medical factors will also be controlled for.

Conclusions: To date, no studies have explored the influence that different types of music have on patients experience with KAT in a group therapy setting. With the results of this study, we hope to fine tune and improve the use of music in future KAT administration.

Quality Improvement Programme on Implementing Co-Production in Care Programme Approach in an In-Patient Rehabilitation Psychiatric Unit to Enhance Patient Engagement and Positive Step-Down Discharges

H. Tahseen^{1,2*}, A. Hassoulas² and K. Umla-Runge²

¹Adult Psychiatry, Cygnet Healthcare, Mold and ²School of Medicine, Cardiff University, Cardiff, United Kingdom

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1481

Introduction: This quality improvement (QI) programme was proposed to integrate co-production principles into rehabilitation psychiatry, focusing on enhancing patient-centred care and promoting positive step-down discharges within the mental health

system. The backdrop of the QI programme was the essential role of rehabilitation psychiatry in aiding the recovery and reintegration of individuals with mental health challenges, and sub-optimal audit results about patient's attendance and positive step-down discharges at an in-patient psychiatric unit.

Objectives: The QI programme aimed to implement and explore Co-production, a transformative approach involving patients and healthcare professionals as equal partners.

- To promote co-production in psychiatric in-patient service
- To improve patient experience in the CPA meetings
- To reduce anxiety associated with the CPA meetings and discharge planning
- To assess staff's limitations and barriers in promoting co-production.

Methods: The QI programme was divided into phases, including diagnostic, problem-solving, and evaluation. It employed diagnostic tools such as the fishbone cause and effect diagram and the 5-Why Technique for root cause analysis. The project's aim was aligned with the Model of Improvement, guided by the three fundamental questions. Change ideas were developed using driver's diagram and were then evaluated through PDSA cycles. Quantitative analysis utilized paired t-tests to assess the significance of changes, and qualitative analysis focused on patient perspectives gathered through the co-produced CPA questionnaire. Emerging themes from the questionnaire responses were integrated into the project's trajectory through narrative synthesis. Predictions were formulated to measure project success: 50% patient attendance in the next CPA meetings, 70% positive step-down discharges, and improved Hamilton Anxiety Rating Scale (HAM-A) scores.

Results: The iterative Plan-Do-Study-Act (PDSA) cycles demonstrated the evolving impact of interventions on patient engagement and discharge outcomes. Implementation of patient information leaflets, staff training, and a CPA agenda template led to increased attendance and positive step-down discharges. Analysis of HAM-A scores revealed a substantial decline in anxiety levels for almost all participants, suggesting the effectiveness of the interventions. Discharge outcomes were influenced by patient engagement and tailored interventions. Patient responses revealed themes such as challenges during transitions to community care, empowerment from shared decision-making, and diverse experiences in communication with healthcare professionals.

Conclusions: The CPA agenda template improved patient experiences by enhancing communication and patient-centeredness.

EPV0872

REVIEW OF MEDICATION INCIDENTS IN MENTAL HEALTH SERVICE

T. C. Gomes

Psychiatry, Tallaght university hospital, Dublin, Ireland
doi: 10.1192/j.eurpsy.2024.1482

Introduction: In this review, medication incidents across different mental health care facilities was reviewed and nuances, challenges, and advancements in the administration and management of

psychiatric medications was noted. Through gaining a better understanding of the complexities surrounding these incidents, valuable information can be gathered that will enhance patient safety, improving healthcare practices, and fostering a deeper understanding of the critical intersection between mental health care and medication management.

Objectives: To identify the most frequent types of medication errors or patterns of medication errors in a mental health service across different settings including inpatient, outpatient, liaison and long term residential unit

Methods: This is a multicentre project as it covers medication incidents in mental health care in a regional area in Ireland. It includes an acute psychiatric Unit, the General Hospital and patients admitted in medical and surgical wards and as well long term residential care. Using the National Incident Management System we collected National Incident Report Forms (NIRF) relating mental health care provided and medication prescribed within a region in Ireland. From these we selected the ones where medication hazard was noted. Data collection happened between July 2020 and July 2021. A statistical analysis was then performed to identify any patterns to medication errors.

Results: A total of 22 incidents were included. On review of these, it was noted, among other findings, that there was a significant increase in the frequency of medication errors during the month of December. It was also noted errors ranged from medication being given to the wrong patient, medication being given twice and medication being missed.

Conclusions: Minimising medication errors requires a comprehensive, multidisciplinary approach that involves healthcare providers, patients, and healthcare systems. Healthcare organizations should foster a culture of safety where medication errors are seen as preventable and where providers are encouraged to report errors without fear of retaliation.

Compassion and the quality of life of the inpatient healthcare team

A.-C. Bredicean^{1,2*}, C. Giurgi-Onu¹, L. Palaghian^{1,2}, D. Tabugan¹, A. Neagu^{1,2}, G. Covaci², R. Homeag¹ and S. Ursoniu¹

¹"Victor Babes" University of Medicine and Pharmacy and ²"Dr. Victor Popescu" Military Emergency Clinical Hospital, Timisoara, Romania
*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1483

Introduction: Nurse-patient relationships and interactions during inpatient care evoke feelings of empathy and compassion. Compassion can lead to satisfaction, but also to exhaustion. Compassion fatigue is a commonly used concept that signifies the exhaustion of healthcare personnel due to the specific activities and repeated exposure to the suffering of others. This manifests through physical and emotional over-tiredness, anxiety, anger and irritability, low vitality, social isolation, diminished sense of enjoyment of one's career, cognitive disorders, and sleep disturbances.

Objectives: To assess the level of compassion of the healthcare staff employed in a Romanian general hospital.

Methods: The study sample included 256 nurses working in a general hospital. To identify socio-demographic data we applied a specific questionnaire, and subsequently we also used the PROQOL scale (Professional Quality of Life Scale). All data were statistically analysed.

Results: The majority of healthcare professionals in our sample belong to the 40-49 age group (39.45%). Regarding work experience in the healthcare system, the majority (43%) have been working for over 10 years. 78.52% of nurses reported a high level of compassion satisfaction. Burnout was not identified in the majority of our sample (54.3%). We noted that the number of the staff affected by compassion fatigue increases proportionally with the years of work experience ($P=0.033$).

Conclusions: A high level of compassion satisfaction in medical professionals leads to a remarkable improvement in the quality of the healthcare they are providing. However, our study results suggest that compassion fatigue tends to increase in line with the years of work in healthcare

The level of consciousness and mental reactions of children after acute brain injury (interdisciplinary rehabilitation)

D. Martyshevskaya^{1,2}, A. Zakrepina^{1,2} and Y. Sidneva^{1,3*}

¹Clinical and Research Institute of Emergency Pediatric Surgery and Trauma (CRIEST); ²Federal state budgetary scientific institution "Institute of correctional pedagogy"/ ICP/ and ³N.N.Burdenko National Medical Research Center of Neurosurgery, Moscow, Russian Federation

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1484

Introduction: The process of recovery of mental reactions in children after acute traumatic brain injury is determined by complex methods with an interdisciplinary approach. Studies of emotional, communicative and behavioral reactions are based on an assessment by a psychiatrist and a teacher-defectologist.

Objectives: to study mental reactions and identify predictors of positive recovery of consciousness after acute brain injury in children in early rehabilitation.

Methods: psychiatric and pedagogical examinations; also - neuroimaging data and others.

Results: Three groups of children were identified, depending on the different severity of emotional, communicative and behavioral indicators:

Group 1 (11%): The level of consciousness is minimal positive. Reactions: stable gaze fixation; emotional reaction to sound (smile) and the face of an adult; short-term tracking of the gaze of the object; the ability to touch an object and hold it; sits himself.

Group 2 (33%): The level of consciousness is minimal positive / negative, with an advantage of positive. Reactions: unstable gaze fixation; emotional reaction and involuntary movements to sound; reflex seizure of an object; sits with support.

Group 3 (56%): The level of consciousness is minimal negative. Reactions: no emotional reactions, low motor and sensorimotor activity.

Conclusions: predictors of emotional-communicative and behavioral indicators of recovery of the level of consciousness were identified: sensory and motor, cognitive and socially-oriented (orienting reactions to the voice and face of an adult, tracking the gaze of an object, sensory and motor activity, etc.). These predictors are the basis for choosing a rehabilitation program with interdisciplinary support and a treatment strategy.

The Effect of Physical Activity on Postural Abilities in Menopausal Women

A. Feki^{1,1*}, I. SELLAMI², F. Ellouze³, M. Yahya³, S. Baklouti¹ and M. H. Elleuch³

¹Rheumatology; ²Occupational medicine, Hedi Chaker Hospital and ³Physical Medicine and Functional Rehabilitation, Habib Bourguiba Hospital, Sfax, Tunisia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1485

Introduction: Menopause marks a significant physiological transition in a woman's life, often accompanied by various health challenges. Understanding the impact of physical activity on postural abilities in menopausal women is crucial for promoting their overall well-being during this transformative stage.

Objectives: The aim of our study was to investigate the effect of a physical activity program on postural abilities, psychological well-being, and the quality of life of menopausal women.

Methods: Nineteen menopausal women, averaging 56 ± 3 years of age, participated in a 12-week Zumba-style physical training program, consisting of three 50-minute sessions per week. The exercise regimen incorporated aerobic workouts, muscle conditioning, balance exercises, and flexibility training, predominantly inspired by Latin dances. Postural balance was evaluated using a stabilometric force platform, measuring the average velocity of the center of pressure (COPvm) under open eyes (OE) and closed eyes (CE) conditions on both firm and soft surfaces. Quality of life and mood were assessed using the SF-36 questionnaire (Short Form Survey-36) and the BMIS score (Brief Mood Introspection Scale). Assessments were conducted before (pre-test) and after (post-test) the 12-week training period.

Results: The findings revealed a significant decrease in COPvm values in the post-test for both conditions (on a firm surface: OE $p=0.05$, CE $p=0.01$; on a soft surface: OE $p=0.001$, CE $p=0.05$). Additionally, improvements in mood ($p=0.05$) and quality of life ($p=0.05$) were observed compared to baseline values.

Conclusions: This study underscores the positive impact of Zumba-style physical training on postural abilities, mood, and quality of life among menopausal women. These results suggest that such exercise programs hold promise in reducing the risk and incidence of falls associated with menopause

Experience real-time, health and biological outcomes of personal recovery in People With mental disorders in Residential facilities (EMPOWER): a cohort study

A. Martinelli* and G. de Girolamo

IRCCS Istituto Centro San Giovanni di Dio Fatebenefratelli, Brescia, Italy

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1486

Introduction: Deinstitutionalization has resulted in diverse mental health care models, influenced by local resources, funding, and cultural factors. In Italy, 127 Department of Mental Health (DMHs) provide care for individuals with mental disorders. People with severe mental disorders (SMD) live independently or in residential facilities (RFs). Approximately half of the Italian DMH budget is allocated to RFs, serving around 3.6% of people with SMD. Italian RFs prioritize personal recovery, empowering individuals with SMD to live fulfilling lives despite symptoms and psychosocial challenges. While personal recovery is known to improve well-being and cost-effectiveness, its implementation in Italian RFs remains incomplete. There is insufficient evidence regarding its impact on various outcomes for residents, including health, psychosocial, and biological factors.

Objectives: The EMPOWER Study aims to assess whether adding personal recovery to Treatment As Usual (TAU) in Italian RFs could improve functioning (primary outcome), health, biological status, productivity and interpersonal relationships (secondary outcomes) among patients receiving the personal recovery-oriented treatment, compared with TAU. Additionally, data will be collected from informal caregivers, mental health professionals, and concerning the recovery orientation of RFs.

Methods: This study employs a longitudinal cohort design, gathering data at baseline and six-month follow-up in Italian RFs. A cohort of residents over 18 y.o. who receive a personal recovery-oriented treatment, the Mental Health Recovery Star (N=20), is compared to a matched group of residents receiving the TAU (N=20). International standardized assessments collect patients' data on functioning, psychopathology, need for care, quality of life (QoL), positivity, social network, service satisfaction, and patient stigma. Informal caregivers' data includes burden, QoL, positivity, and service satisfaction. Mental health professionals' data encompasses burnout, stress, stigma, positivity, and work satisfaction. The working alliance between professionals and patients is assessed. Clinical and biological exams (blood and saliva samples) are collected, along with actigraphy data on patients' circadian rhythm and physical activities. Digital data through a mobile app captures psychopathology, productive activities, social network, using the Experience Sampling Method with questions defined with patients. Focus groups with patients, professionals, and informal caregivers are facilitated by an expert by experience. Recovery orientation of RFs is assessed.

Results: Not yet available.

Conclusions: This study aims to generate novel insight that could improve our treatment approaches for patients in residential facilities.

EPV0877

Awareness and perceptions of managing recovery in psychiatric patients in a rehabilitation center: an observational study

F. Franza*, R. Croce, C. Esposito, I. Ferrara, R. Iannaccone, M. Imbimbo, M. Pizzano, S. Sanseverino, R. Silvestro and V. Vecchione

"Villa dei Pini" Clinic, Psychiatric Rehabilitation Centre, Avellino, Italy

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1487

Introduction: In mental health prevention, person-centered, and rights-based approaches, the role of recovery is highlighted (WHO, 2021). Various evaluation tools are used in rehabilitation objectives and programs, including the Specific Levels of Functioning Scale (SLOF) (Mucci *et al.* Schizophr Res 2014;159 144-50) and the Recovery Assessment Scale – Domains and Stages (RAS-DS), a self-measure of mental health recovery. It includes 38 items clustered into four recovery domains and meets two functions. In addition to measuring self-reported outcomes, it increases service-user control towards objectives and recovery action plans (Honey *et al.* BMC Psychiatry 2023;23 500).

Objectives: To evaluate the efficacy of RAD-DS in a psychiatric rehabilitation facility to be used as a routine tool in daily rehabilitation activity.

Methods: In our observational study, we recruited 103 inpatients (total: 103 patients, females: 38 patients, males: 65 patients) in a psychiatric rehabilitation facility. The patient presented with psychiatric disorders that met the diagnostic criteria of DMS-5 (schizophrenia, bipolar disorder, MDD, personality borderline disorder). Epidemiological data are shown in Table 1.

All patients were undergoing a psychiatric rehabilitation program and were observed during a one-year evaluation.

In all patients, the following rating scales were administered at baseline (T0) and after a year (T1):

For the evaluation of social measures, life outcomes, and functioning and recovery:

- Recovery Assessment Scale – Domains and Stages RAS-DS
- Specific Levels of Functioning Scale (SLOF)
- Global Assessment of Functioning (GAF)

For psychopathological evaluation:

- Brief Psychiatric Rating Scale (BPRS)

The data were statistically analyzed with the EZAnalyze 3.0 software for the Excel platform.

Results: The RAS-DS total score results (Table 2) show a not significant difference between T0 vs. T1 (mean: 101.80 vs. 104.37, p. 0.193). An improvement in the score was observed after one year of rehabilitation treatment in the subgroup "Doing things I value" (T0 vs. T1: mean 16.15 vs. 18.77, p. 0.001). Statistically significant differences were observed in the subgroups "Mastering my illness" (T0 vs. T1: mean 18.3 vs. 20.85, p. 0.021). In the other subgroups, the differences were not statistically significant. Interestingly, these results are comparable to those found with SLOF and GAF (respectively, p. 0.972 and p. 0.873).

Connecting and belonging			
Mean:	17,165	17,738	0.214
Std. Dev.:	3,559	4,494	

Conclusions: The current trend of research and clinical practice is to give more importance to psychiatric rehabilitation treatment (Franza Psychiatr Danub 2022;34(Suppl 8) 9-13). The results obtained with our observational study indicate the possible usefulness of indicators of patient well-being, as well as the RAS-DS in the management of psychiatric rehabilitation programs. The expectations, indications, and perceptions of psychiatric patients can be decisive in improving recovery.

The Recovery concept in Assertive Community Treatment: Truth or Fake?

J. J. Martínez Jambrina*, L. I. Fernández, A. R. F. García, C. C. González, C. P. Martínez, A. F. Llorca, R. A. Díaz, F. V. Ortola and N. S. Guzmán

Psychiatry, Hospital San Agustín, Avilés, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1488

Introduction: The concept of “Recovery” in the context of psychiatric rehabilitation has undergone significant evolution throughout history. This abstract delves into the question of the truth or falsity of this concept, examining diverse perspectives and arguments surrounding its application.

Objectives: The primary aim of this abstract is to critically analyze the concept of “Recovery” in psychiatric rehabilitation and ACT from both favorable and critical perspectives, considering its historical evolution, and highlighting key distinctions between the theories of Mike Slade and William Anthony.

Furthermore, it addresses the significance of measuring and evaluating the fidelity of healthcare practices to this mode

Methods: To conduct this analysis, an exhaustive review of current scientific literature was undertaken. Emphasis was placed on the importance of measuring and evaluating the fidelity of healthcare practices to this model.

Results: Slade and Anthony’s theories emphasize different aspects of recovery, while implementation models translate these theories into clinical practice and services. Additionally, the discussion highlights the significance of measuring and evaluating the fidelity of healthcare practices to this model.

Assertive Community Treatment (ACT) programs have increasingly recognized the importance of the “recovery” concept in promoting the empowerment and self-determination of individuals with severe mental illnesses. This discussion examines how ACT programs have adopted recovery-oriented principles, the ways in which they implement these principles, and the potential benefits and challenges associated with their integration.

Conclusions: The distinctions between Mike Slade and William Anthony’s theories and the implementation models underscore the importance of a precise and differentiated understanding within the field of psychiatric rehabilitation.

The integration of the “recovery” concept within Assertive Community Treatment (ACT) represents a significant shift towards person-centered care in psychiatric rehabilitation. Further research and evaluation are essential to assess the effectiveness and long-term impact of this integration.

Right to attention to sexuality for people with mental disorders: bridges between health and social services

M. T. Campillo Sanz*, M. Vallve Elias, A. Casals Arnau, J. Marti Bonany, D. Garcia Hernandez and R. Sanchez Gonzalez
Salut Mental Institut, Hospital del Mar, Barcelona, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2024.1489

Introduction: The expression of sexuality in the adult with mental disorders depends on the early incorporation of factors for promoting social inclusion. It is fundamental that sexual educators and advisors, in addition to working with the clients, also work with close family members. Intervention programs should establish objectives for developing a positive attitude towards sexuality in people with mental disorders and improving self-esteem (Katz G, *Salud Publica Mex.* 2008;50 Suppl 2:s239-54).

Challenge: Achieving support for people with mental health problems and/or substance use disorder admitted to the Social Rehabilitation Process of a psychiatric hospital so that they develop their sexuality satisfactorily. The right to privacy must be taken into account.

Objectives: Promoting a healthy and satisfactory development of sexuality in people with severe mental disorders. Raising awareness among healthcare teams, families and legal representatives regarding the need and suitability for support. Introducing the concept of sexuality as a dignifying perspective. Promoting sexual education that avoids disadvantages and situations of abuse in the target group. Coordinating the continuity of the project with non-health social services after discharge.

Hypothesis: Possibility of receiving support in the development of sexuality through training, information and improvement in the management of emotions/feelings in people who express the need or willingness to receive it, will contribute to overcoming limitations or difficulties.

Methods: Detecting people who during 2021 wish to work on the objectives through the care team. Searching for community resources aimed at attending sexuality issues in people with mental health problems. Proposing the hospital a collaboration with a non-profit entity that develops a specialized program for attention to sexuality in disability. Coordination between

Treatment team and Entity. Quantitative and qualitative assess-

2022	People included	Percentage of people admitted to the Income Unit (65)
Detection concern sex-affectivity	5	7,69%
Verbalized concern	3	4,61%
Referral to the entity program	2	3,07%

ment of one year of experience according to the parameters of the entity.

Results:

Conclusions: All patients included have a diagnosis of psychosis. Experience was very positive for the participants. Community intervention projects that lead to an education in healthy and respectful relationships in the field of sexuality and affectivity are necessary. This would allow to prevent behaviours and situations at risk of abuse as well as social and emotional instability.

EPV0880

Psycho-social predictors of motivation for treatment in patients with mental disorders: the role of adverse childhood experiences and internalized stigma.

N. Lutova, E. Gerasimchuk, M. Sorokin and M. Bocharova*
V.M. Bekhterev National Medical Research Centre for Psychiatry and Neurology, St.Petersburg, Russian Federation
*Corresponding author.
doi: 10.1192/j.eurpsy.2024.1490

Introduction: Motivation for treatment is an important socio-psychological characteristic of patients, which is subject to the joint influence of various factors, each of which may require specific rehabilitation interventions.

Objectives: To analyze and evaluate the cumulative influence of adverse childhood experiences (ACE), internal stigma, social characteristics on the intensity of treatment motivation in patients with mental disorders.

Methods: 102 patients with mental disorders were examined using Adverse Childhood Experience Questionnaire (ACEQ), Russian-language validated Internalized Stigma of Mental Illness (ISMI) scale and Treatment Motivation Assessment Questionnaire (TMAQ).

Results: As a result of regression analysis (table 1), a model was obtained that predicted an increase in the chances of high patient's motivation for treatment with an increase in the total score of ACEs (ACEQ total score) and with higher education. The overall severity of internal stigma (ISMI total score) did not show a significant effect on the chances of developing intense motivation in patients.

Table 1. Model of logistic regression analysis of educational, ACE total score and ISMI total score with the severity of motivation for treatment.

Predictor	B	SE	p	Exp (B)	95% confidence interval for EXP(B)
Secondary education	1,120	0,699	0,109	3,065	0,778-12,074
Higher education	1,972	0,775	,011	7,189	1,574-32,834
ISMI total score	-0,435	0,773	0,574	0,647	0,142-2,946
ACEQ total score	0,346	0,147	0,019	1,414	1,060-1,886

After post data analysis (table 2), a cut-off point was established for the ACEQ total score of 4 points, corresponding to an increased chances of high patient's treatment motivation.

Table 2. Results of the test ROC analysis for ACEQ total score and the severity of motivation for treatment.

Cutpoint	Sensitivity (%)	Specificity (%)	Youden's index	AUC
3	64.71%	53.57%	0.183	0.689
4	50%	75%	0.250	0.689
5	38.24%	85.71%	0.239	0.689

Conclusions: ACEs may likely be a source of posttraumatic growth in adulthood in patients with mental illness specially if their count amounts to 4 or more variants. The role of social and psychological characteristics of patients with mental disorders in the psychology of the treatment process should be considered systemically, rather than discretely.

EPV0881

Exploring participant's experiences in a multifamily therapy group on schizophrenia : a qualitative approach

O. Amiot*, C. Genis, L. Champlon, S. Said and L. Baziret

92100, GH Paul Guiraud, Boulogne Billancourt, France

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1491

Introduction: Prevention of relapse in schizophrenia is a major public health issue. A recent network meta-analysis investigating interventions for relapse prevention in schizophrenia found that the efficacy of family psychoeducation and systemic integrated interventions were superior to treatment as usual at 12 months (Bighelli I, Leucht S et al. Lancet Psychiatry 2021). Other studies also found that multi-family therapies (MFT) were superior to treatment as usual and family psychoeducation in preventing relapses at 2 and 4 years (McFarlane WR, Lukens EP et al. Archives of General Psychiatry.1995). Considering this, we developped in

our community center an MFT program based on systemic approach and psychoeducation.

Objectives: Investigate the subjective experience of participants of an MFT group focusing on schizophrenia.

Methods: A qualitative study was designed to explore personal experience of participants using the Interpretative Phenomenological Analysis (IPA) method in order to analyse participant's feedback during semi-directive interviews. By using IPA, participants are experts of their experience. Eight participants took part in this study: 4 patients and 4 parents.

Results: Within all participant's feedback around 10 different themes emerged. We identified three major themes which we have described as: "Affiliation to the group", "Framework of Discovery", "Benefits of MFT".

According to "Affiliation to the group", all participants report movements of adhesion or rejection towards the group. This theme has been subdivided into two sub-themes: "Temporality", and "Identification/differentiation". These sub-themes revealed inter-individuals' differences.

According to "Framework of discovery", the MFT group has been identified as a secure place allowing self and other's discovery place. This theme has been divided into two sub-themes: "discovering skills" and "improving oneself and relatives' understanding". Participants experience taking a step back and decentering oneself from usual personal position.

According to "Benefits of MFT", participants report the feeling of belonging to a group, the impact on self-esteem, on mentalization skills, and on the reflexion on family members' experience of the disease.

Conclusions: This study is, to our knowledge, the first qualitative study examining the subjective experience of members who participated in a psychoeducational and systemic MFT group focusing on schizophrenia. It provides insight into the families' experience, both from the patient's and from each family member's perspective. Results highlight that participants seized the MFT group as a learning space at several levels: personal, intra-family and inter-family.

These data could enlighten professionals working with families on the potential apprehensions of participants, their representations of the group and what process MFT could initiate.

Disclosure of Interest: None Declared

Clinical and Psychosocial Impact of Psychoeducational Groups for Psychosis

F. B. F. Leitão*, C. Cunha, J. Loureiro, A. Guedes, M. J. Ribeiro, C. Loureiro, J. Meira, P. Oliveira, J. R. Silva, P. M. Ferreira and A. M. Moreira

Serviço de Saúde Mental e Comunitária do Porto Ocidental, Hospital de Magalhães Lemos, Centro Hospitalar Universitário de Santo António, Porto, Portugal

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1492

Introduction: Individuals with mental health disorders often lack access to appropriate care, including psychosocial rehabilitation programs, which are considered essential for their recovery. In 2019, as part of the intervention by the *Community and Mental*

Health Service, at *Hospital de Magalhães Lemos*, we initiated a psychoeducational group for patients with psychotic spectrum disorders, with the purpose of providing our patients with comprehensive information about their condition and effective management strategies. Our 8-week program consisted of 16 sessions, including icebreaker activities, discussion of certain themes, sharing of experiences and practice of stress management techniques.

Objectives: The aim of this study was to assess and quantify the impact of our 2023 program.

Methods: Out of a total of 20 patients interviewed for our program in 2023, 16 began the program and 12 completed it. The program's evaluation was based on several assessment tools, including a sociodemographic questionnaire, a knowledge assessment questionnaire, the *Positive and Negative Syndrome Scale (PANSS)*, the *Insight and Treatment Attitudes Questionnaire (ITAC)*, the *World Health Organization Quality of Life (WHOQOL)*, and the *Medication Adherence Rating Scale (MARS)*. We also created a health agenda to organize an individual plan of care.

Results: Our findings indicated an improvement in insight and attitudes towards treatment by 8.6%, an enhancement in treatment adherence by 5%, and an increase in knowledge by 11.9%. In terms of quality of life, we observed a slight improvement in the psychological domain by 0.6% and in the social domain by 1.2%. Regarding the impact on psychotic symptomatology, there was an average decrease in 4 points in the negative subscale and in 3 points in the general psychopathology subscale, whereas the positive subscale remained unchanged. None of the patients required hospitalization during this period.

Conclusions: Our study revealed some improvement in nearly all the evaluated parameters. There was an improvement of the therapeutic relationship, which we believe has contributed to lower scores in the negative symptoms and general psychopathology subscale. As for the study limitations, we acknowledge that we will need to expand our sample through additional programs in the next years, to include it in early intervention psychosis programs and to re-evaluate our patients' outcomes after a more extended follow-up period, particularly if they continue to participate in our monthly mutual support group. Additionally, we must consider potential study biases, including the subjectivity of PANSS evaluations and the influence of other confounding factors, such as changes in treatment regimens during the program.

Long-Term Trends in Psychiatric Day Hospitalization: A Retrospective Study in Algarve, Portugal

M. T. Viseu*, B. Luz and C. Solana

Departamento de Psiquiatria e Saude Mental, Centro Hospitalar Universitário do Algarve, Faro, Portugal

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1493

Introduction: Current healthcare policies encourage the investment in transition units between hospitalization and outpatient care. Psychiatry day hospitals (DH) serve as partial hospitalization structures that facilitate this transition. The DH at the Faro Unit of

the Centro Hospitalar Universitário do Algarve (CHUA), began its activity in 2008, is situated in southern Portugal and provides support to the entire eastern Algarve region (approximately 300,000 people). Its focus is on rehabilitating individuals with severe mental illnesses necessitating multidisciplinary care, with personalized therapeutic plans.

Objectives: We aimed to categorize patients based on diagnoses (primary psychotic disorder, depressive disorder, and others) according to the International Classification of Diseases (ICD-11) and to characterize and compare sociodemographic and clinical data among these three groups.

Methods: A retrospective study spanning from May 2008 to June 2023 was conducted. We assessed sociodemographic, clinical, and epidemiological data of patients undergoing treatment at CHUA Faro Unit's DH.

Results: Over this period, 541 treatment cycles were carried out to 433 distinct patients, between 18 and 78 years old. Of the total treatments, 38% were for Primary Psychotic Disorder (PPD), 24% for Depressive Disorder (DD) and among the others (39%) the diagnosis of Bipolar Affective Disorder and Personality Disorder predominated. Statistically significant differences were identified among these three groups. The PPD group exhibited a male predominance, whereas DD and others were largely female. Patients in the PPD group were significantly younger (average age of 36 in PPD, 40 in others, and 48 in DD), more likely to be single, and a majority were unemployed (with several patients retired due to disability). No significant differences were noted regarding drop-outs, expulsions, or the duration of DH treatment. These results are preliminary, and additional relevant data are being collected and processed.

Conclusions: The diagnostic group's consideration revealed differences in the social, demographic, and clinical characteristics of patients. These findings offer insights into patient details, enabling the future adaptation of intervention strategies in a more personalized manner.

The effectiveness of computerized cognitive training on cognitive functions and mental health in people with schizophrenia

Y. Haghgoo^{1*} and H. A. Haghgoo²

¹University of Social Welfare and rehabilitation Sciences, Tehran, Iran, Islamic Republic Of and ²Occupational Therapy, University of Social Welfare and rehabilitation Sciences, Tehran, Iran, Islamic Republic Of

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1494

Introduction: People with schizophrenia have multiple and persistent cognitive deficits. These defects have a deep impact on people's psycho-social functions. Although computerized cognitive training has positive results in some people, the effect of these treatment programs in schizophrenia is not clear.

Objectives: The purpose of this study was to investigate the effectiveness of computerized cognitive exercises on the components affecting the mental health and cognitive functions of schizophrenic patients.

Methods: Fifty-four adults with schizophrenia were randomly divided into two intervention and control groups. Participants in the intervention group received 30 sessions of 5-45 minutes of computerized cognitive training in addition to the usual treatment programs. While the control group only received their usual rehabilitation programs (Pharmacotherapy, psychotherapy and occupational therapy).

Mental health was evaluated with Warwick-Edinburgh Mental Well-Being Scale and Depression-Anxiety-Stress Scale (DASS), and cognitive functions with CANTAB tests Batteries before the intervention, after and two months after the intervention (follow up). The set of CANTAB tests used in this study included the following tests: Spatial Recognition Memory (SRM), Paired Associates Learning (PAL), Stockings of Cambridge(SOC), Spatial Working Memory (SWM), and Spatial Span (SSP).

Results: The analysis of the findings showed that the patients' performance in the cognitive tests related to memory and executive functions improved significantly in the intervention group after the intervention. In problem solving skills, despite the better performance in the intervention group, the difference between the two groups was not significant. Also, the intervention was able to significantly improve mental health and reduce stress. But no significant difference was observed in reducing anxiety and depression.

Conclusions: As a result, the study showed that 30 sessions of computerized cognitive training can have a positive effect on overall mental health and some cognitive functions.

Cognitive Speech Therapy Protocol directed to Autistic Spectrum Disorder (PROFOCO-ASD): construction stage

M. V. Stlpen^{1*}, D. R. M. Avejonas¹ and D. C. Dias¹

¹REHABILITATION SCIENCES, UNIVERSIDADE DE SÃO PAULO, SÃO PAULO, Brazil

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1495

Introduction: Autism Spectrum Disorder (ASD) is considered a neurodevelopmental disorder characterized by changes in cognitive aspects that influence the process of social communication development in these individuals. The Speech-Language Pathologist is the professional qualified to evaluate and intervene in cases of language impairment, however, there are few accessible cognitive assessment instruments. The Cognitive Speech Therapy Protocol (PROFOCO) is a questionnaire to assess cognitive aspects directed to children with a clinical diagnosis of Autism Spectrum Disorder (ASD).

Objectives: The present study aims to present the construction phases of the Cognitive Speech Therapy Protocol aimed at Autistic Spectrum Disorders (PROFOCO-ASD), with emphasis on the panel of experts.

Methods: The Cognitive Speech Therapy Protocol was prepared as a PhD thesis in the area of Rehabilitation Sciences at the Faculty of Medicine of the University of São Paulo (FMUSP). This is a

questionnaire to investigate cognitive aspects aimed at children between 2 and 12 years old, diagnosed with Autism Spectrum Disorder, to be applied by a speech therapist and answered by parents or guardians. The construction of the protocol took place in 4 stages: experience of the authors, review of updated literature, a pre-test applied in person to 10 parents and guardians of children with ASD and the panel of experts where the protocol was analyzed by 3 specialists from area of speech therapy linked to USP AND UNIFESP, with experience in language and in the construction of protocols as criteria for selection, which analyzed the content of the questions, the vocabulary, the structure of the protocol and the answer

Results: The authors' experience in the construction process made it possible to observe the need to introduce issues involving the adequate state of brain regulation, conditions for reception, analysis and storage of information and conditions for programming, regulation and execution of activities. The updated bibliographic review made it possible to elaborate each question based on scientific evidence. The pre-test made it possible to analyze the understanding of the proposed questions, the vocabulary used and the time required for application. The expert panel provided an analysis of the content and vocabulary, leading to relevant changes in its general context, demonstrating the importance of the expert panel phase in the development of a reference protocol.

Conclusions: The present study demonstrates the importance of the expert panel phase in structuring a screening instrument, since a different perspective from people involved in the language area can give more clarity to the questions, as well as the vocabulary used, ease of A protocol capable of being understood by a population in different contexts, its vision also evolves, in different regions.

Insights into Early Onset Dementia: a protocol for an 8-year nationwide retrospective study using administrative data

B. F. Pinto¹, A. R. Ferreira², M. Gonçalves Pinho^{2,3*}, A. Freitas⁴ and L. Fernandes^{2,5}

¹Faculty of Medicine, University of Porto; ²CINTESIS@RISE, Department of Clinical Neurosciences and Mental Health, Faculty of Medicina, University of Porto, Porto; ³Department of Psychiatry and Mental Health, Centro Hospitalar do Tâmega e Sousa, Penafiel; ⁴CINTESIS@RISE, Department of Community Medicine, Information and Health Decision Sciences (MEDCIDS), Faculty of Medicine, University of Porto and ⁵Psychiatry Service, Centro Hospitalar Universitário de São João, Porto, Portugal

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1496

Introduction: Early-onset dementia (EOD) is defined as any type of dementia with an onset before the age of 65. Despite its profound impact on patients and their families, EOD has garnered less attention when compared to late-onset dementia (LOD), often resulting in its underestimation. In comparison to LOD, EOD

commonly manifests with atypical and heterogeneous symptoms, encompassing mainly non-memory problems, ranging from language and executive impairments to behavioral-led dysfunction. Despite the importance of accurate data to organize appropriate healthcare, evidence regarding EOD patients in Portugal is lacking.

Objectives: The primary aims of this study include identifying the causes for hospitalization in EOD patients, diagnosed with dementia either as a primary or secondary diagnosis, and comparing them with inpatients aged 65 and older (LOD). Additionally, the study aims to analyze key hospitalization outcomes for both groups, including length of stay, in-hospital mortality, and readmissions. As a secondary aim, this study seeks to describe subtypes of EOD.

Methods: A retrospective observational study will be conducted following the RECORD statement. Data will be retrieved from an administrative database that gathers de-identified routinely collected hospitalization data from all Portuguese mainland public hospitals. Hospitalization episodes of inpatients younger than 65 years old, with a primary or secondary diagnosis of dementia (ascertained by ICD-9-CM codes 290.0-290.4, 294.0-294.2, 331.0, 331.1, and 331.82), will be extracted. Comparison patients will be selected by propensity score-matching from inpatients over 65 years with a dementia ICD-9-CM code (in any position), matched for Charlson Comorbidity Index (CCI).

Results: Descriptive and analytical statistics will be conducted to describe and characterize both group of inpatients. Variables such as age at admission, sex, place of residence, causes and type of admission, psychiatric comorbidities, length of stay (LoS), destination after discharge, readmissions, in-hospital mortality and hospital charges will be analyzed.

Conclusions: With this nationwide analysis of EOD hospitalizations, we aim to reveal critical aspects of this condition, including common causes of admission, diagnostic features and health outcomes, allowing for appropriate medical interventions and support tailored to the specific needs of this clinical group.

EPV0889

Prevalence and impact of comorbid mental disorders in hospitalized patients with obstructive sleep apnea: a protocol for a nationwide retrospective study

D. Nora^{1*}, A. Freitas², L. Fernandes^{3,4} and A. R. Ferreira³

¹Faculty of Medicine, University of Porto, Porto, Portugal;

²CINTESIS@RISE, Department of Community Medicine, Information and Health Decision Sciences (MEDCIDS);

³CINTESIS@RISE, Department of Clinical Neurosciences and Mental Health, Faculty of Medicine, University of Porto and

⁴Psychiatry Service, Centro Hospitalar Universitário de São João, Porto, Portugal

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1497

Introduction: Obstructive sleep apnea (OSA) is a common sleep disorder in the adult population, often associated with an increased prevalence of comorbid conditions such as obesity and diabetes, but

also several mental disorders that have been independently associated with worse hospitalization outcomes in a variety of situations. However, and despite such associations, there is a relative dearth of studies exploring comorbid psychopathology beyond depression and anxiety, and no studies seem to address the impact of comorbid mental disorders on the hospitalization outcomes of patients with OSA.

Objectives: This study aims to characterize and compare mental comorbidities among hospitalization episodes of adult patients with and without OSA held in mainland Portugal, regardless of the primary cause of admission, and to analyze the impact of such comorbidities on hospitalization outcomes.

Methods: An observational retrospective study will be conducted using an administrative database comprising de-identified routinely collected discharge data from all Portuguese mainland public hospitals. Inpatient episodes spanning from 2008 to 2015 will be categorized into two groups according to the presence of an OSA code (ICD-9-CM codes 780.51, 780.53, 780.57, 327.20 and 327.23). For both groups, mental disorders will be identified according to categories 650 to 670 of the Clinical Classifications Software (CCS) for ICD-9-CM. Descriptive, univariate, and multivariate analyses will be performed. Study reporting will comply with the RECORD statement guidelines.

Results: Out of 6,072,538 sampled episodes, 57,301 have an OSA code. Prevalence of any comorbid mental disorder is 30.4% in the OSA group, and 19.3% in the non-OSA group. For both groups, sociodemographic, administrative, and clinical variables will be characterized and compared, as well as the prevalence of each mental disorder category, yearly hospitalization trends, and most common primary diagnoses. Hospitalization outcomes, including length of stay, in-hospital mortality, and readmissions, will be compared taking into consideration the presence of CCS categories of mental disorders.

Conclusions: We expect to improve the understanding of the prevalence of mental comorbidities among hospitalized patients with OSA, including understudied mental disorders, and to elucidate their impact on relevant hospitalization outcomes, thus highlighting the need to recognize and treat this common association to achieve optimal outcomes.

Methods and experiences of a collaborative research project carried out by academic clinical researchers and experts by experience

M. Ameal^{1,2,3*}, K. Hirsma⁴, T. Majalahti⁴ and P. Soininen^{4,5}

¹Psychiatry, Helsinki University Hospital; ²Psychiatry, University of Helsinki, Helsinki; ³Nursing Science, University of Turku, Turku; ⁴Helsinki University Hospital and ⁵University of Helsinki, Helsinki, Finland

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1498

Introduction: Patient or service user participation in research and development is seen as essential in health research, including in

topics within psychiatry. The process and depth of research collaboration can vary and is not always described adequately.

Objectives: The objective is to describe the collaborative methods and the experiences of experts by experience and academic researchers in a research project on patients' experiences of remote care in psychiatric settings during and after the COVID-19 pandemic.

Methods: We describe our collaborative methods and experiences using the INVOLVE key features (www.involve.nihr.ac.uk).

Results: Collaboration started with an open discussion on research aims and role definitions. Collaborative methods included teaching and training sessions on interview methodologies, collaboratively writing and evaluating documents for ethical approval and research permission, collaboratively planning the recruitment process, preparation, and conducting research interviews and analysis. On-line and in-person meetings have been essential for an an-going dialogue and reflection. The methods and experiences are described in more detail in Table 1.

Openness and building trust have been important and time was needed to achieve these. All academic researchers had been actively working with experts by experience in the clinical settings before the research project. The collaboration in the current study has emphasized the need for active involvement of experts with experience throughout the research process. For the experts by experience, the project has provided new insight into academic research and given them confidence in their ability to participate meaningfully in a collaborative study project. The academic researchers valued the sense of significance of the research topic and shared decision-making that the collaboration has brought into the project.

Image:

Table 1 Methods and experiences of the co-research according to the INVOLVE key features.

Involve Key Feature	Establishing ground rules	Ongoing dialogue	Joint ownership of key decisions	Commitment to relationship building	Opportunities for personal growth and development	Flexibility	Valuing and evaluating the impact of co-produced research	Continuous reflection
Method	Open discussion on roles and aims before the project started	Frequent meetings and contact during the process	Meetings including everyone when difficulties occur, open discussion on possibilities	Frequent meetings during planning and conducting research, leaving spaces for open discussion	Co-presentations, learning by doing	Size and roles in the research team make it possible to share and take turns in roles	Stopping to reflect what we have done and officially acknowledging everyone's contribution	Frequent meetings and contact during the process, reflections after conducted interviews.
Experience	Important for building trust and role clarification "what is expected of me"	Adding meaning/units to the research process.	Possibility to reflect and discuss were important especially when difficulties occurred	COVID-19 restrictions allowed only on line meetings in the beginning made relationship building more difficult but with time we have been able to build trust.	Realizing own capability to conduct interviews, learning from the collaboration.	The research does not depend only on one person, flexibility with events in private life.	Emphasis on the research process and continuous learning.	Especially with difficulties in recruitment reflection has given sense of importance and to continue with the project.

Conclusions: Collaborative research needs time to build trust and to clearly define the roles of participants, from the opening stage of the process. Continuous learning during the research process is emphasized. Since different research methodologies arise from various theoretical backgrounds, we suggest adding a topic on research theory to the INVOLVE key features.

Two Sides of the Same Coin? A Comparison between Internet-based and Paper-based Data Collection for Autism Quotient and Depression, Anxiety and Stress Scale

D. Sönmez*, Y. Abidi and T. R. Jordan

Psychology, Ibn Haldun University, Istanbul, Türkiye

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1499

Introduction: The utilization of internet-based data collection in mental health research has gained popularity for its convenience and affordability. However, concerns often arise regarding the validity and reliability of data collected via the internet. The Autism Spectrum Quotient (AQ) is a self-report questionnaire to measure the traits associated with autism spectrum disorder (Baron-Cohen *et al.* J Autism Dev Disord, 2001; 31 5-17) and the online usage of AQ is common and conducted with large numbers of participants across many studies. However, the effect of using internet-based data collection for AQ rather than conventional paper-based procedures is unknown.

Objectives: To address this issue, we conducted a study comparing the effectiveness of internet-based and paper-based data collection procedures for both the AQ and Depression Anxiety Stress Scale-21 (DASS-21, Lovibond & Lovibond, Behav Res Ther 1995; 33 335–343), which is also a prevalent mental health measurement in the literature and often used for online data collection (Zlomke, Comput Hum Behav 2009; 25 841-843). In addition, to compare internet-based and paper-based methods more fully, we included another variable (type of supervision) where a researcher was either present or absent during the completion of the questionnaires.

Methods: A power analysis was conducted, and a minimum of 90 participants were needed to reach a medium effect size of .30 with an adequate power of .80 at $\alpha = .05$. Accordingly, 96 participants were used and randomly assigned across 4 data collection groups: internet-based (supervision, no supervision) and paper-based (supervision, no supervision). In addition to a Demographic Form, AQ, and DASS-21 were used to obtain the data. Three independent variables were used in the current study: type of presentation (internet-based and paper-based) and type of supervision as between factors, and type of assessment as a within factor.

Results: Using a 2 x 2 x 2 mixed design ANOVA, no significant main effects were found for any independent variables (all $p > .33$) or interaction (all $ps > .17$).

Conclusions: The results of using AQ and DASS-21 were not altered by using internet-based or paper-based data collection procedures, suggesting that both methodologies are equally valid for this purpose. Moreover, these effects were also unaffected by the presence or absence of a researcher during data collection, suggesting that supervision by an authoritative figure does not alter the responses made.

Implementation supports to promote fidelity within a flexible, presentation-responsive MHPSS intervention model: A case study of Baby Friendly Spaces in Cox's Bazar, Bangladesh

K. Le Roch^{1*}, K. S. Rahaman², P. Bubendorff³, L. Clouin¹, S. M. Murray⁴ and A. J. Nguyen⁵

¹Mental Health and Psychosocial Support, Action contre la Faim, Montreuil, France; ²Mental Health and Psychosocial Support, Action contre la Faim, Cox's Bazar, Bangladesh; ³MHPSS Independent expert, Nantes, France; ⁴Mental Health, Johns Hopkins Bloomberg School of Public Health, Baltimore and ⁵School of Education and Human Development, University of Virginia, Charlottesville, United States

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1500

Introduction: As evidence has converged on the feasibility and effectiveness of focused, non-specialized, manualized interventions for treating mental distress in humanitarian settings, challenges persist in how to promote implementation fidelity and rigorously evaluate interventions designed to be more preventive or promotive in addressing risk and protective factors for poor mental health. One such intervention, Baby Friendly Spaces (BFS), is a psychosocial support program implemented for Rohingya mothers and their malnourished children living in refugee camps of Cox's Bazar, Bangladesh. That follows a place-based intervention model in which various activities may be offered either individually or in groups with no specified sequence.

Objectives: This presentation describes the process of establishing standards for implementing optimal mental health and psychosocial support (MHPSS) interventions, training BFS workers, and building monitoring and supervision systems to promote implementation fidelity within this flexible support program.

Methods: As BFS services were already being offered as part of Action Against Hunger programming, we first conducted an audit of current services, determining that there was limited current standardization or support for implementation. Therefore, a manualized protocol was designed and covered the program curricula and self-care using didactic and practice-based learning. A series of online training sessions were conducted for 13 psychosocial workers and psychologists at centers delivering the enhanced intervention. Following the training, a baseline evaluation of attitudes, confidence, and knowledge for delivering BFS services was administered. We also collaboratively designed a systematic supervision process to meet the staff's needs with a focus on capacity building and self-care.

Results: Following the initial training, BFS workers receiving the re-training showed similar levels of knowledge, but greater confidence ($p=0.01$) than MHPSS workers proceeding as usual. Participants reported that the training was useful for their field of work and for improving the quality of their work, and acknowledged they would be able to integrate the new learnings into their work and daily life. The follow-up with the supervision process confirmed their capacity to deliver the services and highlighted the need for workspace improvements, the lack of continuous motivation, their ability to identify specific issues for which they requested additional trainings.

Conclusions: There is a particular need for careful attention to implementation supports and supervision when offering flexible, place-based mental health and psychosocial support interventions. In that process, ensuring a continuity between the training and the supervision is essential for the quality of both the program and the research project.

Neurocognitive functioning and emotional recognition in first-episode psychosis: protocol for a follow-up study

D. Bošnjak Kuharić¹, P. Makarić², K. Brozić¹, L. Tomasić¹, A. Savić³, D. Ostojic³ and M. Rojnic Kuzman^{4*}

¹Department for psychotic disorders- female; ²Department for affective disorders; ³Department for first episode psychosis, University Psychiatric Hospital Vrapce and ⁴Department of Psychiatry and Psychological Medicine, Zagreb University Hospital Centre, Zagreb, Croatia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1501

Introduction: Although deficits in neurocognitive functioning and emotional recognition impact treatment outcomes in schizophrenia since the development of the first psychotic episode (FEP), there is still a lack of longer follow-up studies showing the course of these deficits over time.

Objectives: Our objective is to investigate the changes of cognitive functioning over years in a cohort of patients, since their FEP.

Methods: This study is developed as a follow-up of the project Biomarkers in schizophrenia- integration of complementary methods in longitudinal follow-up of FEP, that was conducted in several Croatian psychiatric clinics during the period from 2014 to 2019. A cohort of patients with FEP took part in the project with psychopathology, neurocognitive functioning and emotional recognition assessment at two time points- at baseline, during the subacute phase of a psychotic episode, and after 18 months of follow-up. In this study, patients with FEP who completed the baseline assessment of the project ($n=159$), will be contacted and included in the follow-up. Follow-up assessment will consist of sociodemographic data including information of their treatment so far, battery of neurocognitive tests (Rey Auditory Verbal Learning Test, Rey-Osterrieth complex figure Test, Wechsler paired memory, trail making test a & b, Digit symbol, Digit span, Semantic & Phonetic Fluency, Stroop 1, 2, 3 and Block design test), emotional recognition test (Penn Emotion Recognition Task) and several scales assessing psychopathology (Positive and Negative Syndrome Scale, Self-evaluation of Negative Symptoms, Scale for the Assessment of Negative Symptoms), functioning (Global Assessment of Functioning, WHO Disability Assessment Scale 2.0), quality of life and recovery. The study is funded by the University of Zagreb programmes (Project No. 10106-23-2394).

Results: We plan to analyze the differences between the three time points (baseline, 18 months, 5 years), taking in account possible correlations with psychopathology, functioning, quality of life and different treatment options.

Conclusions: Identifying specific deficits can help in providing more effective treatment plan including various interventions that can improve treatment outcomes in schizophrenia.

EPV0900

Quality of life and objective-subjective functionality in individuals with schizophrenia

A. M. Lisincki*, L. Csizmadia, F. Á. Szabó, J. Réthelyi and É. Jekkel

Department of Psychiatry and Psychotherapy, Semmelweis University, Budapest, Hungary

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1502

Introduction: Chronic mental illnesses can significantly impact an individual's quality of life and lead to functional disabilities. Scientific interest in overall quality of life and health-related quality of life has been gradually increasing, especially in the context of chronic diseases where the relationship between patients' long-term functionality and symptom development is not always linear.

Objectives: Our research aimed to investigate the factors influencing subjective-objective well-being and in patients diagnosed with schizophrenia and schizoaffective disorder. Specifically, we examined the effects of anticipated discrimination on patients' quality of life, satisfaction with health care, and overall functionality.

Methods: We recruited 25 patients from Semmelweis University Department of Psychiatry and Psychotherapy in Budapest, Hungary. To be eligible, patients had to meet the diagnostic criteria for schizophrenia or schizoaffective disorder according to DSM-5, cooperate with pharmacotherapy, and meet remission criteria (Andreasen et al., *Am J Psychiatry* 2005; 162 441-449). We collected socio-demographic data and clinical history, utilized the Mini International Neuropsychiatric Interview (M.I.N.I.) and the Positive and Negative Syndrome Scale (PANSS) to identify our clinical sample and assess the severity of symptoms. Objective and subjective functionality and well-being were measured using the Lancashire Quality of Life Profile (LQoLP). Self-reported medication adherence were measured with Morisky Medication Adherence Scale (MMAS-8). Additionally, we assessed anticipated discrimination (QUAD), and satisfaction with healthcare (CACHE).

Results: Our findings have unveiled a cross-sectional association between higher self-reported medication adherence and improved quality of life among patients with schizophrenia. Moreover, increased adherence levels, as well as greater satisfaction with healthcare, were linked to enhanced objective and subjective functionality and overall well-being. Additionally, the anticipation of discrimination was found to be associated with reduced quality of life and functionality.

Conclusions: The overall quality of life and objective-subjective functioning in patients diagnosed with schizophrenia and

schizoaffective disorder can be influenced by various factors. Further research is needed to gain a better understanding of the factors associated with higher quality of life in patients.

EPV0901

Cariprazine as monotherapy in a case of First Episode of Psychosis (FEP)

P. Nasiou and D. Antoniadis*

Psychiatric Hospital, Thessaloniki, Greece

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1503

Introduction: First-Episode Psychosis (FEP) is a variable condition, characterized by the emergence of new psychotic features for a period of at least 1 week. (Marques et al., *European Psychiatry* 2016; 33 S258) The treatment is antipsychotic medications, which are generally divided into two categories: first and second generation antipsychotics, and they are dopamine antagonists or dopamine partial agonists.

Objectives: The purpose of this presentation is to assess the efficacy of monotherapy treatment with cariprazine of the First Episode of Psychosis (FEP) in a young patient.

Methods: A 19-year old man was involuntarily admitted to the psychiatric intensive care unit because of aggressive and inappropriate behaviour towards his mother including threats to kill her and exhibiting his genitals. His medical history included short periods of depressed mood, as well as physical symptoms such as loss of hair and gastrointestinal symptoms, since he was 18 years old.

When the patient was admitted he was cautious and anxious. During the interview he made reference to auditory hallucinations that commanded him to sexually stimulate himself in front of his mother and also persecutory delusions. Upon admission his total PANSS score was 127. The positive subscale score was 21. The patient was treated with monotherapy cariprazine, gradually increasing the dose from 1,5 mg to 6 mg per day . Furthermore, he was adjunctively treated with sertraline, gradually increasing the dose from 50 to 150 mg.

Results: After a period 24 days since admission the patient clinically improved and was discharged. His total PANSS score was 73 and the positive subscale was 9. He suffered no adverse effects from his treatment.

Conclusions: The use of cariprazine as a treatment for a FEP of a young male significantly improved his PANSS score after a 24-day treatment and also his disorganised behaviour. Of note, rapid tranquilization was avoided. According to the literature this is considered satisfactory response to treatment (Leucht et al. *Schizophrenia Res.* 2005; 79:231-8.). Nevertheless further investigation on the efficacy of the particular medication is necessary as its use is relatively recent in the treatment of psychosis. (Garnock et al. *CNS Drugs.* 2017; 31:513-525)

Disclosure of Interest: None Declared

EPV0902

Efficacy and tolerability of half-yearly long acting injectable palmitate paliperidone after 12 months follow-upA. Benito^{1*} and A. Sanchez-Cabezudo²¹PSYCHIATRY, SESCAM, TOLEDO and ²PSYCHIATRY, SERMAS, MADRID, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1504

Introduction: This retrospective study analysed the clinical efficacy, tolerability and treatment satisfaction of patients who switched from receiving palmitate paliperidone monthly (PP1M) to palmitate paliperidone six-monthly (PP6M) after 12 months of follow-up. A total of 48 patients (31 men and 17 women) with recently diagnosed schizophrenia were included.

Objectives: To assess the clinical efficacy, tolerability and treatment satisfaction in a sample of recently diagnosed schizophrenic patients who switched from receiving palmitate paliperidone monthly (PP1M) to palmitate paliperidone six-monthly (PP6M)

Methods: The sample included a total of 48 recently diagnosed schizophrenic (1-5 years) from three Mental Health units in the province of Toledo (Spain). The inclusion criteria were a diagnosis of schizophrenia (based on the ICD-10 criteria), the start of treatment with Long Acting Injectable Paliperidone Palmitate six-monthly (previously with palmitate paliperidone monthly), and the non-utilization of another neuroleptic treatment. A series of demographic variables were recorded, PANSS scale was used to identify the presence and severity of psychopathology symptoms and the CGI scale was used to assess the severity of the symptoms finally time to relapse was measured (primary outcome). The scales were again applied at baseline, 3 and 6 and 12 months after the start of treatment

Results: N=48 patients (31 males and 17 females), with a mean age of 31 years. 4.3 years of evolution of illness. During the follow-up period only 2 patients (4%) relapsed. Results showed an improvement in PANSS (baseline 50.8, 3 months 41.9, 6 months 37.3, 12 months 26.1), likewise and improvement in CGI was observed (baseline 4.1, 3 months 3.4, 6 months 2.9, 12 months 2.5).

In terms of tolerability, no secondary effects were reported after treatment change, suggesting a good safety profile and predictable tolerability of PP6M. Patient satisfaction with treatment also improved over time. The study reports that 87% of patients accepted the switch from PP1M to PP6M, with reasons for switching including reduced frequency of administration and increased comfort. Most patients (95%) received antipsychotic monotherapy.

Conclusions: In conclusion, this study suggests that switching from PP1M to PP6M in patients with recently diagnosed schizophrenia was associated with maintained clinical stability, good tolerability and improved patient satisfaction with treatment. These findings support the efficacy and clinical utility of PP6M as a convenient and effective treatment option for patients with schizophrenia.

EPV0905

Connection between self-esteem and discontinuation of medication

S. Laabidi, O. abidi, A. aissa*, R. hosni, U. ouali and R. jomli

Psychiatry A, Razi hospital, MANOUBA, Tunisia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1505

Introduction: Self-esteem entails evaluating oneself positively and often involves the need to be special and above average without comparisons with others. It could play a role in many areas of the patient's life.

Objectives: The aim of the present study was to find the prevalence of self-esteem and investigate the associations between self-esteem and treatment adherence in patients with schizophrenia spectrum disorders.

Methods: This study involved outpatients with schizophrenia spectrum disorders, according to (DSM-V) diagnostic criteria, attending the Department of Psychiatry A, Razi hospital between august and September 30, 2023. The level of self-esteem was measured with Rosenberg's Self-Esteem Rating scale (SERS) and treatment adherence with the Medical Adherence Rating Scale (MARS). Socio-demographic characteristics were also collected.

Results: Thirty stabilized outpatients with schizophrenia (n=18), schizoaffective disorder (n=11), brief psychotic disorder (n=1) were included in the study. The mean (SD) age of the respondents was 43.2 years; the mean number of Hospital admissions was 4.7. Almost two thirds of this population (63.33%) had low self-esteem and 36.67% had high self-esteem. The level of self-esteem did not differ between diagnostic categories. Self-esteem also positively correlated with higher education and negatively with an increased number of hospitalizations. However, no significant association was found between socio-demographic variables and self-esteem. Adherence was further negatively correlated with age and age of onset of disorders. Patients suffering from schizophrenia had the lowest adherence to treatment. The results of the present preliminary study suggest a positive correlation between the SERS total scores and the MARS scores. It was found that higher levels of self-esteem are related with higher levels of treatment adherence and lower levels of self-esteem are associated with discontinuation of medications without a psychiatrist's recommendation. This connection was present in all diagnostic groups.

Conclusions: This study shows positive relationship between self-esteem and treatment adherence. Further studies are needed to investigate whether self-esteem is a factor positively influencing adherence to treatment and show if self-esteem training programs like standard psychoeducation and cognitive behavioral therapy could be beneficial to improve treatment adherence among psychiatric patients.

Disclosure of Interest: None Declared

EPV0906

Is treatment adherence linked to self-compassion in schizophrenia?

S. Laabidi, O. abidi, A. aissa*, R. hosni, U. ouali and R. jomli

Psychiatry A, Razi hospital, MANOUBA, Tunisia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1506

Introduction: Self-compassion is defined as the ability to be open to and touched by one's suffering and to relate to it with kindness and non-judgmental awareness. Although identifying factors related to treatment adherence remains an important challenge in patients with schizophrenia spectrum disorders, self-compassion has rarely been investigated in this population. Further studies are needed to investigate whether self-compassion training can improve treatment adherence in this population.

Objectives: The objective of the present study was to investigate the relationship between self-compassion and treatment adherence in patients with schizophrenia spectrum disorders.

Methods: thirty stabilized adult outpatients with schizophrenia (n=18), schizoaffective disorder (n=11), brief psychotic disorder (n=1) per DSM-5 criteria were included. Self-compassion was assessed using the 26-item Self-Compassion Scale (SCS). Treatment adherence was assessed using the Medical Adherence Rating Scale (MARS). Socio-demographic characteristics, including age, gender, academic level, and mean daily antipsychotic dosages were collected.

Results: There was no significant difference in SCS scores and MARS scores as a function of gender, age, or academic level. The results of the present preliminary study suggest a positive correlation between the SCS total scores and the MARS scores. It was found that higher levels of self-compassion are related with higher levels of treatment adherence in patients with schizophrenia spectrum disorders and lower levels of self-compassion are associated with discontinuation of medications without a psychiatrist's recommendation. This connection was present in all diagnostic groups.

Conclusions: The results of the present preliminary study suggest that self-compassion and treatment adherence are closely related. Improving self-compassion in patients with schizophrenia spectrum disorders may improve their level of treatment adherence. Further studies are needed to investigate whether self-compassion training programs could be useful as an extension of standard psychoeducation and cognitive behavioral therapy to improve treatment adherence in this population.

Treatment adherence and insight in schizophrenia spectrum disorders

S. Laabidi, O. abidi, A. aissa*, R. hosni, U. ouali and R. jomli

Psychiatry A, Razi hospital, MANOUBA, Tunisia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1507

Introduction: Lack of adherence to antipsychotic medication in patients with schizophrenia spectrum disorders is a major risk factor for relapse and rehospitalizations which contributes to major social and economic consequences. A high proportion of patients with schizophrenia are partially or completely unaware of their mental disorder.

Objectives: The aim of this study was to investigate the association between insight and medication adherence.

Methods: A total number of 30 outpatients with schizophrenia spectrum disorders, according to (DSM-V) diagnostic criteria who were attending the department of psychiatry A Razi hospital between august and September 30, 2023 were included in this study. Patients' insight was measured by the birchwood insight scale. The degree of medication adherence was measured by using Medication Adherence Rating Scale (MARS).

Results: Patients enrolled in the study had a mean (SD) age of 43.2. There was no significant correlation between patients' insight and patients' ages, duration of illness and hospitalization times. In addition, there was no significant association between medication adherence and age, duration of illness, number of hospitalization or social level. Impaired insight was associated with poor antipsychotic medication adherence in patients with schizophrenia spectrum disorders. Higher insight was correlated to higher therapeutic adherence. Our results showed that the level of insight and compliance to treatment are positively correlated.

Conclusions: The results of this study support the hypothesis that insight and treatment adherence are closely related. Interventions to enhance insight may be helpful in improving medication adherence.

Efficacy of acetylsalicylic acid in schizophrenia: a literature reviewA. Aissa^{1,2*}, S. Jedda¹, F. Askri¹, O. Maatouk¹, U. Ouali¹, Y. Zgueb¹ and R. Jomli¹¹Psychiatry A, Razi Hospital, Manouba and ²Psychiatry, Faculty of Medicine of Tunis, Tunis, Tunisia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1508

Introduction: There has been growing evidence to support the hypothesis that inflammation is involved in the pathogenesis of schizophrenia.

Objectives: The aim of the present literature review was to assess the efficacy of acetylsalicylic acid (ASA) as an adjuvant agent in the treatment of an acute exacerbation of schizophrenia.

Methods: We searched randomized clinical trials based on regular searches of MEDLINE, Embase, PubMed.

Results: We included four studies. The results were in favor of the efficacy of ASA in the study where authors targeted early psychosis. Illness duration seems to predict response to anti-inflammatory agents.

Conclusions: Further studies of early stages of schizophrenia are helpful.

Patient satisfaction with 6-month paliperidone palmitate versus other long-acting injectable antipsychotics

A. Pérez-Balaguer^{1*}, I. García del Castillo¹, B. Gómez-Esteban¹, M. Vicente-Burguillo¹, H. Vizcaíno-Herrezuelo², S. Castela-Almodóvar², A. Arce de la Riva² and F. Neira-Serrano³

¹Psychiatry, El Escorial Hospital; ²Psychiatry, Puerta de Hierro University Hospital and ³Statistics, Francisco de Vitoria University, Madrid, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1509

Introduction: Long-acting injectable antipsychotics (LAIs) offer advantages for schizophrenic patients compared to oral antipsychotics: less frequent dosing, lower relapse rates, better adherence, and lower healthcare costs. LAIs include paliperidone, aripiprazole, olanzapine, risperidone, and zuclopenthixol. Paliperidone palmitate is the only antipsychotic with two formulations with an administration interval longer than one month (3-monthly and 6-monthly), which could be better for the patient and help ensure treatment continuity, especially in cases of limited access to the health care system.

Objectives: To assess the satisfaction of patients under treatment with 6-month paliperidone palmitate compared to other long-acting injectable antipsychotics with a higher frequency of administration.

Methods: We analyzed the satisfaction level of a sample of patients receiving treatment with LAIs at the Mental Health Center of El Escorial. All patients had a diagnosis of schizophrenia or other psychotic disorders (according to DSM-5). Patients who met the inclusion criteria completed the Treatment Satisfaction Questionnaire for Medication (TSQM), a generic questionnaire of treatment satisfaction that measures four dimensions: side effects, treatment efficacy, comfort of use, and overall satisfaction. Other clinical and socio-demographic variables were collected, as well as the type of injectable, dose, and frequency of administration.

Results: Data from approximately 30 patients will be analyzed and discussed later.

Conclusions: Less frequent administration of LAIs may result in greater patient satisfaction and be just as beneficial clinically. Treatment satisfaction is positively associated with an improvement in psychotic symptoms and seems to be related to better adherence.

EPV0910

Perceived mental illness stigma and self stigma among persons treated for psychotic disorders

A. Jambrosic Sakoman^{1*}, T. Jendričko², D. Bošnjak Kuharić¹ and A. Tomic¹

¹Department for Psychotic Disorders and ²Department for Psychotherapy, University Psychiatric Hospital Vrapče, Zagreb, Croatia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1510

Introduction: Stigma related to mental health has serious impact on persons suffering from psychiatric disorders and on their families. Self-stigma occurs when people with mental health problems internalize public attitudes, negative beliefs and stereotypes associated with psychiatric disorders. Stigma and self-stigma can affect every aspect of life and result in discrimination, social exclusion, feelings of low self-esteem, shame, guilt, and can postpone seeking help.

Objectives: To examine perceived stigma and self-stigma of people treated for psychotic disorders.

Methods: We will include male and female patients older than 18 years of age, diagnosed with psychotic disorders, treated as outpatients. Assessment will include sociodemographic data, Internalized Stigma of Mental Illness Inventory – 9-item Version (ISMI-9) * to measure internalized stigma of mental illness, The perceived devaluation-discrimination (PDD) scale to measure perceived stigma, the World Health Organisation Quality of Life-BREF (WHOQOL-BREF) questionnaire, and Clinical Global Impression Scale (CGI).

Results: We will analyse differences in ISMI and PDD scales in patients treated for psychotic disorders.

Conclusions: Understanding self-stigma and societal stigma associated with mental health is crucial in creating programs aimed at well-being of persons treated for psychotic disorders.

EPV0912

Differential diagnosis in chronic psychosis: a case report

C. Alcalde-Diosdado Crespi*, M. D. P. Almodóvar Rivera and F. Vilchez Español

Hospital Universitario de Jaén, Jaén, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1511

Introduction: A colombian woman aged 62, with previous diagnosis of paranoid schizophrenia. She retired from working 2 years ago, when she started taking care of her sick husband full-time.

Objectives: To describe a chronic psychosis case and discuss the treatment options and differential diagnosis.

Methods: We used the face-to-face interviews during her last hospitalization and her electronic medical history.

We also made a brief research about the effectiveness of risperidone depot in Pubmed.

Results: Psychiatric history

She's had 3 hospitalizations, all of them coincided with stressful vital situations. The first one occurred when she was dealing with a job issue. In the second one she was having an economic conflict with her husband. And the third one has coincided with worries about her retirement pension and her caregiver burden.

Current episode

She came to my hospital emergency department distressed because she thought her husband and her were victims of an international drug trafficking plot. She said a colombian drug cartel had sent 9 prostitutes to her village in order to steal from them, by pretending they were cleaning assistants, as a reprisal against her husband, who used to be a military in Colombia. She explained the nature of

this event with great details. Also, she said the electric company was involved and they had tried to intoxicate her.

The psychopathological exploration was altered with a correct speech in its form but incoherent in its content. She presented a highly structured delusional plot of prosecution. No major affective disorders were detected. She suffered from reactive insomnia and anxiety.

Evolution

At first, it was torpid, she felt perspicacious and angry about the admission. Later, as the antipsychotic started to work, the symptoms improved and she became calm and collaborative. She has never criticized the delusion plot, but it was encapsulated, and the affective resonance disappeared.

We tried oral aripiprazole and paliperidone but retired both due to bad tolerance. Then we tried risperidone, with good tolerance and response, and started her current monthly treatment with Risperidone 100 mg depot.

After one year, she has kept stable with no relapses and good adherence to the treatment.

Differential diagnosis

The patient meets every diagnostic criteria of Delusional disorder (F22), as she has never experienced hallucinations and the functionality has not significantly decreased through the years. Also, she doesn't meet the second criteria for Schizophrenia (F20).

Conclusions: It is important to explore the evolution of a psychotic disorder in order to differentiate between a schizophrenia and a delusional disorder, as the prognosis differs significantly.

Using Risperidone monthly depot can be a good option for treating a psychotic disorder (Sampson et al. Cochrane Database Syst Rev 2016. 14;4(4)).

Disclosure of Interest: None Declared

Initiation of Paliperidone palmitate 3-monthly injectable in an acute inpatient psychiatric unit

A. S. Pareja Zea^{1*}, C. Vera-Varela¹, A. Martínez Martínez², G. García Jiménez¹ and M. De Iceta Ibañez de Gauna¹

¹Psychiatry and ²Pharmacy, Infanta Sofia University Hospital, Madrid, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1512

Introduction: The treatment of patients with severe psychotic disorders presents significant clinical challenges, and the choice of appropriate therapy is essential to ensure long-term stability¹. In this context, long-acting injectable antipsychotics (LAIs) have emerged as a promising therapeutic option. LAIs were developed to counteract poor treatment adherence in patients with psychotic disorders².

Paliperidone palmitate 3-monthly injectable (PP3M) is a novel formulation of intramuscular injectable paliperidone palmitate with a significantly longer half-life than the once-monthly formulation.

PP3M has shown a longer time to relapse and good safety and tolerability in many studies³.

Objectives: The aim of this work was to describe the profile of patients initiating PP3M in an acute inpatient psychiatric unit.

Methods: A descriptive study was conducted on patients admitted to the acute psychiatric unit from January 2021 to December 2022. The sample included 23 inpatients who initiated PP3M during the admission. Data were collected regarding age, gender, diagnosis, substance abuse, previous antipsychotic treatment, antipsychotic treatment adherence and adverse effects during the admission.

Results: 23 patients sample, with an average age of 44.04 years-old, 16 male and 7 female, diagnosed with psychotic disorder (22) and schizoaffective disorder (1). Out of the 23 patients, 7 had active substance abuse upon admission.

Out of the total sample, 9 of them were prescribed LAIs, with 6 on PP1M (Paliperidone palmitate 1-monthly injectable), 2 on PP3M, and 1 on aripiprazole long-acting injection. Twelve were prescribed oral antipsychotics, including 4 on paliperidone, 4 on risperidone, 1 on aripiprazole, 1 on olanzapine, and 2 on other oral antipsychotics. Two patients did not have a previous antipsychotic prescription.

Among the 23 patients, 17 of them did not have previous antipsychotic treatment adherence.

5 out of the 23 patients experienced adverse effects, with 3 of them having extrapyramidal symptoms and 2 hyperprolactinemia. Upon discharge, 11 out of the 23 patients were prescribed antipsychotic monotherapy with PP3M.

Conclusions: In this sample, we observed that inpatients who initiated PP3M in an acute psychiatric unit were males, with psychotic disorders, lacked adherence to previous antipsychotic treatment. Most of them did not experience adverse effects with PP3M during admission.

More research should be done to assess the use of PP3M in an acute inpatient psychiatric unit.

EPV0914

Achieving functional remission in schizophrenia: a pilot study

D. Bošnjak Kuharić^{1*}, A. Jambrošić Sakoman¹, Z. Lovrić Makarić², A. Savić³, A. Papić¹ and M. Herceg¹

¹Department for psychotic disorders- female, University Psychiatric Hospital Vrapče; ²Division for Epidemiology of Communicable Diseases, Croatian Institute of Public Health and ³Department for first episode psychosis, University Psychiatric Hospital Vrapče, Zagreb, Croatia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1513

Introduction: Many patients with schizophrenia are unable to achieve adequate levels of psychosocial functioning and quality of life despite of the remission of illness symptoms. According to previous reports, only one-third of patients with symptomatic

remission reach functional remission. While current pharmacotherapy options seem to be relatively effective for different symptoms of schizophrenia (e.g. positive symptoms), more specific psychosocial interventions that could enable functional remission are yet to be developed.

Objectives: Our objective is to investigate differences in psychopathology, quality of life, functioning, and achieving functional remission before and after specific group treatments developed in our clinic.

Methods: We will conduct a prospective study including a consecutive cohort of female patients older than 18 years of age, which fulfilled the criteria for schizophrenia and schizoaffective disorder according to the International Classification of Disorders, 10th revision. Exclusion criteria are intellectual disabilities, mental disorders due to known physiological or neurological conditions, lactation or pregnancy, treatment with medications that can provoke psychosis, alcoholism, and other addictions. Patients will be recruited after finished hospital treatment or during individual outpatient controls. The Recovery Helm will be used at the beginning of the treatment, to make individual treatment plan and include patients in specific programs including day hospital treatment and/or outpatient group programs: psychoeducation, relaxation, metacognitive training, and social skills training. Besides collecting sociodemographic data, pre- and post-treatment assessment will include the Positive and Negative Syndrome Scale (PANSS), the Global Assessment of Functioning (GAF), the Quality of Life Scale (QLS), and the "Functional Remission of General Schizophrenia" (FROGS) scale.

Results: We will analyze the changes in psychopathology levels, quality of life, functioning, and achieving functional remission between the two assessment points, taking into account different treatment possibilities.

Conclusions: Evaluation of current available programs can help with recognition of specific needs of patients with schizophrenia and provide guidelines for further development of treatment programs that could be helpful in achieving functional remission.

Treatment resistant FEP (first episode of psychosis) with neuroanatomical findings

K. Papageorgiou, I. Retsou, E. Papadopoulou and D. Antoniadis*

Psychiatric Hospital of Thessaloniki, Thessaloniki, Greece

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1514

Introduction: Presentation of the first psychotic episode of a young man and the investigation of the efficacy of treatment with olanzapine and after cariprazine.

Objectives: Assessing the response to treatment of cariprazine in a psychotic patient with relevant neuroanatomical findings.

Methods: A 25-year old man was admitted to the psychiatric intensive care due to his aggressive behavior and verbal abuse, threatening to kill them both. His medical history included long periods of negatively affected mood, social isolation and talking to himself according to his family

Results: When the patient was admitted he was very anxious, alert and extremely aggressive. During the interview he admitted auditory and visual hallucinations alongside delusional ideation with a particular aggression towards his father.

Upon admission his PANSS score was 121. positive scale score was 23.

The patient was treated initially with monotherapy olanzapine, gradually increased up to 20mg OD. Olanzapine caused asymptomatic transaminasemia, a relatively common adverse effect. At this point a change in medication was made and olanzapine was stopped and cariprazine was added gradually increasing its dose from 1,5mg to 6mg OD.

Interestingly the medical investigations (brain CT scan) indicated a calcification in falx cerebri.

After a period of 48 days since admission the patient was clinically improved and was discharged. His PANSS score was 72. Positive scale was 10.

Conclusions: The use of cariprazine as a treatment for a first psychotic episode of a young male improved his PANSS score after a 22-day treatment. According to the literature neuroanatomical findings have been associated with poor prognosis regarding the course of the illness. There needs to be further investigation on the efficacy of the long term treatment for this patient.

EPV0916

Acute Stress Induced Catatonic Psychosis in an Adolescent: A Case Report

E. Yerlikaya Oral

Department of Child and Adolescent Psychiatry, University of Health Sciences, Bakirkoy Prof. Dr. Mazhar Osman Research and Training Hospital for Psychiatry, Neurology and Neurosurgery, Istanbul, Türkiye

doi: 10.1192/j.eurpsy.2024.1515

Introduction: Childhood maltreatment(CM) can precipitate a range of psychiatric disorders in individuals. Some research show that CM rates are as high as 85% in schizophrenia spectrum disorders (Larsson *et al.* 2013). This case report explores an instance of acute catatonic psychosis in an adolescent following a significant episode of physical and emotional abuse.

Objectives: The aim is to elucidate the clinical presentation, diagnosis, and treatment of trauma-induced acute catatonic psychosis in an adolescent. The report seeks to emphasize the potential link between acute trauma and severe psychiatric disorders in young individuals.

Methods: A thorough review of the patient's clinical records was undertaken, focusing on psychiatric history, symptoms, treatment trials and responses. In parallel, an extensive literature review was conducted to understand the current knowledge on the association between acute traumatic stress and acute psychosis with catatonia.

Results: The patient, a 16-year-old female, presented with severe symptoms of catatonia and psychosis including mutism, posturing, stupor, negativism, auditory hallucinations and persecutory delusions, in addition; eating refusal, urinary and fecal incontinence. Symptoms started immediately following physical and emotional

abuse that occurred 10 days ago. She was hit, insulted and detained for 2 days by her parent's friends. Abuse reported to social services and judicial authorities. All laboratory and neurologic examinations performed to exclude an organic pathology. No pathologic results founded. Olanzapine 5 mg/day and lorazepam 0.5 mg/day started and titrated to 30 mg/day and 3.75 mg/day doses. Biperiden 4 mg/day started due to extrapyramidal side effects. A significant improvement observed about her catatonic and positive psychotic symptoms but she still had acute stress disorder symptoms. Trauma-focused cognitive-behavioral therapy added to her treatment. Family-based interventions examined for CM. She discharged in full remission after eight weeks of hospital stay. Lorazepam dose reduced and stopped before discharge.

Conclusions: Neurobiological models are trying to enlight the association between experiencing highly stressful or traumatic events, such as child abuse, may impact on later expression of psychotic disorders by increasing stress sensitivity to later adversity (Fares-Otero *et al.* 2023). This case underscores the potential of acute traumatic stress to precipitate severe psychiatric disorders, including catatonia. It highlights the importance of comprehensive clinical evaluations and the inclusion of trauma history in children presenting with acute psychiatric symptoms. The findings advocate for the integration of trauma-focused interventions in the treatment of similar cases. Further research is needed to understand the pathophysiological mechanisms underlying this association and to develop effective treatment strategies for this vulnerable population.

Long – acting injectable aripiprazole in patients with psychosis is associated with improved quality of life, better general clinical outcome and fewer hospitalizations

E. I. Koiliari^{1,2}, I. Mouzas^{1,2}, G. Alevizopoulos³, O. Lesch⁴, H. Walter⁴ and E. L. Pasparakis^{1,2*}

¹Laboratory of Alcoholology, Department of Pathology, Medical School of Crete, University of Crete, Heraklion of Crete; ²Department of Psychiatry, General Hospital of Agios Nikolaos, Agios Nikolaos of Lasithi; ³Department of Psychiatry, Agioi Anargyroi Hospital, National and Kapodistrian University of Athens, Athens, Greece and ⁴Department of Social Psychiatry, Medical University of Vienna, Vienna, Austria

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1516

Introduction: Aripiprazole, a D2 receptor partial agonist is suggested to enhance Prefrontal Cortex (PFC) dopamine functioning resulting to an improvement of working memory and GABA transmission related to social functioning. The LAI form of the medication is documented to improve the long-term adherence of the patients resulting in a better assessment of the effects of the drug on behavioral parameters that require a longer time to evaluate.

Objectives: Hypothesis testing: “Aripiprazole LAI antipsychotic treatment is associated with i) reduced hospitalizations, ii) improved quality of life and iii) patient functioning”.

Methods: 65 patients participated (Male to Female ratio corresponds to 2:1). 44 of them, the community population manifested psychosis (23 schizophrenia and 21 patients bipolar disorder with psychotic features). The median age was 41 years. 31.8% had dual diagnosis of psychosis and alcohol use disorders, while 25% had dual diagnosis of psychosis and Cannabis Use disorder. 77.3% were on aripiprazole LAI. 21 patients with BD I were prisoners at the Penitentiary of Neapolis of Lasithi of Crete. Median age was 36 years (all men). 90.5% had comorbidity of bipolar disorder type I (BD-I) and alcohol use disorders. 95.2% had comorbidity of BD – I and Cannabis Use Disorder. All were medicated by aripiprazole LAI 400mg/month. For the evaluation of our hypotheses the instruments WHOQOL-BREF questionnaire and the CGI-S scale were used. The quality of life, functionality, and number of hospitalizations were compared in each patient, before the initiation of the LAI medication and during the active treatment period. The minimum of follow-up period was 6 months.

Results: In 44 patients (in community) hospitalizations decreased statistically significantly from 1.3 ± 1.9 to 0.1 ± 0.4 (Paired Samples Wilcoxon Signed Rank Test p -value <0.001). The CGI-S score decreased statistically significantly from 6.0 ± 0.8 to 4.0 ± 1.1 (Paired Samples Wilcoxon Signed Rank Test p -value <0.001). The score of the WHOQOL-BREF scale increased statistically significantly from 0.5 ± 0.5 , to 2.9 ± 0.8 (Paired Samples Wilcoxon Signed Rank Test p -value <0.001). For the group of 21 patients (imprisoned) hospitalizations decreased from 0.6 ± 1.8 to 0.0 ± 0.0 (Paired Samples Wilcoxon Signed Rank Test p -value $=0.066$). The CGI-S score decreased statistically significantly from 5.3 ± 0.8 to 3.2 ± 1.3 (Paired Samples Wilcoxon Signed Rank Test p -value <0.001). The quality-of-life scale score increased statistically significantly from 0.9 ± 0.6 to 3.09 ± 0.7 (Paired Samples Wilcoxon Signed Rank Test p -value <0.001).

Conclusions: Aripiprazole LAI significantly improves the quality of life and functionality of patients with psychosis. We suggest that the improvement might be related to the beneficial effects of the molecule on the Prefrontal Cortex (PFC).

EPV0918

Addressing negative symptoms of schizophrenia in a Psychosis Day Hospital: a case report

F. Mayor Sanabria^{1*}, E. M. Fernández Fonollosa¹, C. M. Gil Sánchez², A. Fuentes Merlos¹, E. X. González Vivero¹, S. Puyal González¹, M. Fernández Fariña¹ and B. Serván Rendon-Luna¹

¹Instituto de Psiquiatría y Salud Mental, Hospital Clínico San Carlos, Madrid and ²Hospital de La Línea, La Línea de La Concepción, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1517

Introduction: Negative symptoms are present in more than two thirds of schizophrenic patients throughout the evolution of the disorder. These include symptoms related to reduced motivation or pleasure, such as avolition, anhedonia and asociality, and reduced expressivity, including alogia and blunted affect.

We present the case of a 24-year-old man who was admitted to our Psychosis Day Hospital after several psychotic episodes, presenting

with prominent negative symptomatology that was imbued with mystical delusional beliefs.

Objectives:

- 1) To describe the clinical particularities of this case, focusing on the improvement of negative symptoms during the course of treatment at our Day Hospital.
- 2) To review the available evidence regarding the pharmacological and psychotherapeutic management of negative symptoms of schizophrenia.

Methods: A review of the patient's clinical history and complementary tests were carried out. Likewise, we reviewed the available literature in relation to the management of negative symptoms of schizophrenia in an ambulatory setting.

Results: The patient was admitted to our Day Hospital after four psychiatric hospitalizations due to mystical delusions, ideas of grandiosity and hyper-spirituality, along with prominent negative symptoms at the moment of inclusion at our centre, including social withdrawal, diminished affective response, lack of interest in the academic sphere and poor social drive. Although previous positive symptoms were present in a lesser degree, the patient interpreted the presence of the negative symptoms described above as a "punishment" or "test" from spiritual creatures.

Management of negative symptoms represents a major unmet need in schizophrenia. Modest effect size evidence for pharmacological approaches favours the use of antipsychotic in monotherapy and augmentation of antipsychotic treatment with other agents, such as antidepressants. Scarce evidence regarding psychotherapeutic approaches to these symptoms points to the use of cognitive behaviour therapy and social skills training.

Conclusions:

- Clinical identification and characterization of negative symptoms is crucial when treating patients with schizophrenia, as these are associated with important disability and poorer functional outcomes.
- Differentiation of primary and secondary negative symptoms is a key aspect in the evaluation and management of schizophrenic patients.
- This case outlines the coexistence of positive and negative symptoms, and illustrates the challenges in the pharmacological and psychotherapeutic management of these symptoms at a Psychosis Day Hospital.

Mental illness as a poor prognosis factor in cancer treatment: a review of the difficulties in diagnosing and treating cancer in patients with schizophrenia based on a clinical case

F. Santos Martins^{1,2,3*} and R. Malta¹

¹Department of Psychiatry, Centro Hospitalar Universitário S. João (CHUSJ); ²CINTESIS and ³Neurosciences and Mental Health Department, Faculdade de Medicina da Universidade do Porto (FMUP), Porto, Portugal

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1518

Introduction: Psychiatric patients, and schizophrenia patients in particular, have a lower average life expectancy than the general population, and the high prevalence of physical illnesses contributes to this. In the case of cancer, the incidence seems to be the same or lower compared to the general population, but on the other, the prognosis is frankly worse.

Objectives: We aim to collect evidence about the relationship between cancer and schizophrenia.

Methods: Based on a clinical case of a patient diagnosed with schizophrenia who died of an occult neoplasm, we conducted a narrative review of the literature concerning cancer screening, incidence, mortality and prognosis in patients with schizophrenia.

Results: A 39-year-old male patient was diagnosed with schizophrenia when he was 26 years older. The patient was single, had no children, lived alone and was retired due to his psychiatric condition. He was admitted to the inpatient ward in January 2023 due to a psychotic relapse after abandoning the prescribed treatment. He remained hospitalised for 14 days, and oral and injectable antipsychotic therapy was reinstated. He was discharged to the psychiatric day hospital unit to promote psychosocial rehabilitation. During this period, he complained about unspecified back pain but did not present any other physical symptoms.

Two months later, he was evaluated by his psychiatrist as an outpatient, and his general condition had become significantly poorer. He had lost over 20 kilograms, his skin was pale, and he complained of back pain. He was referred to an internal medicine consultation. Still, before it was scheduled, he came to the emergency department and was admitted due to digestive bleeding, asthenia and low back pain, with a weight loss of around 25 kilograms.

An abdominal mass was palpated on physical examination, and the chest x-ray showed a "balloon drop" pattern, indicating pulmonary metastases. Two days after being admitted to the internal medicine ward, he died of cardiac arrest.

It is known that the stigma that mentally ill patients suffer often contributes to a delay in diagnosing medical illnesses. In addition, frequent social isolation and poor social family support do not help these patients seek medical care when their physical condition deteriorates. Low adherence to cancer screening and avoidance of routine health care often add to this delay.

Conclusions: As physicians who often deal with individuals with severe mental illnesses, psychiatrists should be extra aware of risk factors and keep a heightened suspicion of medical conditions. They should also promote the adoption of beneficial health behaviours and encourage participation in cancer screening and other relevant health programs.

EPV0922

Evaluation of clinical and sociodemographic characteristics of hospitalised patients with schizophrenia spectrum disorder

H. R. Demirel*, E. Yıldız, S. N. İspir and M. Aydın

Psychiatry, Selçuk University Faculty Of Medicine, Konya, Türkiye

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1519

Introduction: Schizophrenia and other psychotic disorders are disorders in which the individual's assessment of reality is impaired and which progress with exacerbations and become chronic, leading to disability, loss of function, social communication problems and frequent hospitalisations.

Objectives: The aim of our study was to evaluate the clinical and sociodemographic data of patients followed up in the outpatient clinic for psychotic disorders and hospitalized at least once in any time during their treatment.

Methods: The sample of the present study consisted of patients who were followed up in the psychotic disorders outpatient clinic of Selçuk University Faculty of Medicine Hospital and who were hospitalised at least once. Patients were identified by retrospective file search and those with sufficient information about their sociodemographic-clinical characteristics were included. The study approved by the ethics committee of Selçuk University Faculty of Medicine.

Results: Of the 130 patients, 52 (40%) were female and 78 (60%) were male; mean age was 40.8 ± 12.0 years. Almost half of the patients ($n=53$, 40.8%) had primary school education. 73 (59.2%) of 130 patients were receiving long-acting antipsychotic medication. 100 patients (76.9%) were using oral antipsychotics. 63 out of 100 patients were on clozapine. 22 of 63 patients used clozapine as monotherapy. The mean duration of untreated psychosis ($n=90$) was 15.8 ± 32.1 months. The mean number of hospitalisations was 3.4 ± 2.5 . 15 patients (11.5%) were lived in a nursing home. The mean number of hospitalisations of patients receiving long-acting treatment (3.8 ± 2.9) was significantly higher than that of patients receiving oral treatment only (2.7 ± 1.6) ($p=0.004$). There was no significant difference in the mean number of hospitalisations when comparing according to the presence of clozapine in the treatment ($p>0.05$).

Conclusions: The primary goal in the treatment of patients with schizophrenia is to prevent relapses, hospital admissions and improve patients' quality of life and functioning. Therefore, the variables related to hospitalisations, which are an indirect indicator of the frequency of psychotic episodes, should be well evaluated. Our study was mainly descriptive and evaluated the relationship between several parameters and hospitalisations. It was thought that the high number of hospitalisations in patients on long-acting treatment might be related to the fact that long-acting treatment in our country is mostly started in the late stages of the disease. Large-sample studies of predictive parameters are needed to prevent psychotic episodes and reduce the number of hospitalisations.

Impact of negative signs on therapeutic compliance in patients with schizophrenia

H. Ballouk*, H. boukidi, K. taleb, S. belbachir and A. ouanass

Ar-Razi university psychiatric hospital, Salé, Morocco

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1520

Introduction: Schizophrenia is characterized by a heterogeneous clinical expression. Schizophrenic symptoms fall into three main

dimensions: positive, negative, and disorganized. Negative symptoms may be primary or secondary to positive symptoms.

Therapeutic compliance is essential in the management of mental illnesses and in particular schizophrenia. The associations between poor compliance and negative symptomatology are little studied even though it is found in several patients suffering from schizophrenia and is associated with a poor functional prognosis.

Objectives: The objective of this study is to evaluate the link between negative symptoms and medication adherence in patients with schizophrenia.

Methods: This is a cross-sectional study with a descriptive and analytical aim carried out among patients in whom a diagnosis of schizophrenia was made according to the diagnostic criteria of the DSM-5.

Data will be collected using an anonymous hetero-questionnaire including patients' personal and sociodemographic data, as well as the negative symptoms subscale of the PANSS and Medication Adherence Rating Scale (MARS) which assesses therapeutic compliance.

Results: In total, we obtained a sample of 109 patients. The median age of the population is 37 years (± 8.2), the age varies between 18 and 64 years. The majority of patients were single, i.e. 79.6%. On average, patients had good compliance with the MARS with a mean score of 6.3 ± 1.9 [0;10]. A negative correlation between the negative symptoms subscale of the PANSS and the MARS was found significant ($p=0.003$), with a moderate effect.

Conclusions: This study showed that the negative signs of schizophrenia have an impact on therapeutic compliance. Therefore, it would be useful to enlarge the sample and study this association in depth in order to be able to improve these signs to ensure good care and better quality of life for these patients.

Duration of untreated psychosis and involuntary hospitalization in first-episode psychosis

H. J. Gomes*, R. A. Moreira, J. P. Correia, E. Maldonado, J. M. Barros and J. R. Gomes

Unidade Local de Saúde do Nordeste, Bragança, Portugal

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1521

Introduction: Duration of untreated psychosis (DUP) is defined as the time between the onset of psychotic symptoms and the initiation of appropriate treatment. DUP has been the subject of intensive research to understand how it is associated with a poorer prognosis in patients with first-episode psychosis (FEP). Involuntary treatment is often necessary in the context of FEP.

Objectives: To characterize the relationship between the duration of untreated psychosis (DUP) and the type of hospitalization (voluntary versus involuntary) in patients admitted for FEP.

Methods: We conducted a retrospective observational study, collecting data from patients admitted between January 2019 and December 2022, in the psychiatric unit at our hospital in Bragança, Portugal. We used the information recorded in the clinical records

and statistical analysis of the data was performed using the SPSS program.

Results: Over the 4-year study period, 81 patients with first-episode psychotic symptoms at admission were selected. The average age was 46.98 years, with a slight male predominance. 46.9% (n=38) were admitted involuntarily, and 53.1% (n=43) were admitted voluntarily. The average DUP was 73 days. DUP was 95.92 days for patients admitted involuntarily and 54.72 days for voluntary admission. This difference was not statistically significant.

Conclusions: There was a longer DUP in patients admitted involuntarily, although this association was not statistically significant. However, it is important to emphasize that involuntary hospitalization is frequently linked to more severe cases and poorer prognosis. Therefore, recognizing psychotic symptoms as early as possible is essential to facilitate prompt identification and effective treatment for patients experiencing their first episode of psychosis, ultimately leading to an improved prognosis.

The Relationship Between Internal Stigmatisation, Recovery and Treatment Adherence in Individuals with Schizophrenia

M. S. Keskiner¹, S. Aktaş², M. C. Aktaş¹, H. Ayhan¹ and K. Aslan^{1*}

¹Department of Psychiatric Nursing, Yüzüncü Yıl University, Faculty of Health Sciences and ²Department of Psychiatric Nursing, Health Sciences University Van Training and Research Hospital, Van, Türkiye
*Corresponding author.
doi: 10.1192/j.eurpsy.2024.1522

Introduction: Schizophrenia has a clinical course that has a great negative impact on the daily life of the person due to the cognitive and social problems it causes. Internalised stigmatisation is a very common negative phenomenon in individuals diagnosed with schizophrenia. It is known that treatment adherence is low in schizophrenia patients with high levels of internalised stigma. Lack of adequate treatment adherence in these patients is a negative factor in terms of recovery. Reducing the level of internal stigmatisation and reinforcing treatment adherence in schizophrenia has a positive effect on recovery. Considering this situation, it is important to determine the relationship between internal stigmatisation, treatment adherence and recovery in schizophrenia patients. In the literature review, there were no studies in which the relationship between internal stigmatisation, recovery and treatment adherence in individuals diagnosed with schizophrenia was carried out together.

Objectives: In this study, it was aimed to fill the existing gap in the relevant field and to be a resource for further intervention programmes.

Methods: The study was planned as descriptive. The sample of the study consisted of individuals diagnosed with schizophrenia aged 18 years and over who met the inclusion criteria and accepted to participate in the study by purposive sampling method. In the power analysis, the sample number was calculated as (N=80) with a margin of error of 0.5. Personal information form, Internalised Stigma Scale in Mental Illness (ISMI), Recovery Assessment Scale

(RAS) and Medication Adherence Rating Scale (MARS) were used for data collection. IBM SPSS 27.0 package programme was used for statistical analysis.

Results: The data are still being analysed in detail by the researchers. The findings and relational results of the study will be presented.

Conclusions: It is thought that the results of the study will contribute to the reporting of the relationship between intrinsic stigma, recovery and treatment adherence in individuals diagnosed with schizophrenia, and by revealing the relationship between the variables, it is thought that it will be a source for planning interventions that will increase the treatment adherence and recovery perceptions of schizophrenia patients and reduce their intrinsic stigma.

Experience with 6-month paliperidone palmitate in a mental health center: descriptive study in real clinical practice

I. Garcia Del Castillo^{1*}, A. P. Balaguer¹, B. G. Esteban¹, M. V.-B. García del Castillo¹, H. V.-H. García del Castillo², S. Castelao-Almodovar², A. Arce de la Riva² and F. Neira Serrano³

¹Psychiatry, El Escorial Hospital, El Escorial; ²Psychiatry, Puerta de Hierro University Hospital and ³Statistics, Francisco de Vitoria University, Madrid, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1523

Introduction: Extensive evidence supports that the use of long-acting injectable antipsychotics (LAIs) reduces the risk of relapses and maintains functional and symptomatic improvements in patients with schizophrenia, both in the initial stages and in chronic cases. Several LAIs are available but paliperidone palmitate is the only antipsychotic with formulations lasting 3 (PP3M) and 6 (PP6M) months. Longer-duration LAIs achieve stable treatment with fewer injections. Recent studies with PP3M support a reduction in hospitalizations and emergency room visits compared to monthly paliperidone and aripiprazole or oral antipsychotics.

PP6M seems to be at least as effective and well tolerated as other LAIs in preventing relapses in previously stabilized patients with schizophrenia.

Objectives: to assess efficacy and tolerability of PP6M in a real clinical practice compared to previous treatment (oral antipsychotics or other LAIs)

Methods: Patients with a diagnosis of psychotic disorder and treatment with PP6M have been recruited consecutively in a Mental Health Centre in the Community of Madrid (Spain). Clinical stability (CGI and emergency visits and hospitalizations since the start of treatment), tolerability (adverse effects), functionality (PSP scale) and satisfaction with treatment (TMSQ scale) have been studied.

Results: 16 patients were included throughout the first 6 months of treatment with PP6M treated at a CSM in the Community (CSM) of Madrid, of which 2 abandoned the study. Among the 14 patients included, aged between 26 and 60 years, 13 had a diagnosis of

schizophrenia and one of schizoaffective disorder (according to DSM5). No significant adverse effects were recorded, except for pain at the injection site. The majority were psychopathologically stable patients - 2 of them of recent onset (up to 36 months of evolution) and 7 psychopathological decompensations, measured as visits to the emergency room or psychiatric readmissions, have been detected during the first 6 months of follow-up in CSM. All patients had previously been admitted to treatment with PP6M (minimum 1 admission, maximum 20 admissions). The results of the baseline scores obtained on the psychometric scales applied were: CGI (15.35/35), PSP (62.78/100) and TMSQ (53.35/80).

Conclusions: The existing scientific evidence to date indicates that the application of PP6M is giving safe results in the first months of follow-up, with few side effects recorded, and a low rate of decompensations. This study based on data from real clinical practice in a CSM, despite the limitation due to the small sample size, obtains similar results consistent with those described in previous clinical trials.

Catatonic stupor in 32 years old man diagnosed with schizotypal disorder

I. Ljutica^{1*}, Z. B. Otasevic² and D. Otasevic³

¹Psychiatric Clinic, Clinical Center of Montenegro; ²Dusa, Filipovic policlinic and ³Dusa, Dusa, Podgorica, Montenegro

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1524

Introduction: Stupor is a state of numbness of almost all personality functions, accompanied by stiffness, lethargy and abulia (lethargy). A person in a state of stupor is recognized by the fact that he is constantly silent, does not respond to stimuli at all, refuses food, has a motionless body posture, a face immobile like a mask, a gloomy and absent look. We can call a person who is in a stupor only by calling loudly, shaking hard and similar charms. Catatonic stupor is a state of complete loss of spontaneous and active movement, the patient stands stiffly for hours, sits, does not take food, does not speak but registers everything that is happening around him because his consciousness is not clouded.

Objectives: Here, we report on the case of a 32 year-old man. He was brought in the Emergency Center by his mother with the eyes shut and unresponsive to all sorts of verbal and gestural attempts to elicit any kind of response, with extreme complete body rigidity. He was sweating.

Over several weeks, he developed gradually social withdrawal, motoric stereotypies, loss of appetite, body stiffness. Three days before he was admitted to the hospital he stopped eating, drinking water, he was developed body rigidity.

Methods: Case report

Results: He was admitted to a Psychiatric Clinic and first days he was treated with 7,5 mg of lorazepam daily, kariprazin tbl. a 3mg in the morning and olanzapine 10 mg in the evening. Over several days symptoms has diminished.

Conclusions: The patient was reacted very well on the therapy and after several days symptoms diminished. After a month he was released from the hospital. He is in good remission for over a year. He comes regularly for outpatient check-ups

Metabolic syndrome in psychiatric patients with schizophrenia

I. Bakija^{1*}, M. Tripković², S. Kaštelan³, M. Bogadi⁴ and V. Grošić¹

¹Department of Integrative Psychiatry, Psychiatry Clinic Sveti Ivan;

²Department of Psychiatry and Psychological Medicine, University Hospital Centre Zagreb;

³Department of ophthalmology, Clinical Hospital Dubrava and ⁴Psychiatric Hospital for children and adolescents, Zagreb, Croatia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1525

Introduction: Metabolic syndrome and cardiovascular diseases are a very important cause of morbidity and mortality among patients with schizophrenia who live an average of 10-20 years less than the general population. Second generation antipsychotics are associated with obesity and other components of the metabolic syndrome.

Objectives: The aim of this paper was to provide complete insight into the existing recent evidence for metabolic risks associated with the use of new antipsychotics, and establish recommendations for monitoring metabolic syndrome and other risks, as well as current options for treatment and prevention of metabolic syndrome.

Methods: This review article is based on a literature search. We identified relevant publications and articles by searching the PUBMED database from 1999 to the present day according to the given parameters. The search criteria were the keywords "metabolic syndrome" combined with "schizophrenia" and "new antipsychotics".

Results: All researches has convincingly shown that patients with schizophrenia tend to be overweight and have a three to four times higher risk of developing diabetes than the general population. There are also more and more evidence in recent literature about the impact of new antipsychotics on the frequency of metabolic syndrome in patients with schizophrenia. The World Health Organization (WHO) defines metabolic syndrome as an elevated insulin level or a fasting glucose concentration of 5.6-6.0 mmol/l in combination with two or more of the following parameters: abdominal or central obesity and dyslipidemia and/or arterial hypertension. The research results systematically showed a 1.5 to 3 times higher frequency of metabolic syndrome in people suffering from schizophrenia compared to the general population. Therefore, regular control of all components of the metabolic syndrome is necessary, from waist circumference, which is the easiest to measure, to all others that can be carried out and done in the general practice doctor's office.

Conclusions: Metabolic changes in patients with schizophrenia who receive new antipsychotics in addition to their unfavorable lifestyle (improper diet, lack of physical activity, smoking) can lead to the development of metabolic syndrome and increase the risk for diabetes and cardiovascular diseases. It is therefore necessary to establish protocols for monitoring these risks and preventing comorbidities.

The Challenge of Lorazepam Failure: Malignant Catatonia Treated Successfully with Valproate

J. Kim^{1*}, E. Garrels², A. Zamiri², K. Tran² and A. Francis³

¹Psychiatry; ²Bronxcare Health System, Bronx and ³Penn State College of Medicine, Hershey, United States

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1526

Introduction: Despite the unclear nature of catatonia, the treatment response of catatonia to benzodiazepines is widely known for its typical, dramatic recovery. The neurobiological correlates of this phenomenon regarding specific receptors and neurotransmitters are unclear, as are the potential treatment options. This is important to consider when the most commonly recommended treatments of catatonia with Lorazepam or Electroconvulsive Therapy (ECT) are unavailable or unsuccessful. In this report, we describe a case of severe, malignant catatonia and psychosis mostly unresponsive to Lorazepam during two different hospitalizations, but with eventual return to baseline after successful treatment with Valproate.

Objectives:

- To describe a unique case of malignant catatonia that was unresponsive to Lorazepam
- To illustrate the potential utility of Valproate as an alternative treatment strategy for catatonia

Methods: This is a case report.

Results: A 19-year-old Hispanic male presented to our hospital initially with family reports of severe and sudden depression with bizarre behavior. Prior to this admission, the patient had been discharged recently from another tertiary hospital following a 2-week admission for severe catatonia. Chart review from that admission scored the patient's Bush-Francis Catatonia Rating Scale (BFCRS) at 16, which remained mostly unchanged after numerous additional intramuscular doses and standing oral doses of Lorazepam, with a reduction of BFCRS the next day of only 2. During the patient's admission at our hospital, the patient endorsed bizarre, guilt-related delusions, and his catatonia was more severe and malignant with a BFCRS of 19, with tachycardia and diaphoresis. The patient was initially given a total of seven doses of a mix of intramuscular and oral Lorazepam (total 18mg), with a minimal 2-point reduction in BFCRS. As ECT was unavailable, Lorazepam was discontinued in favor of a trial of oral Valproate 500mg twice daily, and after his catatonia subsided (with a serum level of 60.8),

he was started on oral Risperidone 0.5mg once at night, titrated up to 3mg twice daily, and eventually returned to baseline as confirmed by his family members.

Conclusions: The treatment of catatonia with Lorazepam is usually reliable and has been found to be up to 80% effective, but when the recommended use of benzodiazepines and ECT fail or are unavailable, there are few studies exploring the viability of alternative treatment options. With the use of Valproate, previous studies have shown it can treat even severe catatonia (Krüger, J Neuropsychiatry 2001; 13:303-304), or can actually be its cause (Lauterbach, Neuropsychiatry, Neuropsychology, and Behavioral Neurology. 1998 Jul;11(3):157-163). As such, this case report highlights the importance of exploring alternative treatments for catatonia, including Valproate, in order to better tailor the management of this unique syndrome.

Artificial intelligence and virtual reality applied to the clinical care of women with schizophrenia: A systematic review.

J. P. Paolini San Miguel^{1*}, M. Natividad¹, M. V. Seeman², B. Palacios³, A. Balagué¹, E. Román¹, N. Bague¹, E. Izquierdo¹, H. Cachinero¹, J. A. Monreal¹ and A. González Rodríguez¹

¹Mental Health, Mutua Terrassa University Hospital. University of Barcelona, Terrassa, Spain; ²Psychiatry, University of Toronto, Toronto, Canada and ³Clinical and Health Psychology, Autonomous University of the State of Morelos, Morelos, Mexico

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1527

Introduction: Artificial intelligence (AI) and virtual reality (VR) are useful tools that can improve precision medicine and can prove useful in the clinical care of patients with psychosis.

Objectives: Our aim was to determine whether AI and VR have been applied to the prediction of clinical response in women with schizophrenia.

Methods: A systematic review was carried out in PubMed and Scopus from inception to September 2023 by using the PRISMA guidelines. Search terms: ("artificial intelligence" OR "intelligent support" OR "machine intelligence" OR "machine learning" OR "virtual reality" OR "intelligent agent" OR "neural networks" OR "virtual reality" OR "digital twins") AND ("schizophrenia" OR "psychosis") AND ("women" OR gender). Inclusion criteria: 1) English, French, German or Spanish language, 2) reporting treatment response in schizophrenia (as long as information in women was included), and 3) including AI and VR techniques.

Results: From a total of 320 abstracts initially screened (PubMed:182, Scopus:138), we selected 6 studies that met criteria.

- Prediction of treatment response. (1) Clinical information, genetic risk score and proxy methylation score have been shown to improve prediction models. (2) Graph-theory-based measures have been combined with machine learning.
- Therapeutic drug monitoring. (1) A machine learning model has been useful in predicting quetiapine blood concentrations.

- Pharmacovigilance. (1) Machine learning has connected prolactin levels and response in olanzapine-treated patients. (Zhu et al., 2022).
- Treatment-resistant schizophrenia (TRS). (1) Women with TRS have been found to receive clozapine less frequently than men (adjusted for sociodemographic, biological and clinical factors). (2) Statistical learning approach: Women have been found to respond better to clozapine than men.

Conclusions: AI, including machine learning, show promising results in the prediction of treatment response in women with schizophrenia. As of yet, digital twins have not been investigated to test specific interventions or to personalize treatment in women with schizophrenia.

EPV0932

Differential diagnosis of acute psychosis after cocaine consumption: a case report

J. Gimillo Bonaque*, E. Arroyo Sánchez, P. Setién Preciados and C. Díaz Mayoral

Psychiatry, Hospital Príncipe de Asturias, Alcalá de Henares, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1528

Introduction: Psychosis is a common clinical presentation of mental disorder in many psychiatric patients, however, an etiological diagnosis is important when it occurs for the first time in a patient. Regarding a case seen in the Emergency Department recently, with major depression and acute cocaine use, a differential diagnosis was made after adequate organic screening. When presenting delusion of infestation after the consumption of the substance, the main hypothesis was what we call Ekblom syndrome. However, among other possibilities we consider a toxic psychosis or a major depression with psychotic symptoms.

Objectives: Review the different causes of acute psychosis and the importance of a good clinical history to achieve a specific diagnosis. Perform a differential diagnosis between the main causes of psychosis in a patient with depression who has recently consumed cocaine.

Methods: Presentation of the case and review of the available literature on the risk of developing psychosis after cocaine use and depression concomitantly.

Results: There is a low number of reported cases of delusional infestation after acute cocaine use, being more likely toxic psychosis or major depression with psychotic symptoms. A good anamnesis, with systematic questions about toxic habits, can lead us to a more accurate main hypothesis.

Conclusions: We mark the importance of a systematic anamnesis to achieve a better diagnosis, as well as a correct study by the clinician of the specific syndromes described in phenomenology such as Ekblom syndrome, to make a correct association of ideas in the differential diagnosis.

Disclosure of Interest: None Declared

Paliperidone LAI-Induced Leukocytopenia: A Case Report

K. Laškarin^{1*}, K. Matic^{1,2}, S. Vuk Pisk^{1,2}, M. Grah^{1,2}, V. Grošić^{1,2} and I. Filipčić^{1,2,3}

¹University Psychiatric Hospital "Sveti Ivan", Zagreb; ²Faculty of Dental Medicine and Health "Josip Juraj Strossmayer" University of Osijek, Osijek and ³School of Medicine, University of Zagreb, Zagreb, Croatia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1529

Introduction: Antipsychotics effectively manage psychotic symptoms but may have side effects. Patients with schizophrenia often lack insight into their condition, leading to nonadherence. Long-acting injectable (LAI) antipsychotics aim to overcome this, reducing relapse risks. Paliperidone LAI, a second-generation antipsychotic, has a lower side effect profile when compared to first-generation counterparts. Blood dyscrasias, like neutropenia and lymphopenia, increase infection susceptibility. This case report describes an instance of leukocytopenia arising during paliperidone LAI treatment, which quickly resolved after the discontinuation of the medication.

Objectives: This case report describes an instance of leukocytopenia arising during paliperidone LAI treatment, which quickly resolved after the discontinuation of the medication.

Methods:

Results: CASE

A 42-year-old female with schizophrenia, nonadherent to previously prescribed medication was admitted to our acute psychiatric department. She experienced positive symptoms (paranoid delusions), as well as disorganized thinking and behavior. Oral risperidone 4 mg two times a day was recommenced and titrated with mild improvement in her psychotic symptoms with the idea of switching to paliperidone LAI and eventually ceasing oral medication. Oral paliperidone was unavailable for prescription due to local restrictions. At admission her routine laboratory tests showed no abnormalities, but 5 days after receiving paliperidone LAI, routine laboratory tests showed a strong decrease in her WBC and absolute neutrophilic and lymphocytic count (Lkc $2.89 \times 10^9/L$, Neut $1.57 \times 10^9/L$, Lym $0.88 \times 10^9/L$). Antipsychotic-induced blood dyscrasia was suspected and paliperidone depot was discontinued. The patient had rapid improvement in her WBC reaching the reference range in 10 days (Lkc $4.23 \times 10^9/L$, Neut $2.51 \times 10^9/L$, Lym $0.98 \times 10^9/L$). Sertindole was introduced considering her history of a good therapeutic response to the drug, with improvement in psychotic symptoms. She is currently stable taking sertindole 16 mg/day, clonazepam 2 mg/day and alprazolam 0.5 mg/day.

DISCUSSION

The onset of neutropenia and lymphopenia post-paliperidone LAI initiation, resolving in 10 days, indicate a direct association. Few cases report to date describe paliperidone-induced leukocytopenia, with rapid recovery post-discontinuation. Proposed mechanisms include bone marrow suppression and peripheral WBC destruction. It has been proposed that drug-induced neutropenia is often dose-dependent, which could explain why our patient exhibited tolerability to risperidone but developed cytopenia upon transitioning to depot paliperidone.

Conclusions: While cases of agranulocytosis have been reported in association with the use of other antipsychotics these antipsychotics do not require the same monitoring as clozapine. Our case emphasizes the need for vigilant blood dyscrasia monitoring during antipsychotic therapy.

Sleep Matters: Unpacking the Link between Sleep Disorders and Clinical Characteristics in Schizophrenia.

K. Razki*, A. Larnaout, C. Najar, S. Ben Aissa, R. Iansari and W. melki

Psychiatry department, razi hospital, manouba, Tunisia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1530

Introduction: Sleep disorders are a significant concern for patients with schizophrenia, and they can have a profound impact on their quality of life. Studies have shown that sleep disturbances are prevalent in patients with schizophrenia, and they may be linked to the clinical characteristics of the disorder. Despite this, the exact nature of the relationship between sleep disorders and schizophrenia remains unclear. Understanding this relationship is critical as it may lead to better diagnosis and treatment of both conditions, ultimately improving the overall health and wellbeing of patients.

Objectives: To establish the link between sleep disorders and clinical characteristics in a clinical population being treated for schizophrenia.

Methods: We conducted a cross-sectional, descriptive, and analytical study that took place over a period of one month (from 1st to 31st March 2023) among patients consulting the post-care service of Psychiatry Department D at Razi Hospital, Tunisia. We included patients aged between 18 and 65 years, diagnosed with schizophrenia according to DSM-5, and stabilized on psychiatric treatment. We used the Pittsburgh Sleep Quality Index (PSQI) to evaluate sleep quality over a period of one month. The evaluation of the clinical characteristics of schizophrenia was carried out using the Positive and Negative Syndrome Scale (PANSS).

The interview was conducted by a single researcher, and when the questionnaire was distributed to the participants, we explained the framework and the principle of this study as well as the implications of participating in it and explained that the participant could stop participating at any time if he or she wished.

Results: We collected data from 30 male patients with a mean age of 42.5 ± 14.02 . The mean overall PSQI score was 9.23 ± 4.58 . The subscales evaluating the subjective quality of sleep obtained an average score of 1.42 ± 0.72 , sleep latency was 1.61 ± 1.33 , sleep duration was 1.01 ± 0.98 , habitual sleep efficiency was 0.67 ± 0.75 , sleep disturbances were 0.91 ± 0.52 , sleep medication use was 1.36 ± 1.68 , and daytime dysfunction was 1.12 ± 0.96 . The mean scores of PANSS were: positive scale (28.26 ± 5.93), negative scale (18 ± 6.15), and general psychopathology scale (90.03 ± 16.21). We found a statistically significant association between the positive

PANSS scale and sleep latency ($p=0.002$) and sleep medication use ($p<0.003$).

Conclusions: The findings highlight the importance of evaluating and addressing sleep disturbances in the overall management of patients with schizophrenia, as they may have an impact on the severity of clinical symptoms.

An underestimated link: a study of eating disorders in patients followed for schizophrenia

K. Razki*, A. Larnaout, S. Ben Aissa, C. Najar, R. Iansari and W. melki

Psychiatry department, Razi hospital, manouba, Tunisia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1531

Introduction: Schizophrenia is a debilitating mental illness that can cause significant disruptions in a person's life, leading to difficulty with thinking, emotions, and behaviors. While the symptoms of schizophrenia are well-known and extensively studied, comorbidities like eating disorders are often overlooked and undertreated, despite their prevalence in patients with schizophrenia.

Objectives: determine the different eating attitudes among schizophrenic patients and establish the link between eating attitudes, age, weight status, and psychotropic medication.

Methods: This is a cross-sectional and descriptive study that took place from September to November 2022 among patients who consulted the post-care consultations of Psychiatry D service at Razi Hospital, Tunisia. We included patients who had been followed for at least one year for schizophrenia according to the diagnostic criteria of DSM-V and who had not relapsed for at least 2 months. The collection of sociodemographic and clinical data was done retrospectively by referring to the patients' clinical records. Anthropometric measurements (weight, height, waist circumference, etc.) were recorded for each participant at the end of the interview. The Three-Factor Eating Questionnaire (TFEQ) was used to analyze eating attitudes.

Results: According to our results among 30 patients followed for schizophrenia, 74% were men with a mean age of 45 years (3.8). Sixty percent of the participants had a BMI <18.5 , 35% had a BMI between 18.5 and 25, and the rest had a BMI greater than 25. on the therapeutic level, 12 patients were on olanzapine, 15 patients were on risperidone and the rest were on haloperidol. The TFEQ score shows that uncontrolled eating was the most prevalent attitude in our population. A statistically positive association was found between uncontrolled eating and the use of olanzapine ($p<0.05$).

Conclusions: Our study contributes to draw the attention of mental health professionals to the screening of eating disorders in patients followed for long term mental disorders and insists on multidisciplinary management to ensure a better quality of life for patients.

CPAN - A novel transdiagnostic dimensional approach to the assessment of psychotic disorders

L. Hermán*, J. M. Réthelyi, J. Tolna, E. Komoróczy,
I. B. Császár and M. Baradits

Department of Psychiatry and Psychotherapy, Semmelweis University,
Budapest, Hungary

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1532

Introduction: Classification of mental disorders evolved greatly over time, as DSM and ICD dominated both research and everyday practice in the past decades. DSM-5 was planned to represent biological features of psychiatric disorders and include results of genetic and imaging studies in the criteria. Unfortunately, this goal couldn't be fulfilled, since, although there were promising results, evidence wasn't strong enough to fully support the biological background of the currently used diagnostic categories. One possible explanation for this discrepancy is that biological disturbances don't represent the somewhat artificial categorisation of these disorders. Many of the leading symptoms in psychotic disorders are nowadays considered as lying on a spectrum, such as autism, affective and psychotic spectrum disorders. Despite that, DSM-5 still describes schizophrenia, schizoaffective disorder and bipolar disorder as separate entities, however there can be major overlaps in the leading symptoms, moreover symptoms are not necessarily stable over time and can show fluctuations. It should be mentioned though that subgroups of schizophrenia in DSM-5 had been abolished and catatonia is considered as a trans-diagnostic specifier, moreover in ICD-11 certain symptoms can be added as symptoms specifiers to an existing diagnosis of primary psychotic disorder.

Objectives: Our aim was to establish a new trans-diagnostic, dimensional scale to assess the most important symptoms amongst patients with psychotic disorders. This scale is meant to represent the long-term clinical presentation and not a cross-sectional picture of a current state. We believe that long-term trajectories of these symptoms may be more connected to underlying biological features, such as genetic load (i.e. polygenic risk scores) and imaging results than the currently used diagnostic criteria. We think it is very important to create a tool, which is straightforward and short enough, so can be realistically used in everyday clinical work. This could provide important real-life data, which give us information about our patients from a different angle than the currently used diagnostic systems.

Methods: We have created the CPAN scale based on the current symptom specifiers of ICD-11 and the Clinician-Rated Dimensions of Psychosis Symptom Severity, which is an "emerging measure" for DSM-5 and also took into consideration our own clinical experience.

Results: The new tool measures 4 symptoms (catatonia, psychosis, affective symptoms and negative symptoms) on a scale of 5 (0-4). We have also put in specifiers to be able to characterize patients more precisely, and output measures (suicidal risk, functionality) to open the way for further analysis.

Conclusions: We tried to establish a novel symptom scale to help assessing patients with psychotic symptoms in everyday clinical work. Our plan is to test the validity of CPAN in the near future.

Ultra-High-Risk that do not transition to psychosis. What happens?

M. B. Ruas Resende*, F. Agostinho, R. Nogueira, D. Cotovio,
F. A. Silva and R. Lousada

Psychiatry, Hospital Beatriz Ângelo, Lisbon, Portugal

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1533

Introduction: Speaking prospectively we use the concept of "at risk mental state" (ARMS) to describe the state in which a person has a heightened risk of developing a psychotic disorder. Young people who are experiencing ARMS can be more precisely defined as being at ultra-high-risk of psychosis using a specific set of criteria known as the UHR criteria.

Objectives: To clarify the concept of ultra-high-risk individuals and to characterize the clinical and functional characteristics and general psychopathology of those individuals that do not transition to psychosis during the follow-up period.

Methods: Research on UpToDate using the terms "Ultra-High-Risk"; "psychosis"; "transition".

Results: Recent literature has suggested that less than 30% of those who meet established criteria for being at Clinical-High-Risk of psychosis (CHR-P) go on to develop a psychotic illness. It is therefore of crucial importance and relevance to assess and clarify what happens to high-risk individuals who do not transition to psychosis, who make up the vast majority.

One of the most recent studies (NAPLS-2) that encompassed 764 of CHR-P individuals who were followed for 2 years, concluded that 278 did not transition to psychosis during the follow-up period. Three clinical outcomes were recorded: 1 group had experienced a psychopathological remission (39.57%); the other kept symptomatic but not currently meeting criteria for a prodromal risk syndrome (33.45%); the third group had a prodromal progression (26.98%). The study concluded among others that although the remission group had improved social functioning at 2 years compared with the other groups, they were still functioning below the healthy control group.

Another meta-analysis that included a total of 2756 CHR-P individuals with a mean duration of follow-up of 30.7 months evaluated several clinical outcomes in CHR-P that didn't transitioned to psychosis and between CHR-P non-transitioning versus those transitioning to psychosis. It concluded that CHR-P that do not transition to psychosis have an overall improvement of symptoms (APS, negative, depressive) and functioning at follow-up compared to baseline.

Conclusions: The occurrence of a first psychotic episode is often devastating for the patient and their family, especially given its usual onset in adolescence and early adulthood. This is a critical period in the individual's development as a person, and disorders at this stage can threaten the potential for a productive and inclusive adult life. Studies have suggested that less than 30% of individuals classified as UHR actually develop a psychotic disorder.

However, little is known about the individuals belonging to this group who do not transition to psychosis. We therefore consider it is relevant to clarify the clinical and functional outcomes of this group of individuals.

Somatic comorbidities in patients with schizophrenia

N. Boussaid¹, M. Turki², M. Barkallah^{1*}, A. Labyadh¹,
N. Halouani¹, S. Ellouze¹ and J. Aloulou¹

¹psychiatrie B and ²psychiatrie, CHU hedi Chaker, Sfax, Tunisia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1534

Introduction: Patients with schizophrenia have shown a high mortality rate, and life expectancy is shortened by 10-20 years. This seems to be mainly caused by metabolic and cardiovascular diseases. Several risk factors are identified, including sedentary lifestyle, poor diet, low socioeconomic status, cognitive dysfunction, and antipsychotics iatrogenicity.

Objectives: We aimed to explore somatic pathologies reported in patients with schizophrenia, and to assess risk factors predisposing to these impairments.

Methods: We conducted a retrospective descriptive and analytical study, based on clinical and psychiatric observations of 60 patients with schizophrenia, hospitalized in psychiatry "B" department, Hedi Chaker university hospital (Sfax, Tunisia), during the period between 2015 and 2017.

Results: Among our patients, 38.3% suffered from somatic comorbidities: diabetes (21.7%), hypertension (15%), coronary disease (15%), hyperlipidaemia (15%), respiratory diseases (6.7%).

Tobacco consumption was reported in 53.3% of patients. It was significantly associated with the occurrence of cardiovascular diseases ($p=0.036$). Alcohol abuse was noted in 16.7%, while obesity was reported in 6.7% of patients.

Significant associations were found between obesity and diabetes ($p=0.001$), and between organic diseases and cognitive disorganization ($p=0.022$). Somatic comorbidities were more frequent in patients with low socio-economic level ($p=0.015$).

Among our patients, 83.3% were treated with conventional antipsychotics while 38.3% were treated with atypical antipsychotics (AAP). We showed that AAP were associated with the occurrence of organic diseases ($p=0.037$).

Conclusions: Physical health of patients with schizophrenia requires a serious attention. Coordinated care between psychiatrists and other healthcare professionals should monitor the physical health of these patients to prevent a premature death.

Sexual activity and sexual dysfunction in patients with schizophrenia at the Arrazi psychiatric hospital in Salé

N. Ait Bensaid*, Y. Bensalah, H. Boukidi and F. El Omari

Psychiatric hospital Arrazi, salé, Morocco

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1535

Introduction: Sexuality is a natural component of human behavior. Sexual health is "a physical, emotional, mental and social state related to sexuality; it is not merely the absence of disease, dysfunction or infirmity. Sexual dysfunction and poor quality of sex life are

common in patients with schizophrenia. The prevalence of sexual dysfunction is higher in people with mental disorders, and may be related to psychopathology and pharmacotherapy.

Objectives: Evaluate sexual activity, sexual dysfunction and its consequences in patients with schizophrenia followed and hospitalized in the various structures of the Arrazi psychiatric hospital in Salé.

Methods: This is a descriptive cross-sectional study using a questionnaire including sociodemographic and clinical criteria, data on sexual behavior and the Arizona Sexual Experience Scale (ASEX) to assess sexual activity, sexual dysfunction and its consequences in patients with schizophrenia followed and hospitalized in the various structures of the Arrazi psychiatric hospital in Salé. Inclusion criteria: patients of both sexes diagnosed with schizophrenia according to DSM 5 criteria, age greater than or equal to 20 years. Exclusion criteria: intellectual disability, general medical condition known to cause sexual dysfunction (diabetes mellitus, history of vascular accident, congestive heart failure, unstable heart condition, arrhythmia or myocardial infarction in the last six months).

Results: We collected 157 participants. 81% of the participants were men, 67% of whom had left school at college. The majority of patients were born in the city. 85% were unemployed. 89% were heterosexual and 77% were single. 92% smoked cigarettes. 66% had schizophrenia for more than 5 years with 55% having poor adherence to antipsychotics with around 65% on atypical antipsychotics. Around 42% reported currently having sexual relations. 56% of participants had sexual dysfunction, and 67% were dissatisfied with the quality of their sexual relations.

Conclusions: Sexual dysfunction is prevalent in schizophrenic patients, and these problems can be linked to both the illness and its treatment. Sexual dysfunction is also an important factor in therapeutic compliance, which is strongly influenced by the side effects of antipsychotics. It is therefore necessary to know more about the sexual side-effects of medication on patients, and doctors should also systematically ask patients about their sexual history before prescribing psychotropic drugs.

Improving the Sexual Wellbeing of Patients with Psychotic Illness

N. Stanton*, E. Angova and K. Diamantopoulos

General Adult Psychiatry, Central & North West London NHS Foundation Trust, London, United Kingdom

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1536

Introduction: Sexual dysfunction (SD) is common in psychotic illness including schizophrenia, occurring in 30-82% of patients. It negatively impacts wellbeing and antipsychotic compliance, resulting in higher risk of relapse and hospitalisation. Due to over-reliance on spontaneous reports from patients, SD is typically under-identified which prevents investigation and treatment.

Objectives: To establish whether SD is under-identified in patients with psychosis in a general adult community mental health team; to elicit whether the Arizona Sexual Experience Scale (ASEX)

improves identification; to investigate and manage identified cases of SD; to make recommendations about identification and monitoring of SD in this patient population.

Methods: A 12-month retrospective audit of patients with psychosis prescribed a long-acting injectable (LAI) antipsychotic ($n=36$) to identify sexual symptoms was completed. The ASEX was subsequently issued to screen for SD.

Results: Audit: 3/36 (8%) patients had documented sexual symptoms. Of the 18/36 patients that completed the ASEX: 10 (56%) exhibited SD. 4 consented to further investigation. 5 patients experienced significant difficulties with the language used in the ASEX. At the end of the project we revised the ASEX with simpler, colloquial language.

Conclusions: Implementation of the ASEX results in clear improvements in identification and monitoring of SD. Maudsley Practice Guidelines can inform investigation and management of SD. We suggest a review of NICE guidance to incorporate the above into clinical practice. Further work is needed to establish whether the revised ASEX can be developed and validated.

EPV0946

Male gynecomastia linked to antipsychotics: a case report

O. Martin-Santiago^{1*}, P. Martinez.Gimeno¹, M. Calvo-Valcarcel¹, C. Alario-Ruiz¹ and B. Arribas-Simon¹

¹Hospital Clinico Universitario, Valladolid, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1537

Introduction: Gynecomastia refers to the abnormal development of breast tissue in males, often posing a concerning symptom. Often, gynecomastia is associated with multiple factors, including the use of various drugs, notably certain atypical antipsychotics. Gynecomastia is a significant side effect that affects the quality of life of male patients taking antipsychotic medications. Among these, risperidone and paliperidone have been identified as the most prone to causing gynecomastia, although aripiprazole has garnered attention for its superior profile in controlling prolactin and gynecomastia. The relationship between these drugs and the development of gynecomastia lies in their ability to elevate prolactin levels, a hormone that regulates reproductive function and is involved in milk production. Several studies have shown that prolactin levels are more commonly elevated with risperidone and paliperidone prescription, thus triggering gynecomastia.

Objectives: The study aims to investigate the management of gynecomastia in male patients receiving antipsychotic medications.

Methods: This research employs a retrospective analysis of patient records to examine the association between specific antipsychotic drugs, prolactin levels, and the development of gynecomastia, while also evaluating the effectiveness of aripiprazole as an alternative treatment.

Results: We present the case of a 21-year-old male with no prior medical history who initiated treatment with oral paliperidone and later switched to 100 mg of long-acting injectable paliperidone once

monthly during his initial admission for psychotic symptoms. After six months, he developed gynecomastia, which was ruled out as breast tissue and was determined to be an increase in adipose tissue. Since his hospital discharge, he has gained 25 kg (30%) in body weight, and his baseline prolactin level has decreased. This weight gain, a common side effect of several antipsychotics, was linked to gynecomastia. However, a promising approach for gynecomastia antipsychotic-associated treatment is aripiprazole, which has a milder impact on prolactin levels. In this case, during the next appointment, a switch to 400 mg of long-acting injectable aripiprazole once-monthly was made, which led to weight loss, a reduction in breast size and blood prolactin levels in the following weeks.

Conclusions: The detection and management of gynecomastia in these patients are crucial to improving their quality of life and treatment adherence. This management encompasses changes in medication, hormonal therapy, or surgery in severe cases. Physicians must be aware of this potential complication when prescribing antipsychotics and closely monitor at-risk patients. In summary, antipsychotic-associated gynecomastia in men represents a medical challenge that requires careful attention and an individualized treatment strategy for each affected patient.

The role of cannabis and salience alterations in determining the severity of psychotic symptoms: a multi-centric, cross-sectional study on adolescent and adult cohorts

O. Baccaredda Boy¹, G. P. Merola¹, A. Patti¹, I. Fascina¹, B. Bozza¹, D. Flaccomio¹, M. Faldi¹, G. Pitt¹, I. Noschese¹, L. Papini¹, D. Brugnolo¹, C. Ricci^{1*}, V. Pecoraro¹, A. Ballerini¹, V. Ricca¹, F. Mauceri¹, G. Peroni¹, S. Tavano¹, T. Pisano¹, F. De Cesaris¹, S. Gori¹ and D. Cohen²

¹University of Florence, Florence, Italy and ²Department of Pitié Salpêtrière, University of Sorbonne, Paris, France

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1538

Introduction: The aim of this project is to study to which extent salience alterations influence the severity of psychotic symptoms. However, rather than studying them individually, we decided to focus on their interplay with two additional variables, that is: observing their effect in a vulnerability phase (adolescence) and with another added, well-recognized risk factor (cannabis use).

The reason for this study design lies in the fact that, in our opinion, it is fundamental to observe the trajectory of psychotic symptoms over a continuum; however, rather than adopting a longitudinal approach, we decided to structure it as a cross-sectional study confronting patients from two age brackets - adolescence and adulthood.

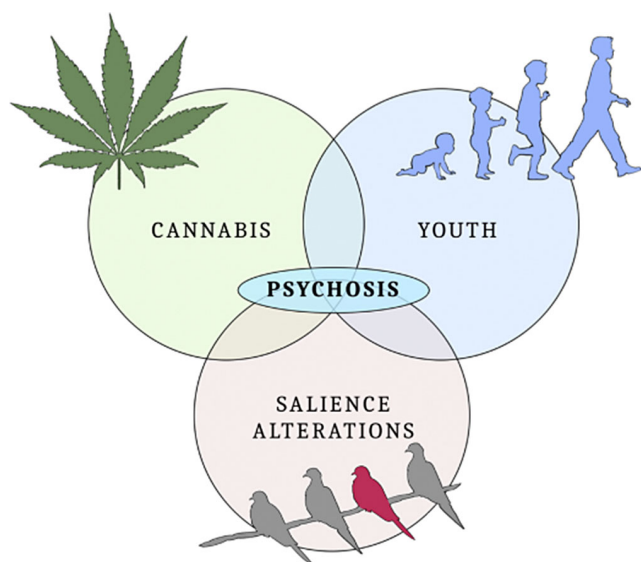

Objectives: The primary purpose of this study was to assess a difference between THC-abusing and non-abusing patients in adolescent and adult cohorts, using the Italian version of the psychometric scale "Aberrant Salience Inventory" (ASI), and the possible

correlation with more severe psychotic symptoms. The employment of several different psychometric scales and the inclusion of a variegated cohort allowed to pursue multiple secondary objectives.

Methods: We recruited 192 patients, subsequently divided into six subgroups based on age and department of recruitment (whether adolescent or adult psychiatric or neurologic units - the latter serving as controls). Each individual was administered a set of questionnaires and a socio-demographic survey; the set included: Aberrant Salience Inventory (ASI), Community Assessment of Psychic Experiences (CAPE), Positive and Negative Syndrome Scale (PANSS), Montgomery-Asberg Depression Rating Scale (MADRS), Mania Rating Scale (MRS), Hamilton Anxiety Scale (HAM-A), Association for Methodology and Documentation in Psychiatry (AMDP) and Cannabis Experience Questionnaire (CEQ).

Results: The data analysis showed statistically significant ($p < 0.05$) differences between adolescents and adults with psychotic symptoms in all of the three scales of PANSS and in MADRS. These two groups were homogenous for both cannabis use and ASI score. The intra-group comparison (either adolescent or adult) showed a hierarchical pattern in the scores of psychometric scales according to the diagnostic subgroup of allocation: patients with psychotic symptoms showed a higher level of psychopathology in all measures when compared to patients from the psychiatric unit without psychotic symptoms, which in turn scored higher than the patients from the neurologic unit.

Image:

Conclusions: The results of the present study may suggest that when salience alterations occur in adolescents with cannabis exposure, we might observe worsened positive and negative psychotic symptoms; their influence might be relevant also in other domains, especially regarding the depressive and anxiety spectrums.

“God speaks to me through a dove”. The evidence of clozapine in treatment-refractory psychosis

B. Rodríguez Rodríguez¹, P. Marqués Cabezas^{1*}, M. Queipo de Llano de La Viuda¹, N. Navarro Barriga¹, G. Guerra Valera¹, M. B. Arribas Simón¹, C. Alario Ruiz¹, M. J. Mateos Sexmero¹, M. Fernández Lozano¹, P. Marín Gimeno¹, M. Calvo Valcárcel¹, M. A. Andreo Vidal¹, M. P. Pando Fernández¹, A. Monllor Lazarraga¹, M. Ríos Vaquero¹, G. Lorenzo Chapate¹, L. Rojas Vázquez¹, C. De Andrés Lobo¹, T. Jiménez Aparicio² and M. D. C. Vallecillo Adame¹

¹Psiquiatría, Hospital Clínico Universitario de Valladolid, Valladolid and ²Psiquiatría, Hospital Clínico Universitario de Valladolid, Valladolid, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1539

Introduction: Clozapine is an atypical antipsychotic synthesised in 1958. It was withdrawn from the market in the 1970s due to the appearance of agranulocytosis, but was reintroduced due to strong evidence of its efficacy and superiority over other antipsychotics in treatment-resistant schizophrenia.

Objectives: To describe the adequate response to clozapine in treatment-refractory psychosis.

Methods: Review of the scientific literature based on a relevant clinical case.

Results: A 16-year-old woman was admitted to a psychiatric inpatient unit for psychotic symptoms and behavioural disorders. She lives with her father and older sister; she has not been in contact with her mother, who lives in another country, for several years. She attends secondary school, with poor academic performance. Maternal diagnosis of schizophrenia. She started using cannabis two years ago, with a progressive increase up to 20 grams per week. He reports the onset of a feeling of strangeness a year ago, with progressive isolation in his room, referring to delirious ideation of harm towards classmates and people from his town, self-referentiality and delirious interpretations of religious mystical content (“God speaks to me through a dove”). He comments on the phenomenon of theft and thought-reading. Soliloquies and unmotivated laughter are observed.

Conclusions: Treatment was started with risperidone, progressively increasing the dose up to optimisation, without achieving a decrease in positive symptoms, but with the appearance of excessive sedation and sialorrhoea. It was combined with aripiprazole up to 20mg, maintained for a couple of weeks, without significant clinical improvement. Given the failure of two lines of therapy, it was decided to change to clozapine up to a dose of 75mg, with adequate tolerance and response, achieving a distancing of the delirious ideation. Regular haematological controls were performed, with no alterations in haemogram or troponins.

²Psychiatric Unit. School of Medicine, University of Salamanca;

³PRINT, Biomedical Research Institute (IBSAL), Salamanca;

⁴Psychiatric Service, University of Valladolid Healthcare Complex, Valladolid and ⁵Biomedical Research Institute (IBSAL), Salamanca, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1540

Introduction: Contrary to classical belief, people affected by this disease are at greater risk of developing organic pathologies. This risk has a very complex origin: a greater exposure to risk factors and specific socioeconomic conditions, a high prevalence of risk behaviors, the use of antipsychotics, and a potential common genetic background. (Reynolds *et al.* Int. J. Neuropsychopharmacol. 2021; 24 854–855, Suvisaari *J et al.* Curr Diab Rep. 2016 16). Multiple studies demonstrate that Schizophrenia confers a high endogenous risk of Diabetes. Before patients diagnosed with Schizophrenia start taking antipsychotics (Andreassen OA *et al.* Am J Psychiatry. 2017;174 616–617), they have an approximately 3 times higher risk of developing Diabetes compared to the general population. The risk increases 3.6 times after the initiation of antipsychotic treatment compared to drug naive patients (Annamalai A *et al.* World J Diabetes. 2017 390–396)

Objectives: To study the association between Schizophrenia or other Psychotic Disorders and Diabetes Mellitus in a sample of patients diagnosed with Schizophrenia or other Psychotic Disorders.

Methods: This is a Descriptive and Cross-sectional Observational Study. Clinical Histories were reviewed and a personal or telephone interview was established to expand data related to the objectives of the study. The patients were recruited among the patients seen in the specific Severe Mental Disorder consultation who had a diagnosis of schizophrenia or other Psychotic Disorders, according to DSM 5-TR criteria.

Results: From a sample of 93 patients, 24 had Diabetes. The Prevalence of Diabetes in patients with Schizophrenia or other Psychotic Disorders was 25.8%. Of the patients without a diagnosis of Diabetes, 15 of them had values of Glycosylated Hemoglobin (HbA1c) for Prediabetes. Using the Chi-Square Test, statistically significant differences were found between the variable Main Psychiatric Medication and Diabetes. Patients treated with Clozapine, Aripiprazole and Olanzapine had a Prevalence of Diabetes of 40.9%, 33.3% and 28.5%, respectively.

Conclusions: Prevalence of Diabetes in our sample was 3.4 times higher than the 7.51% of the general population in Spain. This presumes a significant importance and impact on the health of these patients. The diabetic patients in our sample were diagnosed with Diabetes years after the diagnosis of the mental illness, which seems to indicate that the causes have to do with lifestyle, dietary

habits, weight, and exposure to chronic antipsychotics. Premature death in schizophrenia has several explanations, being of special importance the development of cardiovascular disorders and Diabetes. This can be due to many reasons, but it is worth highlighting the metabolic side effects of some antipsychotics and lifestyle. In this sense, it is essential to carefully monitor this group of patients.

Grading of Recommendations of psychological interventions in the rehabilitation of patients with schizophrenia

R. Vazquez-Noguerol Mendez*, S. Garcia Pineiro, P. G. S. Perez, M. Puime Miguez, C. Cinos Galan, M. J. Veiga Candan, M. Suarez Baldomir and M. Soriano Garcia

SERGAS, Vigo, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1541

Introduction: As part of the intervention, patients with severe schizophrenia who are cared for in psychiatric rehabilitation units need psychological treatments. However, there is great variability within the psychotherapy alternatives that are proposed for rehabilitation in schizophrenia, and it is necessary to know which are the most efficient interventions in order to prioritize their inclusion in intervention programs.

Objectives: To know the level of evidence of the existing psychotherapy alternatives for the rehabilitation treatment in schizophrenia through the systematic review of recently published studies.

Methods: Consecutive systematic searches in the scientific literature were used in a sensitive and specific way, aimed at identifying the existence of documents in databases and clinical practice guidelines based on evidence of psychological treatment in schizophrenia. Psychosocial and social approaches and family members interventions were excluded, and the search was limited to the last 5 years. The PICO format has been used, and a subsequent critical reading using the AGREE II tool, considering the inclusion criteria of presenting a score >60% in 4 domains.

Results: The following interventions have been found to be therapeutically effective: Level 1B (Early intervention in Psychosis; Patient and Family psychoeducational intervention; Basic and social skills training; Social cognition and Metakognition training; Cognitive Remediation; Cognitive Behavioral Individual Therapy; Assertive Community treatment; Supported employment). Level 2B (Family Problem Solving Therapy, Dynamic Psychotherapy; Cognitive Behavioral Group Therapy); Level 2C (Horticultural, Art, Music, Animals Therapies).

Conclusions: Several psychotherapy alternatives are proposed for rehabilitation in schizophrenia, with known level of evidence in order to prioritize their inclusion in intervention programs.

Disclosure of Interest: None Declared

Schizophreniform disorder. Clinical manifestations and diagnosis. Purposely a case

S. M. Bañón González^{1*}, N. Ogando Portilla¹, B. Gamero Bravo¹, M. E. González Laynez², N. Sekade Gutiérrez¹ and F. García Sánchez³

¹Hospital Universitario Infanta Sofía, Madrid; ²Hospital Universitario de Toledo, Toledo and ³Hospital Universitario de Móstoles, Madrid, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1542

Introduction: Schizophreniform Disorder is described pretty similar to schizophrenia, but with the difference of the symptoms duration which have to last for at least 1 month but less than 6 months. Patients have to be back at their baseline functional level once the disorder has resolved. This is a heterogeneous group of patients who have either a disorder similar to schizophrenia or something closer to a mood disorder.

Objectives: To analyze clinical, psychopathological and epidemiological characteristics of schizophreniform disorder and also review causes, incidence, prevalence, diagnostic, therapeutic tools and the importance of maintaining the treatment, because of the abandonment of the treatment, which is a predictor of relapses.

Methods: A review of the main impact literature concerning schizophreniform disorder is done during the last five years: prevalence, incidence, pathogenesis and its relationship with other psychiatric disorders encoded in DSM-V are studied.

Results: The etiology is unknown. Psychotic symptoms can be treated with antipsychotics for 3 to 6 months. They usually respond faster than patients with schizophrenia (75% vs 20% respond within 8 days).

Conclusions: The disease has a favorable prognosis, and has similarities with mood disorders. However, some data suggest a close relationship to schizophrenia. In support of the relationship with mood disorders, patients have more affective symptoms and a better outcome than patients with schizophrenia.

Disclosure of Interest: None Declared

EPV0953

'De Novo' Psychosis following anterior temporal lobectomy: A case report

S. Yoldas^{1*}, I. Yıldırım¹, N. G. Usta Sağlam¹ and Ç. Özkara²

¹Psychiatry and ²Neurology, Istanbul University-Cerrahpasa, Cerrahpasa Faculty of Medicine, Istanbul, Türkiye

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1543

Introduction: Surgical treatments for people living with epilepsy have the potential to provide patients with an opportunity to achieve relief from seizures, thus improving their quality of life, but they are not free of complications. The psychiatric consequences are a significant concern because of the potential risks; however, psychotic illnesses have not received adequate research compared to anxiety and depression.

Objectives: To better identify the psychiatric side effects that can develop following epilepsy surgery, especially psychosis, and to take preventive measures to mitigate its occurrence.

Methods: Presentation of a patient's case and reviewing existing literature regarding de novo psychosis following epileptic surgery.

Results: The case of interest is a 31-year-old male patient who, or his relatives, has had no history of psychiatric disorders. From age 21, the patient had focal to bilateral seizures, which were preceded by olfactory auras and could occur up to 4-5 times a week and was then diagnosed with epilepsy. In June 2021, the patient underwent a right anterior temporal lobectomy for his medically resistant seizures after a presurgical evaluation and had a notable decrease in the number of seizures, occurring only during periods of sleep every six months. In the fourth month following the operation, the patient began experiencing auditory hallucinations characterized by negative and judgmental voices. After that, he engaged in an aggressive act by holding a knife and assaulting another person in a public area. He was admitted to an inpatient psychiatry service for 12 days with a diagnosis of a psychotic episode. His symptoms significantly improved, and he was discharged with paliperidone 6 mg/daily treatment. After five months, he discontinued the medication, subsequently experiencing a recurrence of auditory hallucinations and aggression. The patient was admitted to the inpatient psychiatric clinic in June 2022 as a result of experiencing paranoid delusions and engaging in a suicide attempt by self-inflicted wrist laceration using a razor blade, which was consistent with the patient's delusional beliefs. Following 13 days of hospitalization, he was discharged with amisulpride 800 mg/daily in addition to his antiepileptic treatment. After 15 months of discharge, he showed no signs of active psychotic features, and his functioning was moderate to good.

Conclusions: Current research and reporting of psychiatric outcomes are limited, and the predictive factors and prognosis of psychiatric symptoms in these patients remain obscure. Long-term follow-up is crucial, especially considering the possibility of psychiatric symptoms developing in the months following surgery, as demonstrated by the current case. In addition, preoperative and postoperative assessments may facilitate the management of psychiatric symptoms.

Menstrual Psychosis with Premenstrual Onset: A case presentation

S. Turkan^{1*}, E. Kara², R. S. İlhan¹, S. Yalcın Sahiner¹ and M. C. Saka¹

¹Psychiatry and ²Child and Adolescent Psychiatry, Ankara University, Ankara, Türkiye

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1544

Introduction: Menstrual psychosis has an acute onset and is characterised by confusion, stupor and mutism, delusions, hallucinations, or a manic syndrome lasting for a brief duration, with full recovery. These symptoms maintain periodicity in rhythm with the menstrual cycle. The symptoms may appear in the premenstrual phase or may begin with the onset of menstrual flow (catamenial

psychoses). Usually, menstrual psychosis has a polymorphism of both psychotic and affective symptoms (Brockington I. Menstrual psychosis. *World Psychiatry*. 2005;4(1):9-17.). In this article we present a case of menstrual psychosis with premenstrual onset.

Objectives: A 26 years old, nulliparous single female with one mentally ill relative on her mother's side (her grandmother) presented with an episodic illness characterized by mood swings, irrelevant speech, irritability, suspiciousness and thought disorder related to her menstrual cycles. She had earlier suffered prolonged attacks of mania, developed a recurrent episodic illness which returned every month for five years. Her menses began at 15. She presented with the history of a few episodes of manic illness starting five days before and ending suddenly with the onset of the menses.

Methods: On mental status evaluation during the index episode, the patient was agitated, had labile affect, grandiose and referential delusions and erotomania. A detailed physical examination, routine biochemistry, and gonadal hormonal assay were unremarkable.

Results: She was started on olanzapine 10 mg/day, lithium 1200 mg/day and low-dose clonazepam. Although the severity of the psychotic and affective symptoms gradually reduced during the future menstrual cycles, they did not completely resolve.

Conclusions: The pathophysiology of menstrual psychosis is not exactly understood, but it has been postulated that fluctuation of the sex hormones occurring during the menstrual cycle is responsible. Previous studies have reported the association of psychosis with estrogen withdrawal (Mahé V, Dumaine A. Oestrogen withdrawal associated psychoses. *Acta Psychiatr Scand*. 2001;104(5):323-331.). Treatment strategies for menstrual psychosis include the use of oral contraceptive pills for the regulation of hormones during the menstrual cycle, in our case patient did not want to use oral contraceptive pills.

From childhood trauma to psychosis: Investigating the attachment link

S. Walha*, I. Chaari, F. Guermazi, I. Dhouib, L. Aribi, F. Charfeddine, N. Mseddi and J. Aloulou

Psychiatry « B » department, Hedi Chaker University Hospital, Sfax, Tunisia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1545

Introduction: Childhood trauma encompasses instances of sexual, physical, and emotional abuse, along with neglect experienced during childhood and adolescence. Individuals with psychosis, particularly those with schizophrenia, exhibit a heightened prevalence of childhood trauma. One potential mediator in understanding this connection is insecure attachment.

Objectives: This study aimed to better understand how childhood trauma relates to schizophrenia by examining two aspects of attachment: attachment anxiety and attachment avoidance.

Methods: We conducted a descriptive and analytical cross-sectional study among stabilized female patients with schizophrenia or schizoaffective disorder, in the 'B' psychiatry department at Hedi Chaker University Hospital in Sfax, Tunisia, from May to June 2023. We administered the 26-item Revised Psychosis Attachment

Measure (PAM_R) questionnaire, translated into Arabic, to assess attachment. Additionally, participants completed the 28-item Childhood Trauma Questionnaire (CTQ). We used both the Wilcoxon test for paired samples and the Spearman correlation test to assess the statistical differences and correlations.

Results: We included 41 female patients, of which 65.9% had schizophrenia and 34.2% had schizoaffective disorder. The average age of the participants was 49.19 years. Among the attachment styles, avoidant attachment was the most prevalent (60.97%), followed by anxious attachment (24.39%), and disorganized attachment (14.63%). Regarding childhood trauma, the average total score on the Childhood Trauma Questionnaire (CTQ) was 56.34. Specifically, 39% of patients reported experiencing physical abuse, 24.4% reported sexual abuse, 14.6% reported emotional abuse, and 4.9% reported physical neglect. The Spearman correlation analysis between avoidant attachment and scores on the Childhood Trauma Questionnaire (CTQ) yielded a diverse set of findings. It indicated a significant positive correlation with physical abuse ($p = 0.004$, $p < 0.001$), a significant negative correlation with emotional abuse ($p = -0.045$, $p < 0.001$), a significant positive correlation with sexual abuse ($p = 0.036$, $p < 0.001$), a significant negative correlation with physical neglect ($p = -0.083$, $p < 0.001$), a significant negative correlation with emotional neglect ($p = -0.047$, $p < 0.001$), and a significant positive correlation with denial ($p = 0.080$, $p < 0.001$). On the other hand, the Spearman correlation analysis between anxious attachment and scores on the CTQ showed varying correlations: a significant positive correlation with physical abuse ($p = 0.094$, $p < 0.001$) and sexual abuse ($p < 0.0001$, $p = 0.05$).

Conclusions: Our findings indicate that individuals with an insecure attachment style and a history of childhood trauma should be considered a high-risk group, necessitating early clinical intervention, continuous monitoring, and personalized therapeutic approaches designed to alleviate the psychological effects of trauma.

Attachment styles in Tunisian women with schizophrenia

S. Walha*, I. Chaari, M. Sehli, A. Abdelhedi, L. Aribi, F. Charfeddine, N. Mseddi and J. Aloulou

Psychiatry « B » department, Hedi Chaker University Hospital, Sfax, Tunisia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1546

Introduction: Attachment refers to the emotional bond between a child and their primary caregiver, reflecting the child's confidence in the caregiver's capacity to offer security. Evaluating attachment styles in individuals with schizophrenia spectrum disorders holds significance in pinpointing a potential factor affecting therapeutic relationships. This, in turn, indirectly aids in comprehending the emergence of low adherence as a significant barrier to schizophrenia

Objectives: The goal of this study is to assess attachment styles in women with schizophrenia spectrum disorders.

Methods: We conducted a descriptive and analytical cross-sectional study at the Psychiatry “B” department of Hedi Chaker University Hospital in Sfax, Tunisia, during May and June 2023. Our study involved stabilized female patients diagnosed with either schizophrenia or schizoaffective disorder. We utilized the 26-item Revised Psychosis Attachment Measure (PAM_R) questionnaire translated into Arabic and the Positive and Negative Syndrome Scale (PANSS) score to assess schizophrenic symptoms.

Results: We enrolled a total of 41 female patients in our study, with 65.9% diagnosed with schizophrenia and 34.2% with schizoaffective disorder. The average age of the participants was 49.19 years, ranging from 17 to 79 years old. In terms of attachment styles, avoidant attachment was the most prevalent (60.97%), followed by anxious attachment (24.39%), and disorganized attachment (14.63%). Our study revealed significant associations between avoidant attachment and several factors. Patients who began psychiatric follow-up with hospitalization had a significantly higher level of avoidant attachment compared to those starting with outpatient consultation ($p < 0.001$). The type of therapy also influenced avoidant attachment, with a significant difference ($p < 0.001$). Insight into their condition also played a significant role ($p < 0.001$). Moreover, the age at which psychiatric follow-up began showed a statistically significant correlation with avoidant attachment (Spearman's $\rho = 0.000$, $p < 0.001$). Individuals with higher avoidant attachment tended to have a longer duration of untreated psychosis, supported by a statistically significant positive correlation (Spearman's $\rho = 0.082$, $p < 0.001$). There was also a statistically significant relationship between avoidant attachment and the equivalent dose of chlorpromazine, with a positive correlation (Spearman's $\rho = 0.091$, $p < 0.001$), indicating that individuals with higher avoidant attachment may require higher equivalent doses of chlorpromazine. Finally, higher levels of avoidant attachment were associated with a lower presence of positive symptoms in schizophrenia (Spearman's $\rho = -0.026$, $p < 0.001$).

Conclusions: Insecure attachment is a valuable mechanism for understanding the evolution of schizophrenia spectrum phenomenology and may be a useful target for prophylactic interventions.

Identifying Challenges in Social Functioning Among Women with Schizophrenia

S. Walha*, I. Chaari, A. Samet, C. Ben Ghanem, L. Aribi, F. Charfeddine, N. Mseddi and J. Aloulou

Psychiatry « B » department, Hedi Chaker University Hospital, Sfax, Tunisia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1547

Introduction: Schizophrenia spectrum disorders profoundly impacts social functioning, affecting interpersonal relationships, work interactions, and self-care. This disorder often leads to cognitive, perceptual, motor, and emotional challenges that result in social withdrawal.

Objectives: The aim of the study is to identify the specific challenges in social functioning faced by women diagnosed with schizophrenia spectrum disorders.

Methods: We conducted a descriptive cross-sectional study among stabilized female patients with schizophrenia or schizoaffective disorder, in the ‘B’ psychiatry department at Hedi Chaker University Hospital in Sfax, Tunisia, from May to June 2023. We collected both sociodemographic and clinical data from the participants. The Social Functioning Scale (SFS) and Global Functioning Scale (EGF) were used to assess social and global functioning, respectively.

Results: Forty-one patients were included: 65.9% had schizophrenia, and 34.2% had schizoaffective disorder. The mean age was 49.19 years, ranging from 17 to 79 years. More than a third (39%) of our patients had significant impairment in global functioning ($EGF < 50$). The average total score on the social functioning scale was 13.65, with a range from 6.29 to 20.29. Additionally, 39% of our patients exhibited low social functioning, and 51.21% had a high withdrawal score. The most impacted domains were leisure (63.41%) and employment (60.97%), followed by interpersonal behavior (58.53%), prosocial activities (48.78%), independence competence (41.46%), and lastly, independence performance (36.85%).

Conclusions: Social skills training is crucial for enabling women with schizophrenia to function well in their environment.

Disclosure of Interest: None Declared

Prevalence of Childhood Trauma Among Women with Schizophrenia: A Cross-Sectional Study

S. Walha*, I. Chaari, R. Ben Jmaa, A. Ksentini, L. Aribi, F. Charfeddine, N. Mseddi and J. Aloulou

Psychiatry « B » department, Hedi Chaker University Hospital, Sfax, Tunisia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1548

Introduction: Schizophrenia is a complex and multifactorial disorder believed to arise from the interplay between genetic factors and environmental influences. Among these environmental factors, childhood trauma stands out as a significant contributor to the onset of schizophrenia in adulthood.

Objectives: The objective of this study was to assess the occurrence rates of physical, emotional, and sexual abuse, as well as physical and emotional neglect in a group of Tunisian women diagnosed with schizophrenia spectrum disorders.

Methods: We conducted a descriptive cross-sectional study among stabilized female patients with schizophrenia or schizoaffective disorder, in the ‘B’ psychiatry department at Hedi Chaker University Hospital in Sfax, Tunisia, from May to June 2023. We administered the 28-item Childhood Trauma Questionnaire (CTQ).

Results: In this study, 41 female patients were enrolled, with 65.9% diagnosed with schizophrenia and 34.2% with schizoaffective disorder. The average age of participants was 49.19 years, ranging from 17 to 79. The mean score on the Childhood Trauma Questionnaire (CTQ) was 56.34, with scores ranging from 43 to 98. Emotional neglect was the most prevalent form of trauma, reported by 40 patients (97.6%). Following emotional neglect, physical abuse was found in 16 patients (39%), sexual abuse in 10 patients (24.4%), emotional abuse in 6 patients (14.6%), and physical neglect in 2 patients (4.9%).

Conclusions: Based on these findings, our recommendation is to establish government-operated facilities that offer emotional and psychological support, legal assistance, parenting guidance, and medical monitoring in collaboration with educational institutions and social and child protection services for those in need.

The Impact of Insecure Attachment on Social Functioning in Women with Schizophrenia

S. Walha*, I. Chaari, A. Mellouli, A. Samet, L. Aribi, F. Charfeddine, N. Mseddi and J. Aloulou

Psychiatry « B » department, Hedi Chaker University Hospital, Sfax, Tunisia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1549

Introduction: Attachment styles is intrinsically related to the capacity for forming close social bonds, making it a vital lens through which to understand social functioning.

Objectives: This study investigates the link between attachment styles and social functioning among women diagnosed with schizophrenia.

Methods: We carried out a descriptive and analytical cross-sectional study from May to June 2023, focusing on stabilized female patients diagnosed with schizophrenia or schizoaffective disorder. The study took place in the 'B' psychiatry department of Hedi Chaker University Hospital in Sfax, Tunisia. Data on attachment styles and social functioning were collected using self-report questionnaires: the Revised Psychosis Attachment Measure (PAM_R) and the Social Functioning Scale (SFS). In our study, we employed both the Wilcoxon test for paired samples and the Spearman correlation test to assess the differences and correlations between attachment scores and social functioning scores, respectively.

Results: In the study, 41 female patients were included. The participants had a mean age of 49.19, ranging from 19 to 79 years old. Attachment styles were predominantly avoidant (60.97%), followed by anxious (24.39%) and disorganized (14.63%). A significant portion, 39%, exhibited low social functioning. The domains most affected were leisure (63.41%) and employment (60.97%). Our analysis revealed negative correlations between avoidant attachment and social functioning in leisure activities (Spearman's $\rho = -0.057$, $p < 0.05$) as well as between avoidant attachment and independence performance (Spearman's $\rho = -0.040$, $p < 0.05$). Also, the correlation coefficient for anxious attachment and leisure activities is 0.041, demonstrating a positive association ($p < 0.005$).

Conclusions: These initial findings may imply a potential association between attachment styles and social functioning in schizophrenia.

Kretschmer's Sensitive Delusion Of Reference: Clinical Case Report

S. G. Rodrigues*, J. L. Freixo, T. Novo and D. S. Brandão

Psychiatry, Unidade Local de Saúde do Alto Minho, Viana do Castelo, Portugal

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1550

Introduction: The sensitive delusion of reference represents a clinical entity described by Kretschmer in 1918, arising in people with sensitive personality. This personality type is mainly characterized by a tendency towards social isolation, introversion, low self-esteem and by a greater sensibility to interpersonal judgement. In this personality type, the presence of specific environmental triggers may provoke a reference delusion of persecutory content, feelings of guilty and injustice. Although eliminated from the current diagnostic classifications, the sensitive delusion of reference represents a key milestone in the history of psychopathology.

Objectives: The goal of this report is to report on a clinical case of a patient diagnosed with Kretschmer's sensitive delusion of reference.

Methods: The present work consists on a descriptive report of a clinical case through consultation of the patient's clinical file as well as a survey of relevant articles on *Pubmed*.

Results: This is a 38 year old, married man with no children. He describes himself as a private, introverted individual, who has little interaction with his peers, and has been very sensitive to criticism ever since his adolescence. His first psychiatry appointment took place in April 2021, following the medical referral of his general practitioner as, according to the patient's mother and wife, he had been, for quite some time, implying that his mobile phone had been under wire and that someone had been monitoring him. As stated by these relatives, these ideas surfaced after a workplace conflict. At the time, the patient was medicated with olanzapine 10mg and lorazepam 2.5mg before bedtime, exhibiting significant improvements with full remission of psychotic symptomatology. Succeeding the antipsychotic tapering attempt, the patient had begun to suffer from insomnia and recrudescence of psychotic symptomatology, namely, the delusion ideation of persecutory content and auditory hallucinations, as a result, the previous treatment regimen was resumed, which resulted in significant improvements of the clinical picture. Following new observation, in 2023, the patient mentions weight gain and drowsiness during the day, leading to the switch of olanzapine 10mg for aripiprazole 15mg. The current treatment plan consists of aripiprazole 15mg once a day and lorazepam 1mg 1/2 before bedtime, resulting in an improvement of the previous complaints and maintenance of the psychosocial functioning, unaccompanied by psychotic symptomatology.

Conclusions: In conclusion, and relatively to the condition's prognosis, Kretschmer observed that, although in some situations the episodes were brief and self-limiting, in others, the patients maintained psychotic symptomatology, during the following years. In the present clinical case we recognised the need to sustain the antipsychotic treatment regimen, as the respective dosage reduction lead to an aggravation in symptomatology.

Clinical and cognitive factors associated to insight in first psychotic episodes

T. Gonzalez Salvador^{1*}, I. Cabello Rojano², S. Boi¹,
R. Gutierrez Labrador³ and P. R. Capilla⁴

¹Psiquiatría, Hospital Universitario Puerta de Hierro; ²Medicina Interna, Hospital Infanta Sofía; ³Psiquiatría, Hospital Universitario Infanta Sofía and ⁴Psiquiatría, Hospital La Paz, Madrid, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1551

Introduction: Insight is a field of interest in psychosis, due to its influence on the course and prognosis of the disease and as well as adherence to treatment.

Objectives: The present work aims to evaluate the influence of cognitive and psychopathological variables on awareness of illness in first psychotic episodes.

Methods: It is a cross-sectional study of a sample of 26 patients with diagnosis of a first psychotic episode admitted in a Brief Hospitalization Unit, who have been evaluated using the Positive and Negative Symptom Scale (PANSS), the Screening for Cognitive Impairment (SCIP) and the Scale of Non-awareness of Mental Disorder (SUMD).

Results: A positive correlation was found between SUMD and negative PANSS (the worse insight, the greater negative psychopathology) and between the level of cognitive performance and the awareness of having negative symptoms (affective blunting, anhedonia and associability) and their attribution to the disease.

Conclusions: This findings suggest the importance of addressing awareness of negative symptoms from the first episodes in psychoeducational family therapy and rehabilitation programs, taking into account that this process is hindered by the cognitive dysfunctions.

Spontaneous mentalizing in patients with schizophrenia – a meta-analysis

T. Csulak^{1*}, R. Herold¹, G. Berke², Z. Sipos², K. Farkas², P. Hegyi²,
T. Tényi¹ and A. Hajnal¹

¹Department of Psychiatry and Psychotherapy and ²Institute for Translational Medicine, University of Pécs, Pécs, Hungary

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1552

Introduction: Mentalizing helps us to understand the behaviour of others in our everyday social interactions. Spontaneous mentalizing without explicit instructions refers to representing mental state attribution. Several studies have described social cognitive deficit in schizophrenia, which largely determines the functional outcome of the disease.

Objectives: To better understand the involvement of spontaneous mentalizing in schizophrenia, we consider it important to summarize the results of studies that used indirect instruction to measure spontaneous mentalizing performance in schizophrenia.

Methods: In our meta-analysis, we conducted a systematic search of four large databases (MEDLINE, EMBASE, Cochrane Central Register of Controlled Trials [CENTRAL], Web of Science). A total of 14 articles were involved.

Results: Based on our findings, the performance of patients with schizophrenia is significantly weaker than in the average population for both scripts with mentalizing interactions (MD: -0.63; 95% CI (-0.90, -0.35); p=0.0021), and with goal-directed movements (SMD: -0.55; 95%CI (-0.97, -0.13); p=0.02). The intentionality of expressions used by patients with schizophrenia is significantly lower compared to the average population (for both animations with complex social interactions: MD: -0.99; 95% CI (-1.39, -0.59); p=0.0003; and with goal-directed movements: MD: -0.31; 95% CI (-0.53, -0.08); p=0.0218). We have found no significant difference neither in appropriateness nor in intentionality of verbal terms between the two groups in the case of animations with random movements.

Conclusions: Based on the meta-analysis, we found poorer performance in schizophrenia in spontaneous mentalizing. We also found poorer performance in tasks with goal-directed movements used as control tasks, suggesting a more pervasive impairment of mentalizing in schizophrenia. These deficits may affect the functional outcome of the disease and could potentially have therapeutic implications.

Disclosure of Interest: None Declared

EPV0965

The role of resilience and coping behavior in schizophrenia in the prevention of psychosis relapse

V. Mitikhin*, M. Kuzminova and L. Alieva

Department of Mental Health Services, Mental Health Research Centre, Moscow, Russian Federation

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1553

Introduction: According to scientific sources, personal resources in the form of resilience, stress coping skills play an important protective role in the prevention of psychosis recurrence. Weakening the psychological capacity of the patient and increasing stress are risk factors for psychosis.

Objectives: To study the protective role of such personal resources as resilience and coping with stress in schizophrenia, as well as the influence of negative symptomatology and psychosociorehabilitation intervention on these factors.

Methods: Clinical-psychopathological, statistical, and psychometric methods were used (Alfimova-Golimbet's resilience scale, Amirkhan's coping strategies questionnaire, and PANSS). Patients of two groups participated in the study: 1 - members of a community organization (OO), n=49, who in addition to psychopharmacotherapy were given comprehensive long-term psychosociorehabilitation (3.7±2.5 years), 2 - patients of the medical-rehabilitation department of a psychiatric hospital (MRO), n=48, in whom the psychosociorehabilitation intervention was shorter (40.3±6.5 days).

Results: The results of the study showed that significant predictors of a favorable course of the schizophrenic process were high indicators of resilience, coping behavior, and a small degree of negative

symptomatology. Analysis of the data regarding patients' coping with stress shows that constructive coping strategies are more frequent in both groups. Thus, "problem solving" (24.3 points in GS and 22.9 points in MPO) and "search for social support" (23.0 points and 22.7 points, respectively), that is patients of both groups are generally oriented to a productive way of coping with difficult situations and are ready to seek help from others in a difficult situation. Notably, the strategy of "problem avoidance" is less pronounced (18.5 points and 19.4 points, respectively). The high resilience scores in the GS group (32.5 points), comparable to the norm in the population (33.1 points), are explained by long-term comprehensive psychosociorehabilitation, while the resilience scores in the MPO group are lower - 28.7 points. Negative symptoms of schizophrenia were equally pronounced in both groups, manifested by difficulties in communication (2.6 points each), passive-apathetic social withdrawal (2.7 points each). Such negative symptoms as blunting of affect and emotional indifference were more pronounced in the MPO group - 3.2 points each vs. 2.8 points in the group from the GS.

Conclusions: High levels of resilience and ability to cope with stress as a result of psychosociorehabilitation intervention allow patients to overcome difficult life circumstances more flexibly. They are associated with less pronounced negative symptoms, which generally helps prevent psychosis relapses and contribute to a more favorable course and prognosis of schizophrenia.

EPV0966

Understanding the Complex Relationship Between Gastrointestinal Symptoms and Psychosocial Factors in Schizophrenia

W. Krzyściak^{1*}, M. Szwajca², N. Śmierciak², A. Turek² and M. Pilecki²

¹Department of Medical Diagnostics and ²Department of Child and Adolescent Psychiatry, Jagiellonian University, Medical College, Krakow, Poland

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1554

Introduction: Insensitivity to pain in schizophrenia is a complex phenomenon. Understanding schizophrenia's heterogeneity is crucial for personalized treatments.

Objectives: Individuals diagnosed with schizophrenia often experience gastrointestinal issues and exhibit elevated levels of depression and anxiety. There is an urgent need to understand how these factors interact and how childhood traumas, a significant risk factor for schizophrenia, can affect gastrointestinal symptoms in these individuals.

Methods: The study involved 51 individuals diagnosed with schizophrenia. The hierarchical cluster analysis on the principal components (HCPC) was performed to identify groups of similar observations for test scores and the overall results for 14 tests. Hierarchical clustering was performed using Ward's minimum variance method. Differences in the results of individual tests between clusters were estimated using the *V* test.

Results: The schizophrenia group was categorized into three clusters. The patients belonging to the first cluster are characterized by

high GAF test scores and low scores on tests for gastrointestinal symptoms, ITQ, CTQ, GHQ-28, STAI, CALGARY, BDI II, SAMPS, SANS, and PANNS. In contrast, patients in the second cluster had scores significantly above the group average on the tests SANS, PANNS, and SAPS and low scores on the tests DBZ RZ, CTQ, STAI, BDI II, ITQ, and GAF. Finally, patients in the third cluster had high scores on the tests BDI II, ITQ, STAI, CTQ, GHQ 28, DBZ RZ, gastrointestinal symptoms, TEC PL, CALGARY, and CISS. High CTQ scores may contribute to increased GSSR scores due to childhood trauma's potential to trigger chronic stress, affect the nervous system, and induce psychosomatic symptoms, including gastrointestinal problems. Elevated BDI II and STAI scores can also impact GSSR results by disrupting the connection between emotions and the gastrointestinal system.

Conclusions: This research underscores the intricate interplay of various psychosocial and physiological factors that influence the perception of pain related to gastrointestinal symptoms in individuals with schizophrenia.

"Folie à deux," or shared psychosis: A case report

E. Arroyo Sánchez*, P. Setién Preciados and C. Diaz Mayoral

Hospital Universitario Príncipe de Asturias, Madrid, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1555

Introduction: "Folie à deux," or shared psychosis, is a fascinating psychiatric phenomenon characterized by the transmission of delusional beliefs and psychotic symptoms from one individual (the "inducer") to another (the "recipient") who share a close emotional bond. Despite its rarity, "Folie à deux" presents unique challenges and insights into the understanding of psychosis and the intricacies of interpersonal relationships.

Objectives: The primary objective of this review is to analyze the recent clinical literature on "Folie à deux" to better comprehend its clinical presentation, diagnostic criteria, etiological factors, and therapeutic approaches. By synthesizing the latest research findings, we aim to enhance the awareness and understanding of this intriguing phenomenon among mental health professionals.

Methods: A case report of a couple of a 34-year-old male and a 43-year-old female with a shared delirium. The male was brought to the emergency department by ambulance after being found in the street with behavioral disturbances and delusional symptoms. Individual interviews with both members of the couple revealed shared delirium. He was admitted to the psychiatric ward for the clinical picture consisting of a chronic delusional disorder of years of evolution and new symptoms such as restlessness and behavioral disturbances.

Results: The review reveals that "Folie à deux" remains a rare but clinically relevant phenomenon, with reported cases spanning diverse cultural and familial contexts. Diagnostic criteria, as outlined in the DSM-5, have been useful in guiding clinicians in identifying and managing cases. The literature emphasizes the importance of a thorough psychiatric evaluation to distinguish "Folie à deux" from other psychopathological conditions. Recent

research has also shed light on potential neurobiological mechanisms and genetic factors contributing to shared psychosis. Therapeutically, early intervention and tailored treatment plans are crucial in achieving favorable outcomes. While antipsychotic medications remain a cornerstone of treatment, family therapy and psychoeducation have emerged as valuable adjunctive approaches to address the unique challenges posed by shared psychosis.

Conclusions: In conclusion, “Folie à deux” continues to be a captivating and clinically relevant phenomenon in contemporary psychiatry. This bibliographical review underscores the importance of recognizing and diagnosing shared psychosis in clinical practice. Moreover, it highlights the need for further research to unravel the underlying mechanisms and genetic predispositions associated with this condition. Ultimately, a multidisciplinary approach, including pharmacological, psychotherapeutic, and family-based interventions, holds promise in improving the prognosis of individuals affected by “Folie à deux.”

EPV0968

Ferroptosis affects cognitive dysfunction and the progression of mental illnesses

B. Nycz and K. Krysta**

Department of Rehabilitation Psychiatry, Medical University of Silesia, Katowice, Poland

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1556

Introduction: Ferroptosis is a programmed form of cell death characterized by excessive accumulation of intracellular iron fraction, uncontrolled lipid peroxidation, impairment of glutathione-dependent antioxidant functions, and loss of oxidative-antioxidant balance. Nerve cells are sensitive to excessive amounts of iron, which impairs the functioning of mitochondria and leads to their death. Ferroptosis has been identified in neurological diseases such as stroke, Alzheimer’s disease, Parkinson’s disease. Features of ferroptotic cells have been observed in models expressing cognitive deficits, and ferroptosis-related genes have been associated with the development of mental illnesses.

Objectives: The aim of the study was to analyze the available literature on the relationship between the occurrence of ferroptosis and cognitive impairment occurring in mental diseases, such as schizophrenia

Methods: The publications found in the PubMed database were analyzed after entering the following entries: ferroptosis, mental illness, cognitive functions, schizophrenia.

Results: Ferroptosis occurs in mental illnesses. Increased expression of the TP53 and VEGFA genes, which are associated with ferroptosis, has been identified in patients suffering from schizophrenia. Animal research confirms that disturbed iron homeostasis causes iron overload in nerve cells, which leads to ferroptosis and has a neurodegenerative effect, as well as deepens cognitive deficits. The use of iron chelator has a neuroprotective effect and reduces the occurrence of cognitive disorders.

Conclusions: Genes associated with ferroptosis may influence the development of schizophrenia, which means that ferroptosis may be involved in the pathophysiology of schizophrenia. Excess iron

inside nerve cells, as a feature of ferroptosis, may affect the deterioration of cognitive functioning. Administration of iron chelators protects neurons by reducing the toxic effects of iron.

Determinants of hospital length of stay for patients with schizophrenia

M. Turki, M. Barkallah*, N. Boussaid, A. labyadh, S. Ellouze, N. Halouani and J. Aloulou

Psychiatrie B, CHU Hedi Chaker, Sfax, Tunisia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1557

Introduction: relapse and frequent rehospitalizations. The length of stay (LOS) of these patients has been a concern of researchers. The ability to identify determinants of LOS at admission – and, thus, identify patients who are likely to need a longer stay early on – may help treatment planning.

Objectives: We aimed to investigate socio-demographic and clinical profile of inpatients with schizophrenia, and to identify factors associated with LOS.

Methods: It was a retrospective study carried out among 90 inpatients with schizophrenia admitted to the psychiatry “B” department, Hedi Chaker university hospital (Sfax, Tunisia), during the period between January 2015 and December 2019. Data collection was performed through the patients’ medical records. Statistical analysis was performed using SPSS v.25.

Results: The mean age of our patients was 32 years. Among them, 57.78% were women. The mean LOS was 28 days. Factors found to be significantly associated with LOS were: the number of admissions ($p < 0.001$, $r = 0.404$), involuntary hospitalization ($p = 0.001$), violence and disturbance of public order as a reason of admission ($p < 0.001$) and the lack of social support ($p = 0.039$). As for the clinical symptoms, hallucinations were significantly associated with a longer LOS ($p = 0.001$).

Conclusions: Our findings highlighted several factors associated with a longer LOS. This may be helpful to the management of hospitalization and ensuring that any periods of liberty deprivation do not last longer than necessary to provide appropriate treatment.

Hydroxychloroquine in systemic lupus erythematosus and psychosis. A case report

M. Martínez Grimal*, A. M. Morales Rivero, P. Rivero Rodríguez, E. E. Morales Castellano and N. Molina Pérez

Hospital Universitario de Gran Canaria Doctor Negrín, Las Palmas, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1558

Introduction: Hydroxychloroquine, an antimalarial drug, is an important therapeutic tool in the management of rheumatic diseases such as Systemic Lupus Erythematosus (SLE) due to its anti-inflammatory action. SLE is a chronic autoimmune inflammatory disease that affects the connective tissue of multiple organs. Neuropsychiatric disturbances in SLE are common; however, lupus psychosis is rare, occurring in 2 to 11% of patients. The literature has described the emergence of neuropsychiatric symptoms as an adverse effect of hydroxychloroquine use, with some patients experiencing clinical depression, anxiety, suicidal ideation, and psychotic symptoms.

Objectives: The aim of this work is to review the available evidence regarding neuropsychiatric symptoms secondary to the use of hydroxychloroquine.

Methods: The case of a 50-year-old woman diagnosed with SLE, with no other relevant medical history, has been evaluated. She was brought to the emergency department due to paranoid and persecutory ideas, as well as self-referentiality, coinciding with the introduction of hydroxychloroquine in her treatment. She was admitted to the University Hospital of Gran Canaria Doctor Negrín with a diagnostic orientation of a first psychotic episode.

Results: The presence of neuropsychiatric symptoms in patients diagnosed with SLE is so common that they constitute a diagnostic criterion for the disease. On the other hand, the medications used for therapeutic management of this disease can lead to the emergence of new neuropsychiatric symptoms or exacerbate preexisting neuropsychiatric clinical manifestations.

Conclusions: The study of this case highlights the challenges in establishing a differential diagnosis between primary SLE symptoms that require an increase in hydroxychloroquine and those caused by its own treatment. It underscores the need for further studies to explore the risk of psychiatric symptoms associated with the use of hydroxychloroquine, as well as its impact on the course of underlying mental disorders.

Clinical experience with once-monthly risperidone ISM in a mental health center. A retrospective study.

A. Merino Iglesias*, N. Rodríguez Ortega, L. Montero Quer and M. R. Rodríguez Campos

Psychiatry, Hospital Universitario de Fuenlabrada, Madrid, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1559

Introduction: Long-acting injectable antipsychotics have undergone a great development in recent years, becoming useful tools to facilitate therapeutic adherence. Once-monthly risperidone ISM is a new way of treatment which has been commercialized in Spain since September 2022.

Objectives: In this study we will analyze our clinical experience with this treatment, especially in terms of tolerance and efficacy, during its first year of widespread use.

Methods: Longitudinal retrospective study of monthly risperidone users in a mental health center in the Autonomous Community of Madrid (Spain), between September 2022 and September 2023.

A sample of 13 patients was selected, collecting both sociodemographic (age, gender) and clinical variables (diagnosis, dose, time elapsed, number of hospital readmissions, adverse effects and monotherapy or combined use). A descriptive analysis of the collected data was then carried out.

Results: Monthly risperidone was used in 13 patients: 15% (n=2) were women, and 85% (n=11) were male. The mean age of the patients was 43.6 years. The most frequent diagnosis of these patients was "psychotic disorders" (84,6%, n= 11), with other diagnoses such as schizoaffective disorder (7,7%, n=1) and obsessive compulsive disorder (7,7%, n=1).

The doses used of risperidone were 100mg every month in 61,5% of patients (n=8) and 75mg in 38,5% of patients (n=5). The mean time since the first administration was 4.35 months.

Concerning monotherapy, 84,6% (n=11) of patients on monthly risperidone were on antipsychotic monotherapy, while 15,4% (n=2) required more than one antipsychotic. Among the switches made to monthly risperidone, 69,2% (n=9) were previously treated with oral risperidone, 15,4% (n=2) were treated with once-biweekly risperidone long-acting injectable, 7,9% (n=1) with oral paliperidone and 7,9% with aripiprazole monthly injectable.

During the study period, hospital readmissions for psychiatric decompensations occurred in one patient (7,9%, n=1), while the rest of the patients (92,1%, n=12) did not present decompensations that required psychiatric admission.

Moderate or severe effects occurred in one patient (7,9%, n=1), in the form of acute dystonia, which led to the interruption of injectable treatment. The rest of the patients (92,1%, n=12) did not present severe adverse effects. Minor adverse effects appeared in 3 patients (25%); these adverse effects were already present in the previous treatment with oral risperidone and did not condition the suspension of the treatment.

Conclusions: In the sample analyzed, once-monthly Risperidone ISM had reasonable tolerance levels. Also, it's shown to be effective in preventing psychotic decompensations and hospital admissions. Therefore, this new injectable of monthly risperidone represents a therapeutic alternative to consider in order to guarantee therapeutic adherence and improve the quality of life of patients with psychotic symptoms.

Psychometric assessment of patients with treatment-resistant schizophrenia

V. Kaleda* and D. Tikhonov

Mental Health Research Centre, Moscow, Russian Federation

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1560

Introduction: Treatment-resistant schizophrenia (TRS) is one of the most pressing issues in the field of treatment and research of psychotic disorders. The pronounced decline in social and professional functioning in this group of patients as well as high costs of therapy determine high interest in TRS. This is a part of an ongoing study on the clinical and biological features of TRS.

Objectives: The aim of this study is to identify the leading symptoms in patients with TRS.

Methods: Using the Personal and Social Performance Scale (PSP), Positive and Negative Syndrome Scale (PANSS) and Calgary Depression Scale for schizophrenia (CDSS), 30 male patients (age 28.99 ± 8.08 years) diagnosed with paranoid schizophrenia (F20.0) were examined. All patients had persistent productive symptoms and met the criteria for TRS. The average daily doses of antipsychotics in chlorpromazine equivalent were 1382.07 ± 897.15 mg/day. The average age of onset of the disease was 19.52 ± 5.97 years, the average disease was 9.47 ± 7.61 years.

Results: The average scores were: on the PSP scale: 46.05 ± 9.17 , on the CDSS scale 8.10 ± 4.53 , on the PANSS positive symptoms subscale - 21.52 ± 4.24 , on the PANSS negative symptoms subscale - 24.67 ± 4.42 , on the general psychopathology subscale PANSS - 45.62 ± 6.11 . Positive symptoms were represented mainly by delusions (P1, 4.14 ± 0.85 points) and hallucinations (P3, 4.10 ± 1.76 points). Blunted affect (N1, 4.29 ± 0.56 points) and emotional withdrawal (N2, 3.67 ± 0.73 points) predominated among negative symptoms, while the least prominent negative symptom was poor rapport (N3, 3.24 ± 0.94). The most pronounced general psychopathology symptoms were depression (G6, 4.00 ± 1.10) and lack of judgment and insight (G12, 4.05 ± 0.92). The total score on the PANSS was 91.81 ± 12.40 .

Conclusions: The CDSS score indicates a high incidence of depressive symptoms in patients with TRS. A low PSP score reflects poor social functioning. The most common symptoms according to the PANSS are delusions, hallucinations, blunted affect, emotional withdrawal, depression and lack of judgment and insight.

Delusional parasitosis: the importance of a multidisciplinary approach

M. Calvo Valcárcel, G. Guerra Valera*, M. A. Andreo Vidal, O. Martín Santiago, M. Lorenzo Hernando, M. P. Pando Fernández, P. Martínez Gimeno, M. D. L. Á. Guillén Soto, B. Rodríguez Rodríguez, N. Navarro Barriga, M. Fernández Lozano, M. J. Mateos Sexmero, C. De Andrés Lobo, M. D. C. Vallecillo Adame, T. Jiménez Aparicio, A. Monllor Lazarraga, M. Ríos Vaquero, L. Rojas Vázquez, L. Sobrino Conde, A. Aparicio Parra and G. Lorenzo Chapatte

Psychiatry, Hospital Clínico Universitario de Valladolid., Valladolid, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1561

Introduction: Delusional parasitosis, also known as delusional infestation or Ekbom's syndrome, is a rare psychotic disorder characterized by the false belief that a parasitic skin infestation exists, despite the absence of any medical evidence to support this claim. These patients often see many physicians, so a multidisciplinary approach among clinicians is important. Many patients refuse any treatment due to their firm belief that they suffer from an infestation, not a psychiatric condition, so it is crucial to gain the trust of these patients.

Objectives: The comprehensive review of this clinical case aims to investigate Ekbom syndrome, from a historical, clinical and therapeutic perspective.

Methods: Literature review based on delusional parasitosis.

Results: A 65-year-old woman comes to the psychiatry consultation referred by her primary care physician concerned about being infested by insects that she perceives through scales on her skin for the last three months. She recognizes important impact on her functionality. She is also convinced that her family is being infected too. As psychiatric history she recognizes alcohol abuse in the past (no current consumption) and an episode of persecutory characteristics with a neighbor, more than ten years ago. On psychopathological examination, she shows delusional ideation of parasitosis, with high behavioral repercussions, cenesthetic and cotariform hallucinations, as well as feelings of helplessness and anger. Treatment with Pimozide was started and the patient was referred to dermatology for evaluation, a plan she accepted. Her primary care physician and dermatology specialist were informed about the case and the treatment plan. In the recent reviews, the patient is calmer, however, despite the corroboration of dermatology and in the absence of organic lesions in cranial CT, she is still unsatisfied with the results, remaining firm in her conviction of infestation. It was decided to start treatment with atypical neuroleptics (Aripiprazole), with progressive recovery of her previous functionality.

Conclusions: Despite the increase in the number of studies in recent years, there are still few studies on this type of delirium. The female:male ratio varies in the bibliography (between 2:1 and 3:1). The onset is usually insidious, generally appearing as a patient who comes to his primary care physician convinced of having parasites in different skin locations. It is usual to observe scratching lesions or even wounds in search of the parasite. In the past, the most used and studied treatment was Pimozide. Currently the treatment of choice is atypical neuroleptics due to their lower side effects. The latest reviews on the prognosis of this disorder show data with percentages of complete recovery between 51% and 70%, and partial responses between 16.5% and 20%. Finally, for a good diagnosis and therapeutic management, it is important to achieve a multidisciplinary approach.

From positive projection to delirium. About a case

M. V. Barea*, L. S. Rodríguez and S. C. Bailen

SAS, Jaen, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1562

Introduction: Erotomania, was described in 1942, is more common in women than in men, although the incidence is unknown. This syndrome is usually characterized by a young woman with the illusion that a man whom she considers to be of a higher social or professional position is in love with her. Developing an elaborate delusional process about this man, his love, his pursuit and total commitment to the idea. Two forms, pure or secondary, are described. As well as fixed or recurring
52-year-old female patient in outpatient follow-up with a diagnosis of schizophrenia with long-term follow-up, start of follow-up by a

new therapist, in this context intensive follow-up is carried out in the event of the appearance of pharmacological secondary effects, pharmacological readjustment is carried out with good results.

During the joint follow-up with nursing, the cessation of secondaryisms is confirmed and we are informed of the gradual appearance of overvalued ideas in relation to the new therapist, which are gradually structured in the form of erotomanic delirium that coincides with the cessation of follow-up by said therapist. Consultations in the emergency room occur on a couple of occasions due to mild behavioral alterations secondary to messages and communications that he reports receiving where said love is confirmed. Despite readjustments, there continues to be an increase in clinical symptoms due to abandonment of medication, finally producing serious alterations aimed at the search for said therapist, finally culminating in admission to the acute care unit for containment of said condition.

Objectives: The objectives is the diferencial diagnosis, in this case symptoms could be classified as positive symptoms of schizophrenia, although it is its own nosological entity.

Methods: .

Results: .

Conclusions: This patient represents a classic example of De Clerambault syndrome and is a faithful expression of the recurrent syndrome associated with delusions of grandeur, eroticism and jealousy. There have also been ideas of reference and agitated behavior associated with his delusional process.

The Course of Schizophrenia Spectrum Disorders With Episodes of Catatonic Depressions

A. Barkhatova*, M. Bolgov and A. Smolnikova

Department of endogenous mental disorders and affective states, Mental health research center, Moscow, Russian Federation

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1563

Introduction: Mood symptoms, especially depressive ones, occur in the majority of patients with schizophrenia spectrum disorders (SSD). Therefore, depression is often identified as one of the symptomatological dimensions of schizophrenia. Catatonia is also considered by some researchers as one of the dimensions of schizophrenia, or as an independent transnosological formation. Catatonia in SSD may be associated with affective dysregulation and is often accompanied by depression. Although the clinical course of SSD has been well studied previously, its relationship with psychopathological structure of episodes of SSD remains not entirely clear.

Objectives: To determine the impact of episodes of catatonic depression on the course and prognosis of SSD.

Methods: A sample of 60 patients with episodic course of SSD who met the criteria for catatonia according to the Bush-Francis Catatonia Screening Instrument (BFCSI) and for depression according to the Calgary depression schizophrenia scale (CDSS) was analyzed. An analysis of the clinical course of SSD was carried out on the basis of the medical history of all patients in the study sample and follow-up observation of 42 patients for 5 years. Global

Assessment of Functioning Scale (GAF) was used to assess the prognosis of SSD.

Results: Patients were divided into two groups depending on the period of manifestation of catatonia in the clinical course of SSD: during the first episode or during subsequent episodes. The sample of patients with the first episode (n=43, 71.7 %) was divided into three subgroups. A relatively favorable course of SSD was observed only in 13 patients (30.2 %; 21.7 % of SSD sample). The course of disorder was characterized by similar episodes with a high proportion of affective symptoms, long-term remissions and minimally expressed negative symptoms (GAF score=75.2±5.82). A relatively unfavorable course of SSD was observed in 15 patients (34.9 %; 25.0 % of SSD sample). It was characterized by moderate negative and chronic subdepressive symptoms with low frequency of catatonic and psychotic relapses (GAF score=62.3). An unfavorable course of SSD was also observed in 15 patients (34.9 %; 25.0 % of SSD sample). It was characterized by a high frequency of relapses with a tendency to form a chronic conditions with residual catatonic signs and psychotic symptoms (GAF score=50.1). In the sample of patients with manifestation of catatonia in the second or subsequent episodes (n=17; 28.3 %), the clinical course of SSD was unfavorable. It was characterized by a rapid augmenting of negative symptoms with the formation of psychomotor poverty syndrome with residual catatonic symptoms (GAF score=52.7).

Conclusions: Our study shows that the occurrence of catatonic depressive episodes in the clinical course of SSD in most cases is an unfavorable prognostic factor.

Efficacy and tolerability Aripiprazole once-monthly long-acting injectable in schizophrenia. Two-injection start regimen. A 24 months follow-up and mirror image study

S. L. Romero Guillena^{1*}, F. Gotor Sanchez-Luengo² and B. O. Plasencia Garcia de Diego³

¹Psychiatry, UGC Mental Health Virgen Macarena; ²Psychiatry, UGC Mental Health Virgen Rocio and ³Psychiatry, UGC Mental Health Virgen Rocio, Seville, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1564

Introduction: Relapse prevention is crucial in patients with schizophrenia, as repeated episodes can worsen psychopathology and functionality. There is strong evidence of antipsychotics efficacy in preventing relapse; however, non-compliance rates in patients with schizophrenia are very high. Long-acting injectable antipsychotics (LAIs) are an important treatment option but remain underutilized.

Aripiprazole once-monthly is a long-acting intramuscular injectable formulation of aripiprazole indicated for the maintenance treatment of schizophrenia in adult patients stabilized on oral aripiprazole.

If one injection start regimen is adopted, on the day of initiation, an injection of 400mg Aripiprazole once monthly should be administered accompanied by 10mg to 20mg of oral aripiprazole per day for the successive 14 days New treatment regimen: On the day it begins,

inject 400 mg Aripiprazole twice at different sites and provide one 20 mg dose of oral aripiprazole

Objectives: The main aim of this study is to evaluate the efficacy and tolerance of Aripiprazole long-acting injectable (ALAI) in stable patients with schizophrenia. The initial dose was administered according to the new regimen (Two injection Start).

The secondary objective is to compare hospitalizations and emergency interventions during 24 months before (retrospective) and after (prospective) switching to ALAI.

Methods: The study included 15 patients diagnosed with stable schizophrenia (DSM 5 criteria) who underwent treatment with ALAI. The beginning dosage was administered using the new regimen (Two Injection Start).

Over an 24-month follow-up period, the Clinical Global Impression-Schizophrenia scale (CGI-SCH), treatment adherence, concomitant medication, hospitalizations, emergency assists, and reported side effects were evaluated every three months.

Results: Mean initial scores were 4.24 (± 0.83) on GCI-SCH.

After 24 months, the mean scores varied from baseline by -1.21 ± 0.74 ($P < 0.01$) on the ICG-SCH.

The percentage of patients who remained admission-free at the end of the 24 months was 73%.

The treatment adherence rate for ALAI after 24 months was 66%. The most frequent side effect with an incidence of 20% was transient mild insomnia. None of the patients who started ALAI after the 2-injection start regimen experienced severe adverse effects or severe adverse effects.

There were 20 hospital admissions during the 24-month period prior to the switch to ALI, which fell to 5 hospital admissions 24 months following the switch.

Similarly, there were 38 emergency assists during the 24-month period before the switch to ALI, which dropped to 9 emergency assists 24 months after the switch.

Conclusions: We found of Aripiprazole long-acting injectable (The starting dose was administered following the new regimen (Two injection Start)) is effective, safe, and well tolerated in clinical practice conditions

Disclosure of Interest: None Declared

EPV0977

Paliperidone palmitate 6-month formulation for the treatment of schizophrenia: a 14-month follow-up study

S. L. Romero Guillena*, H. Marín Mateos and G. Rodríguez Menéndez

Psychiatry, U.S.M.C Carmona. UGC Mental Health Virgen Macarena, Seville, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1565

Introduction: Relapse prevention is critical because psychopathology and functionality can worsen in patients with schizophrenia because the repeated episodes and we have strong evidence of antipsychotics efficacy for relapse prevention, but nonadherence rates in patients with schizophrenia are very high, even in comparison with other illness.

There is extensive clinical trial evidence for the use of paliperidone palmitate 1-month (PP1M) and paliperidone palmitate 3-month

(PP3M) formulations for maintaining treatment continuity and preventing relapses and risk of hospitalizations in patients with schizophrenia. (Najarian et al. Int J Neuropsychopharmacol 2022; 25(3) 238-251). Paliperidone palmitate 6-month (PP6M) formulation is a presentation that provides a dosing interval of once every six months.

Objectives: The principal aim of this study was to evaluate the effectiveness, safety, and tolerability of the PP6M in patients with non-acute schizophrenia on an outpatient basis

Methods: Methods: Sample: 22 patients diagnosed with schizophrenia (DSM 5 criteria) that started treatment with PP6M after being stabilized with PP1M (N:10) or PP3M (N:12) (the treatment dose was not changed in the four months before study inclusion) Bimonthly, the following evaluations were performed during a follow-up period of 14 months:

The Clinical Global Impression-Schizophrenia scale (CGI-SCH)

Treatment adherence, concomitant medication, adverse events and the number of hospitalizations and emergency visits

Efficacy values: Percentage of patients who remained free of admissions at the end of 14 months of follow-up.

Other evaluation criteria: Percentage of patients who never visited the emergency department at the end of 14 months of follow-up, average change from baseline visit to the final evaluation as assessed by score obtained on the following scale: GSI-SCH, treatment adherence rate and tolerability.

Results: The percentage of patients who remained free of admission at the end of the 14 months follow-up was 90% in the total sample, 83% in the PP3M pre-treatment group and 100% in the PP1M pre-treatment group.

The percentage of patients who never visited the emergency department at the end of 14 months follow-up was: 81% in the total sample, 75% in the PP3M pre-treatment group and 90% in the PP1M pre-treatment group.

At the end of the study, a mean change of $+0.12 (\pm 0.11)$ on the ICG-SCH-SI scale in the total sample, $+0.25 (\pm 0.21)$ in the PP3M pre-treatment group and 0 in the PP1M pre-treatment group.

The treatment persistence rate at the 14 month of follow-up was 100% in the total sample.

Treatment was well tolerated, and no safety-related adverse events were collected. There were no tolerability-related withdrawals from treatment.

Conclusions: In our study, we found that long-term treatment with paliperidone palmitate 6-month formulation is effective and well tolerated in clinical practice conditions.

EPV0978

Differences in the dynamics of schizophrenia with the formation of episodic and persistent apathetic depressions

A. Barkhatova* and S. Sorokin

Department of endogenous mental disorders and affective states, Mental health research center, Moscow, Russian Federation

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1566

Introduction: Apathy in endogenous depressions is a complex mental phenomenon (it is characterized by indifference and loss

of interests, reduced incentives and motivation, decreased mental and physical activity). Apathy becomes the cause of pronounced social maladaptation and untimely seeking medical help. Different depressions vary in psychopathological features of apathy, in addition, there are also different dimensions of the general dynamics of endogenous disease.

Objectives: Study of the features of the course of schizophrenia, in which apathetic depressions develop with episodic and persistent type of dynamics

Methods: The study included 36 patients (15 men, 21 women, average age 34.9 years) with schizophrenia. In 17 cases, apathetic depressions occurred as short-term episodes, in 19 cases, depression took a persistent (close to chronic) course.

Results: Schizophrenia with an **episodic type of dynamics of apathetic depressions** was characterized by: the predominance of cases with early onset of the disease; alternation of apathetic and other type depressions; equal occurrence of mono- and bipolar types of disease; low severity of negative symptoms and slight changes in social and labor functioning. Apathy has always been present during the whole length of depression, its picture was dominated by a motivational decline. The studied cases were prognostically favorable. The features of the course of schizophrenia with **chronic apathetic depression** were: hyperthymic (10 out of 19 observations) and sensitive schizoid (6 out of 19 observations) premorbid personality; bipolar forms of the disease (94.7%, $p < 0.05$); the predominance of apathetic depression over other depression types, atypical form of depression; short duration of remissions; frequent course of the disease with the presence of only apathetic depressions (12 out of 19, 63.1%, $p < 0.05$); significant severity of negative symptoms. Apathy occupied only as a part of the duration of the state, as a rule, after anxiety depression. The picture of apathy was dominated by a decrease in initiative or motivation. This clinical group is the most prognostically unfavorable.

Conclusions: Schizophrenia, occurring with the presence of persistent forms of apathetic depression, has a greater impact on the functioning of patients and has a less favorable prognosis.

Management of cognitive symptoms in schizophrenia.

T. Jupe^{1*}, I. Kourtesis² and I. Sarris¹

¹Psychiatric Hospital of Attica and ²Thrasio General Hospital of Elefsina, Athens, Greece

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1567

Introduction: Cognitive impairment is the frequent symptom occurring in nonelderly patients with schizophrenia or other neurodegenerative disorders. Cognitive dysfunction in patients with schizophrenia was described by Kraepelin more than a century ago. Increased awareness and advancements in the area of neuropsychological assessment and neuroimaging techniques have now rendered cognitive impairment an important focus of theories on the etiology and treatment of schizophrenia. Cognitive enhancement still remains a clinically unresolved challenge. Till date, there is no effective treatment available for enhancing cognitive function in patients with schizophrenia

Objectives: This e-poster aimed to summarize evidence regarding clinical data on the nonpharmacologic and pharmacologic management of cognitive symptoms of schizophrenia, also known as cognitive impairment associated with schizophrenia (CIAS), and highlight the selection of appropriate treatment options.

Methods: A bibliographical review was performed using PubMed platform. All relevant articles were found using the keywords: schizophrenia, cognitive symptoms, management.

Results: Many different drug targets and strategies for drug development have been employed for enhancement of cognition in schizophrenia. Receptor targets have been identified on the basis of pharmacologic challenges that mimic schizophrenia (e.g., dopamine agonists and NMDA receptor antagonists), receptor abnormalities found on postmortem analysis of schizophrenia brain, and genetic linkage studies. Treatment with a D₁ agonist was shown to “sensitize” D₁ receptors and improve memory in both aged and antipsychotic-treated monkeys. Clinical trials of D₁ agonists in schizophrenia have been delayed due to poor tolerability related to orthostatic hypotension and nausea. The glycine-site agonists, glycine, D-serine, and D-alanine, produced improvement in negative symptoms in small trials and some improvement in measures of cognition, although formal cognitive testing was not performed.

Conclusions: Although the evidence supporting cognitive remediation has not yet achieved the level necessary to merit inclusion in evidence-based treatment guidelines, this approach, combined with other psychosocial interventions, is promising. Several pharmacologic approaches are currently under study to facilitate neuroplasticity.

EPV0981

Cariprazine efficacy in a 40-year untreated case of a woman with predominantly negative symptoms of psychosis: A case report

A. Mara* and S. Myrikas

Psychiatric Hospital, Thessaloniki, Greece

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1568

Introduction: Several studies have demonstrated the unfavorable and neurotoxic effects of untreated psychosis (UP) on the brain. An estimated 10 to 12 cc of brain tissue could be potentially damaged due to neuroinflammation and oxidative stress when a first episode of psychosis goes untreated. Other studies have found a correlation between the duration of untreated psychosis (DUP) and treatment resistance or nonresponse. Evidence-based schizophrenia treatment mainly relies upon the use of first and second-generation antipsychotics, without solid evidence that the former is superior to the latter regarding the treatment of negative symptoms. Both groups, however, can come with a risk of side effects. Cariprazine, a third-generation antipsychotic, represents a safe and effective treatment, targeting both the positive and negative symptoms of schizophrenia.

Objectives: To report a clinical case of a woman with an extreme DUP with predominantly negative symptoms of schizophrenia and highlight the favorable outcome cariprazine monotherapy had on her global functioning.

Methods: We report a clinical case of a 58-year-old woman with a history of a 40-year UP successfully treated with 4,5mg of cariprazine. The woman was brought involuntarily for psychiatric assessment at the emergency department with a clinical image of catatonic stupor and predominantly negative symptoms of psychosis. Her total PANSS score at admission was 129. The negative subscale score was 49. She was initially treated with 3mg cariprazine and 10mg olanzapine and was gradually left on 4,5mg cariprazine monotherapy with an adjunctive 30mg mirtazapine.

Results: The patient was dismissed after 47 days of hospitalization. Cariprazine was effective in targeting both the cognitive and affective symptoms of long-standing UP. In the long-term, cariprazine also improved remnant delusional ideas of somatic and persecutory types, enhancing the patient's social life, ensuring her support network, and assisting her integration into the community. The patient did not report any side effects, and her blood test results were within the normal range.

Conclusions: Not all cases of schizophrenia are dramatic at presentation - some can have a chronic and insidious course predominated by negative symptoms. UP can lead to disastrous consequences for the patient's biopsychosocial well-being, leading to future treatment resistance and disability. Although such cases of untreated psychosis seem to be from the past, we should be conscious of their existence and treat them with a patient-personalized and symptom-centered approach. Cariprazine was successful and effective in treating this patient with a remarkable course of UP.

EPV0982

The influence of the experience of trauma in childhood and the later development of psychosis. A case report

C. Díaz Mayoral*, P. Setién Preciados and E. Arroyo Sánchez
Psiquiatría, Hospital Universitario Príncipe de Asturias, Madrid, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2024.1569

Introduction: The increasingly well-established links between psychosis and distant traumas (often established in childhood) oppose purely neurobiological explanations. The influence of psychosocial factors on the development of a later disorder has been studied. In studies, a strong association has been found between psychosis and childhood sexual abuse, especially when sexual intercourse was involved.

Objectives: A case of a patient with psychotic symptoms is presented followed by a theoretical review on the topic.

Methods: A case is presented with a bibliographic review.

Results: A 37-year-old woman was admitted to the Acute Hospitalisation Unit for behavioural alterations in the form of hetero-aggressiveness towards family members in the context of psychopathological decompensation.

On arrival at the unit, she presented psychomotor restlessness, ideas of harm in relation to her neighbours and an attitude of referentiality, especially towards her father.

At the pharmacological level, Quetiapine 100 mg was replaced by Aripiprazole 10 mg and sleep was occasionally supported with Lormetazepam 1 mg.

Progressively her rest is normalising, she remains calm, behaviourally adequate, approachable and cooperative. She does not spontaneously allude to delusional ideation and no hallucinatory attitude is observed.

Daily individual psychotherapeutic interviews and family meetings are held with her parents, in which they refer to experiences of abandonment by her parents during her upbringing, persistent irritability and ideation of harm towards the family, which seems to be of long standing. They also report that prior to the first psychiatric admission, the patient reported being sexually abused at the age of 6 and suffered repeated physical aggression by a teacher at the age of 9. Both the patient and her parents relate the origin of the current malaise to all these events.

Upon discharge from the unit, throughout the follow-up carried out in the resource specialised in first psychotic episodes, during psychotherapeutic interviews, the feelings and emotions related to the traumatic experiences mentioned above are worked on. This therapy, associated with the pharmacological regimen previously indicated, has promoted a notable psychopathological improvement.

Conclusions: A review of 46 studies in women, both inpatients and outpatients, many of whom had a diagnosis of psychosis, revealed that 48% reported having suffered sexual abuse, 48% physical abuse in childhood and 69% of them both. Among men, the figures were 28%, 50% and 59%, respectively. Childhood abuse has been shown to play a causal role in many mental health problems.

There is clear evidence that physical and sexual abuse during childhood is related to symptoms of psychosis and schizophrenia, particularly hallucinations and paranoid delusions. Also, studying possible variables, a greater severity has been observed the more intense the abuse has been.

Delusion of pregnancy - what the literature says?

I. M. Figueiredo

Clinic 3, Psychiatric Hospital Center of Lisbon, Lisbon, Portugal
doi: 10.1192/j.eurpsy.2024.1570

Introduction: Delusion of pregnancy (DP) is a false and persistent belief of being pregnant despite realistic evidence to the contrary. Being considered a rare phenomenon, more cases of DP have been reported lately, however the literature about this topic is still scarce.

Objectives: Clarify the etiology and clinical aspects of this pathology in order to diagnose and to treat it properly.

Methods: A search on Pubmed was performed using the MeSH terms "delusion pregnancy" or "pseudocyesis". The DSM-5 and ICD-10 were also a source of information.

Results: DP can be sometimes confused with other disorders, like pseudocyesis, pseudo-pregnancy and Couvade syndrome, but it is important to differentiate all of them to have a clear view of the pathology and follow a correct approach to the problem.

DP can manifest isolatedly, but it is more commonly associated with other diseases. Etiologically, several factors can intercede: biological, psychosocial and cultural factors, iatrogenic factors and coenaesthesia processes.

Demographically, about 50% of the patients are 20-40 years old and the most common psychiatric diagnoses are schizophrenia, bipolar disorder and depression.

Concerning the treatment, it is essential to exclude non-psychiatric causes and treat those, if present. After doing so, the therapeutical approach can be non-pharmacological, using psychotherapy or electroconvulsive therapy, although the latter has inconclusive results and sometimes it only remits the comorbid depressive symptoms; or pharmacological using 2nd generation antipsychotics.

In general, there is now a good response in 50-64% of the cases (Bera and Sakar, *Indian J Psychol Med* 2015;37(2)131-137) (Yadov et al, *Indian J Psychol Med* 2012;34(1) 82-84).

Conclusions: DP can be a psychiatric diagnosis itself or a manifestation of other psychiatric or non-psychiatric disorder so we must be alert to make a precise differential diagnosis. Its genesis is multifactorial and that must be taken into account when thinking about its treatment approach.

In the past, the prognosis of the DP wasn't good, but in the recent literature it was found a good response in more than half of the patients treated accordingly.

Psychosocial difficulties as a predictor of overall functioning in individuals with schizophrenia: a case-control study

L. Mustoo Bašer* and O. Aydın

Psychology, International University of Sarajevo (IUS), Sarajevo, Bosnia and Herzegovina

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1571

Introduction: Difficulties in emotional, cognitive, behavioral, and social functions are considered important factors of global functioning in schizophrenia.

Objectives: A better understanding of difficulties in the mentioned facets might lead to the development of better-adjusted treatment approaches for individuals with schizophrenia, as well as impacting to reduction and elimination of stigma in Bosnia and Herzegovina's wider social context in relation to difficulties spanning the daily life of individuals with schizophrenia.

Methods: Thirty- one patients with schizophrenia (SCH), and 30 healthy controls (HC) participated in our study. The Adult Self-Report (ASR), Achenbach's scale for adults (ASEBA- Achenbach System of Empirically Based Assessment), and World Health Organization, Disability Assessment Schedule 2.0 (WHODAS 2.0) tests were administered.

Results: Groups differed in age, education, employment status, marital status, friendships existence, and disability existence.

According to the regression equations, thought problems predicted Getting around; withdrawn predicted Getting along with people and Life activities- Household, School/Work in the group of individuals with schizophrenia.

Conclusions: Our study revealed the role of different facets of difficulties in the prediction of global functioning in SCH. These findings might directly point to the importance of eliminating stigmatizing beliefs in a wider social context, developing techniques for improving the social support segment, focusing on healthy family functioning, as well as investigating job presence and perceived quality of life.

Cognitive impairment assessment in schizophrenia: purposely a case

N. Ogando Portilla^{1*}, S. M. Bañón González¹, B. Gamo Bravo¹, M. E. González Laynez², M. A. Urbanos³ and M. M. Cortés⁴

¹Psychiatry, Hospital Universitario Infanta Sofía, Madrid; ²Psychiatry, Hospital universitario de Toledo, Toledo; ³Psychiatry, Hospital Universitario La Princesa, Madrid and ⁴Psychiatry, Hospital General Universitario de Alicante Dr Balmis, Alicante, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1572

Introduction: Significant and measurable cognitive symptoms are present at the onset of the disorder and these remain stable in the subsequent period between 2 and 5 years. Their deterioration increases with the course of the disease. Attention, concentration, psychomotor speed and resolution of conceptual tasks are usually affected and are more significant in the presence of positive symptoms.

Objectives: Sometimes, the typical positive or negative symptoms of the disease do not adequately reflect the severity of cognitive impairment. Measuring this deterioration can be very relevant when evaluating the severity and the prognosis of the disorder.

Methods: 31-year-old male with a previous diagnosis of schizophrenia of 4 years of evolution. He gets a maintained treatment with amisulpiride 400mg with an apparent good response. A single hospitalization at the onset of the disease. An assassination attempt on his mother is done by suffocation with a pillow and observing a significant cognitive impairment despite an apparent control of the symptoms of schizophrenia.

Results: An exhaustive neuropsychological evaluation is carried out, observing a very important cognitive deterioration that had not been previously detected and allowing a pharmacological adjustment of the underlying disease with global improvement of the patient.

Conclusions: It is very important to evaluate the patient as a whole without forgetting the frequent cognitive damage that these patients can have. An intense neuropsychological study can be very useful to evaluate the prognosis and adequate treatment of the patient in order to reduce serious risks.

Disclosure of Interest: None Declared

The relationship between chronotype and suicidal attempt in patients with schizophreniaN. Göktürk^{1*} and P. G. Özdemir²¹PSYHIATRİK AND MENTAL HEALTH NURSİNG, VAN YÜZÜNCÜ YIL UNIVERSITY and ²PSYHIATRİK AND MENTAL HEALTH, VAN YÜZÜNCÜ YIL UNIVERSITY DURSUN ODABAŞ MEDICAL CENTER, VAN, Türkiye

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1573

Introduction: Individuals with schizophrenia are known to be at an increased risk of suicidal behavior (Sher & Kahn, 2019). However, the relationship between chronotype, which refers to an individual's preference for sleep-wake patterns, and suicidal attempts in schizophrenia patients remains an area of interest and investigation. The relationship between chronotype and suicidal attempts in schizophrenia patients has not been extensively studied. However, research in other populations has shown that individuals with evening chronotypes, also known as "night owls," may be at a higher risk of mental health issues, including depression and suicidal ideation (Verma et al., 2016). It is plausible to hypothesize that individuals with schizophrenia who have evening chronotypes may also be at an increased risk of suicidal attempts. Further research is needed to explore this relationship and its potential implications for clinical practice. In conclusion, the relationship between chronotype and suicidal attempts in schizophrenia patients is an area that requires further investigation. Early identification and intervention are crucial in preventing further suicidal attempts in this vulnerable population. Future research should focus on exploring the relationship between chronotype and suicidal attempts in schizophrenia patients to provide a comprehensive understanding of the factors contributing to suicide risk in this population.

Objectives: This study investigates the relationship between chronotype and suicidal attempts in patients with schizophrenia.

Methods: The study was conducted cross-sectionally using quantitative research methods and using purposive sampling. The personal information form and scales used for data collection in this study, which was planned with patients hospitalized in the psychiatric ward and patients applying to the outpatient clinic, are based on self-report. The personal information form developed by the researcher by reviewing the literature, the Morningist-Evening Scale (SAM), the Suicide Probability Scale, the Suicidal Behavior Scale, the Positive Symptoms Rating Scale (SAPS) and the Negative Symptoms Rating Scale (SANS) were used as data collection tools. Participants signed an informed consent form before the interview.

Results: Data extraction is still ongoing in detailed style by principal authors. A description of the studies and the key findings will be presented.

Conclusions: Reducing the risk of suicide in patients with schizophrenia is of vital importance. Awareness of the risks related to suicide may help reduce mortality rates in schizophrenia patients as in all patients. It is thought that the study's results will be an important resource in knowing the risks related to suicide and determining the risk factors so that prevention studies can be initiated.

Insight and cognitive complaints in stabilized outpatients with schizophrenia

S. Ajmi*, M. Bouhamed, R. Ouali, S. Hentati, I. Feki, R. Sallemi and J. Masmoudi

Psychiatrie A, HEDI CHAKER University Hospital, SFAX, Tunisia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1574

Introduction: Schizophrenia is often considered as pathology of consciousness. Some authors have considered that patients' self-perception of their cognitive difficulties expressed in the form of subjective complaints could represent a source of stress. These cognitive difficulties may then interfere with the interpretation of symptoms, leading to poor insight.

Insight and cognitive complaints in stabilized outpatients with schizophrenia.

Objectives: Study the relationship between subjective cognitive complaints and clinical insight in a Tunisian population with schizophrenia.

Methods: This is a cross-sectional, descriptive and analytical study carried out on 72 stabilized patients followed at the post-cure psychiatry consultation 'A' at the CHU Hédi Chaker in Sfax diagnosed with schizophrenia according to the DSM 5 criteria.

We used the schedule for the Assessment of Insight-Expanded Version (SAI-E) scale to assess Clinical Insight and the Subjective Scale to Investigate Cognition in Schizophrenia (SSTICS) to determine subjective cognitive complaints

Results: The mean age of the patients was 46.83 ± 11.6 years, with a sex ratio (M/F) of 2. In our study, 48.5% were single and 69.4% were unemployed.

The median total SSTICS score was 25.

Using the SAI-E scale, an average score of 20.1 was objectified in our study.

In our study, the better the insight, the greater the subjective cognitive complaints were in all cognitive domains ($p=0.00$).

Awareness of illness was statistically associated with working memory ($p=0.001$), explicit memory ($p=0.004$), attention ($p=0.001$), language ($p=0.01$) and executive functions ($p=0.001$).

Conclusions: Our study highlights the relationship between awareness of illness and cognitive complaints. The clinician, faced with repetitive cognitive complaints, should assess the insight before incriminating another cause (effects of a drug, cognitive deficit, etc.).

Disclosure of Interest: None Declared

Self-stigma in a Tunisian population of stabilized outpatients with schizophrenia

S. Ajmi*, M. Bouhamed, R. Ouali, R. Masmoudi, I. Feki, R. Sallemi and J. Masmoudi

Psychiatry A, Hedi Chaker University Hospital, Sfax, Tunisia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1575

Introduction: The internalized stigma associated with mental illness is considered as an additional burden faced by people with mental disease. Among mental illnesses, schizophrenia is considered as the most stigmatizing.

Objectives: To Assess the level of stigma in a sample of people with schizophrenia

Methods: This is a cross-sectional and descriptive study carried out on 72 stabilized patients followed at the post-cure psychiatry consultation 'A' at the CHU Hedi Chaker in Sfax diagnosed with schizophrenia according to the DSM 5 criteria. Socio-demographic and clinical data were collected using a pre-established sheet

We used The Internalized Stigma of Mental Illness (ISMI) scale to assess internalized stigma

Results: The mean age of the patients in our study was 46.83 ± 11.6 years, with a sex ratio (M/F) of 2.

They were single in 48.5%, unemployed in 69.4%. Their level of education did not exceed primary school in 44.4% and their socio-economic level was low in 63.9%. 2% of the patients had no somatic history and 36.1% had a history of attempted suicide.

The median for the total ISMI score was 2.45, which corresponded to the absence of strong stigma. The median of the subscales was distributed as follows: 2 for the level of alienation, 2.28 for stereotype endorsement, 2.4 discrimination experience, 2.36 for social withdrawal and 2.60 for stigma resistance.

In our study, 45.8% of patients reported experiencing high levels of self-stigma (total score > 2.5).

Conclusions: Our study found levels of self-stigma in individuals with schizophrenia that align with previous research, suggesting that schizophrenia-related stigma is a global phenomenon unaffected by factors such as origin or ethnicity.

Disclosure of Interest: None Declared

EPV0989

Insight evaluation in a Tunisian stabilized outpatients with schizophrenia

S. Ajmi*, M. Bouhamed, K. Makni, R. Masmoudi, I. Feki, R. Sallemi and J. Masmoudi

Psychiatry A, Hedi Chaker University Hospital, Sfax, Tunisia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1576

Introduction: Schizophrenia is a chronic condition that leads to major socio-professional disintegration and personal suffering. In addition to the classic clinical symptoms, these patients also suffer from poor insight.

Objectives: To assess insight in a population followed up for schizophrenia

Methods: We conducted a cross-sectional and descriptive which concerned the patients followed in the unit of outpatient post-cure consultations of psychiatry 'A' at the CHU Hedi Chaker of Sfax. We included 72 stabilized patients diagnosed with schizophrenia according to the DSM criteria 5. For the collection of sociodemographic and clinical data, we used a pre-established sheet. We used the schedule for the Assessment of Insight-Expanded Version (SAI-E) scale to assess clinical insight

Results: The mean age of the patients in our study was 46.83 ± 11.6 years, with a sex ratio (M/F) of 2.

They were single in 48.5%, and unemployed in 69.4%. Their level of education did not exceed primary school at 44.4% and their socio-economic level was low at 63.9%.

In our study, 72.2% of patients had no somatic history and 36.1% had a history of attempted suicide.

Using the SAI-E scale, the mean score was 20.1 with a minimum of 5 and a maximum of 28.

Conclusions: At the end of this evaluation, it is important to emphasize that insight seems to be an important prognostic factor.

Disclosure of Interest: None Declared

EPV0990

Cognitive complaints in schizophrenia: relationship with clinical symptoms, stigma and insight

S. Ajmi*, M. Bouhamed, R. Ouali, S. Hentati, I. Feki, R. Sallemi and J. Masmoudi

Psychiatry A, Hedi Chaker University Hospital, Sfax, Tunisia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1577

Introduction: In addition to the classic clinical symptoms, patients with schizophrenia suffer from cognitive difficulties, self-stigma and poor insight.

Objectives: This study aims to evaluate the impact of stigma, symptom severity, and insight on subjective cognitive complaints in patients with schizophrenia.

Methods: This is a cross-sectional, descriptive and analytical study carried out on 72 stabilized patients followed at the post-cure psychiatry consultation 'A' at the CHU Hédi Chaker in Sfax diagnosed with schizophrenia according to the DSM 5 criteria.

We used the schedule for the Assessment of Insight-Expanded Version (SAI-E) to assess clinical insight, The Internalized Stigma of Mental Illness (ISMI) scale for the assessment of internalized stigma, the Subjective Scale to Investigate Cognition in Schizophrenia (SSTICS) scale to determine subjective cognitive complaints and the Positive and Negative Syndroms Scale (PANSS) to assess positive and negative symptoms.

Results: The average age of the patients was 46.83 ± 11.6 years, with a sex ratio (M/F) of 2. In our study, 48.5% of the patients were single, 52.8% were smokers and 23.6% consumed alcohol. The level of education did not exceed the primary level for 44.4% of the patients. The average age of disease onset was 24.56 ± 5.82 . Our participants had an average score of 25 on the SSTICS total score and 20.1 on the SAI-E. The median ISMI total score and PANSS total score were 2.45 and 46 respectively

The predominant negative symptoms ($p=0.003$), stigma ($p=0.009$), and insight ($p<0.003$) were significant factors associated with increased cognitive complaints.

Conclusions: In schizophrenia, the combination of cognitive difficulties, self-stigma with a low insight makes the management of these patients more difficult.

Relationships between cognitive function and activities of daily living in psychiatric nursing home patients with schizophrenia

F.-Y. Gu^{1*} and S.-Y. Weng²

¹Department of Occupational Therapy, Taipei City Hospital, Songde Branch and ²Taipei City Hospital Songde Branch Psychiatric Nursing Home, Taipei City, Taiwan, Province of China

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1578

Introduction: Schizophrenia is a common chronic disease in psychiatric long-term care institutions. Taipei City Hospital Songde Branch Psychiatric Nursing Home (TCHSBPNH) is the first public psychiatric nursing home in Taipei City. There's not only a complete interdisciplinary care system, but also detail initial evaluation at admission of residents, including basic demographic information, cognitive assessments, activities of daily living, and so on. It is known that patients with schizophrenia are generally accompanied by cognitive impairments, which further affects their activities of daily living (ADL) performance, but we still don't know the correlation between of them.

Objectives: This study aimed to investigate the relationships between cognitive function and ADL function of psychiatric nursing home residents with schizophrenia. The results would promote clinical intervention in ADL training for institutional patients.

Methods: 39 participants with chronic schizophrenia (mean age =63.95±6.59 years) were recruited for the study from 2020 to 2021 in TCHSBPNH. We collected every resident's assessment data, including Mini-Mental State Examination (MMSE), Barthel Index, Lawton - Brody Instrumental Activities Of Daily Living Scale (Lawton IADL scale) and Composite Physical Function (CPF) Scale. The Pearson correlation coefficient was used to examine the correlation between cognitive function and ADL.

Results: Moderate positive correlations were showed between cognitive function and ADL ($p<.05$). The statistic results as follow, MMSE and Barthel Index ($\gamma=.627$, $p<.001$), Lawton IADL scale ($\gamma=.431$, $p=.006$), and CPF ($\gamma=.341$, $p=.034$) respectively exhibited significant correlations.

Image:

		Male (N=19)	Female (N=20)	Average
Age (year)		62.94±7.42	64.91±5.91	63.95±6.59
Education	≤6years	3	5	
	7-9years	3	0	
	10-12years	6	9	
	≥13years	7	6	
Onset(yr)		27.26±8.70	29.55±8.68	28.44±8.54
Years since onset		35.67±10.36	35.36±9.95	35.51±9.89
Days since admission		651±380	598±371	623±371
Marriage	Single	15	10	
	Married	3	2	
	Divorced	1	6	
	Widow	0	2	
Scores (mean±S.D.)	MMSE	25.89±3.54	26.90±3.66	26.41±3.59
	BADL	98.68±3.67	97.50±8.96	98.07±6.85
	IADL	12.47±5.05	15.10±4.58	13.82±4.93
	CPF	18.89±4.39	16.85±3.20	17.85±3.96

Image 2:

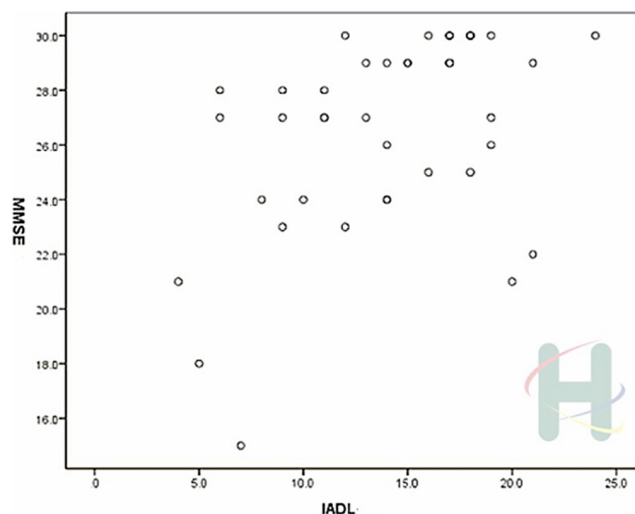

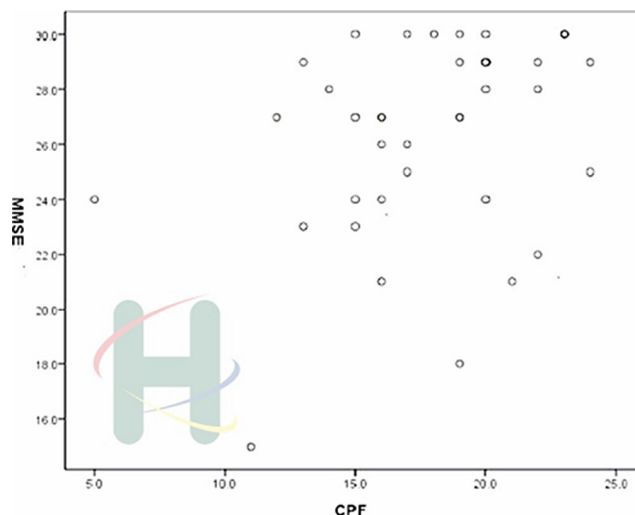

Image 3:

Conclusions: There is a positive correlation between cognitive function and ADL in psychiatric nursing home residents with schizophrenia. The better cognitive function performance becomes, the better independent ADL functions will be. Thus, the psychiatric nursing home residents' independent ADL training will also vary from person to person.

Disclosure of Interest: None Declared

EPV0992

Haloperidol induced Pisa syndrome in a patient with treatment resistant schizophreniaI. Yaich^{1,2,*}, A. Touiti^{1,2}, C. Ben Said^{1,2} and N. Bram^{1,2}¹Forensic Psychiatry Departement, Razi Hospital, La Manouba and ²Faculty of Medecine of Tunis, Tunis El Manar University, Tunis, Tunisia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1579

Introduction: Acute dystonia, an adverse effect of neuroleptics, is linked to D2 neuronal receptor hypersensitivity or neurotoxicity due to oxidative stress mechanisms. Pisa syndrome (PS) or Pleurothotonus, a relatively uncommon condition, manifests as dystonia of the trunk and is potentially reversible with early intervention.

Objectives: To describe PS following haloperidol decanoate injection in a treatment-resistant schizophrenia (TRS) patient, identify associated risk factors, and present therapeutic options.

Methods: We provide a comprehensive case description and perform a PubMed database search using the following keywords: "Pisa syndrome," "dystonia," "schizophrenia," and "antipsychotic".

Results: A 54-year-old man with TRS, previously treated with 100 mg of haloperidol decanoate and 10 mg of olanzapine due to clozapine-induced myocarditis, exhibited hallucinatory delusional syndrome and behavioral disturbances. Neurological examination, lab tests, and brain imaging confirmed a psychotic relapse. Haloperidol decanoate dosage was increased to 150 mg. Four days later, the patient developed a trunk tilt that resolved after receiving anticholinergic treatment. Despite PS being more common in females and associated with brain conditions, this patient presented multiple risk factors, including prolonged typical antipsychotic treatment, advanced age, and an increase in antipsychotic doses. Discontinuing the causative antipsychotic or adding synthetic anticholinergics led to symptom reversibility.

Conclusions: PS is a rare occurrence. Understanding associated risk factors and frequently implicated medications is crucial for elucidating the phenomenon and managing the disorder

Disclosure of Interest: None Declared

EPV0993

Relationship between circadian rhythm and Malondialdehyde serum levels in acute and stabilized schizophrenic patientsE. Díaz-Mesa^{1,2}, C. Cárdenas Moreno¹, A. Morera-Fumero², I. Perez-Sagaseta De Ilurdoz^{1,*}, P. Abreu-González³, M. R. Cejas-Méndez^{1,2}, M. L. Fernández-López² and M. S. Henry-Benítez²¹PSIQUIATRÍA, HOSPITAL UNIVERSITARIO DE CANARIAS;²MEDICINA INTERNA, PSIQUIATRÍA Y DERMATOLOGÍA and³FISIOLOGÍA, UNIVERSIDAD DE LA LAGUNA, SAN CRISTOBAL DE LA LAGUNA, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1580

Introduction: Malondialdehyde (MDA) is a product of polyunsaturated fatty acid peroxidation (Del Rio D, et al. A review of recent

studies on MDA as toxic molecule and biological marker of oxidative stress. *Nutr Metab Cardiovasc Dis.* 2005;15:316-28). It is a biomarker of oxidative stress and is involved in the pathophysiology of schizophrenia (Goh et al. *Asian J Psychiatr.* 2022;67:102932). Schizophrenia is linked to disrupted oxidative balance and inflammation (Więdołcha et al. *Brain Sci.* 2023;13:490). Prior research has shown connections between biomarkers and circadian rhythms in schizophrenia (Morera & Abreu. *Acta Physiol Scand.* 2007;43:313-14) and diabetes type 2 (Kanabrocki EL, et al. *Circadian variation in oxidative stress biomarkers in healthy and type II diabetic men.* *Chronobiol Int.* 2002;19:423-39). To determine if MDA levels have a role in schizophrenia and follow a circadian rhythm may be useful.

Objectives: The aim of our study is to compare diurnal and nocturnal MDA serum levels in patients in acute and stabilized phases of schizophrenia according to CIE-10 to find out if there are variations related with circadian rhythms

Methods: 47 patients were included in our study in two clinical phases: acute episode and stabilization. Blood samples were collected at 12:00h and at 00:00h. MDA serum levels were measured twice: when patients were decompensated (admission) and at clinical stabilization (discharge). The relationship between quantitative variables at both times was analysed by T-Student test

Results: There is no significant difference between night and day MDA levels in the acute phase of the schizophrenia (2.22 ± 1.352 vs. 1.93 ± 1.530 , $p < 0.09$). There is statistical significance between 12:00 and 00:00 (1.90 ± 1.136 vs. 1.34 ± 0.868 , $p < 0.001$) at discharge: it was observed that levels decreased. This result can be interpreted as there is circadian rhythm in stabilized phases.

Conclusions: MDA levels in patients with schizophrenia do not follow a circadian rhythm in the acute episode. When they are clinically stabilized present a circadian change. These patients lose the circadian rhythm in acute episodes. MDA circadian rhythm may help diagnose the clinical phase and its severity. It is necessary to perform more studies to know its utility as an oxidative biomarker

"Ekbom syndrome: delirium engraved on the skin"

C. Perez Aparicio, L. Rodriguez Rodriguez and M. J. Gordillo Montaña*

Hospital Can Misses, Eivissa, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1581

Introduction: Ekbom syndrome also known as Morgellons syndrome or delirium of parasitosis is a psychiatric condition where the patient has the absolute conviction of being infested in spite of medical evidence. Patients may even mutilate themselves or apply toxic substances in order to get rid of these hypothetical organisms. Sometimes they bring samples of these hypothetical parasites to the office to prove their existence, which is known as the "matchbox sign", a pathognomonic finding.

Objectives: The aim of this clinical case is to make visible the impact that this psychiatric condition can have on the patient's quality of life

Methods: We present the case of a 40-year-old woman from Peru who was admitted to the otorhinolaryngology unit for injuries compatible with necrosis of the right pinna. When the patient was examined, scars were found on the lower limbs and back. The patient justifies the scratching lesions with the presence of pathogenic organisms, with no trace of them by the physician.

Results: The patient was evaluated by psychiatry service during her admission in otorhinolaryngology, being diagnosed with Ekbom's delirium and starting treatment with 3 mL of Aripiprazole. Subsequently she was referred to the mental health unit where she left the follow-up until today.

Conclusions: Different effective treatments have been described, among them pimozide, atypical antipsychotics and some SSRIs. However, the complexity of treatment arises when dealing with the irreducible idea that the patient has of being infested, refusing in most cases to receive psychiatric treatment. This can degenerate into major organic and psychological problems that turn the patient's life into a real hell, which often end up losing much of their daily functionality. The fact of empathizing with the patient and trying to elaborate a plan adjusted to the reality and needs of the moment, can help us to establish a good therapeutic bond that facilitates an early start of treatment and greater therapeutic adherence, enabling a significant improvement in their quality of life.

Review of Delusional Jealousy and Its Association with Sexual Dysfunctions

S. A. Pinho*, F. Leitão, J. R. Freitas and F. Coutinho

Hospital de Magalhães Lemos, Centro Hospitalar Universitário de Santo António, Porto, Portugal

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1582

Introduction: Mental state changes can affect one's sexual life, while sexual dysfunction can lead to relationship challenges. Delusional jealousy, also called Othello syndrome, involves a paranoid belief in a partner's infidelity, leading to controlling and violent behaviors. It can manifest as a paranoid disorder, as a delusional symptom of psychiatric, neurological or other medical conditions, or as side effect of dopaminergic medication. Although its exact prevalence remains uncertain, it has been identified in 0.5-1.4% of psychiatry inpatients.

Objectives: To describe sexual dysfunctions associated with delusional jealousy and to explore strategies for addressing these dysfunction.

Methods: A non-systematic review of the literature available at PubMed was conducted using the keywords "Sexual Dysfunction" AND "Delusional Jealousy OR Othello Syndrome".

Results: A number of factors, including sexual dysfunction, can trigger or exacerbate delusional jealousy. This is especially true for middle-aged men who have a history of alcohol consumption, neurological or personality disorders. Individuals with sexual dysfunction experience feelings of insecurity, projecting these concerns onto their partners and suspecting extramarital relationships. On the other hand, sexual dysfunctions such as Hypoactive Sexual

Desire Disorder, Female Sexual Arousal and Orgasmic Disorders, Erectile Dysfunction and Ejaculation Disturbance may occur as consequence of Othello Syndrome. Multiple factors contribute to these dysfunctions, including increased testosterone and cortisol levels, chronic alcohol use, comorbid psychiatric conditions and antipsychotics. There are reports of increased sexual desire, especially in cases of dementia.

Conclusions: Although the evidence is limited and dated, it points to a bidirectional association between delusional jealousy and sexual dysfunction. Further studies are essential to determine the prevalence and types of sexual dysfunctions in Othello syndrome, and the causal relationship between them. Additionally, investigating gender differences is crucial, given the male-centric focus of existing studies. This research can contribute to clinical care by promoting the screening for sexual issues and their integration into delusional jealousy management.

Schizophrenia and Risk of Dementia: A Literature Review.

V. Moraiti^{1*} and G. N. Porfyri²

¹Early Intervention in Psychosis, Ikelos NGO, Athens and ²Psychiatric Department, General Hospital of Papanikolaou, Thessaloniki, Greece

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1583

Introduction: Dementia is a clinical syndrome affecting 1-2% of the population under the age of 65, while at older ages the frequency doubles every five years. The clinical manifestations include memory loss, communication deficits, agnosia, apraxia and executive dysfunction. Schizophrenia is a complex, chronic mental disorder affecting approximately 1% of the population, presenting with disturbances in perception, thought and behavior.

Objectives: To investigate the relationship between schizophrenia and later-onset dementia; more specifically to explore whether schizophrenia increases the dementia risk.

Methods: A review of 35 articles -from 2010 to 2023- on PubMed and Google Scholar regarding patients with schizophrenia or other type of psychosis, who later presented dementia.

Results: Patients with a history of schizophrenia, schizotypal disorder, or delusional disorder are more likely to develop dementia. The greatest risk is presented in patients showing the shortest duration of psychotic symptoms (5 years or less), while at 5-10 years the probability of developing dementia decreases. The most common types of dementia occurring in psychotic patients are Alzheimer's disease (50-70%), vascular dementia (30%) and unspecified dementia (15%). Chronic patients (10+ years of symptomatology) are less likely to develop dementia. Psychotic patients over the age of 65 are more likely to develop dementia later in life, while individuals who develop schizophrenia after their 40s are three to four times more likely to present dementia compared to patients carrying a schizophrenia diagnosis before their 40s. Females with Late-Onset Schizophrenia have an increased dementia risk compared to males carrying the same diagnosis and compared to healthy females of the same age. Physical conditions implicated in the onset of dementia in schizophrenic patients

include cardiovascular diseases, lung disease, substance and alcohol use, head injuries and diabetes.

Conclusions: According to data, there is a strong correlation between schizophrenia and dementia. However, the related studies are limited in number, while their results require further investigation because of limitations (small sample sizes, co-morbidities, selection of chronic elderly patients). Furthermore, most of these studies were conducted in Western countries, highlighting the necessity of pursuing additional research.

The role of Galacto-oligosaccharides (GOS) in the recovery from dysbiosis in patients on long-term atypical antipsychotic treatment

N. De Bles, N. Rius Ottenheim, A. van Hemert and E. Giltay*

LUMC, Leiden, Netherlands

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1584

Introduction: Atypical antipsychotic (AAP) drugs are the gold-standard treatment for psychotic patients but are nowadays also widely prescribed among people with other mental disorders. Notwithstanding the benefits of AAP in terms of symptom improvement, there are severe adverse effects including the metabolic syndrome. A novel hypothesis is that part of these undesirable effects of antipsychotics could be mediated by their deleterious effects on the microbiome. This may result in dysbiosis, the disruption of bacterial species of the gut microbiota. Recently, dysbiosis has been linked to poor quality of life, depression and anxiety through the gut-brain axis. Mounting evidence proposes that prebiotic consumption may be helpful in the recovery of dysbiosis, although this effect is unclear among long-term antipsychotic users.

Objectives: The main objective of this study is to assess the potential beneficial effects of the prebiotic Galacto-oligosaccharides (GOS) in combination with 2'-fucosyllactose (2'-FL) on the gut microbiota, by showing a relative increase in Bifidobacteria in fecal samples following intervention. The secondary objective is to assess the effects of GOS on mental wellbeing, sleep, and metabolic parameters. We hypothesize that GOS+2'FL supplementation will improve gut health, mental wellbeing, sleep, and metabolic parameters. Data will be collected 4 weeks prior to the start of the intervention during an observation only phase [t0], at baseline [t1], and after 2 [t2] and 6 [t3] weeks of GOS+2'FL intake. A follow-up will take place at week 10, 4 weeks after the intervention [t4]. Other outcomes that are assessed include the FiberScreen tool, the form of human faeces (Bristol Stool Chart), side effects and the defined daily dosis (DDD) of antipsychotic medication.

Methods: The study is a single-arm pilot study (non-randomized and non-blinded). We aim to include 30 psychiatric patients on long-term atypical antipsychotic use, irrespective of their specific psychiatric disorder, with a BMI > 25 kg/m². Following a run-in period of 4 weeks (no intervention but all other aspects of the study), the participants will consume GOS^{plus} (7.0 g BiotisTM GOS + 0.7 g 2'-FL) daily during the first consumption moment of the day (preferably in the morning) for 42 days. The GOS^{plus} powder has a

slightly sweet flavour. The primary endpoint is the change in Bifidobacteria in fecal samples from week 0 to week 6.

Results: The study started recruiting participants in October 2023.

Conclusions: Conclusions are expected by the end of 2024.

Rethinking Schizophrenia: Beyond the Voices of Schizophrenia

D. Suchonova¹ and P. Kéri^{2*}

¹European Brain Council and ²GAMIAN-Europe, Brussels, Belgium

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1585

Introduction: Despite improvements and innovation in recent years, people living with schizophrenia face variations in access to optimal treatment and care. There is a lot about schizophrenia that is not fully understood, and the high-quality care and support needed by people living with this condition is often unavailable.

Objectives: Develop an evidence-based, compelling policy narrative on schizophrenia Engage a pan-European, multidisciplinary group of experts Offer concrete tools to patient and professional advocacy groups Disseminate findings Draw from our findings practical solutions on how to implement recommendations **Methods:** Based on carefully selected existing literature and available resources, **literature review** includes but is not limited to: Value of Treatment Recommendations, Global Burden of Disease Study, Comprehensive Mental Health Action Plan, Mental Health Atlas. The aim is to establish state of play, identify problems and solutions and take stock of current recommendations.

We established a **multi-disciplinary working group** to lead the project, and ensured that representation on this group is cross-disciplinary and cross-sector. The expert group includes country-level patient advocates and clinical leads including key opinion leaders (KOLs) to keep the project focused on what is happening at a national level, and to help create ownership at the national level to take recommendations forward within each country.

We conducted **qualitative semi-structured interviews** with people living with schizophrenia where they provided their insights into how to rethink the way we deal with schizophrenia.

Results: Provide clear, concrete and adaptable solutions Joint ownership by key stakeholder groups of a common policy narrative on schizophrenia Sustained policy engagement on schizophrenia at the EU and national level

Conclusions: There is a clear need to rethink the management of schizophrenia and redesign the care pathways to ensure optimal treatment and care for all people living with schizophrenia in Europe. Based around patient testimonies, the aim of the session is to highlight the need to optimise the way we manage schizophrenia by building a strong, coherent, evidence-based policy narrative which speaks to the current priorities in schizophrenia and draws from the current policy landscape in Europe.

Experts involved in the *Rethinking Schizophrenia* project, coordinated by the European Brain Council, have explored the ways in which we can and need to change the way we deal with

schizophrenia. The *Rethinking Schizophrenia* project falls under the *Rethinking the management of brain disorders* series, research-driven projects offering policy recommendations to make tangible changes with the aim to improve the lives of people living with brain disorders, neurological and mental alike, across Europe.

Stigma in first episode patients with schizophrenia

B. Aukst Margetić^{1,2}, B. Margetić³ and M. Vilibić^{1,2*}

¹Department of psychiatry, University hospital center Sestre milosrdnice; ²Catholic University of Croatia and ³Department of psychiatry, University hospital Dubrava, Zagreb, Croatia
*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1586

Introduction: Patients with schizophrenia confront with stigmatization in their everyday life. Differences in their perception of stigmatization based on the number of hospitalizations and duration of treatment are unsufficiently researched.

Objectives: Our aim was to investigate whether patients with first-episode schizophrenia differ in their perception of stigmatization from schizophrenia patients with more than one hospitalization.

Methods: A consecutive sample of 120 stable outpatients (70 males, 50 female) diagnosed with schizophrenia were included in the study. Diagnosis of schizophrenia was established with Neuro-psychiatric Interview. First episode patients consisted 28.3% of the group.

All patients were at least once hospitalized for mental illness. Patients were dichotomised based on the number of hospitalizations.

The study was approved by Ethic committee of the institutions. Stigma was assessed with Internalized Stigma of Mental Illness (ISMI) scale.

ISMI scale contains 29 Likert items rated on a 4-point scale ranging from "strongly disagree" to "strongly agree". It contains five subscales: Alienation, Stereotype Endorsement, Discrimination Experience, Social Withdrawal and Stigma Resistance. The overall internal consistency for the global ISMI was 0,89; Alienation-0,76; Stereotype endorsement- 0,63; Discrimination- 0,72; Social withdrawal- 0,57.

All analyses were performed using the SPSS 25.0. The differences between groups on continuous variables were evaluated using t-test with Bonferroni correction. For all analyses, the level of statistical significance was defined as an alpha less than 0.05

Results: There were no differences in first-episode and more episode patients in ISMI and its subscales. Number of hospitalizations was associated with Stereotype endorsement subscale ($r=0.228$; $p=0.012$) Age was correlated with stigma.

Conclusions: Although stigma did not differ between first-episode patients and patients with two or more hospitalizations, stereotype endorsement was strongly associated with the number of hospitalizations leading to conclusion that stigma is associated with psychiatric treatment and our aim must be to destigmatize the treatment and avoid hospitalizations.

Cognitive and social cognitive function in patients with schizophrenia and affective disorder: effects of combining pharmacotherapy with cognitive remediation

G. Sachs^{1*} and A. Erfurth²

¹Medical University of Vienna and ²1st Department of Psychiatry and Psychotherapeutic Medicine, Klinik Hietzing, Vienna, Austria

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1587

Introduction: In recent decades, there has been increasing interest in neurocognitive function, including non-social and social cognition. Cognitive impairment has a significant impact on functional outcome, especially in schizophrenic disorders, but also in affective and other psychiatric disorders.

Objectives: It is our aim to present the assessment and measurement of cognitive dysfunction through adequate instruments and to evaluate the effects of combining pharmacotherapy and cognitive remediation.

Methods: A review of the modern literature is undertaken and results of own investigations using the Screen for Cognitive Impairment in Psychiatry (SCIP, Sachs G *et al.* Schizophr Res Cogn. 2021 May 12;25:100197; Sachs G *et al.* Schizophr Res Cogn. 2022 Jun 6;29:100259) are presented and evaluated.

Results: Our data show that it is possible to capture cognitive dysfunction in clinical practice.

Conclusions: After a differentiated assessment of cognitive dysfunction, a specific combination of pharmacotherapy and cognitive remediation should be applied to patients with schizophrenia and affective disorders.

Baseline antipsychotic prescription and short-term outcome indicators in individuals at clinical high-risk for psychosis: Findings from an Italian longitudinal study

L. Pelizza¹, E. Leuci², E. Quattrone², M. Menchetti¹, A. Di Lisi³ and C. Ricci^{1*}

¹Università di Bologna, Bologna; ²AUSL di Parma, Parma and ³Alma Mater Studiorum University of Bologna, Bologna, Italy

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1588

Introduction: The prognostic prediction of outcomes in individuals at clinical high-risk for psychosis (CHR-P) is still a significant clinical challenge. Among multiple baseline variables of risk calculator models, the role of ongoing pharmacological medications has been partially neglected, despite meta-analytical evidence of higher risk of psychosis transition associated with baseline prescription exposure to antipsychotics (AP) in CHR-P individuals. In particular, baseline AP exposure in CHR-P individuals may be considered as a functional equivalent of the psychometric transition to psychosis, as already postulated in the original 'Ultra High-Risk' model.

Objectives: The main aim of the current study was to test the hypothesis that ongoing AP need at baseline indexes a subgroup of CHR-P individuals with more severe psychopathology and worse prognostic trajectories along a 1-year follow-up period.

Methods: This research was settled within the 'Parma At-Risk Mental States' program. Baseline and 1-year follow-up assessment included the Positive And Negative Syndrome Scale (PANSS) and the Global Assessment of Functioning (GAF). CHR-P individuals who were taking AP medications at entry were included in the CHR-P-AP+ subgroup. The remaining participants were grouped as CHR-P-AP-. The acquisition of drug and outcome information was collected both at baseline and across the follow-up period. Finally, logistic regression analyses with dichotomized 1-year outcome parameters (previously showing statistically significant differences in inter-group comparisons) as dependent measures and sociodemographic and clinical characteristics as independent variables were also performed.

Results: Hundred and seventy-eight CHR-P individuals (aged 12–25 years) were enrolled (91 CHR-P-AP+, 87 CHR-P-AP-). Compared to CHR-P AP-, CHR-P AP+ individuals had older age, greater baseline PANSS 'Positive Symptoms' and 'Negative Symptoms' factor subscores and a lower GAF score. At the end of our follow-up, CHR-P-AP+ subjects showed higher rates of psychosis transition, new hospitalizations and urgent/non-planned visits compared to CHR-P-AP- individuals.

Conclusions: The current study suggests that AP need is a significant prognostic variable in cohorts of CHR-P individuals and should be included in the current risk calculators. In particular, the results of this study conducted in a realworld clinical setting indicate that the rate of CHR-P individuals who were already exposed to AP at the time of CHR-P status ascription was higher than those reported in recent meta-analyses on this topic. Moreover, our findings confirm that baseline AP prescription appears to increase psychotic transition risk.

Peculiarities of social functioning in patients with negative symptoms in schizophrenia

N. O. Maruta*, Y. A. Kushnir and G. Y. Kalenska

Borderline Psychiatry, "Institute of Neurology, Psychiatry and Narcology of NAMS of Ukraine" SI, Kharkiv, Ukraine

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1589

Introduction: The prevalence of schizophrenia in the world is between 0.4 and 1.4%, and the number of patients with negative symptoms (NS) in this group reaches 90%. NS are considered key components of schizophrenia that negatively affect social functioning (SF) and quality of life in patients with schizophrenia. The purpose of the study was to determine the features of SF among patients with NS in schizophrenia.

Objectives: Features of SF in 252 patients with NS in schizophrenia (main group) and in 79 patients with positive symptoms (PS) in schizophrenia (comparison group) were examined.

Methods: A set of methods was used: Scale of personal and social functioning (PSP), which is a semi-structured interview and allows

to assess the social status of patients, their functioning and satisfaction with the relevant field and statistical methods.

Results: The analysis of the social and personal functioning of patients was carried out in four domains: socially useful activities, personal and social relationships, attention to oneself and one's condition, restless and aggressive behavior patterns. In the sphere of socially useful activities, including work and study, in a significant part of patients with NS in schizophrenia, SF violations were expressed at moderate (41.27 ± 1.26) % and significant (33.33 ± 1.08) % levels. In the sphere of personal and social interaction, 41.27 % of patients had significant violations, 28.97% of patients had moderate violations, and 21.83% had severe violations in the social sphere. In the field of self-care, 21.83% of patients had no violations, in 36.90% - violations in self-care were weakly expressed, and in 26.19% of people - moderately expressed.

When comparing the obtained results with patients with PS in schizophrenia, it was established that among patients with NS in schizophrenia there were more patients with significant impairments in the sphere of social activity (33.33%, $p = 0.033$, $DC = 1.42$, $MI = 0, 07$). Patients with NS in schizophrenia were distinguished by a greater number of patients with significant impairments in the sphere of social interaction (41.27%, $p = 0.001$, $DC = 2.58$, $MI = 0.24$). In the field of self-care, there were more persons with no violations among patients with NS in schizophrenia (21.83%, $p = 0.008$, $DC = 3.33$, $MI = 0.20$). There were more patients with the absence and weak expression of aggressive behavior patterns among patients with NS in schizophrenia (30.95%, $p = 0.0001$, $DC = 10.87$, $MI = 1.55$ and 45.63%, $p = 0, 0001$, $DC = 6.54$, $MI = 1.16$, respectively) in comparison with patients with PS in schizophrenia.

Conclusions: The obtained data should be taken into account when creating psychocorrective programs for patients with NS in schizophrenia.

Acute effects of intranasal oxytocin on affective empathy of patients with refractory schizophrenia and healthy controls: results of a randomized clinical trial

F. D. L. Osório* and A. C. Ferreira

São Paulo University, Ribeirão Preto, Brazil

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1590

Introduction: Oxytocin (OXT) is a neuropeptide associated with social behavior and the modulation of neural circuits related to social cognition and emotion regulation. Schizophrenia is a mental disorder that causes impairment in different areas of social cognition, including empathy. A systematic review of the literature showed positive effects of exogenous administration of this hormone on the empathy of individuals without psychopathology, especially in the affective domain. Studies on the effect of OXT on empathy in patients with schizophrenia are very limited, being restricted to the cognitive domain. Attributions must be overcome in future studies. The effects associated with chronic use of the hormone should be the subject of future studies.

Objectives: to evaluate the effect of a single dose of intranasal OXT (24UI) on affective empathy in individuals with refractory schizophrenia and healthy controls.

Methods: a double-blind, randomized, placebo-controlled clinical trial was conducted. A convenience sample of 51 adult men (mean age 34.4 ± 7.6 , >10 years of education) was recruited, 20 of whom were diagnosed with refractory schizophrenia according to the DSM-5 (exclusively using clozapine or clozapine + mood stabilizer and/or benzodiazepine) and 31 healthy controls. They were randomized into four groups and received OXT or placebo (PLA – vehicle: SCH-OXT (N=11), SHC-PLA (N=9), HC-OXT (N=15), HC-PLA (N= 16)). Before and after 50 minutes of administering the substance, they performed an affective empathy task (Multifaceted Empathy Test – MET).

Results: the baseline levels of affective empathy of patients with schizophrenia were lower compared to healthy controls when faced with negative stimuli ($p=0.003$), but not positive ones ($p=0.39$). After the administration of OXT and PLA (post-pre), a small increase in empathy levels was observed in all groups, which did not reach statistical significance (positive stimuli: Δ SCH-OXT = 0.16 ± 1.08 ; Δ SHC-PLA = 0.53 ± 1.44 , Δ HC-OXT = 0.02 ± 0.67 , Δ HC-PLA = 0.24 ± 0.45 , $p=0.85$; negative stimuli: Δ SCH-OXT = 0.20 ± 1.31 ; Δ SHC-PLA = 1.16 ± 0.79 , Δ HC-OXT = 0.12 ± 0.99 , Δ HC-PLA = 0.31 ± 0.57 , $p=0.11$).

Conclusions: the acute effects of intranasal OXT did not favor improvements in the levels of affective empathy, either in patients with schizophrenia or in healthy controls, contrary to the hypotheses of this study. The limited sample size and context-dependent aspects of OXT may explain these findings. These methodological limitations must be overcome in future studies. The effects associated with chronic use of the hormone should be the subject of future studies.

Lymphocyte level and selected cognitive functions in patients with schizophrenia – preliminary results

B. Nycz and K. Krysta**

Department of Rehabilitation Psychiatry, Medical University of Silesia, Katowice, Poland

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1591

Introduction: Schizophrenia is a mental disorder characterized by negative symptoms, such as cognitive impairment. Recent reports indicate the importance of the immune system in the pathophysiology of schizophrenia. The development of inflammation affects cognitive functioning.

Objectives: The aim of the study was to analyze the association between the level of lymphocytes in venous blood and selected cognitive functions in patients with schizophrenia.

Methods: Lymphocyte levels were determined in the venous blood of patients suffering from schizophrenia and the control group. Additionally, a verbal fluency test (VFT) and a Stroop test were conducted on the same day. The VFT evaluates the ability to express words, and the Stroop test assesses verbal working memory. The inclusion criteria were age up to fifty years, and for the study

group – diagnosis of schizophrenia and treatment with neuroleptics. Exclusion criteria included organic brain diseases, electroconvulsive therapy, and use of benzodiazepines within 48 hours before the study. Currently, six patients and six healthy people have been studied.

Results: Patients diagnosed with schizophrenia have an increased lymphocyte concentration in the blood compared to healthy individuals constituting the control group. There are discrepancies in the results of the phonemic fluency test, no significant differences were found between schizophrenics and the control group. Healthy men and women achieved higher results in the semantic fluency test compared to men and women with schizophrenia. Women constituting the control group achieved higher results in the Stroop test compared to women suffering from schizophrenia. Table 1 illustrates the concentration of lymphocytes in venous blood and the number of points in the phonemic fluency test, semantic fluency test, and in the Stroop test of the study and the control groups.

Image:

People included in the study	Sex	Concentration of lymphocytes in venous blood [K/uL]	Number of points in the phonemic fluency test	Number of points in the semantic fluency test	Number of points in the Stroop test
Study group	Male	1,22	40	47	20
		1,65	30	44	17
		2,13	40	45	20
		1,53	34	41	20
	Female	1,6	33	44	36
		1,61	40	62	21
Control group	Male	2,7	14	27	30
		1,51	32	32	39
		1,53	26	26	46
		4,33	51	46	33
	Female	1,91	39	41	25
		1,53	59	52	22

Conclusions: Patients with schizophrenia are characterized by higher levels of immune system parameters and worse results in terms of semantic fluency. Men with schizophrenia showed no verbal working memory deficits. In turn, women with schizophrenia obtained worse results in the verbal working memory test. In conclusion, there is evidence of immune system activation in schizophrenia, which affects the cognitive functioning of patients.

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1592

Introduction: The main finding of a large-scale collaborative study (Rees et al. Nat Neurosci 2020;23(2) 179-184), which focused on *de novo* mutations in schizophrenia, was the discovery of an enrichment of these mutations in the *SLC6A1* gene. This gene encodes the gamma-aminobutyric acid (GABA) transporter GAT1, thereby encouraging further research into novel schizophrenia targets within the GABA pathway. However, the gene was not highlighted in recent schizophrenia genetic studies, while typically pathogenic *SLC6A1* mutations result in epilepsy, motor dysfunction, autistic spectrum disorder (ASD) and developmental delay. The absence of genetic replication for *SLC6A1*'s involvement in schizophrenia and the differing clinical spectrum for *SLC6A1* mutations led us to study in depth one of the only three original probands from the Rees et al. 2020 study.

Objectives: In our comprehensive case study, we delved deep into the relationship between the *SLC6A1* mutation and schizophrenia.

Methods: Our subject, a patient who first presented with acute mania symptoms at age 15 and was later diagnosed with schizophrenia, carried the *SLC6A1* Arg211Cys mutation. Over a detailed 25-year follow-up, we conducted an array of assessments and tests, including cognitive testing, personality assessments, EEG, and 1H-MRS.

Results: Notably, we discovered abnormal GABA levels, potentially indicating a dysfunction in GABA reuptake, adding a new layer of complexity to our understanding. Further analysis revealed a significant correlation between the patient's clinical picture and a polygenic background, rather than the *SLC6A1* mutation. Despite having a high polygenic risk score for bipolar disorder, the dominant features of his condition were more representative of schizophrenia. Interestingly, neither the patient nor his father, who also showed a higher BP PRS, had a diagnosis of bipolar disorder. The pathogenic significance of the mutation warrants investigation in cells of neuronal origin. We generated induced pluripotent stem cells (iPSC) from the patient and his parents. This approach provides us with a platform for future investigations into the pathogenic significance of the mutation in neuronal cells. The Human Pluripotent Stem Cell Registry accession numbers of those cells are MHRCCGi001-A (patient), MHRCCGi005-A (mother) and MHRCCGi004-A (father).

Conclusions: In the presented case the clinical picture is rather explained by the polygenic background than by the *SLC6A1* Arg211Cys mutation. The study is supported by Russian Science Foundation, grant 21-15-00124 (<https://rscf.ru/project/21-15-00124>)

Short-chain fatty acids in schizophrenia: are they affected by a depressive state?

M. Couce-Sánchez^{1*}, G. Paniagua^{1,2}, L. González-Blanco^{1,2,3,4}, A. García-Fernández², C. Martínez-Cao², C. Sabater⁴, A. Margolles⁴, J. Bobes^{2,3,4}, M. P. García-Portilla^{1,2,3,4} and P. Sáiz^{1,2,3,4}

¹AGC Salud Mental IV, SESPA; ²Psychiatry, University of Oviedo;

³G05, CIBERSAM and ⁴ISPA, Oviedo, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1593

Introduction: Short-chain fatty acids (SCFA) are bacterial metabolites that, within microbiome-gut-brain axis, make a promising research line on etiopathology of mental diseases like schizophrenia (SZ) and major depression disorder. Besides, depressive symptoms are frequent clinical features of SZ.

Objectives:

- Describe fecal SCFA concentrations in SZ patients.
- Analyze differences in SCFA depending on:
- Depression.
- Clinical severity, antipsychotics and antidepressants, comorbidities (pro-inflammatory state/obesity/metabolic syndrome [MetS]), lifestyle.

Methods: Cross-sectional study of 67 outpatients [mean age=43.52 ±12.42, range=22-67; males=40 (59.7%)] with diagnosis (DSM-5) of SZ recruited from their mental health clinics in Oviedo (Spain).

- Assessment:
- Fecal SCFA (gas chromatography;µg/mL).
- Plasmatic C-reactive protein (CPR;mg/dL).
- PANSS, Calgary Depression (CDS), International Physical Activity (IPAQ), Mediterranean Diet Adherence (MEDAS).
- Toxic habits (alcohol use/smoking/cannabis).
- Chlorpromazine equivalent doses (CPZ-ED), use of antidepressants.
- MetS (ATP-III), body mass index (BMI; kg/cm2).
- Statistics: Spearman correlation, U Mann-Whitney, ANCOVA.

Results: 14 patients showed clinical depression (CDS≥5). There were no differences in age or sex between groups. 36 patients (53.7%) showed systemic low-grade inflammation (CPR≥0.3mg/dL) and 32 (30.8%) MetS. Table 1 shows fecal SCFA levels by depressive state. Means (SD) are shown.

Table 1

	CDS≤4	CDS≥5	Total	U Mann-Whitney (p-value)
Acetate	21.449 (12.823)	12.911 (7.189)	19.665 (12.328)	221.000 (0.021)
Propanoate	9.170 (6.819)	6.848 (6.036)	8.685 (6.687)	268.500 (0.114)
Butyrate	8.529 (6.436)	7.875 (8.232)	8.392 (6.787)	320.000 (0.432)
Total SCFA	39.148 (23.770)	31.415 (24.526)	36.742 (23.549)	250.000 (0.062)

Correlations were found in Age with Butyrate ($r=-0.248, p=0.043$) and weekly alcohol units with Propanoate ($r=0.250, p=0.041$) plus trend to significance with Butyrate ($r=0.232, p=0.059$). It also showed a trend towards statistical relation for CPZ-ED with Propanoate ($r=-0.253, p=0.039$) and Total SCFA ($r=-0.253, p=0.039$). We found no correlation in SCFA with MetS, CGI, PANSS-N, BMI, IPAQ, MEDAS and other toxic habits.

ANCOVA was performed to Acetate and Total SCFA using depression state as independent variable and Age and CPZ-ED as covariates. There was a trend towards statistical significance for Acetate ($F=3.937, p=0.052, \eta^2=0.059$) whereas Total SCFA showed no difference ($F=1.350, p=2.250, \eta^2=0.021$).

Conclusions: There seems to be lower levels of fecal Acetate in SZ patients with depressive symptoms, considering age and antipsychotic intake. In our sample there was no relation between SCFA and clinical severity, lifestyle, comorbidities or antidepressant use.

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1594

Introduction: Alterations in motor activity are an extremely important characteristic and one of the leading symptoms of major functional psychiatric disorders. These pattern disturbances can be observed in schizophrenia. Actigraphy is a non-invasive method that can be used to monitor these changes, and recent studies emphasize its significance in the early identification of disorders like schizophrenia.

Objectives: This study uniquely focuses on distinguishing latent liabilities for schizotypy from manifested schizophrenia using specific actigraphy features.

Methods: Actigraphy data were collected using specialized devices from the University of Szeged and Haukeland University Hospital datasets (Berle et al., 2010). At Haukeland University Hospital patients with chronic schizophrenia (N=23) (so-called: manifested group) were collected, separately, at the University of Szeged, healthy university students were recruited and screened for latent tendencies towards schizotypic pathological development. In the latter study, two main groups were formed based on their scores:

a positive schizotypy factor group (so-called: latent group) (N=22) and a control group (N=25), with actigraphy data.

Utilizing the pyActigraphy library (Hammad et al., 2021) and wavelet analysis, features such as activity mean, interdaily stability and sleep movement characteristics were derived. Feature selection employed machine learning algorithms, notably Logistic Regression, Random Forest, ANN, and AHFS aided by Shapley values and Click Forming Feature Selection for insight into the most influential features.

Results: The three models exhibited similar performance with a 60% accuracy threshold. In the latent group, sleep-related movements have a substantial impact, while in the manifested group, in addition to sleep characteristics, features like RA, IV, ADAT, M10, the mean activity level (all of which decreased), and the ratio of zero values also play a significant role. In the latent group, features related to the length of small amplitude movements were dominant, particularly the increased values, along with a decrease in the density of large movements.

Conclusions: Our study indicates that in the latent phase of schizophrenia, actigraphy features related to sleep are most significant, but as the disease progresses, both sleep and daytime activity patterns are crucial. Sleep disturbances may signal early susceptibility, with nighttime movements offering clearer insights. These variations might be influenced by medication effects in the manifested group, reflecting the broader challenges in schizophrenia research where the drug-free study of patients remains elusive. Further studies should explore these features in the Clinical High Risk and prodromal groups to refine our understanding of the development of the disorder.

Manic episode with psychotic symptoms in a patient with Pseudologia Fantastica of years of evolution. A case report

C. Díaz Mayoral^{1*}, E. Arroyo Sánchez¹, P. Setién Preciados¹ and M. Martín de Arriba Lorente²

¹Psiquiatría, Hospital Universitario Príncipe de Asturias and

²Psiquiatría, Hospital Doctor Rodríguez Lafora, Madrid, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1595

Introduction: Pseudologia Fantastica (PF) also called “mythomania” is a disorder centred on the tendency of the sufferer to distort reality through constant lies. These patients find it difficult to moderate their sense of self and their self-esteem. Therefore, they display significant grandiosity, which seems to defend them from intense psychological disturbance, pretending to counteract deep feelings of unworthiness, emptiness and alienation.

Notable characteristics include: normal or above average IQ, absence of formal thought disorder, poor sense of identity, poor sexual adjustment, low frustration tolerance, strong dependency needs and narcissism. The phenomenon of “imposture” (the person's claim of achievement or having connections to famous or influential people) is frequent. The patient's history often shows that one or both parents were experienced as rejecting figures. They

are more likely to be involved in legal problems and 20% receive some form of psychiatric treatment.

The aetiology and pathogenesis of this disorder requires consideration of developmental disturbances, personal history and current life stressors.

Objectives: A case of a patient with PF is presented followed by a theoretical review on the topic.

Methods: A case is presented with a bibliographic review.

Results: We admitted a 47-year-old man to the Acute Hospitalisation Unit for a suspected “psychotic episode with clinical mania”.

He presented manic and psychotic symptoms, with delusional ideation of months of evolution, megalomaniacal and fantastic discourse, centred on his work with high-ranking government officials and other implausible events. Multiple academic, work and personal life failures, with a diagnosis of depression 15 years earlier.

During admission, he constantly confirms his history. He tends to present a rationalising discourse and a minimising attitude towards behavioural alterations. He appears cooperative and docile at certain times, while at others he is irritable, complaining and threatening.

As for medication, olanzapine was initially prescribed at a dose of 20 mg per day, which was reduced to 10 mg given the psychopathological improvement and the difficulties of adherence.

On discharge, the presumptive diagnosis was “delusional disorder and probable personality disorder with narcissistic traits, with a history of PF, which in recent months has presented a manic episode with psychotic symptoms”.

Conclusions: Their management poses challenges in terms of engaging with treatment and building a therapeutic alliance. It is important to assess the social and legal implications. Ensuring that they have stable relationships and adequate social supports is essential for successful treatment. Further exploration and research into this disorder is needed to better understand its manifestations and psychiatric consequences.

Neurodevelopmental outcomes in children conceived by assisted reproductive treatment

B. Abdelmoula*, I. Bouaziz, A. Lamine and N. Bouayad Abdelmoula

Genomics of Signalopathies at the service of Precision Medicine - LR23ES07, Medical University of Sfax, Sfax, Tunisia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1596

Introduction: Impact of assisted reproductive treatment (ART) techniques on the child’s mental development is the focus of numerous studies. Whereas several studies have found potential negative effects on ART children’s psychosocial health, others recognized that the data on the cognitive and psychosocial development of ART children are comforting.

Objectives: Here, we aim to state the current findings concerning psychological outcomes in children conceived by ART.

Methods: Using as key words “assisted reproductive” and as filter “meta-analysis”, we comprehensively reviewed the scientific literature through new meta-analysis during the five last-years resuming the main conclusions of these studies to define principal through psychological conditions in children conceived by diverse ART techniques and approaches.

Results: Our review showed that since 1978, the date of the first birth using in vitro fertilization technology (IVF), more than 10 million children are conceived by ART. Our research revealed 441 meta-analysis. After a comprehensive analysis of abstracts, only four meta-analysis were selected. Chronologically from 2019 to 2023, the first studies showed that the risk of intellectual disability and autism spectrum diseases (ASD) were higher in intra-cytoplasmic sperm injection (ICSI) children compared to conventional IVF children. The differences in the risk of neurodevelopmental disorders in children born after frozen and fresh embryo transfers were not significant. Analysis of potential cofounder effects such as multiple and preterm birth having a significant correlation with neurodevelopmental disorders suggested that ART is unlikely to cause negative impacts on children’s neurodevelopment. The findings of the most recent meta-analysis showed that the use of ART did not associate with the risk of ASD,

Conclusions: Given the multitude of factors modulating ART, from the indication and parental background to the type of used technique and approach, the results of the studies that investigated the association between ART and neurodevelopmental outcomes remain yet contradictory.

Do attachment styles influence the sexual function of an individual?

J. C. Rodrigues, T. P. Soares* and L. M. Ribeiro

Psychiatry, Vila Nova de Gaia/ Espinho Hospital Center, Vila Nova de Gaia, Portugal

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1597

Introduction: Attachment theory, first proposed by John Bowlby and later extended by Mary Ainsworth and others, outlines how experiences of early childhood attachment with caregivers can affect one’s emotional and interpersonal relationships throughout adulthood. Typically, attachment styles are categorised into four main types: secure, anxious-ambivalent, avoidant and disorganised. Conversely, it is recognised that various biological, psychological, relational, social and iatrogenic factors elements can impact an individual’s sexual function.

Objectives: Our aim with this research was to present the most current literature on whether there is a correlation between attachment styles and sexual function.

Methods: We conducted a non-systematic review on the topic using PubMed and PsycInfo.

Results: There is evidence indicating a link between attachment styles and sexual function.

People with secure attachment styles tend to experience more positive and fulfilling sexual relationships. Such individuals

typically have a more positive self-image, they feel at ease with emotional intimacy, and are therefore able to openly communicate their needs and desires. They exhibit a healthy balance between seeking closeness and maintaining independence.

Individuals with anxious attachment styles may experience heightened levels of sexual anxiety and insecurity. Concerns regarding rejection or abandonment within sexual relationships may impact their sexual function and satisfaction. These individuals usually have a negative self-image and may be more prone to seek reassurance and validation through sexual activities.

People with avoidant attachment styles may encounter obstacles in developing emotional intimacy and closeness, which can negatively affect their sexual relationships. Such individuals might experience commitment anxiety and prioritise physical aspects of sexual activity over emotional bonding, ultimately decreasing sexual satisfaction for both them and their partners.

Disorganised attachment styles are linked with challenges in regulating their emotions and behaviours in intimate situations, which can have a negative impact on sexual function and satisfaction.

Conclusions: While the literature proposes attachment styles may impact sexual function, it is important to acknowledge other factors that contribute to sexual function. In addition to biological and iatrogenic factors, individual personality, relationship dynamics, past experiences, and cultural influences all have a significant role in shaping one's sexual behaviour and satisfaction. All of these should be addressed in order to alleviate sexual difficulties.

Moreover, attachment styles may develop and change over time through positive relationships and therapeutic interventions, potentially leading to changes in one's sexual functioning and relationship dynamics.

Breaking the Taboo: Unveiling the Prevalence and Predictors of Female Sexual Dysfunction in Tunisia

K. Razki*, A. Larnaout, C. Najar, S. Ben Aissa, R. Iansari and W. Melki

Psychiatry department, razi hospital, manouba, Tunisia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1598

Introduction: Female sexuality is a complex and multifactorial domain that can be influenced by a variety of psychological, biological, relational, and sociocultural factors. However, sexual dysfunctions in women remain a taboo subject in many cultures and are often underestimated, underdiagnosed, and undertreated. In Tunisia, few studies have been conducted to assess the prevalence of sexual dysfunctions in women and their predictive factors.

Objectives: to determine the prevalence of sexual dysfunctions in a group of Tunisian women and to identify the predictive factors of these dysfunctions.

Methods: This is a cross-sectional, descriptive, and analytical study, over a period of three months, from September to December 2022, conducted online via a pre-established questionnaire to collect various sociodemographic data, personal history, psychoactive substance consumption, weight, and height. We used the Female Sexual Function Index (FSFI) scale to evaluate sexual

functioning in participants. We recruited sexually active Tunisian women over 18 years of age who agreed to anonymously respond to the questionnaire. The form was disseminated on social networks, in groups that focus on women, with a rate of three publications per week.

Results: We collected data from 90 women with a mean age of 35 ± 12.84 years.

More than half of our population (60%, $n=54$) had at least one sexual dysfunction.

The most common sexual dysfunctions reported were arousal disorders (31.3%), followed by desire disorders (26.8%) orgasm disorders (12.4%).

We found that several factors were significantly associated with sexual dysfunctions: Women over 45 years of age ($p < 10^{-3}$), who are divorced ($p=0.02$), have a low socioeconomic status ($p=0.04$), and report having experienced traumatic romantic/sexual experiences ($p < 10^{-3}$) were found to have a higher prevalence of sexual dysfunctions.

According to our results, cannabis consumption had a negative impact on lubrication ($p < 10^{-3}$) and orgasm ($p=0.003$) among our study respondents. Personal psychiatric history also had a negative influence on arousal ($p=0.02$) and sexual satisfaction ($p=0.01$).

Conclusions: By identifying sexual dysfunctions early and treating them effectively, we can improve the quality of life of those affected and avoid serious consequences on their physical and mental health. It is therefore crucial to promote a proactive approach to sexual health and encourage healthcare professionals to approach sexuality openly and comprehensively.

Relationship between sleep and sexual functioning in Indian females

R. Tripathi^{1*}, P. Deedwania² and A. Koparkar³

¹Psychiatry, All India Institute of Medical Sciences, Gorakhpur;

²gynaecology, All India Institute of Medical Sciences, New Delhi and

³Community and Family Medicine, All India Institute of Medical Sciences, Gorakhpur, India

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1599

Introduction: Sexual dysfunction is a taboo. It is a subject in many countries that negatively affects quality of life and may often be responsible for psychopathological disturbances. There is a little research on effect of sleep on female sexual response and behaviour.

Objectives: The aim of the study was to assess prevalence of sexual dysfunction and sleep problems in adult females visiting OBGY OPD in a tertiary health care institution in a developing country and to observe the correlation between both.

Methods: A cross-sectional observational study was conducted in a tertiary health care center in India. Female Patients presenting to Department of Gynecology and Obstetrics for any complaints were assessed for their sexual functioning and sleep profile

Results: The mean age of the sample was 33.5 (6.2) years. All the female participants were married. Most of the participants were housewife and were living in a joint family. Almost 27 percent of the sample reported having sleep problems. The median sleep latency

was 30 (15,60) minutes. The subjective total sleep time was 356.5 (60.3) minutes. The mean PSQI score was 4(2,6). The mean FSFI score was 26 (3.2). More than 50 percent of the females reported mild sexual problems and 10 percent reported mild to moderate problems. Most of the females didn't have any symptoms suggestive of depression. Only two females reported moderate depression.

Conclusions: Depression and anxiety have more effect on sexual functioning.

Disclosure of Interest: None Declared

EPV1014

The Impact of Psychotropics on Sexuality: A Literature Review

B. Abassi*, F. Fekih-Romdhane, F. Baccar, M. Cheour, E. Sana and R. Damak

Ibn Omrane, Razi Hospital, Mannouba, Tunisia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1600

Introduction: Sexual dysfunctions related to psychotropic drugs are among the most distressing adverse effects and can lead to non-adherence to treatment.

Objectives: To elucidate the mechanisms of psychotropic-induced sexual dysfunctions and to suggest strategies for their management.

Methods: Literature review based on the keywords "psychotropics," "sexuality," and "sexual dysfunction".

Results: Psychotropic medications can impact sexuality either directly or indirectly. The direct effect is primarily due to a decrease in the mesocortical dopaminergic atmosphere, either by blocking D2 receptors or by stimulating 5HT2A receptors. D2 receptor blockade in the tubero-infundibular pathway triggers an increase in prolactin secretion, which can subsequently lead to erection problems, decreased libido, and difficulties achieving orgasm. Action in the nigrostriatal pathway may result in an extrapyramidal syndrome, which can, in turn, hinder intimate physical relations. The indirect effect can also be caused by metabolic complications, which are significant risk factors for sexual dysfunction, as they can lead to male hypogonadism and a negative self-image.

Therapeutic strategies suggest either reducing doses (if the patient's condition allows), changing the drug, or adding an adjunctive medication. Aripiprazole, being a partial agonist of D2 and 5-HT1A receptors and an antagonist of D3 and 5-HT2A receptors, appears to cause fewer sexual dysfunctions and can reduce hyperprolactinemia when added to other antipsychotics.

Conclusions: Healthcare professionals must proactively gather information on sexuality given its impact on quality of life and treatment adherence. Prioritizing this dimension of well-being demonstrates a respectful approach toward the patient and establishes the foundation for a strong therapeutic alliance.

Perspectives on Sexual Health Management among Tunisian Primary Care Physicians

F. Baccar¹, B. Abassi^{1*} and B. Amamou²

¹Ibn Omrane, Razi Hospital, Manouba and ²Psychiatry, Fattouma Bourguiba, Monastir, Tunisia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1601

Introduction: Sexual health significantly influences individual well-being. It is thus crucial for primary care physicians to address these concerns effectively.

Objectives: To evaluate the perspectives and approaches of primary care practitioners towards sexual health.

Methods: A descriptive survey was disseminated to 350 primary care physicians via Google Forms in August 2022.

Results: Of the respondents, 53.1% were female. The majority (71.4%) were affiliated with the public health sector, and over 75% were based in urban areas. All acknowledged the importance of addressing sexuality in their patients' health. In this context, 62% spontaneously initiated discussions on the subject with their patients. Also, 72% noted that patients anticipate a regular dialogue about sexual health with their primary care provider. Over 90% believed in the value of addressing sexual dysfunctions more proactively, with 56% comfortable in leading such discussions. Additionally, 64% were inclined to include targeted questions on sexual health in their consultations. Notably, 77.6% expressed interest in creating specialized sexual health consultations in their practice. However, 54% felt unease in discussing sexual health with opposite-gender patients, and 82% lacked referrals to sexologists.

Conclusions: Sexual health issues are not uncommon in general practice. Primary care providers play a vital role in counseling, screening, and educating patients on these concerns, necessitating specialized training to enhance patient management.

Knowledge, perceptions and attitudes of medical doctors toward elderly sexuality in Tunisia

H. jemli¹, A. aissa², U. ouali¹ and R. Ezzaibi Jemli^{2*}

¹faculty of medicine of tunis and ²razi hospital, tunis, Tunisia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1602

Introduction: The sexual health of the elderly presents certain particularities to be taken into consideration in the doctor-patient rapport. The aim of our study was to assess physicians' knowledge and attitudes towards sexuality in the elderly in Tunisia and to determine variables associated with the level of knowledge and the nature of attitudes in this population.

Objectives: The aim of our study was to assess physicians' knowledge and attitudes towards sexuality in the elderly in Tunisia and to determine variables associated with the level of knowledge and the nature of attitudes in this population.

Methods: A descriptive and analytical study was conducted among specialists and medical residents of all specialties, practicing in Tunisia and recruited anonymously online. We included questions on socio-demographic data, medical specialty and medical training of physicians as well as a French translation of the Aging Sexual Knowledge and Attitudes Scale (ASKAS). We determined correlations between the socio-demographic and medical training variables and the ASKAS score among participants.

Results: We included 74 physicians in the study. Sixty-two percent of the doctors surveyed sometimes asked elderly patients about their sexuality (N=46) and the rest of the doctors never mentioned the subject during a medical consultation (N=28). The major obstacles reported when discussing sexuality with the elderly were: a feeling discomfort related to sexuality considered a taboo subject (77%), lack of information and skills (51%) and the duration and setting of the medical consultation considered inadequate (45%). The mean score for the knowledge subcategory of the Aging Sexual Knowledge and Attitudes Scale (ASKAS) was 68.49 ± 5.5 and for the attitudes subcategory was 83.74 ± 4.2 . These results indicated a moderate level of knowledge and moderate to negative attitudes. There was a significant and negative correlation between age and the ASKAS knowledge subcategory score ($r = -0.75$, $p = 0.026$), as well as a significant positive correlation between the knowledge and attitudes subcategories scores and sexology training ($p < 0.001$).

The correlation between the knowledge score and the attitudes score was significant, positive, and good ($r = 0.788$, $p < 0.001$); the lower the level of knowledge, the more negative the attitudes regarding elderly sexuality.

Conclusions: There are several gaps in the knowledge and perceptions of Tunisian physicians regarding the sexuality of older subjects. Theoretical teaching and practical anti-ageing training for health professionals are needed.

EPV1018

Beyond Rest: Exploring the Sleep-Exercise Connection

J. Kim^{1,1*}, T. Kainth², E. Garrels² and K. Tran²

¹Psychiatry and ²Bronxcare Health System, Bronx, United States

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1603

Introduction: The bidirectional relationship between the effects of sleep and exercise is often underappreciated. We aim to explore the bidirectional relationship of sleep and exercise. We further discuss the prominence of poor sleep in both the athletic and general population and understand the underlying mechanisms of interdependencies between the two. The goal is to illuminate practical implications to improve both areas and optimize physical and mental health.

Objectives:

- To explore the bidirectional relationship between sleep and exercise

- To understand how exercise can counterbalance the adverse metabolic consequences of sleep deprivation.

Methods: We conducted a systemic literature review from Pubmed, Scopus, and PsychINFO using the search terms: "(exercise) and (sleep)," "(exercise performance) and (sleep)," "(sleep quality) and (exercise)." We included original studies in English conducted on age groups 18 years and older.

Results: Data from 31 studies shows that a significant number of athletes experience poor sleep quality and daytime sleepiness. 68.5% of Qatar Stars League soccer players and 61% of collegiate athletes in NCAA institutions report daytime fatigue several times a week. Most common causes include overtraining, hectic travel schedules, and sleeping in unfamiliar settings. Studies confirm athletes often sleep less before intense training or competitions. Sleep deficiency may lead to reduced muscular strength and endurance, mood changes, increased perceived effort, impaired cognitive processing, and diminished motor skills. Athletes averaging less than 8 hours of sleep nightly were 1.7 times more prone to injuries. Physiologically, sleep loss alters ventilation, plasma lactate concentration, hormone secretion, and inflammatory responses, hinders muscle glycogen restoration. Extended sleep restriction decreases testosterone levels, which influence muscle mass, energy, bone strength, and more. On the contrary, exercise may counter adverse metabolic impacts of sleep deprivation. High-intensity interval exercise (HIIE) has shown to nullify negative metabolic effects of sleep deprivation, suggesting exercise's protective potential.

Conclusions: Sleep and exercise are fundamental to maintaining physical, mental, emotional, and spiritual health. The bidirectional, interdependent relationship can be best utilized by the providers to optimize overall well being. The critical impact of adequate sleep, particularly among athletes, is frequently underestimated. Poor sleep can detrimentally affect performance, amplify injury risks, and disrupt physiological functions, yet contemporary lifestyles often downplay its significance. It is important for healthcare professionals to emphasize a balanced approach to optimize these vital aspects. Continued research can offer strategies that benefit athletes and the broader populace, aiming to uplift daily life functionality.

EPV1019

Sleeping Problems or Emerging Psychosis? A Review of Emerging Literature

J. Kim^{1*}, G. Gill², S. Prasad², N. Roshan², B. Hasan² and S. Gunturu²

¹Psychiatry and ²Bronxcare Health System, Bronx, United States

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1604

Introduction: Sleep disturbance, particularly insomnia, is prevalent across various mental health disorders. While it is a common sign in mood disorders, emerging evidence suggests that insomnia might act as a precursor or an early sign of psychosis. Our case report and literature review emphasize the importance of evaluating sleep disturbances in the diagnosis and management of mental disorders.

Objectives:

- To explore potential neurobiological underpinnings linking sleep disturbances to psychosis onset.
- To advocate for the importance of early identification and intervention for sleep disturbances in the broader context of preventing or managing psychotic disorders.

Methods: We present a case describing a young patient's first episode of psychosis, which was masked by an initial presentation of insomnia. Additionally, we conducted a review of the relationship between sleep disturbances and psychosis, with a comprehensive literature search from Pubmed, Scopus and psychINFO.

Results: A 20-year-old African-American male with a history of poor sleep was initially diagnosed with Major Depressive Disorder. He was treated with Bupropion, Quetiapine, and Trazodone. However, he later presented with worsening depression, odd behavior, and signs of disorganization, suggestive of a psychotic episode. After switching his medication to Risperidone 4mg twice daily, the patient's sleep and other symptoms markedly improved. Through our literature review, we identified that sleep disturbances, especially insomnia, can be a risk factor for developing psychosis. While a cross-sectional study recorded one-fourth of their study population experiencing First Episode Psychosis (FEP) with clinical insomnia, another study reported close to 80% of their study sample with early psychosis suffering from a minimum of one sleep disorder; insomnia and nightmare disorder being the most frequent. A large sample longitudinal analysis lasting one year also observed patients with sleep disorders to be twice at risk of onset and persistence of psychotic episodes. A growing body of evidence also suggests that structural brain abnormalities and neural development alterations in the early stages of psychosis may lead to sleep disturbances and subsequent psychotic symptoms. Findings suggest that thalamic dysfunction may in particular contribute to sleep spindle deficits and altered EEG microstate dynamics. These deficits are unrelated to antipsychotic medication exposure, and are also not observed in patients with other psychiatric illnesses.

Conclusions: While the correlation between sleep disorders and psychosis has been well-established for decades, very limited literature is available on the role of sleep in FEP. Recognizing and treating sleep disturbances is pivotal in managing psychiatric disorders, including psychosis. Thus, a comprehensive evaluation of sleep issues in patients presenting with psychiatric symptoms is imperative for accurate diagnosis and management.

Disclosure of Interest: None Declared

EPV1020

Exploring the Interplay Between Psychosis and Sleep Disruption: Insights into Course, Insomnia, Nightmares, and Treatment

J. Camilo

Psychiatry, CHTMAD, Vila Real, Portugal
doi: 10.1192/j.eurpsy.2024.1605

Introduction: Psychosis and sleep disruption are complex phenomena that often intertwine, influencing each other in intricate ways. This abstract delves into the dynamic relationship between psychosis and sleep disturbances, shedding light on their course, the prevalence of insomnia, the role of nightmares and dreams, and the impact of psychotic symptoms on sleep patterns. Additionally, it discusses the treatment approaches for individuals with psychosis and sleep disturbances, as well as the consequences of these interventions on both conditions.

Objectives: To investigate the longitudinal course of psychosis and sleep disruption, exploring their temporal connections; to assess the prevalence and characteristics of insomnia among individuals experiencing psychosis; to examine the relationship between nightmares, dreams, and psychotic experiences; to analyze the impact of psychotic symptoms on the pattern and architecture of sleep; to review current treatment modalities for individuals with co-occurring psychosis and sleep disturbances and their effects on both conditions.

Methods: Systematic review

Results: Preliminary findings indicate a bidirectional relationship between psychosis and sleep disruption, with each exacerbating the other over time. Insomnia is prevalent among individuals with psychosis, contributing to the severity of psychotic symptoms. Nightmares and disturbing dreams are common experiences, often mirroring the content of psychotic hallucinations and delusions. Psychotic symptoms disrupt sleep patterns, leading to decreased sleep efficiency and altered sleep architecture. Various treatment approaches show promise in addressing both psychosis and sleep disturbances, but further research is needed to determine their long-term effects.

Conclusions: The intricate interplay between psychosis and sleep disruption, emphasizing the need for a holistic approach to assessment and intervention. Understanding the course of these conditions, the high prevalence of insomnia, and the role of nightmares and dreams in the psychotic experience is crucial for developing targeted interventions. Additionally, recognizing the impact of psychotic symptoms on sleep patterns is vital for improving overall well-being. Effective treatment strategies that address both psychosis and sleep disturbances offer hope for enhanced outcomes, but ongoing research is essential to fully elucidate their potential benefits and long-term consequences.

EPV1021

The Nexus of Sleep Disorders and Violence in Patients with Schizophrenia: What do the Data Say?

K. Razki*, A. Larnaout, C. Najar, S. Ben Aissa and R. Lansari

Psychiatry department, razi hospital, manouba, Tunisia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1606

Introduction: One of the common symptoms of schizophrenia is sleep disturbances, which can have a significant impact on the quality of life of patients. Several studies suggest the existence of a complex link between sleep disorders and aggressive behavior in patients with schizophrenia.

Objectives: to determine the impact of sleep disorders on aggressive behavior in patients with schizophrenia.

Methods: We conducted a cross-sectional, descriptive, and analytical study that took place over a period of one month (from 1st to 31st March 2023) with patients consulting the post-cure of Psychiatry Service D at Razi Hospital, Tunisia. We included patients diagnosed with schizophrenia according to DSM5, and stabilized on a psychiatric plan. We used the Pittsburgh Sleep Quality Index (PSQI) to assess sleep quality over a period of one month. The Buss & Perry Aggression Questionnaire (QABP) was used to measure aspects of aggression. We used the Adult Social Relationships Scales (ASRS), part of the National Institute of Health (NIH) toolkit, assessing six domains of social relationships: perceived rejection, perceived hostility, loneliness, friendship, instrumental support and emotional support.

Results: We collected data from 40 male patients with a mean age of 42.5 ± 14.02 . The mean global PSQI score was 9.23 ± 4.58 .

Ten patients were on typical antipsychotics, 25 patients were on atypical antipsychotics, and the remaining five patients were on a combination therapy (both atypical and typical antipsychotics). Regarding the use of benzodiazepines, 34 patients were taking lorazepam at a dose of 2.5 to 5 mg per day. The mean QABP global score was 45 ± 12.3 out of 72.

For the subjective evaluation, all patients self-reported feeling "irritable," "dysphoric," "unable to communicate with others," and "wanting to break objects" when they experienced insomnia. We found a statistically significant association between QABP and daytime dysfunction ($p=0.003$).

The overall PSQI score was higher, and statistically significantly associated, in patients who reported low emotional support ($p=0.018$) and perceived social rejection ($p=0.04$).

Conclusions: An integrated approach that includes the evaluation of sleep disorders, as well as the prevention and management of violence, can play a key role in the overall improvement of the mental health of patients with schizophrenia.

Disclosure of Interest: None Declared

EPV1022

The impact of sleep deprivation on symptoms of anxiety, depression, stress and on the quality of life in medical staff

M. Pavlo^{1,2*}

¹Psychiatric Department, University Center Hospital "Mother Tereza" and ²Psychiatric Department, Regional Hospital of Lezhae, Tirana, Albania

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1607

Introduction: Sleep deprivation is studied in medical staff, as it is a target group more exposed to chronic lack of sleep compared to the normal population. Chronic sleep deprivation has an important impact in the lifestyle of health workers and in their productivity.

Objectives: The study aims to examine the impact of sleep deprivation on medical staff, who work night-shifts and / or 24 hours on the symptoms of anxiety, depression, stress and quality of life.

Methods: This is a quantitative, cross-sectional study. The research instruments used are two: the DASS-42 questionnaire for measuring the level of symptoms of anxiety, depression, stress and the quality of life questionnaire (WHOQOL-Bref), which was validated before the study. In the study sample participated N = 199 medical staff (primary doctor, resident, nurse) from several specialties. Inclusive criteria are: medical staff, who work night-shifts and / or 24 hours; age 23 - 67 years; have not been previously diagnosed with anxiety disorder and episodes of depressive disorder.

Results: Referring to the DASS-42 scoring, the symptoms of depression in the medical staff are: normal 64.8%, mild 8.5%, moderate 21.1%, severe 4.5% and extremely severe 1%. Referring to the points collected from the DASS-42 questions on the symptoms of anxiety in medical staff, it results: normal 53.3%, mild 8%, moderate 17.1%, severe 14.1% and extremely severe 7.5%. Based on the points collected from the DASS-42 questions on stress symptoms in medical staff, it results: normal 54.3%, mild 18.6%, moderate 17.1%, severe 9% and extremely severe 1%. Also, the lower the level of stress, anxiety and depression the higher the quality of life. ($p.01$, $p.05$). Total WHO- Quality of life ($F = 3.447$, $p \leq .05$) and physical health ($F = 6.482$, $p \leq .05$) show significant differences between the educational level, where it is higher among medical staff with postgraduate education.

Conclusions: Working night-shifts and/or 24 hours affects the mild and moderate onset of symptoms of anxiety, depression and stress. The level of stress symptoms is perceived higher in females. The overall quality of life is perceived as average according to the Likert scale. Sleep deprivation affects free time. Medical staff have a restricted free time. The level of anxiety, depression and has a direct impact in the quality of life. The overall quality of life and physical health are rated higher in medical staff with postgraduate education.

EPV1023

A systematic review of effectiveness and safety of some herbal compounds as treatment for primary insomnia

M. Barbosa* and A. R. Fonseca

SPSM, Centro Hospitalar de Leiria, Leiria, Portugal

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1608

Introduction: Sleep related disorders affect around 30% of people all over the world, and evidence shows that 10% require therapeutic intervention. Insomnia represents the most common disturbance of sleep, defined as the experience of poor sleep for at least 1 month. Most of primary insomnia can be prevented by a proper lifestyle and sleep hygiene rules. Regardless, hypnotic drugs and widely prescribed, and most times, long-term used, which is not recommended because of its negative side effects.

Objectives: Review the scientific evidence about effectiveness of plant extracts for insomnia, natural products with practically no side-effects, and thus be possible to reduce or even avoid the use of hypnotic drugs.

Methods: The Medline database through the Pubmed search engine was used with the following keywords: "insomnia" and "herbal compounds".

Results: Valerian activity on sleep disturbances has been attributed to the presence of isovaleric acids and valepotriates with reported calming action and GABA reuptake inhibition with sedative effects. Considering the data presented in the literature, despite controversial and conflicting, several studies showed that valerian (160-600mg/day) improved sleep quality and reduced sleep latency and duration; also valerian seems more effective for chronic insomnia than acute episodes.

Hop has different properties: calming, sleep inducing, gastric secretion stimulating and spasmolytic.

Increasing GABAergic activity seems to be the main mechanism of action, thus inhibiting the central nervous system and also has demonstrated binding affinities to some of the melatonin and serotonin receptor. It's sedative characteristics have been confirmed in a clinical trial in association with valerian, where sleep latency and quality were improved. However, monotherapy studies showed no relevant effectiveness in sleep.

Kava Kava plant showed promising results, in rats and humans, with decrease sleep latency, better sleep quality and recuperation after sleep. However, raised concern about its potential of hepatotoxicity.

There is also promising evidence of the lavender efficacy for sleep disorders in a wide variety of populations and diseases, it was actually mentioned to be as effective as lorazepam in adults with anxiety and sleeping problems. With studies with dose of 80mg it was observed a reduction in sleep awakenings, sleep duration and overall sleep quality and anxiety.

Conclusions: There is a clear preference from the patient to natural compounds, and with almost nonexistent side effects, some herbal derivatives are showed to have positive effectiveness in mild insomnia, but nonetheless much more studies on this field are needed.

Sleep disorders among university students as underestimated mental health problem

E. L. Nikolaev¹, T. Nikolaeva² and M. Alhasan^{2*}

¹Department of Social and Clinical Psychology and ²Medical Faculty, Ulianov Chuvash State University, Cheboksary, Russian Federation

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1609

Introduction: The effect of sleep disorders on the weakening of the students' mental health potential is still underestimated. Students might not openly complain of having problems with sleep, considering them insignificant. Nevertheless, sleep disorders may be the sign of actual or developing mental health problems.

Objectives: To reveal the prevalence of parasomnic and insomnic disorders in university students, who do not have health related complains.

Methods: We surveyed 77 first and second-year students of both genders by means of a questionnaire that included questions describing the signs of various sleep disorders.

Results: One third of the students revealed having parasomnic disorders in the form of dissociated sleep states – 35.1% of the respondents talk in sleep (states of somniloquy or sleep talking), 6.5% get seated on their beds, 5.2% get up from their beds (states of partial awakenings and confusional arousals), 5.2% walk around the room or house (sleepwalking, or somnambulism). Over half of the students experience night phobias (53.2%), 2.6% out of them experience them constantly. Some students' fears grow into nightmares. Half of the respondents (50.6%) state they very rarely see nightmares. Every fifth student (20.8%) sees nightmares only from time to time. 10.4% of the students see them very often or constantly. Over half of the respondents (55.8%) complain of insomnic disorders in the form of insomnia. 3.9% of them experience it constantly, 10.4% – often, 16.9% – sometimes, and 24.7% – rarely

Conclusions: The frequency of sleep disorders in students is very high. Consequently, it is important to inform university students timely about potential risks and ways to avoid them.

How effective is ketogenic diet in sleep disorders ?

N. Kouki

outpatient and emergency department, razi hospital, tunis, Tunisia
doi: 10.1192/j.eurpsy.2024.1610

Introduction: Sleep disorders vary widely and its treatment are based on a combination of life style changes and pharmacological therapy adapted to the primer health issue. Ketogenic diet has shown not only its efficacy in different health conditions, but it is also becoming a popular health trend. Could the therapeutic spectrum of ketogenic diet cover sleep disturbances ?

Objectives: The aim of our study is to evaluate the effect of ketogenic diet on sleep disorders

Methods: To identify relevant studies ,our literature review was based on the Pubmed interface and adapted for 2 databases : science direct and google scholar. We used the following key words (ketogenic diet [meSH terms]) and (sleep disorders [meSH terms]).

Results: Our research revealed 14 articles published between 2012 and 2022. We selected 8 which corresponded to the purpose of our review. The ketogenic diet affects sleep hemostasis indirectly. In fact, this diet is associated with weight loss and therefore reduction of metabolic and cardiovascular complications disturbing sleep quality. From a neurobiological perspective, this regimen based on limited carbohydrates is associated with a low Tryptophan intake which is the precursor of melatonin. But on the other hand, Ketone bodies trigger adenosine activity which promotes melatonin liberation, the sleep inducing hormone.

Conclusions: ketogenic diet modulates melatonin activity therefore affects sleep architecture. Meanwhile, Its impact on sleep disorders is still controversial due to the variation of its pathophysiological mechanisms.

SCHIZOPHRENIC DREAMS: A Brief Description of Sleep Disturbances in Schizophrenia

S. Jesus Magueta*, A. L. Costa, G. Simões, A. I. Gomes, C. Madaíl Grego and P. Garrido

Departamento de Psiquiatria e Saúde Mental, Centro Hospitalar do Baixo Vouga, Aveiro, Portugal

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1611

Introduction: Shakespeare wrote that “We are such stuff as dreams are made on; and our little life is rounded with a sleep.” Sleep is a fundamental part of our being, so much so, humans tend to spend one third of their lives in this immobile and vulnerable state. Disorders of sleep have been the target of much scientific curiosity and investigation, with numerous articles, reports and books dedicated to the theme. The bidirectional relationship between psychiatric disorders and those of sleep is also well described. Schizophrenia is a heterogenous psychiatric disorder which is often associated with sleep disturbances of various kinds.

Objectives: The authors aim to briefly explore the relationship between schizophrenia and sleep disturbances. Potential underlying mechanisms and risk factors, as well as therapeutic interventions will be addressed.

Methods: The authors conducted a brief non-structured narrative literature review using articles published in the Medline/Pubmed, ScienceDirect and Google Scholar databases. The keywords used during the research, alone or in combination, included: sleep disturbance, sleep disorder and schizophrenia. The studies consulted in this work included: cross-sectional studies, cohort studies, literature reviews and clinical case reports. Works that were included, were written in the English language and deemed as pertinent to the explored theme.

Results: Although sleep disturbances do not make up part of the criteria formal diagnosis of schizophrenia, they are present in approximately 80% of those with the condition and have been identified as a common symptom in prodromic clinical pictures. The problems in sleep are as heterogenous as the presentations in schizophrenia, ranging from insomnia, restless legs syndrome, obstructive sleep apnea, circadian rhythm dysfunctions to hypersomnia. Sleep has been identified as fundamental for the reparation and restoration of various bodily systems, it is no surprise that sleep irregularities, especially in schizophrenia, can significantly reduce quality of life and promote deterioration. Some studies have stated the role that D2 receptors have in the classic symptoms of schizophrenia as well as on sleep disturbances. Second-generation antipsychotics have not only demonstrated much promise on psychotic symptoms, but they appear to aid in sleep regulation and quality.

Conclusions: Sleep is fundamental for mental health. Various sleep disturbances have been identified in those suffering with schizophrenia. Sleep disturbances have been associated with worse outcomes, more florid clinical pictures and significant deterioration. Thus, bettering sleep quality in these patients, would permit better health outcomes which are fundamental in those who live with schizophrenia.

Postpartum insomnia in a woman who has given birth to twins : A case report

E. Arroyo Sánchez*, P. Setién Preciados and C. Diaz Mayoral

Hospital Universitario Príncipe de Asturias, Madrid, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1612

Introduction: Postpartum insomnia is a significant and often overlooked mental health concern affecting mothers during the postnatal period. Sleep disturbances during this critical time can have far-reaching implications for maternal well-being and the quality of care provided to newborns.

Objectives: The primary objective of this review is to analyze recent clinical literature on postpartum insomnia to gain a deeper understanding of its epidemiology, clinical features, and management approaches. By synthesizing the latest research findings, this review aims to inform healthcare professionals and policymakers about the significance of postpartum insomnia and promote early recognition and intervention.

Methods: A case report of a 43-year-old woman in the fifth month postpartum after a twin birth who comes to the emergency department accompanied by her partner with thoughts of death and impulse phobias due to insomnia of months of evolution. Also a systematic search of the PubMed database was conducted using the keyword “Postpartum insomnia,” and articles published between 2013 and 2023 were included. A total of 20 clinical articles meeting the inclusion criteria were analyzed to provide a comprehensive overview of postpartum insomnia.

Results: The review reveals that postpartum insomnia is a prevalent and often underdiagnosed condition, affecting a significant proportion of new mothers. Risk factors such as maternal age, parity, social support, and hormonal fluctuations have been identified. Diagnostic challenges arise due to the overlap of symptoms with postpartum mood disorders, necessitating a comprehensive clinical assessment. Recent research emphasizes the importance of non-pharmacological interventions, including sleep hygiene education, cognitive-behavioral therapy for insomnia (CBT-I), and mindfulness-based approaches, as the first-line treatment options. However, pharmacotherapy may be considered in severe cases. Untreated postpartum insomnia has been associated with adverse maternal and infant outcomes, including impaired bonding, increased risk of postpartum depression, and developmental delays in infants.

Conclusions: In conclusion, postpartum insomnia is a prevalent yet often underrecognized mental health concern with multifaceted clinical implications. This review highlights the importance of early detection and intervention to mitigate its impact on maternal well-being and infant development. The integration of non-pharmacological interventions, particularly CBT-I and mindfulness-based strategies, into routine postpartum care holds promise in improving sleep quality and overall postnatal mental health. Healthcare providers should be vigilant in assessing and addressing postpartum insomnia to optimize the well-being of both mothers and infants.

Sleep satisfaction, and its correlates with stress, health and happiness in university students: cultural and gender issues

E. L. Nikolaev², S. S. Fakhraei^{1*} and T. Nikolaeva¹

¹Medical Faculty and ²Department of Social and Clinical Psychology, Ulianov Chuvash State University, Cheboksary, Russian Federation

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1613

Introduction: Sleep plays an important role in preserving mental health. University students' learning activity, habits and cultural background may negatively affect the duration and quality of sleep.

Objectives: To determine the correlations of sleep satisfaction with the level of stress, health and happiness in university students of different gender and cultural backgrounds

Methods: We have surveyed 134 university students (77 domestic students and 57 foreign students). The numbers of male and female students were the same (67 students). To determine the levels of stress, health, happiness, and sleep quality satisfaction, we used a self-rating questionnaire (Nikolaev, 2023).

Results: The general indicator of sleep satisfaction with all the respondents made up 6.22 ± 2.4 points. We have not revealed any valid statistic differences between the satisfaction levels of males and females, domestic and foreign students ($p > .05$). The males have shown a higher level of stress than females ($p = .0004$). The higher level of health assessment was revealed by foreign students as compared with domestic students ($p = .0137$), and by males in comparison with females ($p = .0054$). We did not determine any cultural and gender differences in other parameters. ($p > .05$). According to the final correlation analysis, all the respondents showed that their level of sleep satisfaction was positively correlated with the level of health ($r = .40$) and happiness ($r = .37$), but negatively with the level of stress ($r = -.23$). Similar interrelations were seen in the male group ($r = .40$; $r = .36$; $r = -.28$). Females revealed correlations of their sleep satisfaction with health ($r = .38$) and happiness ($r = .38$), but there was no evidence of correlation with the level of stress ($p > .05$).

Conclusions: University health development programs aimed at improving their students' sleep quality, which take into account the complex of cultural and gender issues, may help enhance the students' health potential.

EPV1029

Sleep architecture disturbance due to the use of benzodiazepines

T. Jupe*, K. Provi and I. Giannopoulos

Psychiatric Hospital of Attica, Athens, Greece

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1614

Introduction: Insomnia, which is characterized by difficulty in initiating or maintaining a physiological sleep, is a relevant clinical issue, affecting not only the elderly population (from 20% to 40%), but also the general population since 30% of adults

report problems in sleeping properly. In addition, 30-40% of adults report complaints about sleep quality lifetime, and 10-15% report chronic insomnia. Benzodiazepines (BZDs) are commonly prescribed to treat insomnia and sleep disorders. BZDs show a rapid sedative and anxiolytic effect, successfully used in the acute treatment of insomnia as well as anxiety, agitation, or anxiety associated with any type of psychiatric disorder. Their use is associated with potential side effects such as residual daytime sleepiness, ataxia, and dizziness. Long-term BZDs use may lead to drug abuse, tolerance, drug dependency, and abstinence. For instance, BZDs abrupt withdrawal can lead to severe symptoms such as insomnia and/or rebound anxiety, an increase in heart rate and blood pressure, nausea and/or vomiting, sweating, diarrhea, convulsions, and other neurological and psychiatric symptoms.

Objectives: This e-poster aimed to summarize evidence regarding the effect of BZDs treatment on human Sleep Architecture.

Methods: A bibliographical review was performed using PubMed platform. All relevant articles were found using the keywords: benzodiazepines, sleep architecture, insomnia.

Results: Prolonged use of benzodiazepines leads to an increase of time spent in stages 2 and a decrease of time in stages 1, 3, and 4. The increased NREM stage 2 is associated with a subjective improvement in sleep quality. The decrease in NREM sleep time in stages 3 and 4 is usually associated with lesser "rest" for the brain, which leads to a lack of concentration.

Conclusions: BZDs use modified sleep architecture in the short and long term.

Sleep disorders among women with post-menopausal osteoporosis

A. Feki¹, I. Sellami^{2,3*}, B. Trabelsi⁴, Z. Gassara¹, S. Ben Djemaa¹, A. Abbes², M. Ezzeddine¹, M. H. Kallel¹, H. Fourati¹, R. Akrou¹, Y. Mejdoub⁴ and S. Baklouti¹

¹Rheumatology; ²Occupational medicine, Hedi Chaker Hospital;

³Medicine university and ⁴Preventive medicine, Hedi Chaker Hospital, Sfax, Tunisia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1615

Introduction: Osteoporosis (OP) is characterized by low bone mass and microarchitectural deterioration of bone tissue. Recent studies have suggested that sleep may significantly influence the pathophysiology of OP.

Objectives: In the present study, we aimed to determine sleep disorders among women with post-menopausal OP.

Methods: A cross-sectional study was conducted between January and June 2023. Patients with post-menopausal OP who visited the rheumatology department in a university hospital in Tunisia were interviewed. The Pittsburgh Sleep Quality Index (PSQI). It is a seven-component scale, including: sleep quality (C1), sleep latency (C2), sleep duration (C3), sleep efficiency (C4), sleep disturbances (C5), sleep medication use (C6), and daytime dysfunction (C7). $PSQI \leq 7$ indicated normal sleep quality, and $PSQI > 7$ indicated poor sleep quality.

Results: Ninety-three women diagnosed with post-menopausal OP were interviewed. the number of complete questionnaires was 72. The valid rate was 77.4%. All were women. The mean age was 72.5 (± 1.08). The median duration of menopause was 23 years (IIQ = [10.5-28.5]). Forty-five women were diagnosed with bone fractures (62%). Thirty-three patients (45.8%) were obese (IMC>30). The median PSQI score was 16 (IIQ = [6-18]). Forty-seven participants (65.3%) had poor sleep quality (PSQI > 7). According to the items of PSQI: the median score of sleep duration, sleep Efficiency and sleep disturbances was 1 (IIQ = [1 -2]) for each item. The median score of sleep latency was 3 (IIQ = [2-3]). For daytime dysfunction, the median score was 2 (IIQ = [0-3]).

Study analytics revealed a significant association between daytime dysfunction and the presence of bone fractures ($p=10^{-3}$), the same was with sleep disturbances and bone fractures ($p=10^{-3}$). Body mass index (BMI) was significantly and inversely associated with sleep quality ($r= -0.313$; $p= 0.007$). Sleep latency was significantly associated with physical activity ($p<10^{-3}$).

Conclusions: In conclusion, our results suggest that sleep quality is associated with physical activity and BMI. This is consistent with the most recent evidence in the literature. These findings support expanding the scope of wellness programs to promote healthy sleep among osteoporotic women.

The results of a study of the causes and correlations between stress and sleep disorders by medical professionals

P. Sarantuya^{1*}, B. Purev¹ and T. Myatav²

¹medical department, Etugen university and ²Avicenna science center, Ulaanbaatar, Mongolia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1616

Introduction: Prolonged exposure to stress can adversely affect mental health and lead to mental illness, which can adversely affect the provision of medical care. It has been determined that sleep disturbances affect physical and mental health and negatively affect daily activities. Therefore, we conducted this study with the assumption that it is an opportunity to improve health care by examining the prevalence of stress in the medical profession and identifying its causes.

Objectives: To study the prevalence of stress and sleep disorders among doctors and medical professionals in Selenge Province General Hospital2. Identify some factors affecting stress and sleep disorders and their relationship

Methods: Using SRQ20, PHQ9, GAD7, and sleep disturbance questionnaires issued by WHO for doctors of primary health care institutions, according to the analytical research model, the ethics committee with the informed consent form, and the research was conducted.

Results: Doctors and medical professionals aged 23-65 participated in the study, the average life expectancy was 37.05 years. 44.44% are stressed. 8% of stressed people had severe stress, 18.89% had no sleep disorder and 81.11% had a sleep disorder. 46.67% of those

with sleep disturbances had mild sleep disturbances. But 34.44% had sleep disorders. 30% had a non-organic sleep disorder, 5.56% had lucid dreaming disorder, and 3.33% had non-organic insomnia. According to the correlation analysis, the SRQ20 stress score GAD7 anxiety score is $r=0.76$, the PHQ9 score is $r=0.74$, the sleep disturbance score is $r=0.68$, the satisfaction score is $r=-0.44$, the sleep disturbance score GAD7 score $r=0.75$, a moderate positive correlation with the PHQ9 depression score $r=0.45$, and a weak inverse correlation with the satisfaction score $r=-0.24$ was related. In the composite linear regression analysis, the stress score increased by 116.2% when the stress problem score increased by one, the anxiety problem score increased by 44.34%, the body shape problem screening questionnaire increased by 82.86%, and the depression problem score increased by one. 73.18% per increase of one, and 7.18% per increase of PHQ9 depression score was statistically significant. On the other hand, the sleep disorder score increases by 127.05% when the stress problem score increases by one, the anxiety problem score increases by 120.79% and the body shape problem detection questionnaire score increases by one.

Conclusions: Doctors and medical professionals need to increase their coping skills, psychiatric examination and diagnosis, and psychological counseling. Also, by implementing the right lifestyle habits, most of the sleep disorders of doctors and medical professionals can be normalized by themselves. Stress is associated with depression, anxiety, sleep disturbances, years of work, relationship satisfaction, psychological problems, and depression.

A Review of Current and Future Pharmacologic Treatments for Narcolepsy

P. Chue^{1,2*}, J. Chue², M. Tate², A. Andreiev² and A. Abba-Aji¹

¹Psychiatry, University of Alberta and ²Clinical Trials and Research Program, Edmonton, Canada

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1618

Introduction: Narcolepsy is a rare but disabling neurological disorder involving disruption of the sleep-wake cycle that is often under- or misdiagnosed (Barateau L, *et al.* J Sleep Res. 2022;31(4): e13631). It is characterized by a classical tetrad of excessive daytime sleepiness (EDS), cataplexy, hypnagogic hallucinations, and sleep paralysis. Narcolepsy is divided into 3 types: Narcolepsy Type 1 (NT1); Narcolepsy Type 2 (NT2); and Secondary Narcolepsy. The pathophysiology remains unclear but is primarily associated with loss of hypocretin (orexin) neurons involving autoimmune and genetic risk factors, particularly for NT1.

Objectives: To review the currently available therapies for the treatment of narcolepsy.

Methods: The extant literature was reviewed and discussed in the context of clinical relevance.

Results: Treatment historically has included medications developed for the treatment of other conditions such as psychostimulants (methylphenidate, modafinil/armodafinil, pemoline) and antidepressants (SSRIs, TCAs). These agents are also associated with limiting side effects in practice. In more recent years a variety of specific treatments have been approved that act on diverse pathways. Pitolisant, a histamine H3 receptor inverse agonist, is approved for the treatment of EDS or cataplexy in adult patients with narcolepsy (and children > 6 years in European Union) (Keam SJ. *Paediatr Drugs*. 2023;25(4):483-488). Solriamfetol, a dopamine and norepinephrine reuptake inhibitor (DNRI) is indicated to improve wakefulness in adult patients with EDS associated with narcolepsy or obstructive sleep apnea (OSA) (Winter Y, *et al.* *Sleep Med*. 2023;103:138-143). Sodium oxybate (SXB), a GABA_B receptor agonist, is approved for the treatment of cataplexy associated with narcolepsy and (EDS) in patients 7 years or older (Bogan RK, *et al.* *CNS Drugs*. 2023;37(4):323-335). Current research focuses on on-peptide hypocretin receptor-2 agonists (Saitoh T, Sakurai T. *Peptides*. 2023;167:171051).

Conclusions: Despite limited understanding of the pathophysiology of narcolepsy there have been substantial advances in the pharmacotherapy, including medications now approved for children. Early diagnosis and treatment are associated with better outcomes. In view of the chronic and disabling morbidity associated with narcolepsy further research and better access to appropriate medications is necessary.

Suicide planning type interventions as an evidence based alternative for no-suicide contracts

A. Garbacka^{1*} and M. Bzowska²

¹Child and Adolescent Psychiatry, Uzdrowisko Konstancin Zdroj, Konstancin-Jeziorna and ²Psychiatry Private Practice, Warsaw, Poland

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1619

Introduction: Suicidality is a common concern in psychiatric patients and one of the leading causes of death in adolescents and young adults. (*Adolescent health*. (2019, November 26) WHO). Some mental health professionals engage in a no-suicide contract with their patients. In this type of intervention, the patient usually agrees to not harm or kill himself/herself. There is an increasing body of evidence to support brief interventions, such as group of safety planning-type interventions (SPTIs) (McCabe *et al.* *MC Psychiatry*, 2018, May 3; 18(1)). Safety planning is derived from cognitive therapy and cognitive behavioral therapy used for suicide prevention.

Objectives: Our objective was to summarize and critically analyze current evidence of effectiveness of SPTIs and no-suicide contracts in suicide prevention.

Methods: We conducted a literature review to compare no-suicide contract to safety-planning interventions in suicide prevention.

Results: Although no-suicide contracts may work for some individuals, there is not enough quantitative evidence to support such contracts as clinically effective tools. A recent meta-analysis has shown that SPTIs were associated with reductions in suicidal behaviors although no effect was identified with frequency of suicidal thoughts (Nuij *et al.* (2021, April 30). *The British Journal of Psychiatry*, 219 (2), 419–426).

Conclusions: Based on the evidence and straightforward implementation of SPTIs in different clinical settings it may be a more effective alternative to no-suicide contracts.

“Suicide Clusters: Analysis of a Sample of Completed Suicides in Spain”

A. M. G. Alvarez*, J. J. M. Jambrina, I. F. Arias, L. P. Gómez, N. A. Alvargonzalez and C. P. Miranda

Psychiatry, Hospital San Agustín, Aviles, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1620

Introduction: “Cluster suicides,” also known as “suicide clusters,” refer to a phenomenon in which a series of suicides occur within a specific community, group, or geographic area within a relatively short period of time. These suicides often appear to be interconnected, either through imitation or contagion, and may involve individuals who have some form of social or emotional connection to each other.

Objectives:

- Understanding the definition and characteristics of cluster suicides.
- Analyzing common risk factors and triggers in cluster suicide cases.
- Evaluating prevention and support strategies for affected individuals and communities.

Methods: We conduct an analysis of this concept based on a sample of suicides that occurred in a Spanish region over an 8-year period (2015-2022).

We will Analyzethe following aspects:

- Definition and characteristics of cluster suicides.
- Risk factors contributing to the occurrence of cluster suicides.
- Examples of real cases or case studies illustrating this phenomenon.
- The role of imitation and contagion in cluster suicides.
- Prevention and support strategies, including education on warning signs and access to mental health services.
- The impact of media coverage and how it can amplify the contagion effect.
- Measures to reduce access to lethal means of suicide.

Results: We will discuss about the results found:

- Definition and characteristics of cluster suicides.
- Risk factors contributing to the occurrence of cluster suicides.
- Examples of real cases or case studies illustrating this phenomenon.
- The role of imitation and contagion in cluster suicides.
- Prevention and support strategies, including education on warning signs and access to mental health services.
- The impact of media coverage and how it can amplify the contagion effect.
- Measures to reduce access to lethal means of suicide.

Conclusions: The main conclusions of our presentation are :

- The importance of recognizing cluster suicides as a real and concerning phenomenon.
- The need to address specific risk factors and triggers in affected communities.
- The effectiveness of prevention and support strategies in reducing cluster suicide cases.
- The importance of promoting media responsibility in suicide coverage.

Exploring the Role of Attachment Styles, Life Scripts, and Parental Mandates in Suicidal Behavior: Implications for Prevention and Intervention

A. Romero Otalvaro^{1*}, G. Galván Patrignani² and E. P. Ruiz Gonzalez³

¹Cordoba, Universidad de Cordoba, Monteria, Colombia; ²Anguilla, Global Humanistic University, curacao, Curaçao and ³Cordoba, Universidad Pontificia Bolivariana, Monteria, Colombia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1621

Introduction: The scientific literature widely acknowledges the multitude of factors contributing to suicide, emphasizing the intricate and dynamic interplay among genetic, biological, psychological, and social dimensions (Van Heeringen, 2001). Despite this consensus, each suicide case is unique, shaped by an exclusive combination of these factors. One relatively underexplored risk factor in the realm of suicidal behavior is attachment style. As posited by attachment theorists, avoidant and anxious/insecure attachment styles may hold predictive value for suicide attempts (Sheftall et al., 2014).

Objectives: This study undertakes a comprehensive review of the relationships between attachment styles, life scripts, parental mandates, and suicidal behavior.

Methods: This study delves into the interconnections between attachment styles, life scripts, parental mandates, and suicide, drawing from an extensive body of research and theory. A comprehensive review of existing literature was conducted to elucidate the intricate relationships among these variables and their potential influence on suicidal behavior.

Results: The synthesis of existing research highlights a compelling link between attachment styles, life scripts, and parental mandates. Attachment styles, formed in early life, profoundly influence an individual's interpersonal relationships, emotional regulation, and sense of self-worth. These attachment patterns lay the foundation for the development of life scripts—internalized narratives that dictate one's beliefs, values, and expectations regarding their life course. Parental mandates, often transmitted explicitly or implicitly during childhood, further shape these life scripts by imposing conditions or constraints on the individual's choices and aspirations.

Crucially, within this framework, suicidal behavior emerges as a possible outcome. Individuals with maladaptive attachment styles, burdened by parental mandates that discourage autonomous living or impose conditional acceptance, may perceive suicide as a way to escape perceived unmet expectations or alleviate emotional distress.

Conclusions: This study underscores the intricate interplay between attachment styles, life scripts, parental mandates, and suicidal behavior. Understanding these complex relationships is pivotal in both prevention and intervention efforts. Recognizing the significance of family history, parental approaches, maladaptive beliefs, attachment patterns, and early caregiver interactions can inform the development of targeted strategies aimed at mitigating suicide risk in diverse contexts, including schools, communities, and clinical settings. By identifying these factors and their influence on suicidal behavior, practitioners and researchers alike can contribute to more effective prevention and intervention initiatives tailored to individual needs.

Suicide prevention project with young people in the Rocinha slum in Rio de Janeiro

C. Jorgejaber*, V. Soares, P. Zanelatto, A. Muniz and A. H. G. Hollanda

Pesquisa, Clinica Jorge Jaber, Rio de Janeiro, Brazil

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1622

Introduction: The 2019 WHO report on suicide warned of a serious public health problem. It was found that suicide is a serious problem for global public health, causing approximately 703 thousand deaths every year. Self-extinction is among the leading causes of death worldwide, with more deaths than from malaria, HIV/AIDS, breast cancer, war and homicide. More than one in every 100 deaths (1.3%) in 2019 were the result of suicide. Suicide is the fourth leading cause of death in older adolescents (15–19 years). Risk factors are multifaceted and include harmful use of alcohol, which includes abuse during childhood, stigma against seeking help, barriers to accessing care and means of suicide. The total number of deaths due to self-extinction registered in the adolescent population in the period from 2016 to 2021 was 6,588. According to the WHO director-general, “attention to suicide prevention is even more important now, after many months of living with the pandemic and many of the risk factors, such as loss of employment, financial stress and social isolation, still very present.” Therefore, suicide prevention work with young adolescents in Rocinha, one of the largest slums in Rio de Janeiro, is extremely important, given the increase in suicide rates and mental health problems in this age group. This approach must be thoughtful, culturally sensitive, and involve a range of strategies to address the complex issues affecting adolescents in the community. The Community of Rocinha was chosen to host this prevention project. **Objectives:** Create a preventive event by surveying participants’ opinions, integrating, welcoming and deconstructing stigmas about suicide.

Methods: This study investigated, in a population of 140 young adolescents with cultural differences in a theater class, their level of knowledge regarding relevant information about suicide. A structured questionnaire was presented and answered before and after a lecture, resulting in a class at the end, carried out by the young participants themselves. The scenes were filmed and a film produced. This dynamic process also included the distribution of a shirt alluding to the fact, making the participants multiplier references.

Results: The results of the lecture showed a significant improvement in mental health awareness and willingness to seek help among young people, totaling a 20% increase in knowledge.

Conclusions: Students attended the event in significant numbers, taking into account that the slum had a curfew due to armed conflict. The results of the lecture showed a significant improvement in mental health awareness and willingness to seek help among young people, totaling a 20% increase in knowledge. The young people reported a feeling of support and belonging to the community, highlighting the importance of the debate in a final lecture given by them.

Suicide across time and cultures: from a philosophical debate to network analysis

C. Tapoi^{1*}, R. Chancel², S. Baltzis³, U. Cikrikcili⁴, D. Cenci⁵ and J. Lopez Castroman⁶

¹Department of Psychiatry, Dimitrie Gerota Emergency Hospital, Bucharest, Romania; ²Department of Emergency Psychiatry and Acute Care, Lapeyronie Hospital, CHU Montpellier, Montpellier, France; ³University Psychiatric Department, Helsingborg Hospital, Skåne, Sweden; ⁴Deutsche Zentrum für Neurodegenerative Erkrankungen, Magdeburg, Germany; ⁵Department of Transactional Medicine, Università del Piemonte Orientale, Novara, Italy and ⁶Department of Signal Theory and Communications, University Carlos III, Madrid, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1623

Introduction: Suicide is a multifaceted subject that encompasses a broad spectrum of perspectives, spanning philosophy, the arts, social sciences, neuroscience, neuropsychiatry, and public health. The history of suicide is intricately intertwined with the history of humanity itself, and examining the shifting attitudes towards suicide holds significant implications for the field of suicide prevention.

Objectives: The objective of this paper is to offer a timeline of the social perspectives about suicidal behavior throughout history in order to showcase the influence of cultural and contextual factors.

Methods: This poster is based on the Massive Open Online Course (MOOC) “Focus on Suicidal Behaviour” provided by the European Psychiatric Association. We performed a brief overview of the chapter on history of suicide and updated data on this topic with recent literature findings.

Results: In antiquity, suicide was sometimes regarded as justifiable, whether to preserve honor or protest injustices. However, during the Middle Ages, suicide was primarily seen as a criminal act, violating the rules of the Christian religion. The Renaissance brought about a shift in the perception of suicide, as it began to be depicted in art as a heroic or philosophical act. Moving into the Romantic period, suicide took on a tragic and noble connotation, often seen as an escape from unbearable suffering.

The 19th century marked a significant turning point when the social context started being recognized as a crucial factor in the development of suicidal behavior. In the 20th century, suicide was increasingly considered a public health problem. In the 21st century, the discourse on suicide has become multifaceted. On one hand, network analysis has enabled the development of an integrated model of suicide, emphasizing the complex interactions among various risk and protective factors. On the other hand, ethical and moral debates persist regarding assisted suicide and its indications.

This summary primarily centers on the historical context of suicide within Europe. However, attitudes toward suicide vary significantly across cultures. For instance, in China, suicide rates are higher for women than for men, while Japan has historically displayed a relatively tolerant attitude toward suicide, particularly within the military. In contrast, Islamic countries consider suicide a major sin and implicitly associate it with stigma.

Conclusions: The understanding of suicide evolves over time and is deeply influenced by cultural contexts. Familiarizing ourselves with the historical perspectives on suicide is essential for comprehending this

complex social and personal phenomenon. Such knowledge forms the foundation for the creation of effective prevention strategies.

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1624

Introduction: This project proposes a program for the promotion of mental health and prevention of suicidal behavior among individuals experiencing homelessness, with the aim of reducing suicidal ideation and suicide mortality within this vulnerable population.

Objectives: The project aims to implement an evidence-based program to reduce suicidal ideation and suicide mortality among homeless individuals. This will be achieved through two phases: a review of scientific literature and the development of the program in collaboration with experts and homeless individuals.

Methods: The first phase of the project involved a review of scientific literature to identify the most effective content and programs for improving mental health and preventing suicide. These findings were adapted for application in the program and for dissemination to professionals who will directly engage with individuals experiencing homelessness.

In the second phase, the program content was designed in collaboration with experts and validated through the input of educational professionals. Additionally, individuals experiencing homelessness actively participated in the creation of materials and the definition of the approach to be utilized. Subsequently, a four-hour training was provided to professionals working in specialized homeless shelters to guide groups of individuals experiencing homelessness.

Results: The program consists of the following components:

- Training and Awareness: Workshops and campaigns to reduce the stigma surrounding suicide.
- Early Detection and Risk Assessment: Staff training in recognizing suicide indicators and risk assessment protocols.
- Psychological and Social Interventions: Crisis teams, individual and group therapy.
- Access to Services: Mobile mental health clinics and collaborations with healthcare professionals.
- Ongoing Support and Monitoring: Temporary housing programs and support groups.

Conclusions: The proposed program seeks to mitigate the risk of suicide among individuals experiencing homelessness through a comprehensive approach. The collaboration of experts and homeless individuals ensures that the solutions are appropriate and effective. The implementation of this program has the potential to make a significant difference in promoting mental health and preventing suicide within this vulnerable population.

Suicidal impulsivity secondary to traumatic brain injury

J. Fernandez Logroño*, C. I. Vazquez Arjona and I. Romero Mañas
UNIDAD DE SALUD MENTAL, HOSPITAL UNIVERSITARIO CLINICO SAN CECILIO, GRANADA, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1625

Introduction: I present the case of a 58-year-old patient who developed frequent, unpredictable and prolonged suicidal impulsivity (more than 8 years of evolution) after one year of suffering a traumatic brain injury, with very serious suicide attempts in the context of very brief periods of dysthymia and no history of mental illness or any other accompanying psychopathology.

Throughout this admission, a progressive dehospitalization has also been carried out, with afternoon outings in the company of his wife or son up to a full weekend.

Objectives: Shortly before, frequent “déjà vu” crises had also begun. Additional imaging tests (CT and cranial MRI) had been performed privately, which had been normal, and an EEG with sleep deprivation had been requested, but the patient had not attended.

For 8 years he had started various successive antidepressant treatments that had always been ineffective or had produced agitation, which was diagnosed as akathisia, after a week of treatment. In a single previous hospital admission, with the initial diagnosis of major depressive disorder finally ruled out, he was discharged apparently asymptomatic, and was readmitted after making three new successive serious attempts at self-harm a week after discharge.

Methods: Throughout this hospitalization (37 days), a practically invariable mental state is observed from the first day in which only rambling thoughts with very limited content stand out, with permanent and apparently credible criticism regarding previous self-harming behaviors, without appearance of new impulses or self-harming behaviors and reporting a significant decrease in the frequency and emotional impact of “déjà vu” type crises, which are now limited to the moment of waking up in the afternoon, after a brief nap, and occasionally.

Results: He was discharged from the hospital with the diagnosis of post-concussive syndrome (ICD 10-F0.78.2) and remains stable for the moment (one month later) in improvement, maintaining anxiolytic and antidepressant treatment, as well as anticonvulsants, and pending continuation of the study for part of neurology.

Conclusions: We think that this case shows how, within the immense etiological variety of suicidal behavior, there may be a cause conditioned exclusively by brain damage.

Content analysis of suicidal notes - the verbal behaviour

J. D. Fekete^{1*} and S. Fekete²

¹Dept of Language and Communication and ²Dept of Psychiatry, University of Pecs, Pecs, Hungary

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1626

Introduction: There have been numerous studies on attempted and completed suicides in an attempt to understand better the phenomenon - the tragedy- of self-destructive behaviour through the analysis of the suicidal notes – their last personal documents, that many individuals write before carrying out suicide. Understanding and interpretation of these analyses could happen on several theoretical frameworks and background Research has systematically demonstrated what most clinicians assume, namely that individuals sharing significant patterns of nonverbal behavior express these tendencies in their manner of speaking and writing (e.g. in suicidal notes, farewell letters) . Through this research – by analyzing these texts, documents, “messages”, - was it possible to study not only semantic, and linguistic aspects of them but likely also as manifestations of psychological defense or coping mechanisms or reflected psychopathology in speech by isolating categories. A number of clinical investigations have been carried out to associate speech pattern and verbal style (spoken or written) with these psychopathological states

Objectives: The purpose of the present study is to understand better of written “suicidal” communication; to analyze suicidal notes - namely, as last “messages” of the self destructed individuals in suicidal notes in an empirical sample.

Methods: The present study compared the content of suicide notes (n=113) from attempted suicides, completed suicides and a non-suicidal controls. The content analysis examined formal, syntactical characteristics, as well as speech patterns and verbal expressions (Weintraub method, Absolutists index, SPSS, - Anova, KW)

Results: The notes from completed suicides had significantly higher scores for heteroaggression (blaming others, evaluators) negations, absolutistic expressions, nonpersonal references and lower scores for expression of feelings. Sex (male versus female) and age had no impact on these differences.

Conclusions: The suicide notes had reflected irrational thinking, characterized by frequent negation, and absolutistic words, self-preoccupation, high scores for emotional categories and a tendency toward polarized thinking These results may help in the understanding of the psychodynamic background or suicidal individuals’ risk assessment, in clinical work or in suicide hotlines, but also in prevention

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1627

Introduction: Suicide is one of the leading causes of death worldwide and scientific community investigates suicide risk factors relentlessly. Among these, anxiety symptoms were strongly related to suicidal ideation in several studies. Moreover, sleep and its disturbances are closely connected to mental well-being and psychiatric disorders in a bidirectional pathway.

Objectives: The main purpose of the present study is to assess the relationship between anxiety symptoms and suicidal ideation in a sample of psychiatric patients and the mediational role of insomnia in this association.

Methods: Participants were 116 consecutive adult psychiatric inpatients (61 women and 55 men) enrolled to the psychiatric inpatient unit of Sant’Andrea Hospital in Rome. The measures used were a socio-anamnestic form, the Columbia Suicide Severity Rating Scale (C-SSRS), the Hamilton Anxiety Rating Scale (HAM-A), and the Insomnia Severity Index (ISI).

Results: Based on the results of statistical analysis, patients with suicidal ideation showed higher severity of insomnia and higher severity of anxiety symptoms than patients with no suicidal ideation. Moreover, the intensity of suicidal ideation was positively and significantly associated with the severity of anxiety symptoms and with the severity of insomnia. Finally, the mediation analysis showed that the effect of anxiety symptoms on suicidal ideation was completely mediated by insomnia severity.

Conclusions: The main result of the study indicates that patients who perceive more anxiety symptoms were more likely to experience higher suicidal ideation intensity through higher levels of insomnia. These findings implies that screening for sleep disturbances may help identify individuals at risk for suicide, and improving sleep quality through psychosocial and pharmacological treatments could mitigate the association between anxiety and suicidal ideation.

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1628

Introduction: Suicide is one of the leading causes of death worldwide being the fourth major cause of death among young people 15-29 years old. The reduction of suicide mortality is prioritized by the World Health Organization (WHO, 2019). There is a number of internal and external factors associated with suicidality (Soto-Sanz V et al., 2019; Farbstein et al., 2022.). Special attention is paid to the influence of the social media on suicidality (Cheng A. T. A. et al., 2007; Niederkrotenthaler T. et al., 2020; Sedgwick R. et al., 2019). In the Russian Federation, anime, an animation genre and a media cultural phenomenon, is increasingly popular among young people. Characters who are lonely and lost their meaning of life are common in anime. Romanticization and idealization of such characters may lead to increased attractiveness of death and thus have a negative effect on the mental health of adolescents and young adults due to their incomplete identity development (Liu Y. et al., 2022; Backer, H. A., 2023).

Objectives: We aimed to study the influence of the anime on the presence of suicidality and depression in adolescents and young adults in the Russian Federation.

Methods: We interviewed 304 people living in the Russian Federation and watching anime on the regular basis (244 women, mean age 20.9 ± 3.8 years, range 13-36 years). We collected sociodemographic data and age when a person had started watching anime. We performed Reasons for Living Inventory, RFL (M. Linehan et al., 1983), Beck Depression Inventory, BDI (Aaron Beck, 1961). We divided all participants into three groups according to their age: adolescents (13-19 years), young people (20-24 years), adults (25-36 years). In each group, we compared BDI: level of depressive symptoms, cognitive-affective subscale, subscale of somatic manifestations of depression; RFL scales: Survival coping beliefs, responsibility to family, child related concerns, fear of suicide, fear of social disapproval, moral objections between three subgroups based on the age of the anime watching start (<12 years old, 12-15 years old, ≥ 16 years old) using Kruskal-Wallis test and post hoc Mann-Whitney U-test for pair comparisons with Bonferroni correction for multiple comparisons. Level of significance $p < 0.05$.

Results: In the adolescents ($n=130$), we did not find any differences between the three subgroups. In the young people ($n=127$), participants who had started watching anime in childhood (<12 years old) had higher level of depression ($p=0,014$) and higher level of cognitive-affective symptoms ($p=0,006$). In the adults ($n=47$), participants who had started watching anime in childhood had decreased moral attitudes contrary to suicide ($p=0,004$). Other scales not found to differ significantly.

Conclusions: Start of the anime watching in childhood (<12 years old) was associated with increased suicidal risk factors and decreased anti-suicidal factors in the young adults.

The Impact of Patient Suicide on Adult and Child Psychiatry Residents in Tunisia

Y. Ines*, C. Ben Said and N. Bram

Forensic psychiatry department, Razi psychiatric hospital, Manouba, Tunisia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1629

Introduction: Adult and child psychiatry residents encounter unique stressors in their training distinct from those in other medical specialties. Patient suicide has been identified as one of the most distressing experiences during psychiatric training.

Objectives: This study represents the first Tunisian investigation aiming to assess (1) the impact of patient suicide on psychiatry residents and (2) the limitations of the institutional support system in dealing with such cases.

Methods: A Google Forms questionnaire was distributed via email to all residents, gathering socio-demographic data, assessing traumatic impact using the PTSD Checklist for DSM-5 (PCL-5), and soliciting open-ended responses regarding personal experiences and expectations of the institutional support system.

Results: Fifty-three residents participated in the study. Among them, 29 residents had encountered patient suicide, with 12 directly involved. Symptoms of PTSD were detected in three residents. The physician directly involved in treating the suicidal patient reported the highest PCL-5 score. The majority of residents (27 out of 29) expressed the need for a structured support and training program tailored to healthcare professionals dealing with suicide.

Conclusions: The findings suggest that psychiatric residents may require additional training and support to effectively address the complex issue of patient suicide. Implementing specific training programs could significantly enhance their ability to manage such situations.

Prevalence of suicidal behavior in bipolar type 1 patients

F. Tabib*, S. Omri, R. Bouaziz, I. Gassara, R. Feki, L. Zouari, J. Ben Thabet, N. Charfi, M. Maalej, N. Smaoui and M. M. Bouali

¹department of Psychiatry C, UHC Hedi Chaker, Sfax, Tunisia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1630

Introduction: The prevalence of suicidal behavior in individuals diagnosed with Bipolar Disorder Type 1 is a topic of great concern within the field of psychiatry and mental health research. Bipolar

Disorder Type 1 is characterized by extreme mood fluctuations that can contribute to a heightened risk of suicidal ideation, attempts, and completions in affected individuals.

Objectives:

- To examine the socio-demographic and clinical profiles of Bipolar Type 1 patients admitted to the “C” psychiatry department at Hedi Chaker Hospital in Sfax, Tunisia.
- To identify and understand the factors associated with suicidal behavior in this population.

Methods: We conducted a retrospective descriptive and analytic study of hospitalized patients suffering from bipolar disorder type 1 in the psychiatry department “C”, Hedi Chaker Hospital, Sfax Tunisia from 2021 to 2023. Socioeconomic data and clinical profiles of patients were collected from archived files.

Results: The total number of patients was 98, with an average age of 36.74 ± 12.3 years. The majority were single (67%), living with their families (76.5%), jobless (45.9%), and receiving family support (94.9%). In terms of psychoactive substance use, 81.6% have used tobacco, 46.9% have used alcohol, and 34.7% have used cannabis. Concerning family history, 55% of patients had at least one family member being treated for a mood disorder. Among them, 7.1% had attempted suicide, and 6.1% had died by suicide.

Concerning the clinical profile of the study population, 28.6% had a personal somatic history. The diagnosis of bipolar disorder was made at the age of 27.52 ± 8.6 years. 11.2% had a comorbid personality disorder with bipolar disorder.

The majority of patients were on antipsychotics (95.9%), 84.7% were using mood stabilizers, 33.7% were prescribed anxiolytics, and only 4.1% were on antidepressants. Treatment compliance was poor in 61.2% of cases and 63.3% of patients had a poor insight.

Ten percent of these patients had attempted suicide, 50% during a depressive episode, 50% occurring during a depressive episode, 30% during a manic episode, and 40% of attempts were related to discontinuation of treatment. 3.1% had used hanging, and 3.1% had engaged in voluntary drug ingestion as a method of self-harm. None of the suicide attempts necessitated intensive care hospitalization, but 60% of the individuals were admitted to psychiatric care. There was a statistically significant correlation between suicide attempts and a family history of suicide ($p=0.049$).

Conclusions: Bipolar patients face a heightened risk of suicide, which is closely tied to the distinctive attributes of the disorder, including biological factors, thymic decompensation, and psychological aspects. Consequently, managing their condition necessitates a tailored approach, demanding ongoing vigilance for individuals diagnosed with bipolar disorder.

Can high-sensitivity C-reactive protein be a routine trans-diagnostic biomarker for thoughts of death and suicidal attempts?

L. Cavallo*, L. Orsolini and U. Volpe

Unit of Clinical Psychiatry, Department of Neurosciences/DIMSC, Polytechnic University of Marche, Ancona, Italy

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1631

Introduction: Several studies have shown an association between suicidal behavior and increased C-reactive-protein (CRP) levels (Ghayour-Mobarhan M. *et al.* Comb Chem High Throughput Screen 2022; 25 1047-1057) although most studies evaluated the association between CRP levels and suicidal ideation in depressed patients (Olié E. *et al.* Eur Neuropsychopharmacol 2015; 25 1824-31).

Objectives: Our study assessed baseline high-sensitivity CRP (hsCRP) levels in a cohort of adult inpatients affected by severe mental illness (SMI) and their association with Mini-International Neuropsychiatric Interview-5 subscale suicidality (MINI-5-s).

Methods: A naturalistic, observational, cross-sectional study was carried out by retrospectively recruiting 127 adult SMI inpatients, excluding patients with an organic pathology. HsCRP levels were assessed at the ward admission. To assess the suicidal behaviour all patients filled the same day the MINI-5-s.

Results: The number of patients with $hsCRP > 3mg/l$ were significantly higher among those with thoughts of death ($p=0.002$) and suicidal attempt ($p=0.026$). No statistically significant associations were observed between hsCRP levels and other suicidality dimensions. Limitations: Small sample size, heterogeneous diagnoses, lack of diagnostic sub-analysis, cross-sectional design, and lack of a healthy control group.

Conclusions: The study reveals a transdiagnostic association between inflammation, thoughts of death and suicidal attempt in SMI inpatients. Our preliminary findings could support a routine introduction of hsCRP measurement, due to its relatively low cost, possible utility in trans- diagnostically suicide risk assessment. Large-scale clinical trials would be recommended to evaluate the effects of early anti-inflammatory therapy in patients with death ideation and/or suicidal attempt and concomitant low-grade hsCRP elevation. HsCRP could potentially represent an early biomarker for suicidal risk.

Disclosure of Interest: None Declared

EPV1051

Descriptive study of suicidal behavior in adult population attended in an emergency department during a one-year period and comparative study with the following annual period

M. GARCÍA MORENO^{1*}, A. DE COS MILAS², L. BEATOBE CARREÑO², A. IZQUIERDO DE LA PUENTE¹, P. DEL SOL CALDERON¹ and R. DE ARCE CORDON¹

¹PSYCHIATRY, HOSPITAL UNIVERSITARIO PUERTA DE HIERRO MAJADAHONDA and ²PSYCHIATRY, HOSPITAL UNIVERSITARIO DE MÓSTOLES, MADRID, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1632

Introduction: Suicide is the most frequent psychiatric emergency. About 1% of all deaths are due to suicide so around 700,000 people commit suicide each year. Suicide attempt is more frequent in women (3:1) while completed suicide is more frequent in men (4:1). Most suicides occur in the 35-64 age range. The severity of a suicide attempt is assessed in terms of method, potential lethality, rescuability and impulsivity. A previous suicide attempt is the main risk factor for suicide behavior. The majority (more than 90%) of

suicide behavior are related to an underlying psychopathology, mainly depression and substance abuse, especially alcohol. However, there are also numerous cases of impulsive attempts in the context of life stressors.

Objectives: To analyze sociodemographic and clinical characteristics of adult patients with suicidal behavior attended in the emergency department during a one-year period. To study the stability of the data obtained in the following annual period

Methods: A retrospective review of the population over 18 years attended in the emergency department during 2022 because of suicidal behavior, was carried out. Data collection for the year 2023 is in progress in order to be able to carry out a comparative study between both annual periods.

Results: 562 patients over 18 years were attended in the emergency department of our hospital due to suicide behavior during 2022. 383 of these patients were women (68.1%) and 179 men (31.9%), with an average age of 38.6 and 42.2 years respectively. The age range between 18 and 25 years accounted for 28.5% of the total cases. The most frequent suicidal behavior was medication overdose with a total of 307 (54.6%), being more frequent in women than in men (2.6:1). The second most frequent reason for attention was suicidal ideation without suicide attempt, with a total of 212 patients (37.7%). 371 patients were discharged home from the emergency department (66%) and 191 required a longer observation in hospital environment. We are awaiting to complete data collection for 2023 to establish a comparison with those described above.

Conclusions: According to our study, suicidal behavior in adult population is more frequent in women than in men. The most frequent age range in both genders was between 18 and 25 years old. The method most frequently used was medication overdose and suicidal ideation without a suicide attempt was the second most frequent reason of attention. Our patients mostly presented diagnoses of personality disorder, depression and substance use disorder.

EPV1052

Implementing policies and predictive stochastic models to attend to borderline personality disorder crises: rationalising ssri antidepressants prescription in suicide prevention

C. G. Lazzari

Community Mental Health, UK NHS, BRIGHTON, United Kingdom
doi: 10.1192/j.eurpsy.2024.1633

Introduction: We are facing increased suicide attempts and deliberate self-harm from persons with borderline personality disorder (BPD) who are also on antidepressants, multiple antidepressant prescriptions and antidepressant augmentations. Our previous observations suggest that antidepressants might increase suicide attempts in those on this medication and who have BPD. The absent response to antidepressants is due mainly to the comorbid dysthymia, cyclothymia, rumination, autism and ADHD in BPD.

Objectives: To generate forecasting models and preventive policies to deal with BPD crises and improve the effectiveness of the UK National Healthcare Service (NHS) in suicide prevention.

Methods: The underlying analysis framework is stochastic forecasting. We used current knowledge and data to complete systematic future predictions extracted from recent trends. A logical-mathematical model generated the required expressions. The software for logic prediction and annotation was Wolfram Alpha (Wolframalpha.com). The four parameters for stochastic predictions are, BPD (A), antidepressant No. 1 (B), antidepressant No. 2 (C), and suicide attempts (D). Boolean function metrics can help analyse the impact and truth of forecast modelling with truth density.

Results: The logic expression for suicide prediction due to liberal antidepressant prescribing is $\Psi = A \text{ intersects } B, \text{ intersects } C, \text{ intersects } D$; that is, $\Psi = A \cap B \cap C \cap D$, which yields a Boolean truth density of 6.25%. The truth table always has a positive outcome as long as any of the factors exist except when none is present.

Conclusions: The predictive Boolean function and truth table suggest that suicide presentation is predictable if there is a prescribing of one or more antidepressants in BPD and if there is an antidepressant augmentation or dose maximisation. We speculate that SSRI antidepressants block self-regulatory mechanisms of fear of death while triggering impulses to self-harm and suicide from overstimulation of SSRI receptors. Without fear mechanisms, death by suicide is felt as not terrifying.

Disclosure of Interest: None Declared

EPV1053

Implementing policies and predictive stochastic models to attend to borderline personality disorder crises: the dysthymia-suicide cycle

C. G. Lazzari

Community Mental Health, UK NHS, BRIGHTON, United Kingdom
doi: 10.1192/j.eurpsy.2024.1634

Introduction: UK healthcare is undergoing significant challenges in facing borderline personality disorder (BPD) and accommodating the increased demand to allocate sufficient care and carers to deal with BPD's growing number and emotional and suicidal crises.

Objectives: To generate forecasting models and preventive policies to deal with BPD crises and improve the effectiveness of the UK National Healthcare Service in suicide prevention (NHS).

Methods: The underlying analysis framework is stochastic forecasting. We used current knowledge and data to complete systematic future predictions extracted from recent trends. A logical-mathematical model generated the required expressions. The software for logic prediction and annotation was Wolfram Alpha (Wolframalpha.com).

Results: Persons with BPD become suicidal because the team cannot comprehend and address the cycle of dysthymia, rumination and suicide. The BPD crises start from Stage 1 (α), assessing the comorbidity between BPD with dysthymia, cyclothymia, autism and ADHD. Teams shall avoid overmedication as ineffective. Stage 2 (β) is introspection and rumination, which do not respond to pharmacotherapy. The health carers establish if rumination is present and suggest distraction techniques. Stage 3 (γ) is when constant rumination with catastrophising leads to hopelessness. Stage 4 (δ) is when BPD starts feeling more anxious, depressed and

unable to stop rumination. We suggest thought-stopping techniques and discourage social isolation, which triggers rumination. As BPDs use external locus of control and aim for higher dosages of antidepressants and anxiolytics with minimal effect, we explain that medication is not the only solution. Stage 5 (ε) is a crisis and panic attack because constant rumination brings back traumatic thoughts focused on the past, present and future. This is when BPDs self-refer to the hospital, attempt suicide, and feel that hospital admission is the only solution. The stages combined generated Model I. The Model II forecast Δ from this study is that we will observe a higher frequency (Δ) of hospital occupancy ($\Delta_{bo} = A$), suicidal attempts ($\Delta_{sa} = B$), and heavy service use ($\Delta_{su} = C$) by BPDs.

Conclusions: The predictive model algorithm has thus extracted (1) *Model I* (Analysis): $[\alpha \rightarrow (\beta \rightarrow (\gamma \rightarrow (\delta \rightarrow \varepsilon)))] = Z$; The truth density for Model I and its strength of prediction for stage progression is 96.87% in the dysthymia-rumination-suicide cycle; and (2) *Model II* (Prediction): Z implies $(A \text{ And } B \text{ And } C)$, $Z \rightarrow A \cap B \cap C$; the truth density for the Model II is 56.25% for predicting a national shortage of healthcare resources. The combined models predict a truth of 73.81% in the outcomes of BPD crises in the UK NHS due to the dysthymia-suicide cycle.

Esketamine and Hopelessness: Very Short-Term Effects

F. A. Rodríguez Batista^{1*}, E. E. Morales Castellano¹, A. M. Morales Rivero¹, M. Martínez Grimal¹ and S. Trufero Miguel²

¹Department of Psychiatry, Doctor Negrín University Hospital of Gran Canaria and ²Department of Psychiatry, Insular University Hospital of Gran Canaria, Las Palmas de Gran Canaria. The Canary Islands, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1635

Introduction: Treatment Resistant Depression is a challenging condition with a poor outcome and limited therapeutic options. Esketamine is the enantiomer of Ketamine and has recently been approved and marketed for treating depression. Questions remain about its short- and long-term benefit, as well as its usefulness in suicide risk. Hopelessness is one of the symptoms most closely associated with suicide risk.

Objectives: The aim of this paper is to evaluate the effect of this drug on hopelessness after one month of treatment with Esketamine.

Methods: The Beck Hopelessness Scale (BHS) was administered to patients receiving Esketamine at the Doctor Negrín University Hospital of Gran Canaria, who provided informed consent and exhibited suicidal ideations and depressive symptoms at the beginning of treatment. This scale was administered before the intranasal administration of Esketamine and after one month of treatment.

Results: Participants ($n=5$) had an average age of 54.4 years (median 56). We observed variability in the results among the evaluated patients, although the overall trend was a decrease in scores. On average, the patients' scores decreased from 14.6 to 7.4 points (with a median change from 14 to 8 points).

Conclusions: Hopelessness improved in the BHS after one month of treatment with Esketamine. These results could be of clinical significance. Hopelessness is associated with suicide risk, so we hypothesize that the improvement could have an impact on it. Nevertheless, we must exercise caution with these results: the sample size is small, patients were taking different medications, and they have diverse medical histories.

Atypical suicide attempt facilitated by levodopa in a patient with impending Parkinson's Disease masquerading as a mood disorder: a case report

A. Mara*, S. Myriknas and S. Tychala

Psychiatric Hospital, Thessaloniki, Greece

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1636

Introduction: Parkinson's Disease (PD) is a neuropsychiatric disorder whose diagnosis is mainly based on motor impairment. However, increasing evidence suggests that neurodegeneration precedes the appearance of motor disturbances to manifest itself with hyposmia, sleep, and affective disorders. The disease's insidious onset and comorbidity with psychiatric symptoms require specialized knowledge and delicate pharmacological maneuvers to provide the patient with the best possible treatment at the most precise moment. Studies have also highlighted the potential increase in impulsivity patients may experience upon initiation with levodopa.

Objectives: To raise awareness of the complexity of treating patients with PD that also face psychiatric comorbidities that appeared before the motor symptoms, including preoccupation with death, and highlight the need for intensive interdisciplinary medical follow-up of such patients.

Methods: We report a clinical case of a 54-year-old man who was admitted to the psychiatric emergency department after a suicide attempt by self-inflicting severe bilateral neck, wrists, and femoral triangles injuries, as well as self-cutting his Achilles tendon. The patient had a history of a one-year mixed anxiety and depressive disorder and was treated on an outpatient basis with amitriptyline/perphenazine (10+2)mg, sulpiride 50mg, and clonazepam 2mg. One month before his attempt, the patient started experiencing unilateral upper and lower limb rigidity with bradykinesia and "pill-rolling" resting tremor of the same hand and was prescribed levodopa/benserazide (200+50)mg three times per day. After two days of starting the new medication, the patient attempted suicide by the method mentioned above.

Results: After surgical assessment and care, the patient recovered at the psychiatric department for 21 days and was treated with sertraline 50mg, which was later increased to 100mg. As an adjunctive treatment, the patient also received mirtazapine 15mg/day, quetiapine 200mg/day, and lorazepam 3mg/day. On the 15th day of his hospitalization and after a neurological assessment, the patient was started on levodopa/benserazide (200+50)mg one-quarter three times per day. At discharge, he presented significant clinical improvement regarding both his mental health and neurologic somatic symptoms.

Conclusions: Patients with PD require a multidisciplinary approach by a trained medical team. Clinicians should titrate dopamine replacement agents with caution, especially for those experiencing mood disorders, because they might increase the patient's impulsivity, "assisting" a depressive patient with suicidal ideation to finally commit suicide.

When sleep disorders in patients with bipolar disorder indicate a risk of suicidal behavior

K. Razki^{1*}, C. Najar¹, S. Ben Aissa¹, M. Oumaya² and R. Bouzid²

¹Razi Hospital, LaManouba and ²Mental Health Department, Tahar Maamouri Hospital, Nabeul, Tunisia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1637

Introduction: Sleep disturbances and suicidal behaviors are common among patients with type II bipolar disorder (BDII), but the relationship between the two is unclear. Investigating this connection is important to identify interventions that can improve the quality of life and reduce the risk of suicide in this population.

Objectives: Our study's objective is to examine the association between sleep disorders and suicidal behavior in patients with type II bipolar disorder (BDII).

Methods: In order to comprehensively investigate the association between sleep disturbances and suicidal behaviors among individuals diagnosed with type II bipolar disorder (TBI), we conducted a cross-sectional, descriptive, and analytical study over a duration of one month, specifically from the 1st to the 31st of October 2022. Our research was conducted within the follow-up unit of the mental health department at Nabeul Hospital, Tunisia, with the aim of capturing a diverse range of participants representative of the population of interest.

To ensure the integrity and accuracy of our findings, we meticulously selected participants who met specific eligibility criteria. This included individuals aged between 18 and 60 years, who had a confirmed diagnosis of type II bipolar disorder according to the criteria outlined in the Diagnostic and Statistical Manual of Mental Disorders (DSM V). Furthermore, we sought to include participants who were psychiatrically stable, meaning they had not required hospitalization in the six months preceding the study.

The Pittsburgh Sleep Quality Index (PSQI) was used to evaluate the participants' sleep quality over a one-month period, while the Suicidal Behavior Questionnaire-Revised (SBQ-R) was used to assess suicidal behavior. The data was gathered through a questionnaire that prioritized ethical concerns, including obtaining informed consent from participants and maintaining confidentiality and anonymity throughout the study.

Results: In this study, we enrolled 40 male patients with a mean age of 36 ± 13.2 years and evaluated their sleep quality and suicidal behaviors. The results showed that the participants had a mean PSQI score of 7.28 ± 3.35 , indicating that the overall sleep quality was not optimal. Specifically, 65% of the participants had poor sleep

quality (> 5), and 45% reported poor sleep ($PSQI \geq 8$). The mean SBQ-R score was 10.3 ± 3.6 , indicating a moderate level of suicidal behavior. Interestingly, we found a statistically significant correlation between PSQI and SBQ-R subscales, particularly with regard to suicidal thoughts ($p=0.003$) and suicide attempts ($p=0.002$).

Conclusions: Our study found a strong link between sleep problems and suicidal behavior in people with type II bipolar disorder. This highlights the need to address sleep issues to reduce suicide risk in these patients.

Anhedonia and suicidal ideation in young people with early psychosis: findings from a 2-year Italian follow-up study.

L. Pelizza¹, M. Poletti², A. Raballo³ and A. Di Lisi^{4*}

¹Università di Bologna, Bologna; ²AUSL-IRCCS di Reggio Emilia, Reggio Emilia, Italy; ³Università della Svizzera Italiana, Lugano, Switzerland and ⁴Alma Mater Studiorum University of Bologna, Bologna, Italy

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1638

Introduction: Hedonic deficits have been extensively studied in schizophrenia, but little is known about their association with suicidal ideation in early psychosis. Along the clinical staging of psychosis, also Ultra-High Risk (UHR) individuals are characterized by hedonic deficits, which are currently considered as putative predictors of both psychosis conversion and poor social/role functioning.

Objectives: The aim of this research was to examine the relationship between anhedonia and suicidal thoughts across a 2-year follow-up period in people with First Episode Psychosis (FEP) and at Ultra High Risk (UHR) of psychosis.

Methods: Ninety-six UHR and 146 FEP, aged 13–35 years, completed the Comprehensive Assessment of At-Risk Mental States (CAARMS) and the Beck Depression Inventory-II (BDI-II). The BDI-II "Anhedonia" subscale score to assess anhedonia and the CAARMS "Depression" item 7.2 subscore to measure depression were used across the 2 years of follow-up. Hierarchical regression analyses were performed.

Results: No difference in anhedonia scores between FEP and UHR individuals was found. In the FEP group, a significant enduring association between anhedonia and suicidal ideation was found at baseline and across the follow-up, independent of clinical depression. In the UHR subgroup, the enduring relationship between anhedonia and suicidal thoughts were not completely independent from depression severity.

Conclusions: Anhedonia is relevant in predicting suicidal ideation in early psychosis. Specific pharmacological and/or psychosocial interventions on anhedonia within specialized EIP program could reduce suicide risk overtime.

The deaths of invisible people. A literature review

M. I. Santana Ortiz, N. Molina Pérez* and J. Pereira López

Psychiatry, University Hospital of Gran Canaria Dr. Negrin, Las Palmas de Gran Canaria, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1639

Introduction: Suicide is a serious public health problem. Each year it is estimated that it causes almost one million deaths worldwide, much more than those caused by war or homicide. These deaths are also devastating, affecting not only the person who commits them, but also his or her environment (family, friends, professionals involved, etc.) and society as a whole. The risk and protective factors for suicide are well known in the literature, which gives rise to the estimation of possible high-risk groups according to their characteristics, especially when risk factors are added, protective factors are reduced, and unfavorable life circumstances are present. Among these groups with greater vulnerability to suicidal behavior are homeless people with severe mental disorders, who are unfortunately little visible in society and in the investigation.

Objectives: The aim of this paper is to review the current state of the question of suicide in homeless people with severe mental disorders.

Methods: Review of the international scientific literature on the issue published in the last twenty years.

Results: The few studies available conclude the higher prevalence of suicidal behavior in homeless people with severe mental disorders compared to the general population, which has not been translated into the development of specific care and prevention plans and programs.

Conclusions: It is considered essential to expand investigation in this field, which will be very useful to lay the foundations for the development of guidelines, plans and specific programs, and to know the evidence about them.

EPV1062

Coping and suicidal ideation in men from the clinical and control groups

T. I. Medvedeva¹, O. M. Boyko^{1*}, O. U. Vorontsova¹ and S. N. Enikolopov¹¹Clinical psychology, Federal State Budgetary Scientific Institution "Mental Health Research Center", Moscow, Russian Federation

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1640

Introduction: Suicidal ideation is often an indicator of suicidal risk. However, suicidality is one of the most stigmatized themes thus suicidal ideation can be difficult to diagnose using direct questions. So, it's impotent to look for psychological traits those may be linked to suicidal ideation. This can be useful for the diagnostic of suicidal risk and prevention of suicidal behavior. The identification of copings that correlate with suicidal ideation and do not depend on mental health allows finding universal ways to reduce suicidal risk.

Objectives: The aim of the study is to find "copings" which have universal impact on suicidal ideation in men.

Methods: The data were obtained using the study of 193 men (clinical group: 67 men with F20, F31, F33 diagnosis aged 17 to 34 (mean age 21,1±4,25); control group: 126 men aged 18 to 63 (mean age 40,04±14,71) who never asked for psychiatric assistance. 3 questions about suicidal ideation (estimate of frequency of last week with Likert' scale from 0 - "not at all" to 4 - "extremely"), COPE (Carver, 1989). Correlation analysis (Spearman) were used.

Results: The table consists correlation that are statistically significant for both groups.

Control group					
question	Denial	Behavioral disengagement	Mental disengagement/ self-distraction	Substance use	Venting
Feeling hopeless about the future	,218*	,177*	,237**	,208*	,304**
Thoughts of ending your life	,189*	,217*	,240**	,189*	---
Thoughts of death or dying	,117	---	,290**	,215*	,301**
Clinical group					
Feeling hopeless about the future	,494**	,177*	,478**	,208*	,375**
Thoughts of ending your life	,347**	,217*	,363**	,342**	---
Thoughts of death or dying	,353**	---	,302*	,323**	,249*

* - p≤0,05; ** p ≤0,01

Conclusions: Our results demonstrate that avoidant copings (Denial, Behavioral disengagement, Mental disengagement /self-distraction) link to suicidal ideation in all men regardless of their mental state. This can be explained by general pathological effect of avoidant copings of people lives: its hinder an identification and settlement of the everyday problems and its contribute to worsening of the situation. This underlines the importance of promotion more active copings as part of prevention antisuicidal work. The "Substance use" coping comforts for a while and anyway helps to formation suicidal ideation through worsening a mental and physical states, increase impulsivity. All this shows that work aimed the substance use prevention constitutes a suicidal ideation prevention work. Increased frequency of use of a Venting coping can leave men in emotional storm state that carries risk of suicide. This points to the importance of wide popularization of affordable ways to the calm, reduce of the power of emotion.

Characteristics of Single vs. Multiple Suicide Attempters Among Adult Population: A Systematic Review and Meta-Analysis

S. Abascal-Peiró¹, J. Herrera-Sánchez^{1*}, L. Izaguirre-Gamir¹, J. Aznar-Carboné¹, A. Alacreu-Crespo² and A. Porras-Segovia^{3,4}¹Department of Psychiatry, Hospital Universitario Fundación Jiménez Díaz, Madrid; ²Department of Psychology and Sociology, Area of Personality, Assessment and Psychological Treatment, Universidad

of Zaragoza, Teruel; ³Instituto de Investigación Sanitaria Fundación Jiménez Díaz, Madrid, Spain and ⁴Division of Psychiatry, Imperial College, London, United Kingdom

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1641

Introduction: Suicide is one of the leading causes of unnatural death worldwide. There might be meaningful differences between those individuals that attempt suicide once in their lifespan and those who make multiple attempts in terms of sociodemographic and clinical characteristics. There are no previous meta-analysis addressing this topic in the adult population.

Objectives: We aimed to examine the factors that differentiate single and multiple suicide attempters in adult population.

Methods: We followed the Preferred Reporting Items for Systematic reviews and Meta-Analyses (PRISMA) guidelines to conduct this review and meta-analysis. The review protocol was registered in PROSPERO. We carried out a systematic literature search in three databases to identify original studies that explored the differences between single and multiple suicide attempters among adult population. A total of 75 studies were included in the review and 69 were included in the meta-analysis.

Results: Multiple attempters were more likely to present certain disorders such as mood and psychotic disorders, as well as personality or substance use disorders. Higher suicide ideation and suicide intent scores also characterized this group. Childhood trauma experiences, stressful life events, and higher rates of hopelessness were statistically significant in multiple attempters.

Conclusions: Identifying the factors predicting multiple suicide attempts helps to delineate a high-risk suicidal profile that should be taken into account in the clinical and suicide prevention scenario.

Risk factors for suicidal ideations and suicide attempts among medical students

M. Turki¹, W. Abid¹, O. Khardani¹, N. Halouani¹, M. Bakallah^{1*}, S. Ellouze¹ and J. Aloulou¹

¹Psychiatry B, Hedi chaker university hospital, Sfax, Tunisia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1642

Introduction: Medical students are a high-risk population for having suicidal thoughts and behaviors. However, few studies have been fulfilled on this subject.

Objectives: The objective of this study was to provide a systematic overview of risk factors for suicidal ideations (SI) and suicide attempts (SA) among medical students.

Methods: We set out to summarize the literature on the MEDLINE (via PUBMED) and Science Direct databases, regarding risk factors for SI and SA in medical students, using the key words : « medical student » ; « suicide attempt » ; « suicidal ideation », « risk ».

Results: Recent studies showed that poor mental health outcomes including depression, anxiety, burnout, comorbid mental illness, and stress presented the strongest risk for SI among

medical students. In addition, SI was statistically significantly associated with alcohol use, Tobacco consumption, personal history of suicide attempt, female gender and poor social support.

On the other hand, SA were significantly associated with the presence of a long-term illness, anxiety and depression. Conversely, stress, female gender, and alcohol use were not significant risk factors for SA among medical students.

Conclusions: Medical students face a number of personal, environmental, and academic challenges that may put them at risk for SI and SA. Additional research on individual risk factors is needed to construct effective suicide prevention programs in medical schools.

Disclosure of Interest: None Declared

Experiences of the first two pandemic years (2020 and 2021) in regards of the alteration of violent suicide attempts compared to 2016-2021. Presenting demographic features. Research made at Dr. Manninger Jenő National Traumatology Center, Hungary

N. M. Szeifert^{1,2,3*}, B. Sebők⁴, S. Szilágyi⁵ and M. Bérdi⁵

¹Doctoral School of Psychology; ²Clinical Psychology and Addictology, ELTE Eötvös Lóránd University; ³Psychotherapy, National Institute of Sports Medicine; ⁴School of PhD Studies Workgroup for Science Management, Semmelweis University and ⁵Psychiatry and Crisis Intervention, Péterfy Hospital, Budapest, Hungary

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1643

Introduction: During the pandemic years in Hungary the completed suicide rates has risen significantly. Suicide rates had been decreasing until 2019 since 1986. In 2019, 1550 people dead by completed suicide, in 2020 this number increased to 1705, in 2021, 1561 cases were registered. Violent suicide attempts represent the majority of completed suicides.

Objectives: In our study we were analysing the number of alteration of violent suicide attempts between 2016-2021, focusing on the trend in the first two years of the pandemic outbreak. 228 inpatients (65,4% male, 34,6% female) gone under medical treatment due to violent suicide attempts between 2016-2021 at Dr. Manninger Jenő National Traumatology Center, Budapest, Hungary.

Methods: We used an interrupted time-series analysis with Prais-Winsten regression, controlling autoaggressive and seasonal effects, to estimate the effect of the pandemic years on the violent suicide attempt rates in our sample. Demographic features, risk factors for suicidal behaviours, motivation and methods were analysed by Chi-square test and cross tabulation.

Results: Comparing to the previous years, in the first two pandemic years significantly has risen the number of inpatients treated because of violent suicide attempts. After the rapid change in 2020, decreasing numbers could be observed in 2021.

Conclusions: Analyzing the numbers of violent suicide attempts between 2016 and 2021, an increase in the number of attempts was

observed during the first two pandemic years. Detailed demographic data and potential risk factors are also to be presented in the lecture.

EPV1069

A Pilot Predictive Model for Indirect Assessment of Suicidal Ideation

P. Rus Prelog^{1,2*}, T. Matić³, P. Pregelj^{1,2} and A. Sadikov³

¹Centre for Clinical Psychiatry, University Psychiatric Clinic Ljubljana;

²Medical Faculty, University of Ljubljana and ³Artificial Intelligence Laboratory, Faculty of Computer and Information Science, University of Ljubljana, Ljubljana, Slovenia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1644

Introduction: In recent years, there has been a concerning increase in suicidal thoughts and, in some countries, completed suicides, amplified by the COVID-19 pandemic. Screening for suicidal ideation (SI) in the general population is limited due to ethical, effectiveness, and feasibility concerns. Identifying individuals at risk of suicide remains a complex challenge. Our study aimed to develop a predictive model using COVID-19 data, gathering psychometric information from 1790 respondents in Slovenia via an online survey conducted between July 2020 and December 2020, with a second wave of data (n=1200) collected from January 2022 to February 2022.

Objectives: With 9.7% of respondents reporting recent SI in the first wave of data, our primary goal was to estimate SI indirectly using SIDAS. We examined changes in habits, demographics, coping strategies, and satisfaction in key life aspects to discreetly identify potential risk factors.

Methods: We employed four machine learning algorithms (logistic regression, random forest, XGBoost, and support vector machines) and assessed model performance using the area under the receiver operating characteristic curve (AUC). Initial assessment used a held-out dataset, followed by validation with a new cohort of 1,200 users from the late COVID-19 period.

Results: Logistic regression, random forest, and XGBoost achieved comparable AUCs, reaching 0.83 on unseen data. Our analysis revealed significant associations between Brief-COPE subscales and SI. Self-Blame emerged as a strong SI indicator, followed by increased Substance Use, reduced Positive Reframing, Behavioral Disengagement, dissatisfaction with relationships, and younger age, in both 2020 and 2022 models. The model consistently performed well, even with varying population characteristics.

Conclusions: These results suggest that SI presence can be reasonably estimated using selected indicators, offering promise for developing an indirect screening tool without explicit questioning about suicidal thoughts. However, individuals flagged as at-risk should undergo clinical examination, as this model serves as an initial step in identifying SI risk factors in the context of the stressful event's (COVID-19 pandemic) impact on mental health.

The Epidemic of Non-Suicidal Self-Harm in Adolescents and Young Adults in the Kyrgyz Republic

E. Molchanova

Psychology, American University of Central Asia, Bishkek, Kyrgyzstan

doi: 10.1192/j.eurpsy.2024.1645

Introduction: During the last two years, many young people and adolescents in the Kyrgyz Republic started to visit specialists due to Non-suicidal self-harm. A significant rise in the amount of such cases allowed specialists from the Republican Center of Psychiatry in Bishkek to think about an “epidemic” of self-harming behavior. Non-suicidal self-harm (NSSH) is defined as repeated, deliberate, direct injury to the body without suicidal intent that is not socially acceptable (Nixon et al., 2002) to reduce psychological discomfort in the absence of a conscious intention to take one's life (ICD-10 codes X60-X84, and ICD-11 codes PB80-PD3Z).

Objectives: To determine the causes of NSSH among adolescents and young adults who approached specialists in mental health sphere at Institute of Behavioral Health at the American University of Central Asia.

Methods: Over two years, forty-five adolescents and young adults under twenty-five who had committed self-harm visited specialists from the Behavioral Health Institute at the American University of Central Asia.

All the patients received either dialectical behavioral treatment or cognitive processing treatment, medication (paroxetine) was used in three cases.

Results: Thirty patients were girls under twenty-one, and fifteen were boys and young male adults. The overwhelming majority (40 people) had self-inflicted cuts, two had imposed burns with matches and cigarettes, and one had used self-suffocation without a bond. Reasons for self-harm were the following: releasing internal tension and anxiety, getting some rest from intrusive thoughts, relieving the inner pain, and a desire to “feel as a whole person.” All the patients underlined that they did not want to attract attention from their family members; moreover, they tried to hide the consequences of self-harm.

Teens and young adults (twelve patients) from Kyrgyz traditional families visited a consultant or psychiatrist after a long drive through conventional or religious healers. All of the patients knew that they were addicted to self-harm, wanted to stop a problematic behavior, and could not stop it on their own. Ten patients have been diagnosed with borderline personality disorder. Two of them also had eating disorders. Five patients had PTSD, and five had social phobia. The others had recognizable anxiety symptoms.

Conclusions: The enormous rise of non-suicidal self-harm is a phenomenon that needs further research. Those cases often resist treatment due to the “addictive” component in the pathogenesis.

Association Study of Suicidal Behavior, Early Trauma, and Psychological Pain in Depressed WomenV. L. De-Melo-Neto^{1*}, J. F. Melo¹ and L. M. Silva²¹Federal University of Alagoas (UFAL) and ²CESMAC, Maceió, Brazil

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1646

Introduction: The stress-diathesis model, which indicates an interaction between vulnerability and stress factors is the most acceptable paradigm to explain suicide.

Objectives: To assess the association between suicidal behavior, early trauma, and psychological pain among women undergoing psychiatric treatment for a major depression episode.

Methods: It was a cross-sectional study approved by the Research Ethics Committee of the State University of Health Sciences of Alagoas (UNCISAL) - Brazil (approval number: 14689219.1.0000.5011). The final sample of 48 women was obtained through non-probabilistic, convenience, and consecutive sampling. Data were collected from depressed adult women undergoing outpatient psychiatric treatment in public services in the State of Alagoas, Brazil. The instruments used included a sociodemographic questionnaire prepared exclusively for this research, modules A, B, and C of the Mini International Neuropsychiatric Interview (M.I.N.I. 7.0.2), the Beck Depression Inventory II (BDI-II), the Psychache Scale (PAS); and the Childhood Trauma Questionnaire (CTQ). Data were analyzed using SPSS 22. After performing the Kolmogorov-Smirnov test, Student's t tests were conducted for parametric analyses. Statistical significance was established at a p-value less than 0.05

Results: The mean age of the total sample was 42.5 years old. 89.6% presented suicidal behavior. 62.5% of the women had major depression and 37.5% had bipolar disorder diagnosis. BDI-II scores were significantly higher among depressed women with suicidal behavior (27.9 ± 13.4 vs. 16.6 ± 6.9 ; p value:0.04). BDI-II scores were also significantly higher in both passive (29.4 ± 12.6 vs. 13.4 ± 8.5 ; p value:0.01) and active (31.4 ± 12.2 vs. 18.0 ± 11.3 ; p value<.01) suicide ideation groups compared to depressed women who did report these thoughts. Psychological pain scores were also higher in both passive (46.0 ± 12.8 vs. 34.8 ± 14.6 ; p value:0.03) and active (47.7 ± 12.4 vs. 38.1 ± 12.7 ; p value:0.02) suicide ideation groups. Women with active suicide ideation were also more prone to report a history of childhood physical neglect compared to those women who did not report active suicide ideation in the last 30 days (12.5 ± 4.6 vs. 9.2 ± 4.0 ; p value:0.02).

Conclusions: The present study aimed to investigate the association between suicidal behavior, childhood trauma, and psychological pain in depressed women undergoing treatment in outpatient psychiatric public services. The results indicated that suicidal ideation (both passive and active) was associated with a more severe depressive episode and higher scores of psychological pain, demonstrating that psychological pain is an indicator of acute suicide risk in depressed women even when they are undergoing psychiatric treatment. Effectively identifying and addressing psychological pain can play a pivotal role in reducing or mitigating the risk of suicidal behavior.

EPV1073

Understanding the role of mental pain in suicidal individuals: from clinical to neuroimaging perspective.

M. Pompili

Dept. of Neurosciences, Mental Health and Sensory Organs, Sapienza University of Rome, Rome, Italy

doi: 10.1192/j.eurpsy.2024.1647

Introduction: In the attempt to shed light on the phenomenology of suicide, this contribution focuses on the role of mental pain as a main ingredient of suicide.

Objectives: Previous studies have shown that mental pain, childhood negative experiences, and maltreatment are associated with suicide risk. Neuroimaging studies demonstrated that such emotional pain shares the same neuroanatomical circuit of somatic pain. Furthermore, concepts related to death, failure, or other unfortunate circumstances activate specific cerebral areas in a suicidal individual compared to a non-suicidal subject.

Methods: The author, through a multicenter investigation, conducted a sizeable clinical study on mental pain related to psychiatric disorders and suicide risk. With this aim, a dataset of more than 2200 psychiatric patients is explored to investigate suicide risk, mental pain, childhood trauma, and the role of depressive symptomatology. Implications emerging from neuroimaging studies are investigated.

Results: A framework emerges about the role of childhood traumatization in mediating between suicide risk and mental pain; furthermore, when individuals experience high mental pain and high depressive symptomatology, regardless of the diagnoses, they are exposed to higher suicide risk.

Conclusions: Such results are presented in light of neuroimaging studies' role in identifying how mental pain and brain activation are detected in suicidal individuals. Therefore, this contribution aims to understand better mental pain's role in clinical practice and research activities.

Statistical model of the dynamics of suicides in ukraine before a full-scale war

O. Khaustova* and V. Omelyanovich

Bogomolets National Medical University, Kyiv, Ukraine

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1648

Introduction: The problem of suicides is one of the most critical problems of the public health care system. In Ukraine, official data on the number of deaths and their causes were released by the State Statistics Service only in 2021, on the eve of a full-scale military invasion. This made it possible to conduct statistical analysis and build a mathematical model of the seasonal dynamics of suicidal activity in Ukraine.

Objectives: Develop a statistical model of the dynamics of the number of completed suicides, considering regions of Ukraine and months. For this, a time series of the number of suicides from 2005 to 2021 was created, a mathematical and statistical analysis of the dynamic characteristics of the time series was carried out, and a forecast of the dynamics of the number of completed suicides was built.

Methods: Time series analysis using autocorrelation analysis with the calculation of Leung-Box statistics and the method of seasonal exponential smoothing were applied.

Results: Autocorrelation of the absolute indicators of the number of completed suicides made it possible to construct correlograms for each separate region of Ukraine. In order to ensure the statistical reliability of the autocorrelation coefficients, the number of lags was equal to 50, based on the fact that $k \leq n/4$, where k is the maximum number of lags, and n is the number of observations. The correlograms of the regions that characterized the built statistical model of the dynamics of changes in the number of completed suicides were clustered in the form of four groups. The calculation of the coefficient of determination indicated that a high proportion of the total variation for Ukraine as a whole ($R^2=0.656$) and for its individual regions ($R^2=0.731 \pm 0.051$) can be explained using the model we built, and the model itself should be evaluated as consistent. Based on the developed model, it was established that the period from March to May, July and, to a lesser extent, January is characterized by the highest number of suicides.

Conclusions: The constructed statistical model of the dynamics of suicides in Ukraine is coherent and statistically reliable. It can be used for forecasting, provided corrections are made, taking into account the social changes of wartime. The study of chronobiological aspects that drew attention during the analysis is promising for further targeted scientific research and may be of practical interest for the creation of national suicide prevention programs in Ukraine.

Deliberate self-poisoning in children and adolescents

S. Hmimou¹, S. Boukhorb¹, S. Irnat^{1*}, F. Hadrya², N. Rhalem³, M. A. Bellimam⁴, A. Soulaymani¹, A. Mokhtari¹, R. Soulaymani-Bencheikh³ and H. Hami¹

¹Laboratory of Biology and Health, Faculty of Sciences, Ibn Tofail University, Kenitra; ²University Hassan First of Settati, Higher Institute of Health Sciences, Health Sciences and Technologies Laboratory, Settati; ³Moroccan Poison Control Center and ⁴Forensic Institute of Royal Gendarmerie, Rabat, Morocco

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1649

Introduction: Suicide is a significant global public health issue that has a severe impact on children and adolescents.

Objectives: This study examined the epidemiological features of self-poisoning events among these groups in Morocco.

Methods: In this retrospective study, data on intentional poisoning cases among children under 15 years of age and adolescents aged 15-19 years were analyzed. The Moroccan Poison Control Center has reported these cases over a period of 34 years.

Results: During the study period, 7,111 deliberate self-poisoning cases were documented among children and adolescents, representing 30% of all reported self-poisoning cases (out of a total of 23,711 cases with known ages). The vast majority of the cases (80.8%) involved females, indicating a significant female-to-male ratio of 4.2. The patients had a mean age of 16.05 ± 2.10 years. Notably, drugs were the predominant method of self-poisoning, comprising 51.7% of the cases, followed by pesticides at 31.3%. The symptoms of poisoning manifested with significant variation, contingent on the type of toxin involved, the amount ingested, and the time passed before medical care was administered. Of the 4,711 cases with known outcomes, 144 (3.06%) were fatal. Nonetheless, the outcomes were favorable for the remaining cases, with or without lasting sequelae.

Conclusions: The ongoing prevalence of suicide and suicide attempts among children and adolescents is a prominent issue in public health. Our research emphasizes the crucial necessity to address suicide, as it remains one of the primary causes of mortality in young individuals.

EPV1076

Understanding collective suicides in Morocco: A 35-year epidemiological study

S. Boukhorb¹, S. Hmimou¹, S. Irnat^{1*}, F. Hadrya², N. Rhalem³, M. A. Bellimam⁴, A. Soulaymani¹, A. Mokhtari¹, R. Soulaymani-Bencheikh³ and H. Hami¹

¹Laboratory of Biology and Health, Faculty of Sciences, Ibn Tofail University, Kenitra; ²University Hassan First of Settati, Higher Institute of Health Sciences, Health Sciences and Technologies Laboratory, Settati; ³Moroccan Poison Control Center and ⁴Forensic Institute of Royal Gendarmerie, Rabat, Morocco

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1650

Introduction: Suicide is a major public health concern, ranking among the leading causes of death worldwide.

Objectives: This study investigated the epidemiological features of collective suicide incidents in Morocco.

Methods: We performed a retrospective analysis of suicidal poisoning cases recorded by the Moroccan Poison Control Center (MPCC) over a 35-year period.

Results: During the study's duration, the MPCC recorded 168 suicide cases. The mean age of those involved in these incidents was 23.9 years, with a female-to-male ratio of 1.57. The majority of those affected were adolescents and young adults, specifically between 15 and 34 years of age. Pesticides and drugs were the most commonly used methods of suicide and accounted for 31.1% and 20.1% of the cases, respectively. The majority of incidents occurred in the home environment and were primarily caused by oral exposure. The symptoms of poisoning varied according to the consumed substance, amount ingested, and elapsed time until medical treatment. The symptoms included disturbances in the neurological, gastrointestinal, respiratory, and cardiovascular systems. Of the 100 cases with known outcomes, one person died due to poisoning, whereas the remaining cases survived, although some enduring complications.

Conclusions: Suicide accounted for 1.3% of global mortality, ranking as the 17th most common cause of death in 2019, according to data from the World Health Organization (WHO). This trend emphasizes the urgent need for continuous efforts at all levels to address and mitigate this rapidly growing issue.

Investigation of peripheral inflammatory biomarkers in association with suicide risk in major depression

B. Petho^{1*}, T. Tenyi¹, R. Herold¹, P. Osvath¹, V. Voros¹, D. Simon², C. Molnar¹ and M. A. Kovacs¹

¹Department of Psychiatry and Psychotherapy and ²Department of Immunology and Biotechnology, University of Pecs, Clinical Centre, Pecs, Hungary

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1651

Introduction: Suicide is the most severe consequence of major depressive disorder (MDD). The most novel researches assume the role of immunological dysregulation in the background – several studies have reported alterations of inflammatory cells related to both MDD and suicidal behaviour (SB).

Objectives: Changes in the number of certain immune cells and their ratios have been proposed as potential biomarkers of suicide risk (SR). The aim of our research was to investigate alterations of these values related not only to MDD as an assumed inflammatory state, but also to an increased risk of SB.

Methods: In our retrospective cohort study carried out between January 2015 and January 2020, we investigated laboratory parameters of psychiatric patients diagnosed with MDD ($n=101$). Individuals with recent (≤ 48 hours prior) suicide attempt (SA) ($n=22$) and with past SA (>48 hours prior) ($n=19$) represented the high SR group. MDD patients with no history of SA ($n=60$) composed the intermediate SR group. We compared the number of neutrophil granulocytes, monocytes, lymphocytes, platelets, leukocytes, neutrophil-to-lymphocyte (NLR), monocyte-to-lymphocyte (MLR), platelet-to-lymphocyte ratio (PLR), red blood cell distribution width (RDW) and erythrocyte sedimentation rate (ESR). Furthermore, we evaluated alterations of these parameters related to antidepressant (AD) treatment, which has been proved to have anti-inflammatory effects. Statistical analyses were carried out using GraphPad 9.5.0 and MedCalc 16.8 programmes.

Results: We found a significant increase in neutrophil granulocyte count ($p=0.016$), NLR ($p=0.031$, Fig. 1), monocyte count ($p\leq 0.0001$), MLR ($p=0.005$, Fig. 2), leukocyte count ($p=0.048$) and ESR ($p=0.037$) in patients with recent SA compared to patients with no history of SA. Moreover, there was a significant elevation in monocyte count ($p\leq 0.0001$), MLR ($p=0.020$, Fig. 3), ESR ($p=0.041$) and RDW ($p=0.037$) in patients with high SR compared to patients with intermediate SR. AD treatment resulted in a significant decrease in neutrophil granulocyte count ($p=0.0163$) and NLR ($p=0.016$), however, it did not affect the rest of the parameters.

Image:

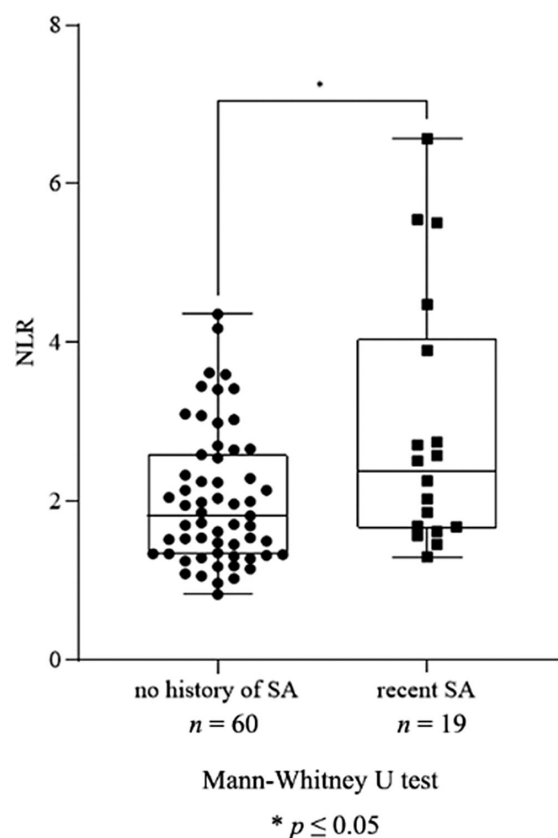

Image 2:

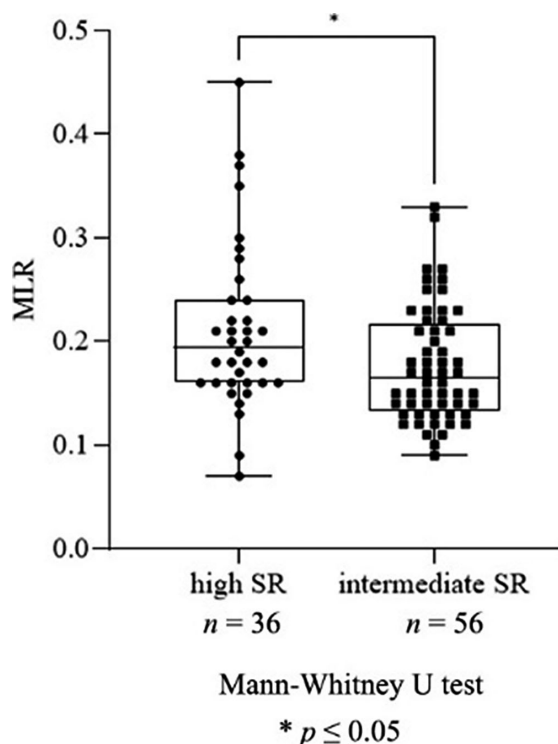

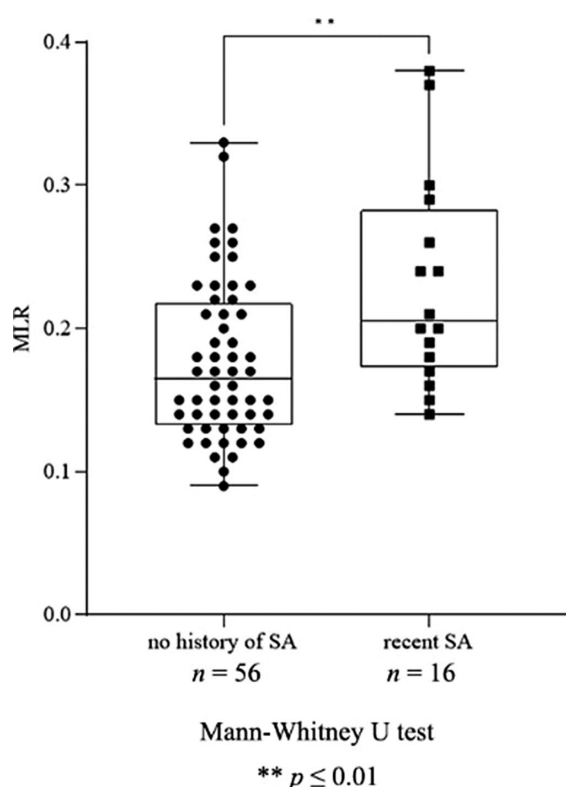

Image 3:

Conclusions: Assuming immunological mechanisms in the background of MDD and SB, our findings support the role of NLR as a biomarker of acute SR, though its alterations may be masked by AD therapy in the long term. However, MLR – remaining unaffected by AD treatment – may be a possible indicator of both acute and long term suicidal vulnerability. In order to further specify the diagnostic value of these parameters, future prospective research is needed. The study was supported by the FIKP-IV and the TNIL projects.

Training in Psychiatry

EPV1077

Supervision an essential tool in medical (and psychiatric) training

R. J. Van Der Gaag

Psychiatry, Radboud University Medical Centre, Nijmegen, Netherlands

doi: 10.1192/j.eurpsy.2024.1652

Introduction: Supervision is an essential tool in medical training and especially in psychiatry and psychotherapy. It encompasses two distinct aspects namely: coaching in the workplace aimed at

developing competences (pyramid of Miller) and on the other side a safe place to reflect on one's personal development as a professional. This mentoring should be distinguished from the personal training psychotherapy. The mentoring supervisor will take the doctor's pledge as a starting point of professional development. But will also encourage the resident to become aware of elements of transference and counter transference in his/her clinical work, helping to foster empathy "maximal understanding with respect for professional distance. This, not only for the benefit of the patient and his/her security, but also in order to take care of one's own health and developing a sound balance between work and private life.

Too often supervision is taken for granted once the resident has become a consultant. Along with examples of the techniques and the pitfalls of supervision, the presenters will plea for training and intervention as part of the development of the supervisor!

Objectives: Raise awareness for the competences needed to become a valuable supervisor and the place supervision in its two aspects (coaching and place of reflection) should take in the training of medical doctors and especially psychiatrists

Methods:

- an inventory of the place of supervision in training in psychiatry throughout Europe
- looking into competences needed in order to develop a sound professional attitude
- looking into the competencies needed to become a valuable supervisor

Results:

- supervision is differently defined and given in training in psychiatry throughout Europe
- the competences needed in order to develop a sound professional attitude are defined in the Doctor's Pledge (World Medical Association 2017) but should be refined according to the specialty with special attention to aspects of psychiatry alien to other specialities
- along with Teaching the Teachers - special trainings are available to become a supervisor

Conclusions: Supervision is an essential tool in medical/psychiatric training, but it needs to be taken seriously in terms of developing the competences needed but also maintaining them in intervention with the colleagues of the training staff

Disclosure of Interest: None Declared

EPV1078

Promoting well-being: Investigating self-efficacy and academic burnout among trainee teachers

Z. Boumaaize¹, A. Bouhaba^{1*}, M. A. Lafraxo¹, H. Guider¹, Y. El Madhi² and H. Hami¹

¹Laboratory of Biology and Health, Faculty of Sciences, Ibn Tofail University, Kenitra and ²Regional Center for Education and Training Professions, Rabat, Morocco

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1653

Introduction: Burnout is a widespread problem with far-reaching implications for mental health. Recent studies on working conditions in Morocco have drawn attention to the increasing prevalence of psychosocial hazards, notably stress and burnout, in various professions. The emergence of burnout is mainly determined by the intricate interplay of organizational, environmental, and individual factors. In education, the teaching profession is susceptible to various burnout symptoms. Educators can mitigate this syndrome by maintaining a positive outlook driven by a strong sense of self-efficacy.

Objectives: This study investigated the correlation between academic burnout syndrome and personal resources, specifically a sense of efficacy.

Methods: A cross-sectional survey of 160 Moroccan trainee teachers, with an average age of 27.94 ± 5.44 years, was conducted. Data were collected through a self-administered questionnaire that included the Maslach Burnout Inventory-Student Survey (MBI-SS) and Teachers' Sense of Efficacy Scale (TSES). The MBI-SS evaluated academic burnout across three dimensions: emotional exhaustion, cynicism, and academic efficacy, whereas the TSES examined efficacy for classroom management, student engagement, and instructional strategies. The questionnaires were translated into Arabic and validated for use in the Moroccan context.

Results: The findings revealed a moderate and statistically significant correlation between efficacy for classroom management and the two components of efficacy related to instructional strategies ($r=0.32$; $p<0.001$) and student engagement ($r=0.49$; $p<0.001$). Additionally, a significant and positive correlation was observed between instructional strategies' efficacy and the efficacy for student engagement ($r=0.23$; $p<0.01$). A moderate and significant correlation was found between emotional exhaustion and cynicism ($r=0.45$; $p<0.001$), whereas academic efficacy and cynicism were negatively and significantly correlated ($r=-0.13$; $p<0.05$). It is worth noting that the key component of academic burnout, "emotional exhaustion," was significantly related to academic efficacy ($r=-0.58$; $p<0.001$). Additionally, Pearson's correlation test demonstrated a positive and statistically significant correlation between emotional exhaustion and efficacy for student engagement ($r=0.14$; $p<0.05$). Furthermore, the correlation between academic burnout and self-efficacy showed a negative and statistically significant association ($r=-0.13$; $p<0.05$).

Conclusions: Trainee teachers face a range of stressors that affect their well-being. By focusing on personal traits, well-being can be improved and burnout mitigated. This study highlights the key role of self-efficacy as a critical resource in preventing academic burnout, particularly among teachers at the start of their careers.

Training on Addressing Patients' Values (including Spirituality and Worldview) in Decision Making

A. L. H. Peh^{1*}, D. C. L. Teo¹, E. K. Ong² and M. S. Q. Tan¹

¹Psychological Medicine, Changi General Hospital and ²Palliative Care, National Cancer Centre Singapore, Singapore, Singapore

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1654

Introduction: Patients' values are relevant in patient-centred care (PCC) as awareness and recognition of these can lead to better decision making and improved outcomes. Training in decision making is sorely lacking, especially in the area of spirituality and worldview.

Objectives: Our poster describes a training workshop to provide such medical education to healthcare professionals. The half-day training covers: importance of addressing patients' values in decision making; using decisional aids; role of spirituality and worldview of the patient.

Methods: Clinicians of the hospital, including doctors, nurses and allied healthcare professionals were invited to attend the training. The evaluations by the participants for the workshops conducted in 2021-2023 were collated and presented.

Results: Four workshops in 2021 to 2023 were conducted, with a total of 43 participants. We achieved overall ratings of above average and excellent in more than 80% of responses; content relevance and usefulness to work, presentation and facilitation were similarly rated. Most participants would recommend it to colleagues.

Conclusions: The "Addressing Patients' Values in Decision Making" workshop for clinicians will allow the hospital to promulgate a culture of quality care through patient engagement.

"Thoroughly out of my depth - A quality improvement project to improve junior clinician's confidence in undertaking adult ADHD clinic appointments

B. Marron¹ and L. McKeown^{1*}

¹NHS Argyll & Bute, Lochgilphead, United Kingdom

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1655

Introduction: There has been a 1000% increase in referrals for assessment of adult ADHD within Scotland over the past three years (The Scottish Government. 2023. *NAIT adult Neurodevelopmental Pathways Report*). These referrals are sent by general practitioners to the local community mental health team. The most junior clinicians (doctors who are pre-membership with the Royal College of Psychiatrists) in the team are often responsible for undertaking the initial assessment of these patients. Patients have on average waited almost a year to be seen and expectations are high.

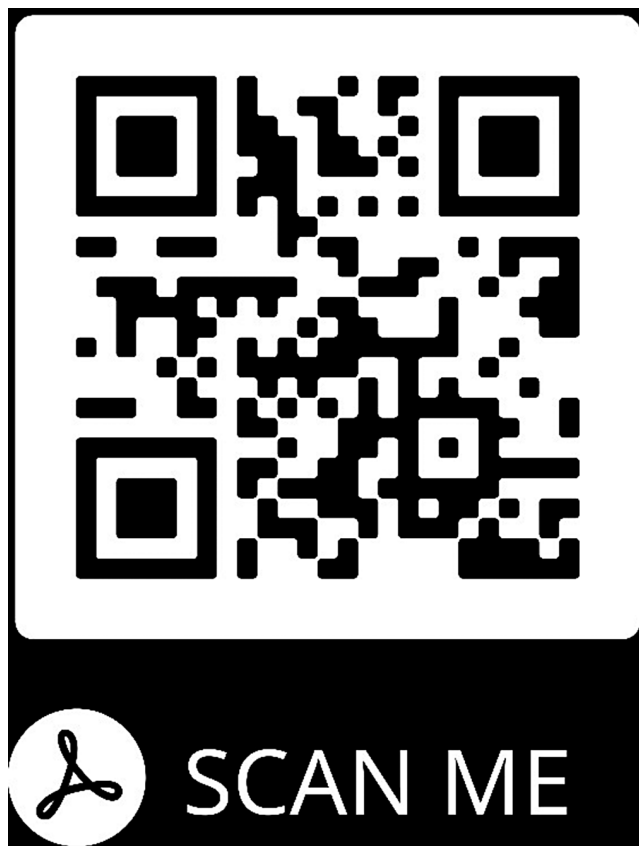

Objectives: The diagnosis of ADHD can be challenging, and adult ADHD is still a relatively new and evolving diagnostic entity. We set out to explore how junior clinicians were coping with this in their daily practice.

Methods: We developed a questionnaire that was sent to all junior clinicians working within Argyll & Bute ($n=8$) via an anonymised email link. The link was open for 1 week and then results were analysed.

Results: The response rate to our survey was 87.5%. Prior to starting their current roles none of the respondents had ever undertaken an ADHD assessment before. All respondents answered "No" when asked if they felt they had adequate

knowledge on ADHD in order to perform assessments. Only 14% (n=1) felt they had access to adequate resources about how to make an ADHD diagnosis. Participants were asked on a scale of 1-10 (1= not at all, 10= very) to rate their confidence in conducting ADHD assessments. The average confidence score was 2.43. There was a space for free text feedback in which participants reported the following: “felt thoroughly out my depth”, “I felt chucked in the deep end”, “I felt very under qualified”

Image:

Conclusions: Our results showed that junior clinicians did not feel confident or knowledgeable about undertaking adult ADHD assessments. In response to this we have now produced, in association with the consultant psychiatrists within our health board, an informative and engaging quick reference poster which explains how to undertake an ADHD assessment (see QR code attached as Image 1). It contains useful pointers about diagnosis, and more importantly guidance on language/phrases to use when explaining to patients whether or not you feel a diagnosis of ADHD is appropriate. It then also explains next steps that can be offered i.e. psychological support/medication options and how to prescribe these. We plan to send out a repeat questionnaire to the next cohort of junior clinicians to assess if they have improved confidence in managing and diagnosing ADHD following this intervention.

Disclosure of Interest: None Declared

EPV1083

Enhancing Psychiatry Resident Bonding and Education using an Escape Room Challenge Activity

G. Lee*, G. Russell, H. Farhan, J. Lin and L. Spring

Psychiatry, Stony Brook University Hospital, Stony Brook, United States

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1656

Introduction: An “escape room” is a game requiring teamwork and problem-solving during which a series of puzzles are solved to escape a locked room. Various escape room activities have been designed for healthcare professionals, including internal medicine residents and nursing students (Anderson *et al.* Simulation & Gaming 2021; 52(1) 7-17; Rodríguez-Ferrer *et al.* BMC Med Educ 2022; 22:901; Khanna *et al.* Cureus 2021; 13 (9) e18314). Escape rooms provide an opportunity for social activity, an important component of resident wellness (Mari *et al.* BMC Med Educ 2019; 19(1):437). This abstract describes an escape room challenge designed and implemented at our psychiatry residency program quarterly wellness afternoon event, which is an afternoon session dedicated to resident wellness.

Objectives: The objective of this project was to design and implement an escape room challenge containing multiple game mechanics, including hidden roles, information asymmetry, acting, logical deduction, and spying. This activity was conducted to enhance bonding among residents while reinforcing knowledge in psychiatry.

Methods: We designed and implemented an escape room for 22 residents. Residents were divided into four teams each tasked with completing a sequence of puzzles to open the final lockbox. Two novel mechanics were added to the activity. Each team had a “clue holder” with clues to help solve all the puzzles. This team member had to conceal their identity because, if any of the other teams identified this person, the original winning team would have to give up the prize to the team that guessed the identity of this person. One member of each team was assigned a “spy” role whose mission was to make it hard for the clue holder to reveal all the clues. An anonymous post-activity survey was completed using Google Forms.

Results: The script was set in a fictional, abandoned psychiatric emergency room. The first task was a visual puzzle of a historic figure in psychiatry. The second activity involved residents guessing the psychotropic medication being acted out by another resident in the style of charades. The third activity required residents to apply developmental milestones to decode a combination lock. The fourth puzzle involved residents solving riddles by using information gathered from resident profiles on the residency program website.

Eleven (50%) residents completed the post-game survey. All residents answered true or very true that they enjoyed the game and that participation helped them better connect with their peers. Eight (73%) residents answered true or very true that they learned something from the activity.

Conclusions: An adapted escape room challenge is a novel wellness activity that enhance resident collegiality, teamwork, and bonding. All residents who completed the post-activity survey indicated that

they enjoyed the activity and felt more connected to their peers afterwards.

EPV1084

Psychiatry training in Hungary, difficulties and advantages

I. A. Van Der Wijk

Sántha kálmán Member Hospital, SzSzBM County Hospital, Nagykovács, Hungary

doi: 10.1192/j.eurpsy.2024.1657

Introduction: While in theory our training program is quite satisfactory, in practice it often falls short. The first two years give a more general knowledge, including spending time at internal, ICU and neurological wards as well as attending a month-long course about communication, palliative care and basic legal principals important in healthcare. The second three years provide the opportunity to engage in profession-related rotations, like psychotherapy, psychiatric rehabilitation and addictology.

Objectives: The design in itself is clear, but the supervision for its enactment is insufficient. This leads to regional differences between the four faculties of our country, not everyone is able to partake in the supposedly mandatory rotations (mostly because of shortcomings in staff) and the organization of our theoretical education varies greatly in each region to the point of non-existence in one area, since the COVID-19 pandemic started. The personal supervision of each psychiatry trainee also leaves much to be desired both on professional and – in psychiatry very important – mental levels. Competence and responsibility limits are often vague, and, especially in country hospitals, too much is expected of the resident (i.e. doing a nightshift alone, without direct supervision).

Methods: It is a positive thing that in theory there are standards in place, the problem is that they are more viewed as guidelines, than demands to be met. Nevertheless, some of the faculties provide well-organized education (even subdivided per year of training) and/or take rotations outside of the 'home ward' seriously. The opportunity to gain a basic knowledge in psychotherapy is also beneficial and a good aspect of our training. Easily accessible or even obligatory participation in psychotherapy for ourselves during our training however, is lacking.

Results: The decreasing number of psychiatry trainees sadly is a worldwide trend and Hungary is no exception. This poses more difficulties, i.e. making it harder to let a resident go on 'outside' rotations, especially from wards already struggling with staff shortages. Because of the latter, there is also little time to teach the trainees appropriately and pay them the attention they need.

Conclusions: All in all, there is much potential in our training program and its standards, also leaving room for substantial improvement in realizing the practical aspects. The decline in numbers of psychiatry trainees is worrisome and calls for more general intervention on a European or even global level.

EPV1085

Experiences and attitudes of UK early career psychiatrists towards electroconvulsive therapy

L. Alexander^{1,2*}, G. Bhatia¹ and M. Pinto da Costa^{1,2,3}

¹South London and the Maudsley NHS Foundation Trust; ²Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom and ³Institute of Biomedical Sciences Abel Salazar, University of Porto, Porto, Portugal

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1658

Introduction: Electroconvulsive therapy (ECT) is effective in treating severe major depressive disorder, manic episodes, and catatonia. Despite this, it is a controversial treatment amongst patients, carers, and even some psychiatrists in the UK.

Objectives: To determine the experiences and perceptions of UK psychiatric trainees and early-career psychiatrists regarding the use of ECT in clinical practice.

Methods: An anonymous survey was distributed online to UK psychiatric trainees and early-career psychiatrists across the country. The questionnaire consisted of 36 multiple-choice and Likert scale questions.

Results: So far, 44 trainees and early-career psychiatrists have responded. The vast majority had witnessed ECT administration during training and had administered ECT under supervision. Most respondents agreed or strongly agreed that ECT was a safe and effective treatment, and most respondents disagreed or strongly disagreed that ECT is cruel or outdated. There were more varied views regarding perceptions of side effects and contraindications: a minority of respondents were unsure about whether ECT had long-term side effects, and whilst most respondents disagreed or strongly disagreed that ECT has many risks and contraindications, just under half were unsure or agreed.

Conclusions: Most UK psychiatric trainees and early-career psychiatrists have experience of ECT during training and believe ECT is a safe and effective treatment. Respondents had a mixed view regarding the side-effect profile and risks/contraindications of ECT, which may be an important area for further education and training.

EPV1086

Psychiatry Trainees' Perspectives on Psychotherapy Training in Residencies Worldwide

R. M. Salgado^{1,2*} and O. von Doellinger¹

¹Centro Hospitalar do Tâmega e Sousa, Penafiel and ²Faculty of Medicine of the University of Porto, Porto, Portugal

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1659

Introduction: Incorporating psychotherapy into the curricula of psychiatry residency programs has been proven difficult, even in countries where psychotherapy training is a requirement for psychiatry residents to become psychiatrists. There is a risk that future psychiatrists lacking psychotherapy skills will be restricted in managing the wide scope of disorders and personalities they will face in clinical practice. It is important to assess what psychiatry trainees

around the globe have to say about psychotherapy training as part of their residency curricula.

Objectives: The primary purpose of the article was to assess psychiatry trainees' perspectives on psychotherapy training in residency programs worldwide.

Methods: The authors performed a narrative review, resulting in 19 original research studies, published between 2001 and 2021, evaluating psychiatry residents' perspectives by the application of a questionnaire.

Results: Nineteen articles were included in this review. Most of the studies were developed across European countries (47.4%) and in the USA (36.8%). Psychiatry residents are interested in and value psychotherapy training, and some consider it should be an obligatory competency for psychiatrists, as it already occurs in some countries worldwide. Even though, most psychiatry trainees feel dissatisfaction with the existing training in residency curricula, pointing out concerns related to the quality of resources such as courses of psychotherapy and supervision of cases, time within the residency period, and financial constraints. In terms of personal psychotherapy, we found contrasting views of its importance in psychotherapy training for psychiatry residents. A crucial finding was that psychiatry residents tend to lose interest in psychotherapy during the years of the residency, and dissatisfaction with the quality of the psychotherapy curricula, lack of support, and low self-perceived competence in psychotherapy by trainees were factors associated with reduced interest in psychotherapy training.

Conclusions: At a time when psychotherapy is increasingly becoming acknowledged to play a central role in the treatment of most psychiatric disorders, current training is failing to provide these competencies to psychiatry trainees. Serious reflection must be given to both the extent of the guidelines and the practical opportunities for psychotherapy training so future psychiatrists can be qualified to provide an accurate biopsychosocial model of psychiatric care. The authors postulate that maintaining residents' interest in psychotherapy requires improvements in the residency curricula and departmental leadership must support trainees' goals of becoming comprehensively trained psychiatrists.

Psychedelic-assisted Therapy Training: Firsthand Experience of Non-Ordinary States of Consciousness in the Development of Competence

S. Dames¹, C. Watler¹, P. Kryskow², P. Allard¹, M. Gagnon³ and V. Tsang^{3*}

¹VIU; ²Roots to Thrive, Nanaimo and ³UBC, Vancouver, Canada

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1660

Introduction: This review explores the benefits of incorporating personal experience(s) with non-ordinary states of consciousness as a core component of Psychedelic-Assisted Therapy (PaT) training. The program incorporates an optional experiential training component. We collaborate with professionals affiliated with a Canadian non-profit organization specializing in PaT experiential training. As do other stakeholders in this field— including program developers, educators, and researchers—we navigate a rapidly

evolving and often ambiguous landscape, where infrastructure and regulations are lagging scientific data and best practices. Given the potential for differing perspectives, the authors acknowledge that their personal experiences could be a potential source of bias, influencing objectivity.

Objectives: Conversely, these lived experiences could be seen as valuable contributions, enriching perspectives on the role of experiential training. In that context, our intention is to provide a comprehensive review, presenting arguments both in favour of and against the integration of experiential training in PaT.

Methods: There is an urgent need for establishing legal training and practice options, bridging the underground with best practices, with all practitioners operating within a regulated and ethically accountable framework. Such a proactive strategy would mitigate the risks associated with unregulated training in a field with relatively few guidelines on how to develop competency.

Results: An in-training PaT experience supports personal comfort, self-assuredness, and confidence supporting others in non-ordinary states of consciousness, with contemporary researchers/experts highlighting the specific challenges among therapists who lack lived experience. These might include holding unrealistic expectations, being unaware of the impacts of set and setting, and misunderstanding

Conclusions: Whether or not therapists engage in experiential training - serving a dual in one's own healing process, it is imperative that they maintain their own wellness practices. This proactive/primary prevention strategy would improve well-being and resilience, reducing secondary mental health consequences for patients and providers. Cultivating a culture of self-care within the mental health field should be an overarching priority for training programs and professional organizations, without which we are left with broken people in support of broken people. Current rates of burn-out, absenteeism and early retirement suggest that we are already on that trajectory and should serve as a call to action.

doi: 10.1192/j.eurpsy.2024.1661

Introduction: Becoming a psychiatrist, clinical psychologist or psychotherapist involves a complex set of skills that require extensive training. Clinical practice development and professional and personal identity formation are closely intertwined and continue throughout one's career. Individual and environmental factors influence dropout. The beginning stages of training are incredibly challenging for trainees and can be a time of vulnerability as they face early professional hurdles. We propose that certain educational factors, such as inadequate practical training and insufficient emotional support during professional dilemmas, play a crucial role in manifesting burnout or other symptoms, potentially leading to stagnation in one's career.

Objectives: The main objective of our study is to identify causes of disruption and/or discontinuation of the training/residency programs in psychiatry, clinical psychology, and psychotherapy. Our study also aims to highlight the causes of chronic exhaustion among trainees in mental health professions.

Methods: The research team has developed a comprehensive questionnaire including two validated psychometric scales, the Effort-Reward Imbalance Questionnaire (ERI, Siegrist *et al.* Soc Sci Med 2004; 58 1483-99, Salavecz *et al.* J Men Psychosom 2006; 7 231-246) and the Mental Health Test (MHT, Vargha *et al.* J Men Psychosom 2020; 21 281-322). A quantitative analysis (Braun *et al.* Qual. Res. Psychol. 2006; 3 77-101) will be performed on the responses, following which interviews will be conducted with previous volunteers who participated in the study. The interviews will be evaluated through content analysis. Our survey is prepared with the involvement of all significant training centers in Hungary. The study was approved by the United Ethical Review Committee for Research in Psychology (EPKEB, approval numbers: 2021-109, 2023-101).

Results: The participants' main characteristics and the questionnaires' results will be summarized with standard statistical methods, while the interviews will be analyzed with the help of qualitative methods.

Conclusions: Based on the results of the described study, we aim to investigate the educational system's impact on the career development and commitment of psychiatrists, psychologists, and psychotherapists in Hungary. Additionally, the research will yield valuable perspectives on how these factors affect the mental well-being of these professionals. Ultimately, the results could help address areas of concern and improve mental health professionals' training.

Perceived stigma evaluation among residents in psychiatry

R. Masmoudi, S. Ajmi*, A. Guermazi, F. Cherif, R. Sallemi and J. Masmoudi

Psychiatry A, Hedi Chaker University Hospital, Sfax, Tunisia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1662

Introduction: The nature of psychiatry as a specialty dealing with mental health and emotional well-being may contribute to the

perceived stigma. These misconceptions and biases can impact the way psychiatry residents perceive their profession, their own self-esteem, job satisfaction, and overall well-being.

Objectives: Our goal was to evaluate the experience of stigma among psychiatry residents.

Methods: A descriptive cross-sectional online survey was conducted in January 2022 among psychiatry residents at Hedi Chaker University Hospital in Sfax, Tunisia.

The Clinician Associative Stigma Scale (CASS) was used to assess stigmatization experiences.

Results: A total of 34 residents participated in this survey. Their average age was 27.94 years \pm 2.43, with 91.2% being female. Of the participants, 61.8% were adult psychiatry residents, and 39.2% were child psychiatry residents. Additionally, the choice of adult psychiatry or child psychiatry specialty was self-determined in 91.2% of cases. The participants had an average of 2 years of experience in psychiatry. They reported a personal medical or surgical history, a personal psychiatric history, and a family history of psychiatric disorders in 32.4%, 8.8%, and 50%, respectively. The average CASS score was 47.09 \pm 8.32.

The mean scores for the "discomfort with disclosure" factor, the "stereotypes about mental health professionals" factor, the "negative stereotypes about individuals with serious mental illness" factor, and the "negative stereotypes about effectiveness" factor were respectively 8 \pm 3, 9.44 \pm 2.57, 15.62 \pm 5.7, and 11.35 \pm 3.33.

Conclusions: Our study highlighted that residents in psychiatry suffered stigma. Special attention should be given to reducing this phenomenon in this population.

Professional quality life of psychiatry residents in Tunisia

R. Masmoudi, S. Ajmi*, A. Guermazi, F. Guermazi, I. Baati and J. Masmoudi

Psychiatry A, Hedi Chaker University Hospital, Sfax, Tunisia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1663

Introduction: The professional quality of life for psychiatry residents is a complex and multifaceted aspect of their careers. However, the demanding nature of their work can place significant stress on their own psychological well-being. Balancing the need to care for patients while also managing personal and professional responsibilities can be challenging. Nevertheless, psychiatry residents have the opportunity to make a profound impact on the lives of their patients and find fulfillment in their work.

Objectives: To assess the prevalence of burnout (BO) and secondary traumatic stress (STS) among psychiatry residents.

Methods: We conducted a descriptive online cross-sectional survey in January 2022 among psychiatry residents practicing at Hedi Chaker University Hospital in the Sfax region in Tunisia. Professional life quality was evaluated using The Professional Quality of Life Scale - 5 "ProQOL-5".

Results: The total number of residents was 34, of which 91.2% were female. Their mean age was 27.94 years \pm 2.43. They were single in 67.6%. They were residents in adult psychiatry in 61.8% and in child

psychiatry in 39.2%. For 91.2% of them, the specialty of adult or pediatric psychiatry was their own choice. The individuals had been practicing psychiatry for an average of two years. They reported a personal medical or surgical history, a personal psychiatric history, and a family history of psychiatric disorders in 32.4%, 8.8%, and 50%, respectively.

On the ProQOL-5 scale, we found that 88.2% of the residents had a moderate level of compassion satisfaction, 67.6% had a moderate level of burnout, and 52.9% had a moderate level of secondary traumatic stress.

Conclusions: Our study showed a moderate professional life quality among psychiatry residents, hence the importance of implementing intervention strategies.

Traumatic symptoms and institutional support expectations among psychiatry residents dealing with patient suicide

I. Yaich^{1,2*}, C. Ben said^{1,2}, T. Ben hamida^{1,2} and N. Bram^{1,2}

¹Forensic Psychiatry Departement, Razi Hospital, La Manouba and ²Faculty of Medecine of Tunis, Tunis El Manar University, Tunis, Tunisia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1664

Introduction: Adult and child psychiatry residents encounter unique stressors in their training distinct from those in other medical specialties. Patient suicide has been identified as one of the most distressing experiences during psychiatric training.

Objectives: This study represents the first Tunisian investigation aiming to assess (1) the impact of patient suicide on psychiatry residents and (2) the limitations of the institutional support system in dealing with such cases.

Methods: A Google Forms questionnaire was distributed via email to all residents, gathering socio-demographic data, assessing traumatic impact using the PTSD Checklist for DSM-5 (PCL-5), and soliciting open-ended responses regarding personal experiences and expectations of the institutional support system.

Results: Fifty-three residents participated in the study. Among them, 29 residents had encountered patient suicide, with 12 directly involved. Symptoms of PTSD were detected in three residents. The physician directly involved in treating the suicidal patient reported the highest PCL-5 score. The majority of residents (27 out of 29) expressed the need for a structured support and training program tailored to healthcare professionals dealing with suicide.

Conclusions: The findings suggest that psychiatric residents may require additional training and support to effectively address the complex issue of patient suicide. Implementing specific training programs could significantly enhance their ability to manage such situations.

Evaluation of a Simulation Based Training Course for Non-Consultant Hospital Doctors (NCHDS) in Psychiatry

K. Corrigan^{1,2*}, G. Crudden^{2,3} and A. Doherty⁴

¹St Vincent's University Hospital; ²St. Vincent's University Hospital;

³Holles Street, The National Maternity Hospital and ⁴The Mater Misericordiae Hospital, Dublin, Ireland

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1665

Introduction: Simulation-based training (Sim) is an established method of teaching in medical education and can help bridge the gap between medical theory and clinical practice. While sim is well-established in medical and surgical specialties, it is less well developed in psychiatry. Psychiatric emergencies often occur out of hours when there are fewer senior staff available on-site. Sim offers a safe setting for development of essential clinical skills with carefully delivered feedback.

Sim can be high-cost involving specialized simulation facilities, especially when utilising high-fidelity equipment. Even lower-fidelity techniques requiring standardized patients (SPs) require funding for actors and this can be a barrier to utilising Sim.

Objectives: We piloted a Sim course to NCHDs working in psychiatry in a tertiary university hospital with the aim of improving trainee skills and confidence in managing psychiatric emergencies on-call including risk assessment, involuntary admission and acute behavioural disturbance. A low-fidelity approach was taken with minimal use of SPs.

Methods: A sim handbook developed by Irish Centre for Applied Patient Safety and Simulation (ICAPSS) was used for reference in developing the simulation modules. Three modules were delivered in a structured manner over three hours; involuntary admission, risk assessment and management of acute behavioural disturbance. Each module involved the simulation exercise (20 minutes) followed by debrief (20 minutes). The facilitated debrief involved open discussion and prompted reflective learning. Anonymous, paper-based questionnaires were used to collect feedback on participants' experience of the training.

Results: There were 12 attendees and ten participants completed the feedback. All participants (100%, n=10) agreed or strongly agreed that sim helped them to learn and all agreed that the topics covered were relevant to their clinical role. All participants (100%, n=10), indicated that they enjoyed the workshop. Eighty percent (n=8) agreed or strongly agreed that they would like to do more sim-based workshops. The supportive environment and debrief sessions were reported as the most enjoyable aspects of the workshop.

Conclusions: Participants unanimously agreed that the training was useful to them in their clinical roles and helped them to learn. Sim was effective in teaching high risk complex psychiatric cases to psychiatry NCHDs and consideration should be given to expand this teaching method within postgraduate psychiatry training in Ireland.

ADHD in a women during (peri)menopause: missed diagnoses and cardiac complaints

J. S. Kooij^{1,2*}

¹Psychiatry, Amsterdam UMC/VUMC, Amsterdam and ²Adult ADHD, PsyQ, psycho-medical programs, the Hague, Netherlands

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1666

Introduction: (Abstract for the accepted case-based workshop by the NDAL section at EPA)

Women with ADHD are underdiagnosed in mental health care, and although ADHD starts in early childhood, the symptoms and impairment of women with ADHD may only be recognised for the first time during (peri)menopause.

Objectives: The relationship between decreasing levels of estrogen and the interaction with dopamine function in the brain in women with ADHD will be discussed and illustrated by a clinical case vignette of Mary, age 54.

Methods: Mary presents with a history of repeated burnout episodes, mood swings, lifetime difficulty concentrating, planning and organising daily life, restlessness, sleep problems, and cardiac complaints. Mary has been working hard her whole life to overcome all difficulties, but her problem is she can never stop, leading to getting burnout several times. This time she is exhausted and can no longer cope; she is visiting the cardiologist for palpitations, hypertension and a recent myocardial infarction.

Results: After a positive screening for ADHD, based on her lifetime symptoms of inattention, restlessness and impulsivity, as well as mood swings, she is referred to a psychiatrist for assessment of ADHD, mood and sleep problems. The pathophysiology behind this cluster of disorders during (peri)menopause, as well as the treatment options will be discussed based on Mary's case.

Conclusions: Both ADHD in women, (peri)menopausal mood disorders as well as the heart complaints in women during menopause are underrecognised and undertreated, leading to unnecessary suffering and cardiac death in women. It is time for psychiatry to join forces with cardiology and gynaecology for better recognition, sharing knowledge and multidisciplinary treatment of women with mental disorders such as ADHD during menopausal transition (see www.h3-netwerk.nl).

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1667

Introduction: Affective disorders are among the most common mental health problems in women of reproductive age. A life-changing condition, such as pregnancy, may trigger or intensify symptoms of affective disorders, rather than pregnancy being a protective factor for the development of the disorder, as previously thought. Previous research indicates that 18% of women suffer from perinatal depression. One in 7-10 pregnant women and 1 in 5-8 midwives develops a depressive disorder, which is more than half a million women a year. Untreated perinatal depression has significant repercussions for both mother and child. Given that there are no controlled randomized studies during pregnancy, and the results of previous research on the harmfulness of the use of psychotropic drugs are contradictory, we need to nurture an individualized and integrative approach to the use of psychotropic drugs in pregnant women and in the postpartum period. The goal of this lecture is to point out the necessity of treating perinatal depressive disorder with an emphasis on the need to work on dilemmas and selected sources of information by pregnant women themselves, as well as health professionals. In the end, I must emphasize the importance of choosing an adequate psychopharmaceutical in that sensitive period for a woman, nurturing an individual approach as well as the latest knowledge.

Objectives: The aim of this research is to examine the attitudes of psychiatrists, GP doctors, gynecologists and pregnant women about prescribing and taking pharmacotherapy during pregnancy.

Methods: The research will be conducted at the psychiatry clinic, the gynecology clinic and in health centers through semi-structured questionnaires, which will be filled out by psychiatrists, gynecologists, doctors and pregnant women.

Results: Preliminary results (given that the research is still ongoing) indicate that most psychiatrists avoid prescribing drugs during pregnancy, and if they decide to do so, then diazepam is prescribed. The views of gynecologists, family medicine doctors and pregnant women are still pending.

Conclusions: This lecture aims to point out the factors contributing to the fear of prescribing psychotropic drugs perinatally, based on our own research, which included psychiatrists, gynecologists, family medicine doctors, and pregnant women.

EPV1096

A Case of Severe Polyhydramnios During Pregnancy Associated with Long-Term Use of Lithium

A. Stoppa^{1*}, E. Roda¹, A. S. Hernández² and A. Roca¹

¹Perinatal Mental Health Unit and ²Department of Maternal-Fetal Medicine, Hospital Clinic of Barcelona, Barcelona, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1668

Introduction: The perinatal period poses heightened vulnerability to bipolar affective episodes. Lithium serves as first line in the management of bipolar disorder, demonstrating efficacy in stabilizing mood episodes and preventing relapses. Therefore, it also a recommended treatment during the pregnancy period. However, its use presents potential risks for both the mother and the developing fetus. Given the prevalence of bipolar disorder in reproductive-age women, it is crucial to investigate the risks

associated with lithium use during pregnancy, along with its subsequent obstetric and neonatal complications.

Objectives: This report outlines a case of severe polyhydramnios in a 42-year-old primigravida patient, under long-term lithium and antipsychotic treatment. Additionally, a systematic search for similar case reports was conducted to provide an overview of the existing literature.

Methods: The patient's medical history and perinatal medical care are documented in this case report. A systematic literature search on MEDLINE (PubMed) was conducted using Boolean operators.

Results: The patient was diagnosed with bipolar disorder type I and had a history of lithium treatment for over 20 years, supplemented later with antipsychotics. During her pregnancy, she experienced a polyuria-polydipsia syndrome and a severe polyhydramnios. She also suffered renal impairment. Together, it is indicative of a nephrogenic diabetes insipidus (NDI), likely induced by prolonged lithium treatment. As the pregnancy progressed, she experienced premature rupture of membranes at 34 weeks and 5 days. The newborn needed medical support and was admitted to the neonatal unit, without further complications.

Systematic research showed three published case reports describing nephrogenic diabetes insipidus (NDI) and polyhydramnios associated to lithium treatment.

Conclusions: Chronic administration of lithium may contribute to the development of resistance to antidiuretic hormone (ADH), leading to polyuria-polydipsia syndrome and potentially severe obstetric complications. The co-administration of lithium and antipsychotics may exacerbate these effects. Further research is needed to elucidate their combined clinical impacts.

Impulse phobias during pregnancy: a case report of a 37 year-old woman pregnant of her first child

M. Ríos-Vaquero, G. Lorenzo-Chapatte, L. Rojas-Vázquez, A. Monllor-Lazarraga, L. Sobrino-Conde, M. J. Mateos-Sexmero, T. Jimenez-Aparicio, M. Calvo-Valcarcel, M. A. Andreo-Vidal, M. P. Pando-Fernández, P. Martínez-Gimeno, M. D. L. A. Guillen-Soto, B. Rodriguez-Rodriguez, N. Navarro-Barriga, M. Fernández-Lozano, A. Aparicio-Parras, M. D. C. Vallecillo-Adame, C. DeAndres-Lobo and A. Rodríguez-Campos*

Psiquiatría, Hospital Clínico Universitario de Valladolid, Valladolid, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1669

Introduction: Pregnancy and puerperium are two critical stages for women's mental health due to the biological stress of pregnancy itself, as well as the emotional stress that surrounds this vital moment. (1) Debut and aggravation of psychiatric symptoms may occur, as well as relapse in women previously diagnosed with Severe Mental Disorder (SMD).

Symptoms of the anxious spectrum are the most frequent within the perinatal mental pathology, being impulse phobias an entity that appears in about 25% of women previously diagnosed with

OCD and up to 10-15% of women without previous psychopathology (2)

Objectives: Exposing the importance of Perinatal Mental Health from the presentation of a clinical case.

Methods: Review of the literature available in PubMed. Presentation of the pathobiography and evolution of the patient.

Results: Our case is about a 37-year-old woman, 30 weeks pregnant with her first child and history of having required admission to Psychiatry with subsequent follow-up in Mental Health for anxious-depressive symptoms with the presence of self-injurious ideas who, after two weeks with multiple life stressors, came to the Emergency Department for the presence of impulse phobias focused on pregnancy with significant internal anguish and ideas of death as a resolution to it, which is why it was decided to hospitalize her. During admission, and taking into account the patient's gestational state, treatment was started with diluted Mirtazapine and Aripiprazole solution at minimal doses, which in this case were sufficient for symptom control.

The latest guidelines addressing psychopharmacology during pregnancy and lactation point to sertraline among the antidepressants and Lorazepam among the benzodiazepines as the safest drugs during pregnancy (3).

Conclusions:

- The exacerbation of anxious symptomatology and the presence of gestation-focused impulse phobias are frequent during pregnancy and their intensity increases as the time of delivery approaches.
- Sertraline, Lorazepam, Mirtazapine and Aripiprazole are safe drugs during pregnancy.
- In these women, a close and multidisciplinary follow-up by Psychiatry and Gynecology is advisable.

The Influence of Gender Roles on Eating Attitudes: A Study Among Female College Students Abstract

B. Ozel*, Y. Hosgören Alici, O. M. Kocak and S. Ceran

Department of Psychiatry, Başkent University, Ankara, Türkiye

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1670

Introduction: Eating disorders (ED) are serious mental and physical illnesses that involve complex and damaging relationships with eating, exercise, and body image. They emerge due to a multifaceted interplay of factors, including familial predispositions, personality traits, and cultural influences. While societal beauty standards are recognized as significant risk factors, it is hypothesized that the roles and responsibilities associated with adult womanhood may also contribute to their development. In particular, the unique challenges faced by women, especially in developing countries like Turkey, may lead to discontent with traditional gender roles.

Objectives: This study aims to explore the connection between eating disorders, female identity perceptions, body attitudes, expectations regarding women's roles within families, and their potential association with body dysphoria. We investigate whether eating disorders are linked to a form of sexual dysphoria and body

dysmorphia related to femininity rather than solely driven by societal beauty ideals.

Methods: Data from 228 female college students, both undergraduate and graduate, were collected via online surveys. The survey instruments included a sociodemographic form, the Eating Attitude Test, the Gender Roles Attitude Scale, and the Multidimensional Body-Self Relations Questionnaire.

Results: The average age of the participants was 24.41 (18-33) years. Regression analysis revealed that age ($\beta = -0.155$, $p = 0.015$), the belief that physical appearance would be less important if they were male ($\beta = 0.292$, $p < 0.001$), and maternal criticism about weight ($\beta = 0.239$, $p < 0.001$) were influential factors in shaping eating attitudes. Surprisingly, no significant relationship was found between eating attitudes and traditional gender roles ($\beta = 0.072$, $p = 0.246$). However, we did establish a connection between aspiring to meet ideal thinness standards and perceiving women as disadvantaged in the workplace due to their traditional gender roles ($t(226) = 2.32$, $p = 0.021$), as well as with maternal criticism ($t(225) = 3.55$, $p < 0.001$).

Conclusions: Our findings suggest that the absence of a direct link between eating attitudes and traditional gender roles may be attributed to an individual's perception of their environment rather than their self-assessment of masculinity within an egalitarian context. Notably, maternal influences specifically their criticism regarding their daughters' weight and the roles assigned to mothers significantly shape these perceptions and, consequently, eating behaviors, aligning with existing literature (Ferreira et al., 2021). This underscores the need to consider eating disorders within a broader biopsychosocial framework, encompassing attitudes toward the world and one's role within it.

Disclosure of Interest: None Declared

The approach of physiotherapists in the management of patients with persistent pain and comorbid anxiety/depression: are there any differences between male and female professionals?

G. Nicolini^{1*}, M. Chiesa² and M. Buoli³

¹Department of Mental Health, Department of Biomedical and Clinical Sciences Luigi Sacco, Luigi Sacco Hospital, University of Milan;

²Department of Psychiatry, University of Milan and ³Department of Neurosciences and Mental Health, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1671

Introduction: Chronic pain is a prevalent condition that is frequently complicated by concomitant mood and anxiety disorders. Very preliminary data indicate that female physiotherapists could have a better attitude towards psychiatric disorders.

Objectives: Purpose of the present article is to identify eventual differences in the management of patients with chronic pain and anxiety/mood disorders depending on the physiotherapists' gender.

Methods: An ad-hoc questionnaire was developed and sent to physiotherapists by e-mail. The two group identified by gender were compared by unpaired sample t tests for continuous variables and χ^2 tests for qualitative ones. A binary logistic regression was

then performed with factors resulted statistically significant at univariate analyses as independent variables and gender as dependent one.

Results: Female physiotherapists (compared to male ones) resulted to be more confident in the prosecution of physiotherapy by patients with Generalized Anxiety Disorder (GAD) comorbidity ($t = 2.46$, $p = 0.01$) and by patients who had received a visit with a mental health professional ($t = 2.79$, $p = 0.01$). Furthermore, female physiotherapists versus male ones believed that pharmacotherapy was less associated with motor side effects ($t = 2.90$, $p < 0.01$) and more frequently recognized the importance of a training to identify affective disorders ($t = 2.65$, $p = 0.01$) and the need of more education in mental health ($t = 2.85$, $p = 0.01$). The binary logistic regression model confirmed that female professionals (compared to male ones) were less likely to work as freelance in private institutions ($p = 0.015$) and were more confident in the prosecution of physiotherapy by patients with GAD comorbidity ($p = 0.05$).

Conclusions: Female compared to male physiotherapists resulted to be more comfortable with patients affected by mental conditions and to be more aware of the need of training on mental health. Implementation of mental health education for male physiotherapists is probably necessary and further studies are needed to confirm the results of the present study.

Influence of neuromarketing on the increase in shopping anxiety in women in the city of santa marta

K. L. Perez Correa^{1*} and A. Guardiola Esmeral¹

¹Magdalena, Universidad Cooperativa de Colombia, Santa Marta, Colombia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1672

Introduction: New technological trends and access to more information have generated an anxious disorder and the need to obtain everything that the consumer society has to offer, this has increased with the influence of neuromarketing in internet ads.

Objectives: The objective that was raised in the present investigation was to analyze the influence of neuromarketing in the increase of anxiety reflected in compulsive purchases of women in the city of Santa Marta.

Methods: The field research design is non-experimental and cross-sectional, the sample taken was of 500 women with purchasing power of more than three Colombian minimum wages.

The IDARE Ch. Spielberger, R. Díaz Guerrero et al. (1966) checklist was applied; To review the relationship between advertising with neuromarketing, anxiety and compulsive purchases, a Likert-type scale instrument was designed and validated with the Alpha Cronbach Coefficient. Analysis of Covariance ANOVA, inferential statistics and SPSS were performed.

Results: 57% of the women meet the criteria for the IDARE clinic. The analysis of the questionnaire showed a goodness of fit of $R^2 = 0.697$. The result indicates that the more hours women spend on the internet with access to ads focused on neuromarketing, the more they feel the need to buy, and this generates anxiety processes.

Conclusions: The mental triggers used by neuromarketing accelerate the need in women to buy the solutions that they sell and the same need to buy is evident in the signs of anxiety that is reflected in the women under study. Training that educates women to spend less time connected to the Internet is recommended, but it is also essential that they understand that advertising and marketing exert pressure that increases their anxiety and need to purchase, so it is recommended the implementation of training in personal management and control.

From legislation to reality: Understanding gender-based violence in Tunisia

K. Mahfoudh*, S. Hamzaoui, S. Walha, D. Mezri, A. Ouertani, U. Ouali, A. Aissa and R. Jomli

Psychiatry "A", Razi Hospital, Manouba, Tunisia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1673

Introduction: Tunisia marked a significant milestone in the fight against gender-based violence with the adoption of Organic Law No. 2017-58. This pioneering law in the region enhanced the protection of women and girls' rights and introduced harsher penalties for perpetrators of sexist violence. However, the journey toward eradicating violence against women is complex and multifaceted.

Objectives: Our aim is to explore how tunisian women perceive gender-based violence and their attitudes towards it.

Methods: A cross sectional online survey designed using Google Forms and distributed on social media platforms (Facebook, Instagram) was conducted from August 30th to September 25th 2023. The questionnaire, presented in the tunisian dialect, included questions about personal experiences with violence, knowledge of gender-based violence laws as well as their perceptions and attitudes towards gender-based violence. The sample consisted of women from various regions of Tunisia.

Results: In our study, we analyzed a sample comprising 110 tunisian women, with 46.4% falling within the 20 to 30 age bracket and 36.4% belonging to the 30 to 40 age range. Half of the survey participants were unmarried, and the majority of them (97.3%) had attained a university-level education.

Our research revealed that 45.5% of the surveyed women reported instances of gender-based violence in Tunisia. However, only a minority of these individuals (22.2%) initiated legal proceedings, primarily citing a lack of confidence in the judicial system and fear of potential reprisals as their reasons.

A majority of the participating women expressed deep concern regarding the issue of violence against women in Tunisia. When asked about their perceptions of the most prevalent types of violence in Tunisia, 76.36% believed that psychological violence was the most common, followed by sexual violence (21.3%). Economic and physical violence were perceived as less frequent (9.9%; 12.6%). These women attributed the primary factors contributing to violence against women in Tunisia to cultural norms and laws that they considered inadequately stringent. Indeed, 83.3% of them believed that the current legislation was not stringent enough to

deter potential perpetrators, and 37.3% indicated that they were unaware of the existing legal framework.

Conclusions: Despite legislative advancements, gender-based violence remains a pressing concern in Tunisia. These findings underscore the importance of increasing awareness about available resources for victims, educating individuals about women's rights and mental health, and building trust in the judicial system.

Pros and cons of alternative therapy omega-3 fatty acids during pregnancy and lactation for mental problems

L. Boronin* and I. Nastas

Department of Mental Health, Medical Psychology and Psychotherapy, State University of Medicine and Pharmacy, Chisinau, Moldova, Republic of

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1674

Introduction: Fatty acids omega-3 are irreplaceable. They stabilize cell membranes, nerve impulses, homeostasis, immune reactions, the birth process, the psycho-emotional state of the fetus-mother dyad. Correlations between adequate dietary intake of omega-3 and cognitive health have been described in detail. According to the literature, docosahexaenoic acid is associated with the synthesis of serotonin, dopamine, acetylcholine, glutamate, neuroprotective and anti-apoptotic action, has antidepressant effect. Omega-3 makes up 60% of neuronal membrane phospholipids. Under clinical aspect, according to publications, fish oil reduces the risk of preterm birth by 44%.

Objectives: The aim is to study the risks and benefits of using omega-3 during pregnancy and lactation in patients with mental disorders.

Methods: Comparative analysis of evidence-based scientific publications for the use of omega-3 fatty acids in pregnancy and lactation.

Results: The body level of omega-3 depends on the quantitative intake from food, as well as gene polymorphism and age. For pregnant and lactating women are recommended 200-300 mg per day or about 300 g per week from food. Deficiency of omega-3 (proteins) affects the processes of myelination, neurogenesis, synaptogenesis, the metabolism of neurotransmitters, cell differentiation, neuronal migration and inflammatory responses.

Conclusions: There are many probably mechanisms of action of omega-3, namely: Enhances peroxisomal oxidation, reduces the synthesis of triglycerides in the liver; inhibits plasma acyltransferase. Omega-3 acts on phospholipids of the cell membranes of the nervous system and retina, their adequate functioning, improve psychomotor development of newborns. It was found the effect of decreasing the levels of cytokines and depressive symptoms, as well the risk of food allergies and depression. In conclusion, in adequate doses, omega-3 fatty acids seems to be useful in deficiencies and for prophylactic purposes in pregnancy and lactation.

Keywords: omega- 3 fatty acids, pregnancy, lactation, mental disorders.

Fear of childbirth in a sample of Tunisian women: factors related to pregnancy

M. Abdelkefi^{1*}, R. Feki¹, R. Walha², W. Zid², I. Gassara¹, N. Smaoui¹, S. Omri¹, N. Charfi¹, L. Zouari¹, J. Ben thabet¹, K. Chaabene², M. Maalej bouali¹ and M. Maalej¹

¹Psychiatry C department and ²Gynecology-Obstetrics department, Hedi Chaker university hospital, sfax, Tunisia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1675

Introduction: Fear of childbirth is attracting growing interest because of its impact on the experience of pregnancy and on the progress of childbirth and it seems that some women are more susceptible to fear of childbirth than others are.

Objectives: Our objective is to identify pregnancy factors that predict the fear of childbirth.

Methods: We approached 350 pregnant women consulting at the Gynecology-Obstetrics department of the Hedi Chaker University Hospital of Sfax. We collected their sociodemographic and clinical data. Fear of childbirth was assessed using the French version of the Traumatic Event Scale (TES), adapted to assess fear of childbirth.

Results: The mean age of the participants was 28 years (16-41) and the mean gestational week was 36.27. Half of the participants (53.7%) were nulliparous, and eight reported a history of infertility. The pregnancy was not planned in 61% of cases. As many as 67% of the participants had regular checkups, 50.3% had exaggerated somatic symptoms and 34.3% had pregnancy-related diseases.

The mean score for the TES was 48.73 ± 13.72 .

We found a positive correlation between the TES score and nulliparity ($p=0.01$), gestational age ≥ 40 weeks ($p=0.01$), planned pregnancy ($p=0.002$), exaggerated somatic symptoms ($p=0.03$), and pregnancy-related diseases ($p<0.001$).

Conclusions: Identification of women at risk for fear of childbirth could help in preparing them before or during pregnancy to improve their childbirth experiences.

What link between violence against women and self-esteem?

M. Abdelkefi*, R. Feki, A. Turki, I. Gassara, N. Smaoui, S. Omri, N. Charfi, L. Zouari, J. Ben thabet, M. Maalej bouali and M. Maalej

Psychiatry C department, Hedi Chaker university hospital, sfax, Tunisia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1676

Introduction: Violence against women is a public health problem worldwide and a violation of human rights. It affects women's lives due to its potential short-, medium- or long-term physical and psychological consequences.

Objectives: The aim of our study is to explore the link between violence against women and self-esteem.

Methods: A descriptive cross-sectional study was conducted from March to August 2023 among Tunisian women consulting in three health care centers in Sfax, Tunisia. We have included women victims of violence (psychological, physical, sexual, and economic). We have used a semi-structured interview and the Rosenberg scale to determine the quality of self-esteem.

Results: Among one hundred interviewed women, fifty-four women who had reported being violence victims were included in our study. The mean age of the participants was 44 years with the majority being married (87 %). Only 29.6% had a high school level and 51.9% had a profession. A total of 29.6% had a low socio-economic status.

We found that 79.6% are victims of domestic violence (57.4% being victims of spousal violence). Psychological violence seemed to be the most frequent type (59.3%).

Almost all those who were abused (90.6%) experienced psychological (emotional) violence.

The mean score of the Rosenberg self-esteem scale was 31.54.

Self-esteem was very low in 16.7%, low in 37%, medium in 18.5%, and high in 27.8% of the women.

A statistically significant association was found between being a victim of spousal violence and low self-esteem ($p=0.032$). The semi-structured interview demonstrates that women with low self-esteem are more likely to accept violence.

Conclusions: These results justify the implementation of screening and support programs for women victims of violence to improve their self-esteem.

Association between Educational Attainment and Risk of Postnatal Depression: Findings from the Czech Republic

M. Kuklová^{1,2,3*}, K. Hrdličková¹, A. Horáková¹, H. Němcová¹ and A. Šebela¹

¹Centre of Perinatal Mental Health, National Institute of Mental Health, Klecany; ²Department of Epidemiology and ³Department of Demography and Geodemography, Charles University, Prague, Czech Republic

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1677

Introduction: Postnatal depression is a common mental health condition that affects women across the globe. Lower education is frequently considered to be linked to an increased likelihood of postpartum depression. Nevertheless, inconsistent epidemiological evidence has been reported concerning the associations between education and postpartum depression risk. This study investigates the correlation between education level and postpartum depression in the Czech Republic.

Objectives: The aim of this study was to examine whether there is an association between educational attainment and the risk of postnatal depression in women who have recently given birth in the Czech Republic.

Methods: Women aged 18-45, who spoke Czech and had an email address, and had given birth in the hospital were eligible to participate in the study. The research was conducted in the maternity

unit, where a medical professional presented the opportunity to take part. All participants were screened using the Edinburgh Postnatal Depression Scale (EPDS), with the cut-off score of ≥ 10 showing increased of postpartum depression.

Education data was collected via self-reported questionnaires. Binary logistic regression was employed to calculate the odds ratio (OR) with 95% confidence intervals (CI) to assess the relationship between educational attainment and postpartum depression risk, with sociodemographic and health-related characteristics being stepwise adjusted.

Results: Our study consisted of 3,739 postpartum respondents (mean age of 31 years). The prevalence of increased postpartum depression (≥ 10 EPDS points) was 22.7%. Compared to individuals with higher education (reference category), those with basic education had a higher risk of postpartum depression (OR 1.67; 95% CI 1.26–2.23; $p < 0.001$), even after adjusting for all covariates (OR 1.55; 95% CI 1.08–2.22; $p = 0.017$). Basic education was found to have the strongest association with an increased risk of postpartum depression, even when adjusted for covariates. The association between education and postpartum depression was explained by the covariates.

Conclusions: Having only basic education is a significant risk factor for postpartum depression. Interventions to reduce the burden of postpartum depression ought to focus on individuals with low levels of education.

An educational program, «Women victims of domestic violence: Detection, clinic, help»: Working with the complexity of teaching and Interpreting practice through research

N. D. Semenova^{1*}, M. A. Kachaeva² and S. V. Shport³

¹Laboratory of Psychological Counseling, Moscow Research Institute of Psychiatry – a branch of V. Serbsky National Medical Research Centre for Psychiatry and Narcology; ²Department of forensic psychiatric examination and ³Administration, V. Serbsky National Medical Research Centre for Psychiatry and Narcology, Moscow, Russian Federation

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1678

Introduction: Firstly, we will speak on the violence against women from a Russian perspective. The selected reports from regional psychiatric services and police department reports of domestic violence cases will be presented.

Objectives: Secondly, we will draw upon our work developing and providing a new educational program, «Women victims of domestic violence: Detection, clinic, help» mainly based on teaching several modules, WPA International Curriculum for Mental Healthcare Providers on Violence Against Women.

Methods: In this present paper, we examine evidence-based practice from the starting points of research as illumination and psychiatry as a discipline with hermeneutic potential, to consider relationships between research and practice and the opportunities

available within the current research agenda for psychiatrists and clinical psychologists working in clinical settings.

Results: We contend that the quality of women's mental health services will only improve when they can acknowledge the considerable impact that intimate partner violence and sexual violence, as well as social inequalities, especially those based on gender, have on women's mental health. We do not underestimate the difficulty of providing practical help to women whose mental health has been profoundly affected by the violence, damage that is often further compounded by years of mistreatment and revictimization in services.

Conclusions: The paper provides commentaries and reflections on the steps that must be taken to create opportunities to foster dialogue, discussing and exchanging ideas on a diverse range of topics relevant to the advancement of the program in the broader context.

doi: 10.1192/j.eurpsy.2024.1679

Introduction: Men and women with psychosis have different courses and presentations of symptoms. Men with psychosis have an earlier onset of illness, more negative symptoms, and worse premorbid functioning. Women, on the other hand, have better social functioning and less substance abuse. Despite these evident differences, there are few studies that delve into these distinctions, especially from a subjective perspective.

Objectives: The aim of this study is to understand the differences in the perception of psychosis between men and women.

Methods: Five women and five men diagnosed with schizophrenia participated in the study. They were matched so that the age difference between them was no more than 5 years, with ages ranging from 40 to 56 years. Participants had not experienced acute decompensation of their underlying illness and had not required admission to an Acute Care Unit in the 6 months prior to inclusion in the study. Data collection was conducted through the Spanish translation of the Indiana Psychiatric Illness Interview, consisting of five parts: a narrative about their life, a narrative about the illness, questions related to how the illness has changed their life and what has not changed, the overall influence of the illness on their life, and lastly, expectations for the future.

Results: Men expressed more concerns about work (4 men versus 2 women), while women expressed more concerns about not having become mothers (3 out of 5 women, compared to one man). All participants shared experiences of isolation in intimate relationships, including romantic relationships. Regarding stigma, three women believed that people treated them like children and dismissed their opinions. However, two of them viewed this behavior from their loved ones positively. Two women discussed the impact that psychosis and medications had on their bodies and how others had reacted to these changes

Conclusions: The concerns and stigma associated with mental illness differ between genders. These differences should be taken into account when developing specific biopsychosocial treatment plans.

Conjugal violence in Tunisia: the characteristics of marriage

R. Jbir*, L. Aribi, I. Chaari, A. Samet, R. Ben jema, N. Messedi and J. Aloulou

psychiatry B, Hedi chaker hospital university, Sfax, Tunisia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1680

Introduction: Violence is a global phenomenon, destroying the fabric of society and threatening the lives, health and prosperity of all. In recent years, there has been an upsurge in domestic violence in Tunisia. Unfortunately, few studies have focused on the relationship within these couples.

Objectives: To describe the characteristics of marriage between Tunisian couples where domestic violence prevails.

Methods: Our study was descriptive and analytical cross-sectional, carried out with women victims of domestic violence examined in the context of psychiatric expertise.

An anonymous survey was asked to these ladies concerning the socio-demographic characteristics of the wife and spouse and the characteristics of the marriage.

Results: Our population was made up of 122 couples. The average age of ladies was 35.66 years (from 18 to 64 years). As for the spouses, their average age was 41.68, with extremes of 22 and 70. 92.6% of couples had at least one child.

Professionally, (6.6%) of the husbands were inactive and 51.6% (n=63) of couples had an average socio-economic level.

43.4% (n=53) lived in rented houses, 41% (n=50) owned their own homes, 14.8% (n=18) lived in a room with their in-laws and 0.8% (n=1) were homeless.

The average duration of marriage in our study was 11.16 ± 9.12 years and extremes of 1 and 40 years. Judicial records were found in 28.7% of assailants (n=35). The majority of women surveyed, 92.6% (n=113), were victims of three types of violence at once (verbal, psychological and physical). Sixty-two women (50.8%) were victims of four types of violence simultaneously (verbal, psychological, physical and sexual). Various causes of violence were reported, dominated mainly by claims for money, sexual problems, drunkenness and infidelity, with prevalence rates of 38.5%, 23.8%, 22.1% and 21.3% respectively. The majority

of women, 66.4% (n=81), had been assaulted by their spouses during the first year of marriage. Forty-seven ladies (38.5%) were subjected to violence on a daily basis. According to the survey, 86.9% of women have been assaulted at least once before, and 38.7% of them have reported previous assaults to the police. The first person contacted after the violence was the mother, with a percentage of 48.4% (n=59). 53.3% of ladies were assaulted during pregnancy, 43% of whom suffered obstetrical complications of varying severity.

Conclusions: According to our results, there is no typical profile of a couple where conjugal violence can reign.

Neither the length of the marriage nor pregnancy prevented the woman from being a victim of domestic violence.

Domestic violence in Tunisia: which forms of physical violence?

R. Jbir*, L. Aribi, I. Chaari, F. Guermazi, A. Samet, N. Bouattour, N. Messedi and J. Aloulou

psychiatry B, Hedi chaker hospital university, Sfax, Tunisia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1681

Introduction: Domestic violence is a universal phenomenon that destroys the fabric of society and threatens the lives, health and prosperity of all.

It can take different forms, including physical abuse. This is one of the most serious form of violence, as it can range from a simple shove to homicide.

Objectives: To determine the prevalence and describe the various forms of physical violence perpetrated by husbands against their wives.

Methods: We contacted women who consulted at the psychiatric emergency of 'Hedi Chaker hospital', Sfax examined in the context of medical expertise on the period between May 2021 until January 2022.

A questionnaire regarding the violence was asked to responders. It included a section for collecting socio-demographic and clinical data on the woman, and a section for assessing the various forms of domestic violence.

Results: 122 women were surveyed. The average age of victims was 35.66 years with extremes of 18 and 64 years. 78.7% (n=96) of ladies were of urban origin. The majority of them (44.3%) had secondary level education.

The half of the population (51.6%) had an average socio-economic level and 43.4% (n=53) lived in rented houses.

All the women of our population were married: it was the first marriage in (89.3%) and the majority (86.1%) had children.

Almost all women (95.1%; n=116) were victims of physical violence.

Different types of physical violence were reported with decreasing prevalence: slap (65.6%), punch (58.2%), strangle (46.7%), kicking (38.1%), stabbing threat (28.7%), kidnapping (4.9%), and gun threat (3.3%).

Should be noted that some women experience different forms of violence simultaneously.

Conclusions: Our study showed a high prevalence of physical violence with different shapes.

These figures must be taken into account by the authorities given the gravity of physical and psychological consequences of this form of violence.

Assessing coping strategies among intimate partner violence victims

F. Tabib*, F. Guermazi, S. Hentati, D. Mnif, I. Feki, I. Baati and J. Masmoudi

Department of psychiatry A, UHC Hedi Chaker, Sfax, Tunisia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1682

Introduction: Intimate partner violence (IPV) is a major source of perceived stress for the women who suffer from it. To cope, they tend to implement multiple coping strategies depending on a number of contextual factors including, among others, the severity and frequency of abuse, the duration of the relationship, and available resources such as social support and financial resources.

Objectives: To study the coping strategies used by women who are victims of IPV.

To study the factors associated with coping strategies among these women.

Methods: We conducted a descriptive and analytical cross-sectional observational study, carried out over a 10-month period from March 2021 to December 2021, among female victims of IPV consulting psychiatric emergencies at UHC Hedi Chaker, Sfax, Tunisia for medical expertise at the request of the court.

The Brief-COPE is a 28-item self-assessment questionnaire designed to measure coping with a stressful life event. It can be divided into 3 subscales: problem-focused, avoidance-focused, and emotion-focused.

Results: The total number of participants was 120 with an average age of 37.27 years. The majority had secondary education or less (62.5%), were professionally active (53.3%), and were financially dependent on their partners (26.7%). As for the women's clinical characteristics, 19.2% were under psychiatric care and 15% had attempted suicide (SA). Almost all the women surveyed (99.2%) had reported at least one previous incident of IPV. These incidents were daily in 60.5% of cases. Emotional violence was severe in 75.8% of women.

The emotion-focused strategy was the most widely used, with a mean score (29.68) on the Brief cope scale. It was correlated with the absence of a personal psychiatric history ($p=0.02$), the absence of SA ($p=0.036$), and the occasional frequency of IPV ($p=0.037$). The scores for problem-focused coping and avoidance-focused coping are 19.3 and 17.24 respectively. Avoidance-focused coping was negatively correlated with the presence of severe emotional abuse.

Conclusions: The most used strategy by our population was the emotion-focused strategy, with a relatively high average score compared to the other strategies. Indeed, it may be an extremely effective strategy for recovering from a traumatic event, through actions designed to help these women manage and relieve their psychological distress and reduce its negative impact.

Women with borderline personality disorder and pathophilia: understanding causes of pandemic diffusion of transmissible diseases through samos syndrome

C. G. Lazzari* and M. Rabottini

International Centre for Healthcare and Medical Education, Psychiatry, London, United Kingdom

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1683

Introduction: When faced with perilous transmittable infections, individuals defend themselves or welcome them, such as the Samos Syndrome, a pathophilia (people attracted by illnesses). As borderline personality disorder (BPD), found in Samos Syndrome, becomes more common, so will people who reject primary protection from transmittable diseases and health behaviour as their choices. Pandemics would sinisterly draw pathophiles and persons with borderline personality disorder who might surf pandemics risk as a parasuicidal behaviour.

Objectives: To investigate why pandemics (HIV, COVID-19) cannot be stopped. We have conducted a long-term assessment of HIV-discordant couples where a female partner, HIV-negative, voluntarily chooses to decline any prevention during stable and consensual relationships with HIV+ve partners. We also explored sociodemographic data that could explain health behaviours and condom use in HIV serodiscordant couples at risk of pandemic diffusion, those where one of the partners, usually male, already has a transmissible disease.

Methods: We used a mix of naturalistic and ethnographic approaches to understand the dynamics of Samos Syndrome. We also utilised a questionnaire to extract salient points in the sexual prevention of HIV infection. We assessed 475 HIV-serodiscordant couples.

Results: Pathophilia is defined as an excessive, abnormal desire to be sick, also known as nosophilia, from the Greek word 'pathos' indicating illness and 'philia', meaning attraction. Women diagnosed with BPD can become high diffusers during pandemics of transmissible diseases as suffering from pathophilia, a form of parasuicidal behaviour. In the couples assessed, when the HIV-negative woman comes from a socially disadvantaged family, the couple uses condoms in 87% of cases ($p<0.001$); when she comes from a middle-high class, the couple uses condoms in 59% ($p<0.001$) of sexual relationships. Suppose the HIV-negative female partner has conflicting relationships with their parents. In that case, condom use is only in 40% ($p<0.001$) of cases, compared to 83% ($p<0.001$) of instances where she has a good relationship with parents. If the female partner with BPD has a higher level of education than the HIV+ve partner the frequency of use is 90% ($p<0.001$) of cases compared to 60% ($p<0.001$) of instances where she has the same level of education as the male partner.

Conclusions: The current study confirms that female persons diagnosed with BPD are at high risk of becoming high diffusers during transmissible diseases and pandemics. Parasuicidal

behaviours and self-harm in BPD could increase the risk of entering into relationships with persons who are already infected by sexually communicable diseases or are at risk of diffusing viral infections (HIV and COVID-19).

Home Treatment and Perinatal Psychiatry: An Alternative to Acute Psychiatric Wards

J. Marti Bonany^{1*}, D. García Hernández¹, R. Romar Navia¹, D. Tolosa Merlos¹, F. Casanovas Martínez¹, C. Llimona Sánchez¹, A. Pérez Oms² and G. De Iturbe Catania¹

¹Salut Mental Institut, Hospital del Mar, Barcelona and ²Hospital Universitari Son Espases, Mallorca, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1684

Introduction: Women experiencing severe perinatal mental health problems require specialized services and care. Perinatal mental disorders are common and can contribute to maternal mortality, affecting neonatal, infant, and child outcomes. Home treatment can prevent hospital admissions and promote strategies within the patient's support network.

Objectives: Our aim is to describe a clinical case in perinatal psychiatry managed by a Psychiatric Home Treatment Unit.

Methods: We present a case of perinatal psychotic depression in a 26-year-old pregnant woman.

Results: We describe the case of a patient with no prior history of mental health issues. She was 25 weeks pregnant when she first sought psychiatric help in July 2023 and was diagnosed with depressive disorder with psychotic symptoms. She reported symptoms such as low mood, psychomotor inhibition, delusional guilt thoughts, and auditory hallucinations beginning three weeks before her initial visit. Due to her clinical presentation, the patient was admitted to the hospital, where pharmacological treatment was initiated with Olanzapine 5 mg, Sertraline 50 mg, and Lorazepam 1.5 mg. She remained in the hospital for four days, during which she showed gradual improvement but did not achieve full recovery.

Considering the improvement observed, home treatment was proposed and accepted by the patient and her relatives. During home treatment, she continued to exhibit persistent depressive and psychotic symptoms, including low mood, inhibition, and delusional thoughts of ruin and catastrophe. Therefore, her treatment was adjusted, with Olanzapine increased to 10 mg, Sertraline raised to 100 mg, and Lorazepam reduced to 0.75 mg. Over time, significant improvement in her clinical symptoms was noted. Throughout the follow-up period, she reported no significant side effects from the pharmacological treatment. After a month of follow-up in our department, she was discharged with outpatient care provided by a specialized community perinatal psychiatric unit.

Conclusions: We illustrate the possibility of home treatment for perinatal psychiatric disorders. The potential benefits of remaining close to one's support network and developing coping strategies can be advantageous during the course of illness. Further studies should be conducted to explore these potential benefits.

Postpartum Depression: Plaguing the Joy of New Mothers

G. Sonkar¹ and M. Sonkar^{2*}

¹Anaesthesia, Ram Manohar Lohia Hospital and ²Mental Health First Aider, Noida, India

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1685

Introduction: Depression is a significant global mental health problem and is very common compared to how it is perceived. In 2020 alone, 264 million people globally suffered from depression and its different forms as per the World Health Organisation. It is a leading cause of disability in individuals, affecting their ability to perform their daily chores, work, study, and even maintain relationships. The impact of depression is deeper and affects families, the economy, health care systems, and so on.

In India, the problem is grave and leads to serious consequences, thanks to the stigma and unawareness attached to mental health disorders. It is estimated that India has one of the highest rates of depression in the world, but it is hardly acknowledged.

Post-Partum Depression (PPD) is the most neglected and unreported subtype of depression in India. Globally, 1 in every 7 women suffers from Post Partum Depression. India is such a diverse country in terms of prevalence varies from 15% to 25% based on region, population, cultural and social expectations, economic status, living standard, climate factors, and others.

Objectives: The objective of the study is to spread awareness, identify the risk factors, root cause analysis of risk factors, possible solutions, and treatments.

Methods: This study is conducted to capture the awareness level of PPD in females across different ages, regions, income classes, cultures, working statuses, and societies. This is carried out using a detailed yet anonymous survey, it captures the demography, knowledge of signs and symptoms of PPD, personal experiences, attitudes, expected support for PPD, and awareness of possible healthcare options. The result of the study tries to understand and conclude the most common risk factors, groups at highest risk, a root cause analysis of the risk factors, and possible solutions and treatments.

Results: PPD occurs in the postnatal period, typically within the first year after childbirth. This condition can have a significant impact on the new mother and the infant's well-being. The mother's ability to take care of the child and herself is hugely impacted, impacting the child's development and family dynamics negatively. Pushing to the limits, certain communities that believe in superstition and taboo often take PPD as an excuse to blame the mother resulting in the extremities like suicides.

Conclusions: PPD occurs in the postnatal period, typically within the first year after childbirth. This condition can have a significant impact on the new mother and the infant's well-being. The mother's ability to take care of the child and herself is hugely impacted, impacting the child's development and family dynamics negatively. *Corresponding author.

doi: 10.1192/j.eurpsy.2024.1686

Introduction: Pregnancy and the postpartum period involve several physiological adaptations crucial for offspring care. Recent research has highlighted reproduction-related brain plasticity in human mothers. Associations with aspects of maternal caregiving suggest adaptive changes that facilitate a woman's transition to motherhood. However, the dynamic changes that affect a woman's brain are not merely adaptive, and they likely confer a vulnerability for the mental disorders. To elucidate the pathophysiology of psychiatric problems that occur during the perinatal period, gaining insights into the physiological changes in brain function due to pregnancy is crucial.

Objectives: Although it has been hypothesized that pregnancy enhances social cognitive functions in mothers to adapt to the offspring care, there are few reports to support this hypothesis. This study aims to investigate whether social cognitive functions change during the first pregnancy, with a focus on maternal adaptation to offspring care.

Methods: The study included a first pregnancy group and a never-pregnant control group. We conducted a prospective study comparing pregnant women between two-time points (T1, T2); at less than 21 weeks of gestation [T1] and those after 30 weeks of gestation [T2]. To assess the effects of pregnancy and gestational age (< 21 weeks or 30 weeks or more), both the control (never-pregnant) group and pregnant group were evaluated at two time points with similar intervals. The Emotion Recognition Task [ERT] of the Cambridge Neuropsychological Test Automated Battery (CANTAB) was performed to examine the emotion recognition of six basic emotions in facial expressions. We analyzed a cohort of 26 participants in the pregnant group and 25 in the control group. We performed a two-way repeated measures analysis of variance with pregnancy status and gestational period (T1, T2) as independent variables.

Results: Significant interactions between group and time points (T1, T2) were observed only for Unbiased Hit Rate Anger ($p < 0.01$); facial recognition accuracy for anger increased with the progression of pregnancy. There were no significant interactions for Unbiased Hit Rate Sadness, Happiness, Fear, Disgust, or Surprise.

Conclusions: This is the first study to demonstrate that facial recognition of anger enhances with the progression of pregnancy, utilizing never-pregnant women as a never-pregnant control group. The results of this study contribute to the physiological effects of pregnancy on the brain and cognitive function and have potential for further study of perinatal mental health problems.

doi: 10.1192/j.eurpsy.2024.1687

Introduction: Rheumatoid arthritis (RA) is a chronic inflammatory disease that significantly impacts patients' quality of life (QOL), affecting both physical and mental well-being. QOL is predictive of morbidity and mortality, making its consideration increasingly important in treatment decisions.

Objectives: This study aims to assess the Quality of Life in Female Rheumatoid Arthritis patients.

Methods: The study included 87 female patients with confirmed RA, diagnosed by an experienced rheumatologist based on the ACR 1987 or ACR/EULAR 2010 criteria. Quality of life was assessed using the World Health Organization Quality of Life assessment, short form (WHOQOL-BREF scale). The scoring ranged from 0 to 100 for each domain. Disease activity was assessed using the Disease Activity Score (DAS28), and functional disability was evaluated using the Health Assessment Questionnaire (HAQ).

Results: The study included 87 patients with a mean age of 54.7 ± 12.2 years and a mean disease duration of 12 ± 9.1 years. The majority of patients had a medium socioeconomic level (81.6%), and a low cultural level with 31% being illiterate, 6% attending university, and 76.9% unemployed. Regarding marital status, 74.7% were married. RA was erosive in 77% of patients, deforming in 68%, and 40% were seropositive (FR and/or anti-CCP). Extra-articular manifestations were present in 34.5% of patients. Sixty-seven patients (77%) were on disease-modifying antirheumatic drugs (DMARDs), with 67.8% on methotrexate. Eighteen percent were treated with biological agents. Corticosteroids were used by 47.1% of patients, while 12.6% used non-steroidal anti-inflammatory drugs, and 6.9% used both. Disease activity varied, with 9.2% having low activity, 43.7% moderate activity, and 24.1% high activity based on DAS28. The mean HAQ index was 1.1 ± 0.8 , indicating moderate to severe disability for more than 60% of patients. The mean WHOQOL scores were substantially reduced in the physical health (43 ± 16.2), psychological health (50.3 ± 14.4), social relationships (51.5 ± 18.6), and environment domains (46.8 ± 15). There was a significant inverse correlation between HAQ and the physical health ($r = -0.52$, $p < 0.001$), psychological ($r = -0.57$, $p < 0.001$), social relationships ($r = -0.37$, $p = 0.001$), and environmental domains ($r = -0.45$, $p < 0.001$) of QOL. There was no correlation between any domain of QOL and DAS28.

Conclusions: Patients with RA experience reduced QOL across multiple domains, including physical function, mental health, and social relationships. Functional disability, as reflected by HAQ, is the most significant factor affecting QOL in RA. The WHOQOL-BREF should be considered a valid outcome measure for

interventions aimed at improving the quality of life for people with rheumatoid arthritis.

Postpartum Psychosis and Maternal Filicide- Case Report and Literature Review

O. Ali^{1*}, S. Islam², H. Raai¹ and L. Troneci¹

¹Psychiatry, SBH Health System and ²CUNY School of Medicine, New York, United States

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1688

Introduction: Postpartum period is defined as the 12 weeks following the birth of a child as per ACOG guidelines. This period is crucial for women to physically and emotionally adapt to major changes in their lives. If concerns are not addressed properly it can result in fatal outcomes such as filicide and suicide in context of untreated mental illness with postpartum onset. Postpartum psychosis is considered a psychiatric emergency and literature shows that up to 4.5% of patients with depressive symptoms with psychosis commit filicide. However, postpartum psychosis is not recognized as a formal psychiatric disorder in DSM-5, leading to a delay in identification and treatment of the condition in a timely fashion.

Objectives: The primary purpose of the case report is to inform the clinical picture and the legal implications associated with postpartum psychosis, a poorly understood and underdiagnosed psychiatric illness and to emphasize the importance of considering other psychiatric illnesses with peripartum onset that affect maternal and pediatric population wellbeing.

Methods: A comprehensive review of literature using databases, such as PubMed and Google Scholar as well as observation of the patient in the Emergency Department by the psychiatry team.

Results: We present the case of a female in her 20s, mother of two toddlers, with a history of PTSD and postpartum depression, who was brought to our Emergency Department for stabbing her children in the context of a psychotic episode. The patient endorsed persecutory delusions and religious preoccupation, stating that she was experiencing “demonic energy inside” and that demons were speaking through her sons. Upon further assessment, it was noted that symptom onset was during the peripartum period, initially with depressed mood, and later with psychotic features. Organic causes of psychosis were ruled out with an extensive workup. Patient was transferred to an inpatient forensic unit for further stabilization. From a legal perspective, literature review shows that mothers may face the death penalty in the US in contrast with other countries such as England for instance. In the context of the current case, the plausible diagnoses are MDD with psychotic features or the first psychotic episode with peripartum onset that was left untreated resulting in a fatal health and legal outcome.

Conclusions: As postpartum psychosis is not currently recognized as an independent diagnosis under the DSM-5, further attention is warranted for such critical psychiatric condition that afflicts the lives and well-being of the maternal and pediatric populations globally. Postpartum psychosis affects mothers despite their past psychiatric history, socioeconomic status, educational level, and

supportive network. Thus, it is essential to target proper and timely identification of symptoms and address those to prevent filicide and maternal suicide.

Women's economic empowerment and maternal mental health: A qualitative study in Rural Kenya

C. W. Wainaina*, E. Igonya, F. M. Wekesah and E. M. Sidze

African Population and Health Research Center, Nairobi, Kenya

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1689

Introduction: Background: Maternal mental health is increasingly becoming a public health concern in developing countries because of predominant health and socio-economic inequalities. Mental well-being is essential for a woman to cope with daily life stresses and contribute positively to her community. Initiatives that empower women can enhance their well-being and improve the health of their families. However, limited evidence shows how women's empowerment affects maternal well-being in a rural setting.

Objectives: This paper explores the perspective of women's economic empowerment in a rural Kenyan community and its effect on women's mental well-being.

Methods: We purposively sampled women and men from the rural community who met the eligibility criteria (women who were pregnant and or with a child less than two years old and married men and residents in the community. We conducted two focus group discussions with the men and women separately, 11 key informant interviews with community stakeholders, and a four-month participant observation of 20 women participants who were pregnant and or with a child less than one year old.

Results: The study found that economically empowered women had greater decision-making power and self-efficacy. However, cultural expectations and barriers that dictated the role of women prevented them from accessing and controlling resources and participating in important decisions such as land and property ownership. Women faced domestic violence (physical, verbal, and denial of basic needs) and inadequate support (emotional, physical, and financial) from spouses and other family members. These challenges and barriers increased their mental stress. To cope, women engaged in economic activities individually or in groups to meet the basic needs of their families.

Conclusions: Women's economic empowerment can positively and negatively affect their overall well-being. Positively, women gain greater access to resources, improved decision-making, and the ability to plan and achieve their goals. Negatively, empowerment can lead to reduced spousal and kin support and an increased risk of domestic violence. Furthermore, these negative consequences can also affect women's mental well-being. To ensure the well-being of mothers, it is crucial to engage men in empowerment programs and raise awareness in communities to address socio-cultural norms that impede women's economic empowerment and negatively affect the well-being of women. Additionally, mental health support should be incorporated into these empowerment

programs to mitigate the negative effects of women's empowerment and improve resilience.

Dominant depressive, anxious and cyclothymic affective temperaments lower the chance of infertility treatment success

G. Szabó^{1,2*}, J. Szigeti F³, M. Sipos⁴, S. Varbiro⁴ and X. Gonda⁵

¹Doctoral School of Mental Health Sciences, Semmelweis University; ²Buda Family Centre Mh Centre Department Of Psychiatry, North Centre Buda New Saint John Hospital and Outpatient Clinic; ³Institute of Behavioral Sciences; ⁴Department of Obstetrics and Gynecology and ⁵Department of Psychiatry and Psychotherapy, Semmelweis University, Budapest, Hungary

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1690

Introduction: Affective temperaments can play a significant role in the development, progression and outcome of various somatic diseases, as well as in the effectiveness of their treatment. Although infertility is influenced by both physical and psychological factors, the relationship between affective temperaments and infertility treatment success remains unexplored.

Objectives: The aim of this retrospective cohort study was to assess how dominant affective temperaments influence the outcome of infertility treatments.

Methods: Data was collected from a cohort of infertile women who underwent infertility treatment at an Assisted Reproduction Center in Budapest, Hungary. The study recorded treatment success defined as clinical pregnancy, detailed medical history, demographic parameters, and administered the Temperament Evaluation of Memphis, Pisa, Paris, and San Diego Autoquestionnaire (TEMPS-A). TEMPS-A scores then were classified into nondominant and dominant temperaments for each scale, based on their score being above or below the mean+2 standard deviation for the given temperament. The predictive value of dominant temperaments on assisted reproduction outcomes were analyzed by multivariate logistic regression models, using age, BMI and previous miscarriage as covariates.

Results: In the cohort of 578 women who underwent infertility treatment, besides age, BMI, and previous miscarriage, dominant depressive, anxious and cyclothymic temperament decreased the odds of achieving clinical pregnancy by 85% ($p=0.01$), 64% ($p=0.03$), and 60% ($p=0.050$), respectively).

Conclusions: The findings of this study suggest that dominant affective temperaments have a significant impact on the outcomes of infertility treatments. As a clinical consequence, screening for affective temperaments, Identifying dominant affective temperaments, stratifying high-risk patient groups, and offering personalized treatment options may enhance the likelihood of successful pregnancy and live birth for women undergoing in vitro fertilization treatment.

Maternal mental health and trajectories of Preterm Behavioural Phenotype in infants born after a threatened preterm labour

J. Andreu^{1*}, J. Buesa¹, B. Almansa², C. Zapata³, M. Lizarán², N. Gómez², F. Ghosn², A. Moreno², L. Campos¹ and A. García-Blanco³

¹Psychiatry, Hospital Universitario y Politécnico La Fe de Valencia;

²Psychology, La Fe Research Institute and ³Psychology, Hospital Universitario y Politécnico La Fe de Valencia, Valencia, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1691

Introduction: Infants born preterm usually show a Preterm Behavioural Phenotype, which includes mixed symptomatology characterized by lack of attention, anxiety and social difficulties, with a 3-4 times greater risk of disorders in further childhood. Critically, this behavioural pattern is also observed in infants born after a threatened preterm labour (TPL), regardless of the presence of prematurity. It is known that the course of this Preterm Behavioural Phenotype shows high variability. Nevertheless, the predictors of this Preterm Behavioural Phenotype prognosis remain unknown.

Objectives: This study aimed to explore the predictors of change of Preterm Behavioural Phenotype symptomatology during preschool ages in order to improve prognosis.

Methods: In this prospective cohort study, 117 mother-child pairs who experienced TPL were recruited. Preterm Behavioural Phenotype symptoms were assessed at age 2 and 6 using Child Behaviour Checklist. Gestational age at birth, maternal anxiety trait, maternal history of psychological traumas, prenatal and postnatal maternal depression, anxiety, and cortisol as well as parenting stress were included as predictors in a regression model.

Results: Whereas increased internalizing problems were associated with a previous trauma history ($p = .003$), increased externalizing symptoms were linked to prenatal and postnatal maternal anxiety ($p = .004$ and $p = .018$, respectively).

Conclusions: Identifying modifiable risk factors, such as the history of maternal traumas and anxiety at TPL diagnosis and postpartum is recommendable to enhance better prognosis of Preterm Behavioural Phenotype in the offspring.

Disclosure of Interest: None Declared

EPV1129

The impact of maternal psychopathology on psychomotor development trajectories in infants born after a threatened preterm labour from 6 to 30 months of age

J. Andreu^{1*}, J. Buesa¹, N. Gómez², F. Ghosn², A. Moreno², L. Campos¹, B. Almansa², C. Zapata³, M. Lizarán² and A. García-Blanco³

¹Psychiatry, Hospital Universitario y Politécnico La Fe de Valencia;

²Psychology, La Fe Research Institute and ³Psychology, Hospital Universitario y Politécnico La Fe de Valencia, Valencia, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1692

Introduction: Threatened preterm labor (TPL) represents an adverse prenatal event that can impact maternal mental health in the long term. Additionally, this prenatal event can disrupt fetal neurodevelopment, primarily during the third trimester of pregnancy when neuronal connections in the fetus are established. Indeed, infants born following TPL exhibit delayed communication and socio-individual skills at 6 months of age, regardless of prematurity. Furthermore, maternal mental health during the postpartum period can also influence the offspring's psychomotor development.

Objectives: The aim of this study is to examine the impact of maternal psychopathology on psychomotor development trajectories in infants born after a TPL from 6 to 30 months of age.

Methods: This prospective cohort study recruited 117 mother-child pairs who suffered from a TPL. Psychomotor assessment was performed at 6 and 30 months of age using the communication and socio-individual subscales of Ages & Stages Questionnaires for psychomotor development. A regression model was carried out, including gestational age at birth, maternal anxiety trait, maternal history of psychological traumas, prenatal and postnatal maternal depression, anxiety, and cortisol as well as parenting stress as predictors.

Results: Increased communication delays were associated with higher maternal anxiety levels ($p < 0.001$), elevated maternal depression scores ($p = .0003$), and increased cortisol levels ($p = .004$) during postpartum. Similarly, elevated cortisol levels after 6 months postpartum were predictive of increased Personal-Social delays ($p = .0018$).

Conclusions: Maternal postpartum psychopathology was the main determinant of the course of psychomotor developmental disturbances. Therefore, infants born after TPL, whose mothers display postpartum psychopathology, should be identified and considered for psychological treatment to improve psychomotor delays in infants.

Disclosure of Interest: None Declared

EPV1130

Is relevant postpartum maternal psychopathology on the prognosis of psychomotor development in infants born after a threatened preterm labour across preschool ages?

J. Andreu^{1*}, J. Buesa¹, F. Ghosn², A. Moreno², L. Campos¹, B. Almansa², C. Zapata³, M. Lizarán², N. Gómez² and A. García-Blanco³

¹Psychiatry, Hospital Universitario y Politécnico La Fe de Valencia;

²Psychology, La Fe Research Institute and ³Psychology, Hospital Universitario y Politécnico La Fe de Valencia, Valencia, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1693

Introduction: Threatened preterm labour (TPL) is associated with long-lasting neurodevelopmental challenges, independent of prematurity. For instance, it is known that infants born a TPL show delayed communication and socio-individual skills, regardless of the gestational age at birth. Furthermore, TPL constitutes an adverse prenatal event that can induce maternal anxiety or depression, even during postpartum period, which can produce a

deleterious effect of the prognosis of infant's psychomotor development.

Objectives: This study aimed to explore the influence of maternal psychopathology as well as other peripartum variables on the course of psychomotor development in children born after a TPL between the ages of 2 and 6.

Methods: In this prospective cohort study, 117 mother-child pairs who experienced TPL were recruited. Psychomotor development was assessed using the Ages & Stages Questionnaires-Third edition at age 2 and 6. A regression model was carried out, including gestational age at birth, maternal anxiety trait, maternal history of psychological traumas, prenatal and postnatal maternal depression, anxiety, and cortisol as well as parenting stress as predictors.

Results: Low gestational week at birth emerged as the most relevant factor in the course of increased communication delay ($p < 0.001$). However, parental psychopathology during prenatal or postnatal stages was not a relevant factor in the prognosis of Communication skills or Socio-Individual development.

Conclusions: Gestation age at birth rather than parental psychopathology during peripartum period was the most relevant predictor of the course of psychomotor development between 2 to 6 years of age. Further studies should examine other potential modifiable predictors to moderate the impact of gestational age on psychomotor development.

Sex perspective on mandatory admission in acute psychotic patients

M. Delgado-Marí, À. Fernández-Ribas, A. Toll Privat, M. Giral-López, B. Jiménez-Fernández*, N. V. Motta-Rojas and J. Cuevas-Esteban

Psychiatry, Hospital Universitari Germans Trias i Pujol, Badalona, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1694

Introduction: Psychotic disorders are strongly linked to a higher risk of mandatory hospitalization, often affecting men more, though some studies report the opposite. Recent investigations also show a higher rate of involuntary admissions in younger individuals. Knowledge in this area is still limited despite extensive research.

Objectives: Analyze whether there is an association between sex and age with involuntary admissions of individuals with psychotic disorders.

Methods: Retrospectively, 254 people with psychotic disorders admitted between 2018-2023 to the adult psychiatric inpatient unit at Hospital Universitari Germans Trias i Pujol were selected, collecting their nature of admission, sex, age, and discharge diagnosis. Comparisons between voluntary and involuntary admissions, with respect to sex and age variables, were conducted using independent sample t-tests, Mann-Whitney U tests, Fisher's exact test, and chi-square tests. A logistic regression model was used to identify variables significantly associated with mandatory admission.

Results: In both the male and female groups, there were no statistically significant differences in terms of the mean age at admission

($p = 0.162$) or the nature of admission ($p = 0.586$) (Table 1). When analyzing the voluntary nature of admission based on age and sex, statistically significant differences were only found in the female group ($p = 0.01$), resulting in a 9.18 year age difference among those admitted voluntarily (Table 2). The model that best predicted the probability of involuntary admission in individuals with psychotic disorders included the sex variable (OR = 4.88) and the interaction between sex and age (OR = 0.97) (Table 3).

Table 1: Differences between sex regarding voluntariness of patients with psychotic disorders.

	Male	Female	<i>p</i> value
N (%)	122 (48%)	132 (52%)	
Age, m (SD)	38.39 (16.64)	44.15 (18.44)	0.162
Admissions, N (%)			
Voluntary	38 (31.1%)	37 (28.0%)	0.586
Involuntary	84 (68.9%)	95 (72.0%)	

Table 2: Analysis of voluntariness by sex and age.

Age, m (SD)	Voluntary	Involuntary	<i>p</i> value
Male	37.45 (16.38)	38.81 (16.84)	0.677
Female	50.76 (18.19)	41.58 (17.98)	0.01*
Total	44.01 (18.44)	40.28 (17.46)	0.127

Table 3: Predictors of involuntariness in psychotic patients: Logistic regression model (ENTER METHOD).

Predictor	-2log likelihood	Nagelkerke R ²	x ² (df*)	OR* (95% CI*)	<i>p</i> value
	301.22	0.039	0.03 (1)		
Age				1.01 (0.98; 1.03)	0.674
Sex				4.88 (1.15; 20.72)	0.032*
Age x Sex Interaction				0.97 (0.94; 0.99)	0.046*

Conclusions: Young women with psychotic disorders face a higher risk of involuntary admissions, emphasizing the need for gender-specific strategies to improve care of these patients.

Current situation regarding psychedelics and magic mushroom in Korea

J. S. Seo

Psychiatry, Gwangmyeong Hospital, Chung-Ang University, Korea, Gwangmyeong-si, Korea, Republic Of
doi: 10.1192/j.eurpsy.2024.1695

Introduction: Recently, the pros and cons have been debating in Korea even before the approval of use of medical marijuana with very strict limitations. And the next controversial topic is psychedelics. In 1890, when mescaline was first isolated from peyote cactus, clinical researches began, but due to its harmful effects, it was thereafter legally prohibited in 1970 in USA. However, a pernicious debate over the medical efficacy of psychedelic drugs has begun again with the release of a study that uses psychedelic mushrooms to be effective against treatment-resistant depression, alcohol dependence, and depression and anxiety in terminal cancer patient.

Objectives: To make a consensus on the medical use of these, we reviewed wild mushrooms containing hallucinogenic ingredients living in Korea.

Methods: To make a consensus on the medical use of these, we reviewed wild mushrooms containing hallucinogenic ingredients living in Korea.

Results: Mushrooms have long been popular as a food ingredient in Korea. Psilocybin, a classical psychedelic, can be obtained from magic mushroom (*Psilocybe cubensis*). The psilocybin on the CNS and causes hallucinations. Intoxication symptoms include pleasant or nervousness, sudden laughter, hallucinations, visual impairment, tachycardia and hypertension, reflexes, agitation, cognitive impairment, confusion, and aggressive behavior. These symptoms last for 2-4 hours after ingestion, and most disappear within six hours.

Among 114 species of *Psilocybe* containing psilocybin around the world, only five wild mushrooms found in Korea that cause nervous system hallucinations are as follows: *P. argenteipes*, *P. coprophila*, *P. peridaria*, and *P. subcarulipes*.

In Korea, there is acute poisoning case suffering with GI symptoms caused by mushrooms, but it is difficult to find records of abuse or dependences case caused by psychedelic mushrooms. In addition, although oriental medicine treatment is relatively active, it is not used as an herbal medicine.

Conclusions: Currently, the Korean government classifies psychedelic mushroom-derived substances, Psilocybin and Psilocin, as psychotropic drugs by law. If researcher intends to clinical trial with eve very small amount of it for academic purpose, it is only possible after obtaining approval from Korean FDA. In order to determine the usefulness of psychedelics, many clinical studies are needed in Korea.

'Guttas Campus' - participants' experiences of a group-based intervention to prevent school dropoutG. Ramdal¹ and R. Wynn^{2,3*}¹Social Education; ²Clinical Medicine, UiT The Arctic University of Norway, Tromsø and ³Department of Education, ICT and Learning, Østfold University College, Halden, Norway

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1696

Introduction: It is important to prevent school dropout and to help students who have dropped out re-enroll in school. Dropping out of school is associated with an increased risk of unemployment, low salaries, and receiving social security or disability benefits. In this study, we interviewed participants in 'Guttas Campus' (The Boys' Camp), which is a group-based intervention that aims to support disengaged boys from the 9th grade and through their transition to high school. The intervention consists of a two-week learning camp. The students subsequently participate in mentoring groups, with teachers and other camp participants, for a period of 18 months.

Objectives: We present a study of a school dropout prevention program.

Methods: 16 students were interviewed qualitatively. The interview data were analysed by drawing on the method of Grounded Theory.

Results: When the students who have completed the learning camp were asked what they believed were the most important and useful parts of the intervention, some common themes emerged: 1) The learning camp community provided a safe environment and helped give the participants learning and coping experiences that increased their self-confidence. 2) The students brought up the method of teaching, which they described as more persistent, adaptive and encouraging than they had been used to from regular school. 3) The students also mentioned the intervention's focus on character strengths such as willpower, self-control and optimism as central to increasing their motivation to learn.

Conclusions: The students that were interviewed were generally positive to the intervention, as mentioned several factors that they believed were useful in increasing their motivation and ability to learn.

EPV1137

Adjustment disorder among undergraduate students at Prince Mohammad Bin Fahd University, Al Khobar, Saudi Arabia

S. Aamir

Core Humanities and Social Sciences, Prince Mohammad Bin Fahd University, Al Khobar, Saudi Arabia

doi: 10.1192/j.eurpsy.2024.1697

Introduction: Adjustment disorder is characterized by an emotional or behavioral response to a stressful event or change in life. This condition can impact a student's academic performance, social life, and overall well-being. Adjustment disorder with the

stressor is a psychological response to identifiable stressors that result in the development of emotional or behavioral symptoms. These symptoms cause significant impairment in various areas of functioning, such as social, occupational, or academic performance.

Students with adjustment disorder may experience a range of symptoms, including feelings of sadness, anxiety, hopelessness, and a lack of concentration. They may also have trouble sleeping, feel overwhelmed, and struggle to cope with daily responsibilities. These symptoms can be triggered by various factors such as academic pressure, relationships, family issues, or cultural adjustments.

Objectives: This study aims to determine the prevalence of adjustment disorder among undergraduate students and investigate the potential risk factors of stress that can lead to adjustment difficulties.

Recognize the signs of adjustment disorder, how to access support, and how to create a supportive environment, therefore, students can effectively manage this condition and thrive in their academic and personal lives.

To prioritize mental health and provide the necessary resources for students to navigate the challenges of adjustment disorder effectively.

Methods: Adjustment Disorder-New Model 20 (ADNM-20) was used to assess prevalence of adjustment disorder among undergraduate students. It is a diagnostic tool used to assess adjustment disorder in individuals experiencing significant life stressors. The ADNM 20 is specifically designed to capture the nuanced manifestations of adjustment disorder with the stressor, enabling clinicians to make accurate assessments and develop targeted treatment plans.

Results: Adjustment disorder is a real and impactful challenge and a common mental health condition among undergraduate students at Prince Mohammad Bin Fahd University, Al Khobar, Saudi Arabia.

Conclusions: Adjustment disorder can significantly affect a student's academic performance. The inability to focus, persistent feelings of distress, and a lack of motivation can lead to a decline in grades and overall achievement. By recognizing the signs, accessing support, and creating a supportive environment, students can effectively manage this condition and thrive in their academic and personal lives. It's crucial to prioritize mental health and provide the necessary resources for students to navigate the challenges of adjustment disorder effectively.

EPV1138

Myasthenia Gravis presenting as a Dissociative Disorder: a case report of a differential diagnosisA. P. Laizāne^{1*}, A. Blekte² and A. Bērziņa³¹Riga Stradins University, Riga; ²Psychiatry, Hospital Ģintermuiža and³Neurology, Jelgava Central Hospital, Jelgava, Latvia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1698

Introduction: Conversion disorder is characterised by symptoms that can impact sensory or motor function. The average incidence

of conversion disorder is between 4 -12 per 100,000 per year. Conversion disorder has a wide variety of somatic and neurological differential diagnoses.

Objectives: A 22-year-old woman was admitted to the hospital due to COVID-19 pneumonia. During the hospitalisation period, she developed progressive weakness, due to which she couldn't move, eat or take care of herself. In terms of history, she is healthy, married and gave birth to her first child almost 9 months ago. Two days postpartum, the patient experienced an inability to connect with the child and provide care, as well as a decline in her mood. The husband reports episodes in which the patient had difficulties holding the child while being able to perform house chores, which required more physical strength. Two years prior to hospitalization, during stressful situations she experienced similar episodes and difficulty swallowing. While hospitalized, extensive testing was done, including an acetylcholine receptor antibody test, which was negative at first. Because of the initially negative testing results a psychiatrist was called. On the first visit, the patient remained in a supine position and reported a lack of strength in both arms and legs, occasionally experiencing difficulty raising her head, however managed to stand up from the bed, walk independently for 5–6 meters, turn around, and, as soon as she reached the bed, descend into it. The staff reported her inability to walk earlier in the day. On the second visit, she notes that she feels tired but now can feed and take care of herself; however, some weakness persists in the proximal muscle groups. In between visits she received treatment with corticosteroids because of the COVID infection. After repeating the acetylcholine receptor antibody test, there was a positive result, and a diagnosis was established.

Methods: This case report demonstrates how a somatic disorder can mimic a psychiatric one because of the overlapping symptoms and initial negative test results. While receiving symptomatic therapy with glucocorticoids due to the COVID infection, the patient's condition improved; she began to eat and walk on her own.

Results: From the psychiatric aspect, it was associated with separation from the child—a relieving of the stress factor, due to which dissociative symptoms decreased.

Conclusions: Before considering a diagnosis of a dissociative disorder, a patient should be examined by other specialists according to their symptoms. A thorough neurologic and physical examination, as well as diagnostic tests, should be performed to exclude a physical pathology. Myasthenia gravis has a comorbidity with a number of psychiatric conditions and can also be very similar to a dissociative disorder, especially due to stress aggravating the symptoms of myasthenia gravis.

EPV1139

The Imperative of Trauma-Informed Care: A Comprehensive Review and Strategies for Implementation in Health Services

C. Cunha^{1*} and M. Gomes²

¹Hospital de Magalhaes Lemos, Porto and ²Hospital de Braga, Braga, Portugal

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1699

Introduction: Psychological trauma is a significant public health concern with long-lasting effects on physical and mental well-being. Trauma-informed care is an approach to providing support and services that acknowledges and integrates an understanding of the pervasive impact of trauma on individuals. This review delves into the critical imperative of trauma-informed care within the realm of health services. Recognizing the pervasive impact of trauma on individuals' physical and mental well-being, this REVIEW aims to explore existing literature, identify key objectives, and propose effective methods for implementing trauma-informed strategies in health services.

Objectives: To Review Existing Literature on Trauma: Conduct an review of the literature to comprehend the varied dimensions and consequences of trauma on individuals' health; To Identify Key Principles of Trauma-Informed Care: Explore established principles of trauma-informed care, highlighting their relevance and applicability within health service settings; To Propose Implementation Strategies: Develop practical strategies for integrating trauma-informed care into health services, ensuring a comprehensive and sensitive approach to patient care.

Methods: A review of published articles, books, and reports related to trauma and trauma-informed care to establish a foundational understanding.

Results: Psychological trauma can have profound and multifaceted impacts on individuals, affecting their mental, emotional, and even physical well-being. The consequences of psychological trauma can vary widely based on the nature, severity, and duration of the traumatic experience, as well as individual factors such as resilience and support systems. Trauma-informed care aims to create an environment that is sensitive to the needs of those who have experienced trauma, and it is based on six key principles: safety, trustworthiness, peer support, collaboration, empowerment, and cultural competence. Healthcare providers need to understand trauma beyond the personal and acknowledge the cultural, historical, social, political, and structural trauma that impact individuals and communities across generations. This approach recognizes that there is a risk of retraumatization in social and health services, especially for minority communities.

Conclusions: This review underscores the pressing need for health services to adopt trauma-informed care strategies. By acknowledging the prevalence and impact of trauma on health outcomes, the healthcare sector can transition towards a more patient-centered and empathetic approach.

Risk-taking propensity and emotional intelligence: an emotional version of the balloon analogue risk task (BART)

A. Megías-Robles*, M. Sánchez-López, R. Gómez-Leal and P. Fernández-Berrocal

Department of Basic Psychology, University of Málaga, Málaga, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1700

Introduction: It is well known that emotions guide decision-making processes in risk contexts. Several studies in the literature have showed the influence of emotions on risk-taking using the Balloon Analogue Risk Task (BART).

Objectives: The aim this research was to investigate the influence of emotional intelligence (EI) levels on the impact of emotions in risk-taking propensity assessed by the BART.

Methods: To this end, we developed a variant of the BART in which each balloon displayed a face with an emotional expression: happiness, fear, or neutral. EI was assessed from the performance-based ability model by the MSCEIT. The sample consisted of 120 participants ($M_{age} = 21.52$; 80% women).

Results: A repeated measures ANOVA revealed a higher tendency to take risks when happy faces were presented, compared to the fear and neutral conditions. Moreover, participants with higher levels of EI showed a lower tendency to take risks across all emotional conditions. This relationship was particularly strong in the fear faces.

Conclusions: Our findings support the effect of incidental emotions on risk-taking and suggest the role of EI as a protective factor for risk engagement.

The relationship between workaholism and perfectionism among trainee doctors

S. Ellouze, N. Boussaid, A. Mellouli*, M. Turki, E. Miledi, N. Halouani and J. Aloulou

Psychiatry "B", Hedi Chaker University Hospital, Sfax, Tunisia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1701

Introduction: In the medical field, work addiction is a double-edged phenomenon. It can be regarded as a positive addiction leading to high motivation to work, but it can also have adverse mental, physical, and social consequences.

Objectives: To assess the relationship between work addiction and perfectionism in trainee doctors.

Methods: We conducted a cross-sectional descriptive and analytical study among trainee doctors. We used the "Work Addiction Risk Test" (WART), and "The Big Three perfectionism scale short form".

Results: A total of 99 doctors were included. The mean age of participants was 27.6 years, with a sex ratio (M/F) of 0.33. The doctors in our study worked 5.39 ± 1.6 hours a day and were on call 3.84 ± 2.87 times a month. Their average number of hours of sleep was less than 7 hours in 43.4 % of participants. The mean score of the WART was 61.2 ± 14.83 . Among the trainee doctors surveyed 39% were considered at high risk of workaholism. The mean WART score was significantly higher among female physicians and those who slept less than 7 hours per day on average. In addition, the average score on the WART scale was significantly associated with the number of calls per month. We found a statistically significant association between perfectionism scores and work addiction scores.

Conclusions: Our study showed that work addiction is common among doctors in training and is favored by high levels of perfectionism. It is therefore essential to explore and define preventive measures to help them find a balance allowing them to aim for high standards and be able to progress, without setting unrealistic expectations, which can lead to work addiction.

Disclosure of Interest: None Declared

EPV1143

The relationship between perfectionism and self-esteem among trainee doctors

S. Ellouze, N. Boussaid, A. Mellouli*, M. Turki, E. Miledi, N. Halouani and J. Aloulou

Psychiatry "B" departments, Hedi Chaker University Hospital, Sfax, Tunisia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1702

Introduction: Perfectionism is often seen as a beneficial trait for trainee doctors since it means they have high standards and a drive for success. However, it demands a flawless level of performance regardless of one's physical or mental health and well-being. Consequently, perfectionism is now viewed from a different perspective.

Objectives: We aimed to study the impact of perfectionism among doctors in training on their self-esteem.

Methods: We conducted a cross-sectional descriptive and analytical study among trainee doctors. The following psychometric instruments were used: The "Work Addiction Risk Test" and the "Rosenberg Self-Esteem Scale".

Results: We included 99 doctors in training. Their mean age was 27.6 ± 2.2 years. The sex ratio (δ/ϕ) was 0.33. Most participants were single (63.6%) and of middle socioeconomic level (86%). Tobacco use was reported in 6.1% of cases, and alcohol use in 4.1% of cases. Among all participants, 58 % had low or very low self-esteem. The mean score of Rosenberg Self-Esteem Scale was 30 ± 5.13 and the mean score of the big three perfectionism scale short form was 41.11 ± 13 . Higher self-esteem scores was significantly associated with lower self-critical perfectionism scores.

Conclusions: Our results point to the negative impact of self-critical perfectionism on self-esteem. In fact, perfectionism can hold you back, both personally and professionally. Perfectionists see their own self-worth as tied to what they achieve, and they believe that others judge them on this as well. They can never live up to the standards they set for themselves, and this can lead to a downward spiral of self-criticism and blame.

Tell me who you're coming with, I'll tell you what you have!

B. Castro Sousa^{1*}, Z. Correia² and J. Ramos²

¹Chuch, ahflivoCahlivoC and ²Chuch, ahflivoC, Portugal

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1703

Introduction: Psychiatric care is unique in its scope and complexity, as it involves the assessment and treatment of a wide variety of pathologies and, as these patients seek treatment, it is imperative to understand who accompanies them in clinical consultations and how the presence of these companions influences the treatment path. The dynamics between psychiatric patients and their companions in consultation, is extremely important as it can have

significant implications for the effectiveness of treatment and the well-being of the patient.. Therefore, the presence of companions can take different forms, varying according to the diagnosis and needs of each person.

Objectives: Thus, the authors intend, through carrying out a research study, to fill a critical gap in the understanding of presence of companions in psychiatric consultations, exploring the diversity of companions and their profiles in relation to patients psychiatric patients with specific diagnoses. Furthermore, they intend to understand how their presence impacts the process of adherence to the treatment.

Methods: To achieve this, they defined a two-year follow-up period, where they examined in detail the composition of companions in psychiatric consultations, including who they are, their relationship with the patient and how this relationship varies according to different psychiatric diagnoses.

Results: The presence of companions in psychiatric consultations is expected to prove to be a significant facet in the field of mental health, providing valuable insights into the dynamics of consultations and the treatment of patients with different psychiatric diagnoses. In this study we highlight how the presence of companions varied in relation to psychiatric diagnoses and how this influenced the process therapeutic. One of the main results was the identification of the different types of companions who were present at the consultations psychiatric disorders, reflecting the diversity of available social support and highlighting the importance of understanding the available support networks. A notable variation in the presence of companions in relation to psychiatric diagnoses was also observed, emphasizing the variations monitoring needs according to the nature of psychiatric disorders, suggesting the need for management strategies personalized treatment. This study also highlighted the influence of the presence of companions on doctor-patient communication and on adherence to treatment, in which the presence of family members often facilitated communication, allowing for a better understanding comprehensive history of the patient.

Conclusions: In conclusion, this study contributes to a more holistic understanding of mental health care provision, highlighting the importance to consider not only the patient, but also the support context in which they are inserted

EPA 2024, Budapest - Abstract - ePoster Viewing Digital Psychiatric Innovations from a Business Perspective – new era, new business models

B. Kiss^{1*}, T. Kurimay¹ and B. Nagy^{1,2}

¹Semmelweis University and ²Syreon Research Institute, Budapest, Hungary

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1704

Introduction: The advent of digital innovations in psychiatry has ushered in a new era in mental healthcare. These innovations offer the potential for enhanced diagnosis, treatment, and patient care. Establishing scientifically backed, dynamic, and adaptive

business models is necessary to launch sustainable innovations onto the healthcare market.

Objectives: This poster aims to provide a comprehensive understanding of the complex business-related challenges posed by digital innovations in psychiatry and to offer insights into potential strategies to address these challenges. The objectives include illuminating the dynamic landscape of digital psychiatric care from a business perspective.

Methods: A systematic review of the current literature was conducted, encompassing scholarly articles, industry reports, and expert perspectives. This method enabled the synthesis of insights regarding how digital innovations are reshaping the business models of psychiatric medical markets and the unique challenges.

Results: Digital innovations in psychiatry are catalyzing a transformation of business models in the field. Telepsychiatry, Digital platforms, VR technologies, and AI-driven diagnostic tools have expanded the reach of psychiatric services, potentially attracting new patient populations and offering innovative payment models. The opportunities presented by these technologies are promising. However, substantial challenges exist in parallel. Safeguarding data privacy and security is paramount, given the sensitive nature of patient information. Navigating the evolving regulatory, managing the costs associated with the adoption and maintenance of these technologies pose significant hurdles. Complex pricing structures and reimbursement models further add to the complexity of the challenges, necessitating adaptability and innovative strategies.

Conclusions: This poster underscores the dynamic and multifaceted nature of business models in the market of psychiatric innovations. While these innovations offer expanded service reach, improved patient engagement, potential for innovative payment models, addressing the business-related challenges is of utmost importance. Compliance with data privacy regulations, cost management, adaptability in pricing and reimbursement strategies are fundamental for psychiatric innovators. Proactive measures are pivotal as the mental healthcare field continues to embrace digital innovations. By addressing these challenges, the mental health industry can fully harness the transformative potential of these innovations to enhance patient care, improve access to services, and ensure the sustainability of high-quality psychiatric care. The evolving business models in psychiatry require astute management and innovation to thrive in this digital era.

Fahr's Disease and its neuropsychiatrist manifestations: A case report

B. Fernández*, R. A. Moreira, H. J. Gomes and J. M. Justo
Psychiatry, ULSNE, Bragança, Portugal

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1705

Introduction: Fahr's Disease, also known as Fahr's Syndrome, is a rare genetically dominant disease, characterized by the abnormal accumulation of calcium deposits, or calcifications, in various areas of the brain, particularly the basal ganglia. These calcifications, which are typically bilateral and symmetrical, can lead to a wide range of neurological and psychiatric symptoms, making diagnosis

and management challenging. It usually manifests between the ages of 40 and 60, primarily after the age of 30.

Objectives: To contribute to the medical literature by sharing this rare case, thereby increasing awareness and knowledge about Fahr's Disease among healthcare professionals.

Methods: Non systematic review of the literature and access to the medical history of the patient.

Results: We present a case of a 42 year old woman, who came to our hospital with behavior changes, with increasing confusion and new mystical beliefs, insomnia and agitation.

According to the patient's husband, the patient sounded confused and inappropriate in her speech. The patient was admitted for evaluation of altered mental status. The patient was alert and oriented to person, place, time, and situation in the emergency department, with shudder while neurologically intact. The patient was unpolite, agitated.

Psychiatry was consulted for evaluation. We decided to admit the patient and did a posterior study with a CT scan and MRI. The MRI, as well as CT scan revealed "dense calcification of the dentate nuclei and the basal ganglia", highly suggestive of Fahr's syndrome. The patient's phosphorus level was 3.5 mg/dl (normal level: 2.5-4.5 mg/dl). Parathyroid hormone (PTH) intact was 53 pg/ml (normal level: 15-65 pg/ml), and calcium level was 10,3 mg/dl (normal level: 8.4-10.5 mg/dl). The vitamin D 25-hydroxy concentration was 43,5 ng/ml (normal level: 30-60 ng/ml).

Conclusions: In conclusion, Fahr's Disease is a rare and complex neurological disorder characterized by idiopathic calcification of the bilateral basal ganglia, resulting in a diverse range of neurological and psychiatric symptoms. Diagnosis involves clinical evaluation and neuroimaging, while treatment is primarily symptomatic. Further research is needed to better understand the underlying genetic and biochemical mechanisms driving calcification in the brain and to develop more effective therapeutic strategies for this challenging condition.

EPV1147

Issues around vulnerability among people attended by a Portuguese community-based association: a qualitative secondary analysis

C. Laranjeira^{1,2*} and A. I. Querido^{1,2}

¹School of Health Sciences and ²ciTechCare, Polytechnic University of Leiria, Leiria, Portugal

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1706

Introduction: Despite vulnerability being a poorly understood concept is a key concept in health and social care disparities. Typically, vulnerable groups include individuals with physical and/or mental disabilities, children, the elderly, members of the lower social classes, and refugees. In Portugal, the pandemic was responsible for worsening inequalities in access to health and social care for the most vulnerable. To the best of our knowledge, there is a dearth of qualitative research on vulnerability from the viewpoint of those who are vulnerable or work with the most vulnerable.

Objectives: As expressions of vulnerability are strongly influenced by cultural factors, this study aims to examine issues of vulnerability

among people who attend and work in a Portuguese community-based association.

Methods: Secondary analysis of qualitative data from twelve vulnerable people and fifteen professionals who attended these people. The manifestations of the vulnerability reported by participants included being homeless, being a migrant, having an infectious disease, being drug dependent, living with socioeconomic difficulties (unemployment), and experiencing a process of loss and grief. They also reported having a mental or physical health problem, or both. Depression and anxiety were the most often reported mental health disorders. Regarding the academic background of professionals, most of them (n = 12) are from social sciences (e.g., social workers, social mediators, and psychologists).

Results: Three main themes emerged from the study: (1) meanings of human vulnerability; (2) barriers to vulnerability mitigation; and (3) approaches to addressing vulnerability. Our findings revealed that vulnerability is a very dynamic process of openness to conditions that impact individual outcomes. However, there is a conceptual gap: being vulnerable is perceived as something negative, but vulnerability also has the potential to change priorities in life for the better. Some participants emphasized the importance of self-care to avoid becoming vulnerable themselves, particularly in terms of mental health.

Conclusions: Understanding the social determinants of vulnerability is necessary to achieve satisfactory care for human groups. Practitioners need to be aware of these larger societal dynamics, understand them, and make sure their services are responsive to cultural differences. In order to develop interventions that promote social and health outcomes, practitioners should be encouraged to share knowledge on best practices.

The importance of including ADHD in the differential diagnosis in adults. About a case

E. González Laynez^{1*}, B. Gamo Bravo², S. M. Bañón González² and N. Ogando Portilla²

¹Psychiatry, Hospital Universitario de Toledo, Toledo and ²Psychiatry, Hospital Universitario Infanta Sofia, Madrid, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1707

Introduction: ADHD is a diagnosis almost always made in childhood or adolescence and oftentimes difficult to make it new in adults because it is not thought of in the differential diagnosis process and for the lack of experience from adult devices.

- ADHD in adults is characterized by symptoms of executive dysfunction, inattention, emotional dysregulation. The symptoms of impulsivity and hyperactivity tend to be less evident.

Objectives:

- Frequently, the adult patient with ADHD comes to the consultation with a secondary symptom and the primary pathology is hidden and often not evident at first glance.

Methods:

- A 20-year-old woman, university student, with no relevant medical or psychiatric history, without toxic habits, who

attended her first consultation referred by her primary care physician for long-standing insomnia, restless legs and anxiety.

- The patient's underlying complaint and her bigger concern is her poor academic performance. It is striking that she has just started her third year at the university, the first year she did not pass any subjects, the second year she changed majors and only passed two, now she is repeating the course.
- The examination did not reveal overt affective symptoms, nor psychotic symptoms or other notable psychopathology. The patient's speech tended towards superficiality, inconcretion, it was salty, it was difficult for her to express herself, even suggesting a certain intellectual disability.
- In the first consultation sleep study is requested. And referral to clinical psychology consultation for psychometric study.

Results:

- She is administered Clinical interview and WAIS IV (Adult Intelligence Scale), Trail Making Test, d2 and Stroop, Diagnostic Interview for ADHD in adults (inattention items).
- The WAIS-IV demonstrated global cognitive abilities within normality, although with significantly lower scores in the IMT and IVP indices which involve the functions of attention, concentration, mental control and short-term visual memory). Trail Making Test, d2, Stroop and Diagnostic Interview of ADHD in adults (inattention items) yielded profile results highly suggestive of Attention Deficit Disorder without Hyperactivity.
- The insomnia subsided with a regimen of 7.5 mg of mirtazapine per day. Subsequently, after starting treatment with low-dose methylphenidate (20 mg/day), the patient improved very significantly, both academic performance and social functioning and mood, self-esteem and subjective well-being.

Conclusions:

- We must always include ADHD in the differential diagnosis of a young adult patient when faced with a wide variety of consultation symptoms, especially if they report some type of deterioration or dysfunction in their social, family or academic life.
- An adequate clinical evaluation supported, if possible, by psychometric tests is essential to reach the diagnosis, which allows establishing an effective treatment that modifies the patient's overall prognosis.

The future of psychiatry and psychotherapy - An Early Career psychiatrist's view

F. H. Kraxner

Department of Psychiatry and Psychotherapy, Hospital of Affoltern am Albis, Affoltern am Albis, Switzerland
doi: 10.1192/j.eurpsy.2024.1708

Introduction: Psychiatry is one of the most fast developing and agile discipline within human medicine. But more work is necessary to complete these advances.

Objectives: I address the following questions:

How does the future of psychiatry look in the eyes of early career psychiatrists?

What strengths, weaknesses opportunities and threats will come?

And what can we learn from different mental health systems and regions?

Methods: Oral or written statements to the raised questions followed optimally by a discussion

Results: In low- and middle-income countries, a vast majority of people with mental disorders do not receive adequate treatment. Even in high income countries, roughly a third of people with severe forms of mental illness are not receiving the appropriate therapy. Laws concerning mental health are outdated in different countries. The protection of the human rights of the mentally ill is still incomplete and imperfect. The emphasis on economic gain and the digitalization of medicine in recent years has not helped. And new technical advancements such as artificial intelligence are becoming more important.

Conclusions: More discussion needs to be done on the identity and understanding of the psychiatric profession.

Attitude and Perceptions of Healthcare workers regarding ionizing radiation

A. Haddar¹, I. Sellami^{1,2*}, M. A. Ghrab¹, M. Hajjaji^{1,2}, K. Jmal Hammami^{1,2} and M. L. Masmoudi^{1,2}

¹Occupational medicine, Hedi Chaker Hospital and ²Sfax University, Sfax, Tunisia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1709

Introduction: In operating rooms, the routine use of radiological procedures is commonplace. However, this essential tool brings about significant concerns for healthcare workers due to the associated radiological risks. Understanding healthcare workers' attitudes and perceptions about ionizing radiation is crucial for addressing these concerns.

Objectives: This study aims to assess the perceptions and concerns of healthcare workers regarding radiation risks and their practices in the operating room.

Methods: A cross-sectional study was conducted in February and March 2023 among the operating room staff of Habib Bourguiba University Hospital in Sfax, Tunisia. We used a self-administered questionnaire that included socio-professional data. Self-assessment of exposure risk and protection level against ionizing radiation was evaluated on a scale from 0 to 10, and attitudes were assessed using a 5-item Likert scale.

Results: Our study population consisted of 92 healthcare workers, with 54.3% being male. When asking operating room workers about the availability, accessibility, and quality of lead aprons, the median scores were 3 (IQR [0;6.5]), 2 (IQR [0;5]), and 2 (IQR [0;5]), respectively. The median self-assessment score for exposure risk was 8 (IQR [5.5; 10]), while the median self-assessment score for protection against ionizing radiation was 1 (IQR [0;3]). Sixty percent of the population had limited knowledge of the harmful effects of ionizing radiation, with a median self-assessment knowledge score of 1.5 (IQR [0;3]). Sixty-two percent reported concerns regarding radiological risks. In terms of practices, 44.5% of the staff maintained a distance from the radiation source during intraoperative radiography, and 21.7% used the

apron for protection. Dosimeters were not used by any of the participants. Concerns level was associated with self-assessment of exposure risk ($p = 0.027$).

Conclusions: In conclusion, awareness of the risks generates anxiety and concern among staff; however, it alone is insufficient to alter our practices. This underscores the imperative for a proactive approach in implementing robust safety measures and comprehensive training programs.

Disclosure of Interest: None Declared

EPV1153

Low back pain and psychological distress according to the job tenure among electricians

I. Sellami^{1,2*}, A. Feki^{2,3}, A. Abbes¹, M. Hajjaji¹, S. Baklouti³, M. L. Masmoudi¹ and K. Jmal Hammami¹

¹Occupational medicine, Hedi Chaker Hospital; ²Medecine univeristy and ³Rheumatoloy, Hedi Chaker Hospital, Sfax, Tunisia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1710

Introduction: Low back pain (LBP) is common among electricians caused by work conditions. Even when symptoms are short-term and not medically serious, LBP can be associated with psychological distress.

Objectives: This study aimed to assess the link between LBP and psychological distress according to the job tenure among electricians.

Methods: The study was conducted in a group from a Tunisian Electricity society. Data were gathered between January-June 2022 using a self-administered questionnaire including socio-professional characteristics, the Nordic musculoskeletal questionnaire during the last 12 months and Kessler Psychological Distress Scale (K6). Our population was divided into two groups according to job tenure. The first group (G1) consisted of electricians with less than ten years of job tenure and the second (G2) consisted of electricians with more than ten years of seniority.

Results: G1 consisted of 10 participants with a mean age of 30.6 ± 6.7 years and with average job tenure of 3.3 ± 1.1 years. G2 consisted of 64 participants with a mean age of 40.7 ± 10.3 years and average job tenure of 17.4 ± 10.9 years. According to the Nordic musculoskeletal questionnaire, LBP during the last 12 months was present in the first and the second group in 30.8% and 14.3% of participants, respectively.

The proportion of respondents with high levels of psychological distress (K6 score of 13 or greater) in the first and the second groups was 10 % and 9.4% of participants, respectively. The presence of low back pain during the last 12 months was significantly associated with a high score of K6 in the second group ($p < 0.05$).

Conclusions: From the results of this study, we conclude that LBP was associated with psychological distress when the job tenure is high. Therefore, the prevention of LBP should go through programmes to build ergonomically safe working conditions to enhance the mental health of electricians.

Disclosure of Interest: None Declared

EPV1154

Musculoskeletal disorders and psychosocial risks among electricians

I. Sellami^{1,2*}, A. Feki^{2,3}, A. Abbes¹, K. Jmal Hammami¹, M. Hajjaji¹, S. Baklouti³ and M. L. Masmoudi¹

¹Occupational medicine, Hedi Chaker Hospital; ²Medecine university and ³Rheumatoloy, Hedi Chaker Hospital, Sfax, Tunisia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1711

Introduction: There is a growing concern about the link between musculoskeletal disorders (MSD) and psychosocial risk (PSR) among electricians. Both MSD and PSR represent a threat to the electrician's health, quality of life and productivity.

Objectives: This study aimed to assess the link between PSR and MSD among electricians.

Methods: The study was conducted in a group from an electricity society. Data were gathered between January-June 2022 using a self-administered questionnaire evaluating socio-professional characteristics, the Nordic musculoskeletal questionnaire during the previous year and the validated French version of the questionnaire KARASEK.

Results: Our study included 68 male electricians. The mean age was 39.2 ± 10.3 years. The average job tenure was 16 ± 11.4 years. According to the Nordic musculoskeletal questionnaire, 50% of participants experienced pain during the last 12 months.

About half of the electricians had high psychological demand (48.5%), 63.2% had a low latitude, and 76.5% had low social support. According to the Karasek model, tense electricians accounted for 26.5% and assets 22.1%. MSDs were associated with high psychological demand at work ($p = 0.02$).

Conclusions: This study demonstrated that PSR and MSDs are associated among electricians and are highly prevalent. They represent an important concern of the occupational and safety health system. The prevention of MSD should take into account the specific working conditions of electricians to reduce their exposure to psychosocial risk factors in the workplace.

Medical fitness for work in physicians with psychiatric disorders

S. Chemingui¹, D. Brahim¹, I. Youssfi¹, M. Mersni¹, M. METHNI^{2*}, H. Ben Said¹, N. Mechergui¹, I. YAICH³, C. Ben Said³, N. BRAM³ and N. Ladhari¹

¹Occupational pathology and fitness for work department Charles Nicolle Hospital, tunis, Tunisia; ²Occupational pathology and fitness for work department, Charles Nicolle Hospital and ³Forensic Psychiatry department, Razi Hospital, La Manouba, Tunis, Tunisia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1712

Introduction: Being a doctor is a profession with special medical requirements. Therefore, the assessment of medical fitness for work

among physicians remains a complex decision, particularly for those with psychiatric disorders.

Objectives: To assess the fitness for work decisions among physicians with psychiatric disorders.

Methods: Descriptive and retrospective study including physicians with psychiatric disorders referred to the occupational department of the Charles Nicolle Hospital in Tunis for a medical fitness for work from January 1, 2018 to August 30, 2023.

Results: The study included 28 patients with a female predominance (sex ratio M/F at 0.3) and a mean age of 44.1 ± 12 years. Participants were general practitioners (N=12), junior doctors (N=10), specialists (N=5) and one dentist. They worked in the public health sector in 93% of cases, and had a mean professional seniority of 12.4 ± 9.3 years. A psychiatric history was found in 20 patients. Current psychiatric disorders recorded were: depression (N=15), bipolar disorder (N=7), anxiety-depressive disorder (N=4), personality disorders (N=1) and addiction (N=1). Concerning the fitness for work, six patients were fit for work and 11 were temporarily unfit. Job adjustments were proposed for 11 physicians, mainly night shift exemption.

Conclusions: Physicians are exposed to several occupational hazards and require strict medical qualifications. The impact of psychiatric disorders on medical fitness for work is considerable, and could be avoided by appropriate prevention by occupational health practitioners, starting from professional orientation.

Facilitating effect of the hypnotically altered state of consciousness on decision-making in a situation modeling real-life

Z. A. Kovács¹, S. László², A. Albert¹, Z. Janka¹ and I. Szendi^{3,4*}

¹Department of Psychiatry; ²Doctoral School of Interdisciplinary Medicine; ³Department of Personality, Clinical and Health Psychology, University of Szeged and ⁴Department of Psychiatry, Kiskunhalas Semmelweis Hospital, Szeged, Hungary

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1713

Introduction: Numerous studies have shown a link between hypnotic susceptibility, the hypnotically altered state of consciousness, and the intensity of experienced emotions (De Pascalis et al., 1987; De Pascalis, Marucci, & Penna, 1989; Bryant & McConkey, 1989; Crowson, Conroy, & Chester, 1991; Crawford, Kapelis, & Harrison, 1995). One of the most suitable experimental psychological methods for modeling real-life decisional conditions is the Iowa Gambling Task (IGT) (Bechara, Tranel, & Damasio, 2000). Hypnosis has the potential to provide several benefits in decision-making, although there is limited scientific research on the subject.

Objectives: The main goal of this study was to determine if a hypnotically altered state of consciousness could affect decision efficacy in a real-life modeling situation.

Methods: Forty-eight healthy students (including 28 females and 20 males) from the University of Szeged participated in both the delayed punishment and delayed reward versions of the Iowa Gambling Task under alert and hypnotic states.

Results: During the mid-phase of the tasks while in hypnosis, notably higher performance levels were recorded compared to the alert state. In a simulated real-life scenario, the delayed reward had a more pronounced effect on decision-making efficiency than the delayed punishment. It became evident that the efficient decision-making strategy evolved more rapidly under hypnosis than in an alert state.

Conclusions: The hypnotic state of consciousness in an experimental decision situation modeling real life may accelerate the development of somatic markers, leading to earlier correct decision-making.

The meaning of work for teachers in educational institutions in the department of magdalena

K. L. Perez Correa¹, L. P. Pedraza Álvarez², J. Vilorio Escobar^{3*} and J. J. Gómez Rangel²

¹Magdalena, Universidad Cooperativa de Colo; ²Magdalena, Universidad del Magdalena, Santa Marta and ³Magdalena, Instituto Nacional de Formación Técnica Profesional Humberto Velásquez García, Cienaga, Colombia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1714

Introduction: The psychosocial and mental health-oriented variables of people are determinants for their life in society and their roles within organizations, especially educational institutions that are endowed with social complexities.

Objectives: The objective of this research was to understand the meaning of work for teachers in educational institutions in the department in order to recognize elements such as the level of importance that work holds for them and the factors that either promote or hinder that centrality.

Methods: This is a descriptive study with a quantitative methodology, and the sample selection was done for convenience, taking into account ethical aspects such as the handling of confidentiality for both the individuals who participated in this study and the educational institutions involved.

Results: Regarding the meaning attributed to work by teachers, the results indicate that 29.6% of teachers declare themselves neutral when it comes to the statement that “the most important things in people’s lives are related to work”. 26.8% of teachers are neutral regarding the statement that “the primary function of work is to generate income”, and 17.9% somewhat agree. 20.7% disagree to some extent. 15.6% disagree with the statement that “people’s primary goals in life should be oriented toward work”. 25.1% of teachers are neutral, and 17.9% somewhat agree with the statement that “the main function of work is to enable interesting contacts with other people”. Only 11.7% strongly agree with the statement that “work is, in general, one of the most important things in people’s lives.”

Conclusions: It is concluded that there is a need to implement strategies that contribute to the strengthening of the teaching profession and contribute to improving educational quality

Disclosure of Interest: None Declared

Dissociative Identity Unveiled: A Case Report of 17 Distinct Identities Emerging in a Clear Timeline Following Trauma Events

J. Li^{1*}, N. M. Childs² and H. Raai¹

¹Department of Psychiatry and Behavioral Health, SBH Health System and ²Medicine, CUNY School of Medicine, New York, United States

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1715

Introduction: Dissociative Identity Disorder (DID) is a complex and enigmatic mental disorder in which an individual maintains two or more distinct identities or personality states. We present a rare and captivating case report of a 27-year-old female patient who exhibited a remarkable 17 distinct identities, developed in a clear and unprecedented timeline following a series of specific traumatic events. The novelty of this case lies in the comprehensive documentation and analysis of the sequential emergence of these identities, offering valuable insights into the development and progression of DID.

Objectives: Our aim in presenting this case study is to offer a unique presentation to the constantly evolving understanding of DID. This case offers insight and provokes the need for research into the traumagenic nature of DID. This case showcases the influence on the chronological evolution of the patient's 17 identities following a multitude of traumatic events.

Methods: Structured interviews, psychiatric assessments, and psychological measurements, including self-reported measures of the Dissociative Experiences Scale, were employed to assess the identities and their individual experiences of the traumatic events. The patient was diagnosed with DID and received treatment including pharmacotherapy, psychoeducation, and trauma-focused psychotherapy. As a result of the therapeutic process, the patient was able to develop a higher sense of self-awareness and thus was able to integrate their 17 fragmented identities into a single host identity, demonstrating improvement in the functioning of interpersonal relationships.

Results: The patient's history reveals that the onset of her DID was linked to a traumatic event that occurred during early childhood, triggering the emergence of her first alternate identity. Over time, additional identities manifested, each appearing to serve as a coping mechanism to contend with the psychological distress stemming from subsequent significant trauma episodes. This case report meticulously outlines the chronological development of these identities and explores the distinct characteristics, behaviors, and roles assumed by each personality.

Conclusions: This case report offers valuable information on the complex development and pathogenesis of DID with a trauma influence. The presentation of this patient may lead to further research and more tailored therapeutic interventions for individuals suffering from DID.

doi: 10.1192/j.eurpsy.2024.1716

Introduction: Psychosocial and mental health-related variables are crucial determinants of individuals' lives in society and their roles within organizations, especially in educational institutions that are characterized by social complexities. In this regard, this research aims to determine the levels of emotional intelligence among teachers in educational institutions in the Department of Magdalena.

Objectives: Determine the levels of emotional intelligence among teachers in educational institutions in the Department of Magdalena

Methods: Methodologically, it is situated within the empirical-analytical paradigm with a quantitative approach, using the descriptive method. A convenience sample of 179 teachers was used, and the TMMS-24 questionnaire was administered.

Results: The results revealed that 37.7% of the teachers completely agree, and 30.9% strongly agree with the statement that they pay a lot of attention to their feelings. On the other hand, only 12.2% somewhat agree, and 1.2% strongly disagree with the statement that they normally worry about what they feel.

Additionally, 33.9% agree with the statement that they usually take time to think about their emotions, while 25.6% somewhat agree, and only 1.2% strongly disagree with the statement that it is worth paying attention to their emotions and mood. Furthermore, 6.4% agree, and 5.2% strongly agree with the statement that they let their feelings affect their thoughts.

As for thinking about their mood constantly, 16.7% strongly disagree, and 39.1% somewhat agree. Moreover, 6.9% strongly disagree, and 21.4% somewhat agree with the statement that they pay a lot of attention to what they feel.

Only 1.1% strongly disagree with being able to frequently define their feelings, and only 1.7% strongly disagree, and 10.2% somewhat agree with the expression "I often become aware of my feelings in different situations." 34.1% strongly agree, and 26.6% completely agree with the statement "I can always tell how I feel." Finally, 5.1% strongly disagree, and 19.4% somewhat agree with the statement "Sometimes I can tell what my emotions are."

Conclusions: In conclusion, the study emphasizes the importance of teachers' emotional intelligence and its potential impact on their performance and students' learning outcomes. It also highlights the need for intervention strategies to strengthen this psychosocial variable in educational institutions in the Department of Magdalena.

Understanding Attitudes and Perceptions Towards Blood Donation in Greece: An Analysis Aligned with the Health Belief Model

M. Theodoratou^{1,2*}, D. Papandrea¹, I. V. Papathanasiou^{1,3}, P. Andriopoulou⁴, C. Dafogianni⁵ and I. Farmakopoulou⁶

¹Social Sciences, Hellenic Open University, Patras, Greece; ²Health Sciences, Neapolis University Pafos, Pafos, Cyprus; ³Nursing, University of Thessaly, Larissa; ⁴Psychology, University of Ioannina, Ioannina; ⁵Nursing, University of West Attica, Athens and ⁶Social Work, University of Patras, Patras, Greece

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1717

Introduction: This study explores attitudes toward blood donation in Greece, where maintaining an adequate supply is challenging. Using the Health Belief Model, we examine factors like perceived severity, vulnerability, and self-efficacy.

Objectives: The main aims of this study are to assess public perceptions and barriers concerning blood shortage in Greece, and to identify motivators and self-efficacy levels for regular blood donation.

Methods: A cross-sectional study was conducted using a self-administered questionnaire distributed to a sample of Greek adults. The questionnaire was designed based on the constructs of the Health Belief Model and included questions related to perceived severity, vulnerability, self-efficacy, and barriers and facilitators to blood donation. Descriptive statistics were used to analyse the responses, calculating means and standard deviations (SDs) for each variable.

Results: Perceived Severity and Vulnerability

Participants in our study show a heightened awareness of the severity of blood shortages, especially in summer months and during increased surgical interventions. They also acknowledge Greece's dependency on more than just voluntary donations to meet blood supply needs. These findings align with the Health Belief Model's constructs of perceived severity and vulnerability, suggesting avenues for promoting donation.

Perceived Benefits and Barriers

A significant 74% of participants believe they can regularly donate blood and plan to do so in the next six months. However, fear of needles, health concerns, and fears of transmissible diseases act as barriers. According to the Health Belief Model, targeting these barriers could facilitate blood donation.

Self-Efficacy

A high percentage (74%, SD=5) of participants displayed strong self-efficacy, suggesting they are likely to engage in blood donation if encouraged. This aligns with the Health Belief Model's emphasis on self-efficacy as a motivator for health actions.

Cues to Action

Participants identified informational campaigns, digital reminders, and social encouragement as cues to action, with a disfavor for financial incentives. These cues could serve as triggers for blood donation, consistent with the Health Belief Model.

Conclusions: By aligning these findings with the Health Belief Model, it becomes evident that there are strong perceptions of severity and vulnerability, but also considerable barriers to

overcome. The high self-efficacy among participants and the cues to action identified could serve as bases for targeted interventions to improve blood donation rates.

Knowledge, attitudes, and beliefs about psychotropic medication among patients with mental disorders

M. Abdelkefi*, R. Feki, I. Gassara, S. Omri, N. Smaoui, N. Charfi, L. Zouari, J. Ben thabet, M. Maalej bouali and M. Maalej

Psychiatry C department, Hedi Chaker university hospital, sfax, Tunisia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1718

Introduction: Non-adherence to treatment is a major concern for mental health professionals. Knowledge of prescribed medications can influence patients' willingness to adhere to them.

Objectives: The aim of this study was to assess the knowledge of patients with mental disorders about their prescribed medication and to evaluate their attitudes and beliefs toward treatment.

Methods: Our quantitative descriptive study involved 52 patients hospitalized in the psychiatric "C" department of the Hedi Chaker University Hospital in Sax between the 23rd and 30 October 2023. Excluded were aggressive patients, those who were unable to communicate, and those who refused to participate. Thirty-nine patients were included. For each patient, we collected socio-demographic, clinical, and disease progression data, as well as information, beliefs, and attitudes concerning the prescribed treatment.

Results: The mean age of our patients was 35.49 ± 10.24 years, with an exclusively male sample. Most patients had no occupation (69.2%). Only 10.3% were married. Over half of the patients had achieved primary school (61.5%) and lived in rural areas (64.1%). The mean duration of the mental disorder was 10.69 ± 9.07 years. Patients were hospitalized 3.62 times on average. The most frequent diagnoses were schizophrenia (35.9%) and bipolar disorder (33.3%). More than half of the patients (61.5%) knew the color and shape of the prescribed medication, and 48.2% knew the name and dose.

The source of treatment information was mainly doctors (33.3%) and family members (15.4%). Adherence to treatment was poor in 69.2% of cases. The majority of patients denied stopping treatment and 12.8% reported that they stopped treatment because of financial difficulties. Twenty-four patients confirmed that taking the treatment made people see them differently and that they preferred not to reveal they were taking it. Two-thirds of patients reported that the treatment relaxed them (71.8%) but could be stopped when they felt better (69.2%).

Conclusions: It is essential for mental health professionals to develop and implement effective intervention strategies that maximize therapeutic impact and reduce the risk of relapse.

The relationship between childhood trauma and adulthood anxiety and depression among Tunisian university students

M. Turki¹, W. Hammemi², S. Ellouze¹, M. Barkallah^{1*}, I. Mannoubi¹, N. Halouani¹ and J. Aloulou¹

¹Psychiatry "B" department, Hedi Chaker university hospital and
²Higher college of health science, Sfax, Tunisia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1719

Introduction: Traumatic childhood has increasingly high incidence rates and can be predictive of negative health outcomes. There is a large consensus indicating that childhood trauma is significantly involved in the development of mood disturbances in adulthood.

Objectives: The aim of this study was to examine the relationship between retrospectively recalled childhood trauma and adulthood anxiety and depression in a sample of undergraduate university students.

Methods: A cross-sectional study was conducted among a sample of 365 university students randomly selected from 8 universities in Sfax (Tunisia). Information about childhood maltreatment, depressive and anxiety symptoms were gathered through the Childhood Trauma Questionnaire-Short Form (CTQ-SF), and the Hospital Anxiety and Depression Scale (HADS) respectively. To test the hypothesis, examining the relationship between anxiety, depression, and childhood trauma, we used Spearman's correlation test. Multivariate logistic regression models were used as well.

Results: The mean age of our participants was 20.3 years. More females (68.2%) than males participated in the study. Our findings showed that the five childhood trauma subtypes (emotional abuse and neglect, physical abuse and neglect, sexual abuse) were significantly correlated with anxiety and depression symptoms severity ($p < 0.01$). Emotional abuse was the strongest risk factor for adulthood anxiety symptoms (OR=6.002, 95% CI= [3.238; 11.125]) while emotional neglect was the strongest risk factor for depressive symptoms in adulthood (OR=6.214, 95% CI= [3.428; 11.267]). Multivariate analysis revealed that, in subjects with childhood trauma, scores of anxiety symptoms were positively and highly associated with the severity of emotional abuse (adjusted B=1.438, 95% CI= [1.951; 9.092], $p=0.000$). Depression symptoms severity were as well positively correlated with severity of emotional abuse (adjusted B=0.848, 95% CI= [1.043; 5.224], $p=0.039$), and severity of emotional neglect (adjusted B=1.044, 95% CI= [1.263; 6.389], $p=0.012$).

Conclusions: This study highlighted the relevance of childhood trauma as a factor contributing to anxiety and depression in adulthood. Thus, early psychological support of victims of childhood trauma can reduce the rate of anxiety and depression among these subjects.

Acute Stress Disorder among Tunisian Population in the Palestine-Israel War

N. Messedi¹, M. Sehli^{1*}, A. samet¹, I. Chaari¹, F. charfeddine¹, L. Aribi¹ and J. Aloulou¹

¹Psychiatry B, Hedi Chaker University Hospital of Sfax, sfax, Tunisia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1720

Introduction: The Gaza-Israel conflict has far-reaching consequences that extend beyond the immediate geographic confines of the conflict zone. This war certainly has repercussions on people who follow it via the media.

Objectives: To study the prevalence of acute stress disorder among Tunisian people and determinate the factors associated to it.

Methods: It was a cross-sectional, descriptive and analytical study, conducted among Tunisians. Data were collected during October and November 2023, through an anonymous online questionnaire, spread throughout social media (Facebook/Instagram), using the Google Forms® platform.

We used the the National stressful Events survey acute Stress Disorder Short scale (NSESSS) to assess the severity symptoms of acute stress disorder .

The National Stressful Events Survey Acute Stress Disorder Short Scale (NSESSS) is a 7-item patient assessment measures that assesses the severity symptoms of acute stress disorder in individuals age 18 and older following an extremely stressful event or experience.

Results: A total of 1091 participants completed the questionnaire. The participants had a mean age of 32.7 ± 9.8 years. More females (77.7%) than males (22.3%) participated in the study with a sex ratio (F/M) = 3.5. They were divorced in 2.1% .A history of psychiatric follow-up was found in 19,5% of case.

Results demonstrated that 100% of the respondents closely monitored the war, primarily relying on social media (98.6%) as their primary source of information.

According to the NSESSS ,83.4% of the participants had an acute stress disorder. The breakdown of acute stress disorder severity indicated that 29.7% experienced mild symptoms, 27.5% moderate, 21.6% severe, and 4.6% extreme symptoms.

The factors associated with high score of NSESSS were: female sex ($p=0.000$), the divorced people ($p=0.001$)and previous history of psychiatric follow-up ($p=0.000$)

Conclusions: These findings indicate a substantial impact of the Palestine-Israel conflict on the mental well-being of the Tunisian population, as evidenced by high rates of acute stress disorder.

Understanding the heightened prevalence of acute stress disorder among different demographic groups following such international conflicts is crucial for developing tailored interventions to support the mental health and well-being of affected individuals.

The Delicate Balance: Aptitude of Physicians with Psychiatric diseases

N. Khaterchi¹, G. Bahri², I. Youssef², M. Mersni², H. Ben Said², D. Brahim², N. Mechergui², M. Methni^{3*}, C. Ben Said³, N. Bram³ and N. Ladhari²

¹occupational medicine; ²Charles Nicolle Hospital and ³Forensic Psychiatry department, Razi Hospital, La Manouba, Tunis, Tunisia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1721

Introduction: The delicate balance between the need to ensure quality patient care and the reality of physicians dealing with psychiatric diseases poses a major challenge within the medical field. This issue raises fundamental ethical, legal, and medical questions, highlighting the complexity of decision-making regarding professional aptitude for practitioners affected by mental disorders.

Objectives: To examine the impact of psychiatric diseases on the medical aptitude of physicians.

Methods: This was a retrospective descriptive study that focused on physicians with psychiatric diseases referred to the occupational pathology clinic at Charles Nicolle Hospital in Tunis for medical evaluations of their work aptitude between January 1, 2021, and September 15, 2023.

Results: During the study period, we collected data from 20 patients. The mean age was 38 ± 11 years, with a sex-ratio (F/M) of 4.5. Five examined physicians had family histories of psychiatric disorders. Medical specialties were the most represented (N=17), including three general practitioners, two family medicine practitioners, and two anesthesiologists. The study population included 10 residents, eight hospital assistants, and two medical interns. The most common psychiatric diagnosis was depression (N=7), followed by bipolar disorder (N=5). The medical treatment prescribed was combinations of antidepressants and anxiolytics in seven cases, antipsychotics in five cases, and antidepressants in two cases. Medication adherence was noted in 10 physicians. Fourteen physicians had taken long-term sick leave, with an average duration of 203 days. Five physicians were declared fit to continue their regular professional activities, seven physicians were declared fit with restrictions on night work, and one physician was declared fit with workplace accommodations.

Conclusions: This study highlights the challenges surrounding the medical aptitude of physicians with psychiatric diseases. However, it is imperative to promote mental health awareness and to implement support measures to ensure both compassion for physicians and patient safety.

Disclosure of Interest: None Declared

EPV1169

Assessment of the Capability of Artificial Intelligence for Psychiatric Diagnosis

N. Laherrán, R. Palacios* and A. Vázquez

Psychiatry, Jerez de la Frontera University Hospital, Jerez De La Frontera, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1722

Introduction: Psychopathological exploration (PPE) involves an assessment of the mental state of patients, where psychological signs and symptoms are analyzed, which collectively form a syndrome. To conduct this assessment, the clinician must utilize their expertise to identify the presence and authenticity of a series of symptoms that, once recognized, allow for a diagnosis (1). The presence of this subjective component could explain why, despite the continuous growth of artificial intelligence (AI), its application in clinical psychiatry practice remains limited. However, the combination of the clinician's work with AI could enhance diagnostic accuracy and our understanding of diseases (2).

Objectives: The objective of this study is to investigate whether AI can make accurate diagnoses through an initial psychopathological evaluation.

Methods: A random sample was selected from our medical records of all patients admitted to our acute mental health inpatient unit through the hospital's emergency services in the year 2022. An anonymized database was created, including sociodemographic information, the results of the psychopathological assessment in the emergency department, and the diagnosis at the time of discharge. The psychopathological assessment conducted in the emergency department was provided to the AI chatbot ChatGPT, with a request to establish a diagnosis according to the DSM-5. Diagnoses such as brief psychotic disorder, schizophreniform disorder, and schizophrenia were considered, given their acute symptom similarities, as well as major depressive disorder (unipolar) and bipolar disorder. The level of agreement between both diagnoses was evaluated using the kappa coefficient.

Results: The sample consisted of 15 patients, of whom 60% were male, with a mean age of 45 years (standard deviation = 15.6). 73.3% of the patients had prior mental health follow-up, and 66.7% had been previously hospitalized. Diagnoses included psychotic disorder in 33.3% of cases, bipolar disorder with manic episode in 26.7%, depressive disorder in 13.3%, delusional disorder in 13.3%, schizoaffective disorder in 6.7%, and borderline personality disorder in 6.7%. A kappa value of 0.561 was obtained, indicating a moderate degree of agreement between the diagnoses.

Conclusions: Despite the inherent subjectivity in psychopathological assessment, this study suggests that AI, in the form of natural language processing chatbots like ChatGPT, can be a useful tool to assist mental health professionals in the diagnostic process. While AI shows promising potential, it should not entirely replace the experience and clinical judgment of mental health professionals. Instead, the importance of potential collaboration between AI and clinicians for achieving more precise and comprehensive diagnoses is highlighted.

EPV1172

Dermatitis artefacta in a 60 year old man: a case report

P. Setién Preciados*, C. Díaz Mayoral and E. Arroyo Sánchez

Servicio de Psiquiatría, Hospital Universitario Príncipe de Asturias, Alcalá de Henares, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1723

Introduction: Dermatitis artefacta (DA), also known as factitious dermatitis, is a condition among factitious disorders, whereby self-

induced skin damage is the means used to satisfy a conscious or unconscious desire to assume the sick role, particularly in those with an underlying psychiatric diagnosis or external stress. DA should be distinguished from malingering, in which skin damage may be inflicted for the purpose of secondary gain.

Objectives: Review what dermatitis artefacta and factitious disorders in general consist of and the challenges they present.

Methods: Presentation of a patient's case and review of existing literature, in regards to factitious dermatitis and factitious disorders.

Results: In general, in regards to factitious disorders in literature, the majority of patients were female with mean age at presentation at thirty. A healthcare or laboratory profession was reported most frequently, as well as a current or past diagnosis of depression was described more frequently than personality disorder in cases reporting psychiatric comorbidity, and more patients elected to self-induce illness or injury than simulate or falsely report it. Patients were most likely to present with endocrinological, cardiological and dermatological problems. In our patient's case, common factors described previously are dermatological lesions, comorbid psychiatric disorder and the beginning of the disorder at an earlier age.

Specifically, when it comes to DA, the hallmarks of diagnosis include self-inflicted lesions in accessible areas of the face and extremities that do not correlate with organic disease patterns. Importantly, patients are unable to take ownership of the cutaneous signs.

Management in these cases is challenging, and different modalities may be employed, including topical therapies, oral medications, and cognitive behavioural therapy; adopting a multidisciplinary team approach has been shown to be beneficial in allowing patients to come to terms with their illness in an open, non judgmental environment.

Conclusions: DA is a rare cutaneous condition that must be considered when the clinical presentation is atypical and investigations do not yield an alternate diagnosis. Few are referred to psychiatric services and even fewer accept care. They have a protracted course, complicated by repeated hospitalizations, ultimately leading to their premature deaths. Clear guidelines on the management of these patients need to be set to protect both patients and providers in light of the ethical and legal considerations.

Exploring Exercise Intervention as a Therapeutic Catalyst within the Mental Health and Addiction Program in Nova Scotia: A Proof-of-Concept Study

S. Obeng Nkrumah^{1,1*}, R. da Luz Dias², E. Eboime², B. Agyapong³, S. Sridharan¹ and V. I. O. Agyapong¹

¹Department of psychiatry, Nova Scotia Health; ²Department of psychiatry, Dalhousie University, Halifax, NS and ³Department of psychiatry, University of Alberta, Edmonton, AB, Canada

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1724

Introduction: Many mental health conditions, including anxiety, mood disorders, and depression, can be effectively treated at a relatively low cost. Exercise interventions can be a therapeutic strategy, but even though exercise has consistently been shown to improve physical health, cognitive function, and psychological

well-being, as well as reduce depression and anxiety symptoms, this intervention is often neglected in mental health care services.

Objectives: The study aims to assess the feasibility of incorporating an Exercise Intervention Program (EIP) as a therapeutic pathway within the Mental Health and Addictions Program (MHAP) in Nova Scotia, as well as to evaluate the effectiveness of the program on mental health outcomes and incremental costs, and the patient acceptability and satisfaction with the program.

Methods: This proof-of-concept study has a pragmatic, prospective, controlled observational design with an embedded one-phase qualitative component. Patients with a primary diagnosis of depression or anxiety attending the Rapid Assessment and Stabilization Program (RASP, Halifax, Nova Scotia, Canada) will be offered to receive 60-minute exercise sessions three times per week, per 12 weeks. Patients with similar mental health conditions that have opted to wait for Cognitive Behavioral Therapy (CBT) with the community provider and declined from the EIP will be part of the control group. A certified recreational therapist will conduct the EIP. Participants of both groups (EIP and control condition) will be assessed at baseline and then weekly for four weeks, six weeks and then at 12 weeks post-enrollment. Primary outcomes include differences in the mean change in functional (well-being, resilience, and recovery) and symptom variables (depression, anxiety, and suicidal risk), which will be assessed through online validated scales/questionnaires. Service variables (patient acceptance and satisfaction) and health care utilization (crisis calls, emergency department visits, hospital admissions and readmissions, length of stay for each admission) will comprise the secondary outcomes.

Results: The results of the study will provide information about the effectiveness of EIP in the treatment of anxiety and depression compared to those only wait-listed to receive CBT or counselling from a CMHA provider. The study will also inform about the acceptability and satisfaction of the EIP, as well as the incremental cost-effectiveness of the intervention compared to the control condition.

Conclusions: This proof-of-concept study will demonstrate the effectiveness of EIP as an adjunctive or alternative therapeutic option for the treatment of anxiety and depression in patients seeking mental health support from the MHAP in Nova Scotia.

Disclosure of Interest: None Declared

EPV1175

Negative factors of personality hardiness that effect on ability to control situation and cope with the stress

S. Tukaiev^{1,2*}, D. Kashpur^{3,4}, N. Pogorilska³, M. Makarchuk², I. Zyma² and J. M. A. Ferreira⁵

¹Faculty of Communication, Culture, and Society, Institute of Public Health, Università della Svizzera italiana, Lugano, Switzerland;

²Institute of Biology and Medicine; ³Faculty of Psychology, National Taras Shevchenko University of Kyiv; ⁴Research Institute, National University of Ukraine on Physical Education and Sport, Kyiv, Ukraine and ⁵Faculdade de Medicina, Universidade de Coimbra, Coimbra, Portugal

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1725

Introduction: Personality hardiness expresses the characteristics that help to overcome stress and achieve well-being.

Objectives: This study focused on the Hardiness as the important personality trait, which allow coping with stress and the relationship of empathy, emotional sensitivity and the personality hardiness.

Methods: 88 healthy volunteers, students aged 17 to 26 years (mean age = 19, SD = 1,69), participated in this study. We used Cloninger's Temperament and Character Inventory (TCI), the Maddi Hardiness Survey (adapted by Leontyev), Buss Perry Aggression Questionnaire (BPAQ), the Barratt impulsiveness scale (BIS-11), Maslach Burnout Inventory (MBI), the Questionnaire Measure of Emotional Empathy (QMEE).

Results: The cluster analysis was used to identify groups of hardy personalities. We demonstrated a negative relationship between hardiness and depression and burnout. It revealed significant differences between these groups by the following traits: Attention (BIS-11), Self-Control (BIS-11), Cognitive Complexity (BIS-11), Hostility (BPAQ), Exploratory activity (NS1 TCI), Shyness of strangers (HA3 TCI), Resourcefulness (S3 TCI). Regression analysis was used to identify Hardiness factors and to build the following regression models. For the first group the models describe 100% of dispersion (R-square=1,000, Durbin-Watson statistic = 1,419) and are:

$Control = -16,998 - 2,922 \cdot C2 + 3,549 \cdot C5 + 3,264 \cdot CI + 0,723 \cdot ST2 + 0,747 \cdot S4 - 0,306 \cdot SC + 0,166 \cdot RD3 - 0,020 \cdot C - 0,003 \cdot NS2$, where $C2$ – scale Empathy (TCI), $C5$ – scale Principles (TCI), CI – cognitive instability, $ST2$ – Transpersonal identification scale (TCI), $S4$ – Self-acceptance (TCI), SC – Self-Control (BIS-11), $RD3$ – Social attachment (TCI), C – Cooperativeness (TCI), $NS2$ – Impulsive decision making (TCI).

The *Hardiness* model described 50% (R-square=0,456) of dispersion: $Hardiness = 63,527 - 4,080 \cdot C2$, where $C2$ – Empathy scale (TCI) ($p=0,003$).

The regression models of the second group explain 50% of group dispersion (R-square=0,512) and are Independent variables significance $p<0,05$:

$Challenge = 12,484 + 0,389 \cdot SC + 0,197 \cdot EE - 0,702 \cdot RD1 - 0,206 \cdot A$, where SC – Self-Control scale (BIS-11), EE – Emotional Empathy (Personality test of Emotional Empathy), $RD1$ – Sentimentality scale (TCI), A – Anger (BPAQ).

The *Hardiness* model describes 35% of dispersion (R-square=0,364, Durbin-Watson statistic = 2,066):

$Hardiness = 100,352 + 0,941 \cdot SC - 0,527 \cdot H$, where SC – Self-Control scale (BIS-11) ($p=0,009$), H – Hostility scale (BPAQ) ($p=0,021$).

Conclusions: Thus, the attention and self-control problems, hostility, cognitive complexity and shyness have a negative impact on hardiness. Our results suggest that the excessive use of empathy leads to decrease of ability to control situation and cope with the stress.

EPV1176

Somatic disorders in patients followed for a psychiatric disorder at the Ar Razi hospital in Morocco

Y. BENSALAH^{1*}, S. BELBACHIR¹ and A. OUANASS¹

¹Psychiatric hospital Ar Razi, Salé, Morocco

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1726

Introduction: Somatic disorders in patients suffering from psychiatric disorders have become an important issue in the overall care of these patients

Comorbidity studies show that 30 to 60% of patients consulted or hospitalized in psychiatry present an associated organic pathology. However, the detection of somatic conditions in psychiatric patients remains too late and this exposes them to sometimes lethal somatic complications

Objectives: To evaluate the prevalence of somatic disorders in patients followed for a psychiatric disorder at Ar Razi hospital in Salé – Morocco, and to determine the associated factors

Methods: We carried out a cross-sectional study with 80 patients followed for a psychiatric disorder at Ar Razi hospital in Salé presenting clinical signs in favor of an organic pathology and transferred for specialized advice to the medical-surgical services, in the period from September 1st, 2022 until August 31st, 2023.

Results: Most of our patients were male (65%) with ages ranging from 18 to 65 years. Addictive behaviors were found in more than half of our patients.

The most frequent reasons for requests for advice from medical-surgical services was the suspicion of an organic cause of psychiatric symptoms in 25% of cases or the presence of an organic warning sign in 30% of cases.

The comorbidity of somatic illness and psychiatric disorder was noted in 35% of cases.

Somatic comorbidities were essentially: infections and cardiovascular diseases.

Side effects of psychotropic drugs were predominantly neurological in 40 % of cases

Conclusions: Somatic comorbidities in patients hospitalized or in consultation in psychiatric hospitals are very common, often unrecognized, hence the need for early screening in order to improve care.

Introduction of Hungarian Association of Psychiatric Trainees - EPA - Hungarian NPA Joint Symposium

F. Kupcsik

Psychiatry and Psychotherapy, Semmelweis University, Budapest, Hungary

doi: 10.1192/j.eurpsy.2024.1727

Introduction: The purpose of my presentation is to introduce the Hungarian Association of Psychiatric Trainees (HAPT), - our NAT - to you, which includes residents and young specialists within five years of training.

Objectives: Currently we have 108 members, from 15 cities and villages throughout Hungary, and one person is working in Denmark. The vast majority (58 %) of the members are from Budapest, our capital city. There are 14 members, who are young specialists, the others are doing residency training. We have 21 members who are working in child and adolescent psychiatry.

HAPT has been existed since 2013, so in the previous years, our founder members have reached the point when they no longer meet the criteria of being 'psychiatric trainee' or 'young specialists', however every year we encourage the new residents to join us.

Methods: -

Results: OUR DUTY: The main goals of HAPT are educating ourselves, forming a community and making connections with colleagues country-wide and last but not least, trying to stand up for our interests, when needed.

Throughout the year we organize educative presentations about topics that are somehow left out of focus during the official training program. Every year our main event is a three-day long weekend, where we can go deeper into a couple of topics via presentations or workshops, and it is also a great opportunity to get to know each other better.

We also organize case-discussion-groups according to the Balint method, considering the residents' daily difficulties and trying to pay more attention to their mental well-being.

Last year we tried some other ways to broaden our perspectives in the form of cultural events, when we watched a movie or a play and then discussed it together as a group, had been led by a psycho-therapist.

HAPT is part of the Hungarian Psychiatric Association and the relationship between the two Organizations has a constantly changing dynamics – in some ways we are trying to be more independent, however, there are common goals that are important for all of us, for example being present on at international events.

Conclusions: FUTURE GOALS: One of our future plans include being more active in the European community, like getting to know the EFPT or the ECP better. This conference is a perfect opportunity for all of us to make new professional connections.

Exploration of dreams in Charaka Samhita – an Ayurveda text and their content analysis of prodromal dreams in various conditions

A. K. Iyer^{1*} and W. Upadhyaya²

¹Unaffiliated, Independent, London, United Kingdom and ²Centre Ahimsa, Paris, France

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1728

Introduction: Research into dreams, have shown the association between increased frequency of distressing dreams, specific content themes (analysed using the Hall Van de Castle system) and greater incidence of progression of neurological conditions and dementia. The history of predicting illnesses by the content of dreams, in the western world is popularly traced backed to the ancient Greek medicine. This stimulates the curiosity if any such practices existed in the ancient medical practises of the eastern world. Ayurveda is one such traditional system of medicine, that is native to the Indian subcontinent. Charaka Samhita is one of the oldest texts on Ayurveda consisting of 8 sections and 120 chapters totally. This text was selected for the purpose of this review, with the line of enquiry such as what does Ayurveda say about dreams associated with illnesses? What are the contents of such dreams? Furthermore, the dream content analysis was done using the Hall Van de Castle system, which is probably the first time being done on an Ayurveda text content.

Objectives: 1) To explore if, Charaka Samhita mentions, describes dreams in relation to illnesses, stages of illnesses and their prognosis. 2) To analyse content of the dreams seen in prodromal stage of illnesses.

Methods: 1-The Charaka Samhita text was scanned chapter by chapter, to answer the questions- a) What are the types of dreams? b) Are any associated with illnesses? c) Are any dreams mentioned in the prodromal stage of illnesses? d) What do they imply? e) What are their contents? 2- The contents of prodromal dreams were analysed against the categories of Hall Van de Castle system.

Results: As per Charaka Samhita, the types of dreams are, i) those based on what was seen ii) heard iii) reflected upon iv) desired v) imagined vi) those of prophetic type and vii) those caused by illnesses. Specific dreams in the prodromal stage, predict manifestation of specific illnesses (mild or fatal). In the diverse dream contents (18 themes mentioned) ranging from things animals to gods and demons, except the elements of the past, rest of the general categories occur, at least once. The categories characters, objects, activities and social interactions were more common than the rest.

Conclusions: Thus akin to the ancient Greek medicine, Ayurveda too had the practice of predicting illnesses based on the dream contents.

Subjective discomfort and lack of volitional drive with neuroleptic pharmacotherapy - a phenomenological case study

L. Korošec Hudnik¹ and I. Kosmačin^{1*}

¹Department for Intensive Psychiatric Treatment, University psychiatric clinic Ljubljana, Ljubljana, Slovenia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1729

Introduction: In comparison to extrapyramidal and metabolic side effects, the subjective aspects of neuroleptic treatment have been less extensively researched. Nevertheless, they are equally significant given their potential to influence adherence and functional outcome. Historically, terms such as “neuroleptic dysphoria,” “neuroleptic-induced psychic indifference,” and “neuroleptic-induced deficit syndrome” were used to characterize a range of unpleasant mood states on the one hand and a documented and observable motivational deficit on the other. The latter aligns with the findings from preclinical neuroscientific studies and animal models highlighting the significant involvement of mesolimbic dopamine in motivational processes. Despite an abundance of anecdotal data these adverse effects are often undetectable in large-scale clinical studies that utilize standardized assessment measures.

Objectives: To present adverse subjective changes in arousal, mood and volitional drive resulting from neuroleptic intake from a patient's perspective.

Methods: The subject is a patient, with no reported negative symptoms or lasting functional impairment described, who underwent a gradual 6-month discontinuation of risperidone in an outpatient setting following a complete recovery after a single psychotic episode. A semi-structured interview modelled after

The Clinical Assessment Interview for Negative Symptoms (CAINS) was conducted. We aimed to elicit descriptions of the subjective experience while ensuring our approach remained non-suggestive.

Results: In addition to describing potential akathisia and lethargy at higher doses, the subject reported a significant lack of motivation and a notably reduced willingness to exert effort towards achieving specific goals or engaging in activities that he still found rewarding or pleasurable. Furthermore, he consistently noted gradual improvements across various psycho-social aspects following the discontinuation of the medication. These adverse and unpleasant experiences were presented as the primary reason for wanting to discontinue pharmacological treatment.

Conclusions: Certain adverse effects of antipsychotic medications can only be elucidated by the clinician through the examination of the patient's subjective experiences. Medication induced dysphoria and volitional deficits have the potential to profoundly impact treatment adherence, leading to unrecommended discontinuation of neuroleptics, and can cause important functional impairment.

Association of prosocial personality traits with symptoms of depression, anxiety and stress in psychiatric nurses; Single-centre cross-sectional study in Croatia

K. Bosak^{1*}, I. Topolić Šestan¹, P. Folnegović Grošić², Ž. Bajić³, I. Filipčić¹ and V. Grošić¹

¹Psychiatric Clinic Sveti Ivan; ²Department of Psychiatry, University Hospital Centre Zagreb and ³Research Unit "Dr. Mirko Grmek", Psychiatric Clinic Sveti Ivan, Zagreb, Croatia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1730

Introduction: Symptoms of depression, anxiety and stress are more common in the population of nurses working in psychiatric hospitals than in many other segments of the health care system. These three elements of psychological distress (depression, anxiety, stress) may reduce the nurse's ability to establish quality therapeutic relationships with patients, which are very important in the treatment of mental disorders. Some studies suggest that prosocial personality traits may have a protective role. Other research suggests that high levels of empathy, for example, may increase secondary traumatisation and lead to more pronounced symptoms of distress.

Objectives: The main objective of the study was to examine the association of prosocial personality traits with symptoms of depression, anxiety and stress in nurses employed in a psychiatric clinic. The hypothesis was that more pronounced prosocial personality traits are associated with a lower expression of symptoms of depression, anxiety and stress.

Methods: The target population were nurses employed in a psychiatric hospital working directly with patients. No sample was selected, but the whole available population was invited to participate. The independent variable was prosocial personality traits measured by the Prosocial Personality Battery (PSB). The outcome was symptoms of distress (depression, anxiety and stress) measured

using the Depression, Anxiety, Stress Scale-21 (DASS-21). The hypothesis was tested using three linear regression analyses.

Results: Total of 63 MST were included with a median (interquartile range) age of 34 (24-42) years. Prosocial personality traits were statistically significantly associated with scores on the DASS-21 subscale measuring depression: personal distress (PD) ($r = 0.32$; $P = 0.01$) and self-reported altruism ($r = 0.30$; $P = 0.02$). Only the subscale measuring the specific personality trait of personal distress (PD) was statistically significantly correlated with the scores of the other two DASS-21 subscales, anxiety and stress (anxiety: $r = 0.54$; $P < 0.001$; stress: 0.46 ; $P < 0.001$). Helpfulness was negatively related to anxiety ($b = -0.29$; $P = 0.03$).

Conclusions: This research partially confirmed the hypothesis that stronger prosocial personality traits are associated with a lower prevalence of symptoms of depression, anxiety and stress in the MST of employees in a psychiatric clinic.

Factors Driving the Emigration Intentions of Young Tunisian Medical Professionals

W. Haouari^{1*}, S. Omri¹, A. Labyadh¹, R. Feki¹, I. Gassara¹, N. Charfi¹, J. Ben Thabet¹, M. B. Maalej¹, N. Smaoui¹, L. Zouari¹ and M. Maalej¹

¹Psychiatry C, Hedi Chaker university hospital, Sfax, Tunisia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1731

Introduction: Emigration has a substantial impact on Tunisia's healthcare sector. Graduates, including medical students at different educational levels, as well as general practitioners and specialists, often choose to emigrate. Some do so to pursue further studies abroad, while others seek careers and settlement primarily in Europe. This phenomenon exerts a significant influence on the quality of healthcare systems in their home countries.

Objectives: To evaluate the inclination to emigrate among medical residents employed in Tunisian healthcare institutions and to identify the factors associated with this intention.

Methods: This is a descriptive cross-sectional study conducted among medical residents undergoing their training in various healthcare facilities in Tunisia. The study employed an online questionnaire to assess the degree of satisfaction with various aspects of their professional life and the socio-economic situation in the country, as well as their intention to emigrate. Satisfaction levels were measured using a 4-point Likert scale, ranging from "very dissatisfied" to "very satisfied".

Results: A total of 50 physicians participated in the survey. Among them, 72% were female, 80% were single, with an average age of 27.72 years at the time of the study. Regarding their professional status, 84% worked in university hospitals, 16% specialized in surgery, 40% specialized in medicine, and 44% were family physicians. The majority were students from the Faculty of Medicine in Sfax (56%), with 30% in Monastir, 8% in Tunis, and 6% in Sousse. The study found that 68% of medical residents expressed an intention to emigrate. Among the participants, 74% were dissatisfied with their working conditions, and 68% were dissatisfied with workplace safety. Additionally, 84% were dissatisfied with their

salaries, 40% with their workload, 54% with supervision, and the quality of training provided in their hospitals. The political situation in the country and social security were considered unsatisfactory by 92% and 90% of the participants, respectively. Among the potential reasons studied to explain this emigration phenomenon, working conditions were a factor in 54% of cases, salary in 56%, training in 36%, and quality of life in 56%.

Conclusions: The emigration of young Tunisian medical professionals is driven by a range of factors, including working conditions, salaries, training opportunities, and quality of life. To counteract this phenomenon, it is crucial to enhance these aspects in order to retain these talented individuals in the country and thereby bolster the Tunisian healthcare system.

Prevalence and Risk Factors of Burnout Among Medical Residents in Tunisia: A Cross-Sectional Study

W. Haouari^{1*}, S. Omri¹, A. Labyadh¹, I. Gassara¹, R. Feki¹, N. Charfi¹, J. Ben Thabet¹, M. B. Maalej¹, N. Smaoui¹, L. Zouari¹ and M. Maalej¹

¹Psychiatry C, Hedi Chaker university hospital, Sfax, Tunisia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1732

Introduction: The burnout syndrome is a blend of physical exhaustion and emotional fatigue that impairs an individual's performance at work. In Tunisia, factors like working hours, the frequency of monthly shifts, and the physical and emotional abuse that physicians face from patients have collectively led to a significant incidence of burnout among medical professionals.

Objectives: To evaluate the prevalence of burnout syndrome among medical residents working in healthcare facilities in Tunisia and to pinpoint the contributing factors.

Methods: This study is a descriptive cross-sectional survey conducted among medical residents completing their training in various healthcare facilities in Tunisia. The study employed an online self-administered questionnaire and assessed burnout across three dimensions: personal burnout, professional burnout, and relational burnout, using the Copenhagen Burnout Inventory (CBI).

Results: A total of 50 physicians took part in the survey. Among them, 72% were female, 80% were single, and the average age at the time of the study was 27.72 years. Concerning their professional status, 84% worked in university hospitals, 16% specialized in surgery, 40% specialized in medicine, and 44% were family physicians. The majority were students from the Faculty of Medicine in Sfax (56%), with 30% in Monastir, 8% in Tunis, and 6% in Sousse. Regarding their work hours, more than 40 hours per week were reported by 32% of participants. According to the CBI scale, 12% of participants had scores indicating severe personal burnout, while 20% had scores indicating moderate personal burnout. Additionally, 16% reported severe professional burnout, and 12% had scores suggesting severe relational burnout. In contrast, only 8% had scores indicating moderate relational burnout. The socio-demographic and professional factors that were studied, such as weekly working hours, monthly shifts, specialty, and workplace, did

not show a significant correlation with the presence of burnout syndrome.

Conclusions: Burnout syndrome among medical resident physicians not only impacts their physical and mental well-being but also reduces their effectiveness and motivation at work. It is essential to introduce stress management strategies within hospitals to foster a healthier work-life balance.

Women's Attitude Toward Fertility And Childbearing in Saudi Arabia

A. A. Aloraini¹, R. A. Alamri¹, D. S. Alassaf^{1*}, E. Alenzi¹, D. A. Alateeq¹, N. I. Almutlaq¹, R. H. jahhaf¹, A. A. Almajhad¹ and S. S. Aloglla¹

¹College of Medicine, Princess Nourah bint Abdulrahman, Riyadh, Saudi Arabia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1733

Introduction: The decline in fertility is one of the major problems worldwide that could affect family structure. Many studies have been conducted to assess attitudes toward fertility and childbearing around the world, but there's a lack of research about that in Saudi Arabia (SA). The study aims to assess women's attitudes toward fertility and childbearing in SA and to investigate its association with sociodemographic, medical, and psychological factors.

Objectives: Aim of the Study: The purpose of the study is to assess women's attitudes toward fertility and childbearing in Saudi Arabia and to investigate its association with sociodemographic, medical and psychological variables.

Specific Objectives:

1. To assess women's attitudes toward fertility and childbearing in Saudi Arabia.
2. To investigate association between attitudes toward childbearing with sociodemographic characteristics in Saudi Arabia.
3. To investigate association between attitudes toward childbearing with medical and psychiatric history in Saudi Arabia.
4. To investigate association between attitudes toward childbearing with the childbearing preferences in Saudi Arabia.

Methods: This cross-sectional study of a convenient sample of 2172 women in SA in Dec 2022 and Jan 2023. Data were collected through a survey link that contains: 1) Sociodemographic data, 2) medical and psychiatric history, 3) childbearing preference and 4) the Arabic version of the Attitudes toward Fertility and Childbearing Scale (AFCS). Data were analyzed by SPSS 25 ; We described the variables in means \pm SD or percentage as appropriate. Student's t-test and ANOVA were performed to analyze differences between the components and background characteristics.

Results: Individuals in the age group of 18-25 years (25.54 ± 9.08 , $p < 0.001$), unmarried (25.23 ± 8.87 , $p < 0.001$), and diagnosed with a psychiatric disorder (24.76 ± 9.51 , $p < 0.002$) scored lower in importance of future of childbearing. In terms of hindrance at present and childbearing preparation, individuals in the age group of 18-25 years (25.66 ± 8.66 , $p < 0.001$) (18.53 ± 5.08 , $p < 0.001$) respectively,

unmarried (25.71 ± 8.58 , $p < 0.001$) (18.46 ± 5.08 , $p < 0.001$) respectively, and students (25.92 ± 8.82 , $p < 0.001$) (18.55 ± 5.15 , $p = 0.001$) respectively were more likely to score high. Participants who had not made a decision about having children (9.36 ± 3.32 , $p < 0.001$) scored lower in the female identity domain.

Conclusions: In conclusion, the findings of this study indicate that the younger age group (18-25 years) and those with psychiatric illnesses scored lower in the importance for future of childbearing compared to women of older age group (36-49 years) and those without psychiatric illnesses. On the other hand, college students showed more concerns related to childbearing hindrance and preparation.

doi: 10.1192/j.eurpsy.2024.1734

Introduction: Neuropsychiatric disorders are the leading cause of disability worldwide, as seen in cases such as depression, anxiety, bipolar mood disorder and schizophrenia, which can be developed or exacerbated by the use of psychoactive substances. Most mental disorders have an early onset, often leading to early and/or permanent disability, increasing the need and cost of healthcare. Therefore, it is necessary to improve the identification of the epidemiological profile of these cases in the South of Brazil in order to enhance the diagnosis and reduce the costs associated with managing these disorders.

Objectives: The present study aimed to analyze statistical data regarding hospitalizations related to mental disorders caused by the use of psychoactive substances and alcohol in the southern region of Brazil, highlighting the pathological scenario and identifying the most prevalent profiles of these disorders in this region.

Methods: A cross-sectional, descriptive, retrospective, and quantitative study was conducted on hospitalizations of individuals diagnosed with mental and behavioral disorders due to the use of psychoactive substances and alcohol in the states of the Southern region of Brazil (Paraná, Santa Catarina, and Rio Grande do Sul)

between February 2020 and December 2022. Data of January 2020 were not available. The data used were collected through the Department of Health Informatics of the Brazilian Unified Health System (DATASUS) in the "Hospital Information System of SUS" section, gathering information regarding the nature of the care, age range, gender, and ethnicity of the patients.

Results: The study covers the years 2020 to 2022, indicating a total of 81,608 hospitalizations, with the year 2022 having the highest number of cases ($\approx 37.13\%$), followed by 2021 ($\approx 33.30\%$) and 2020 ($\approx 29.55\%$). The states with the highest number of hospitalizations were Rio Grande do Sul ($\approx 54.90\%$), Paraná ($\approx 29.29\%$), and Santa Catarina ($\approx 15.79\%$). Urgent hospitalizations accounted for $\approx 87.29\%$ of the total. The most affected age group was 30 to 39 years old ($\approx 25.61\%$). Men were more affected than women ($\approx 81.70\%$ and $\approx 18.28\%$, respectively). Caucasians accounted for $\approx 64.29\%$ of the hospitalizations. The average length of stay was 20.8 days, and the mortality rate was 0.32%.

Conclusions: There is a clear increase in the number of hospitalizations related to mental disorders caused by the use of psychoactive substances in the period from 2020 to 2022 in the southern region of Brazil, with the highest number of cases in the state of Rio Grande do Sul. The most affected population consisted of Caucasian men aged 30 to 39 years old. Furthermore, these results may be related to the increasing trend of psychoactive substance use among the Brazilian population and also the COVID-19 pandemic, which led to a period of underreporting due to social isolation.

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1735

Introduction: The Choice giving birth by cesarean section when it is not biologically necessary implies a greater risk to the health of the mother and child Toral *et al.* *Eletrônica Estácio Saúde* 2018; 95 (1) 27-30, refers the psychological relevance to identify perinatal effects of a good medical practice at birth. In this respect Poojari *et al.* *Early Hum Dev* 2019;115 93-98, state that a cesarean section as a surgical risk, causes decrease fetal oxygenation and an impairment release of stress-related hormones in the maternal-fetal binomial that does not favor neural connections at birth

Objectives: Identify the neurodevelopmental lags in infant on children under 24 months of age born by cesarean section and vaginal delivery,

Methods: A cross-sectional descriptive correlational; Sample consisted of 100 children of a term gestation, 70 with spontaneous vaginal birth and 30 whose birth was by cesarean section, aged between one and twenty-four months; using the Abbreviated Development Scale, an instrument created and validated for the Colombian population (Cronbach's alpha, 0.94). All parents signed the informed consent.

Results: All test scales were applied (gross and fine motor, language and social personal), the results showed that children born by cesarean section had better development in areas of fine motor and language, while children born by vaginal delivery had better development of gross motor. See (graphic 1).

Graphic 1: Areas of development according to the type of delivery.

Emotional burnout in psychiatrists during the war: experience of Ukraine

N. O. Maruta^{1*}, V. D. Mishiev², T. I. Levin², H. A. Prib³ and A. R. Markov³

¹Institute of Neurology, Psychiatry and Narcology of the NAMS of Ukraine" SI, Kharkiv; ²P.L. Shupyk National University of the Health Care of Ukraine and ³Academy of Labour, Social Relations and Tourism, Kyiv, Ukraine

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1736

Introduction: Psychiatrists being one of the significant groups associated with one of the highest risks of emotional burnout (EB). The risks of EB increase significantly in the conditions of war, which places increased demands on their physical, mental and psychological resources, and determines the relevance and necessity of studying the predictors, clinical phenomenology, psychological and psychopathological mechanisms of EB, and necessitates the development of innovative approaches to its corrections.

Objectives: The study the features of EB among psychiatrists in war period.

Methods: The examination included the usage of clinical-psychopathological, psychodiagnostic and psychometric research methods.

Results: The study sample consisted of 120 psychiatrists who worked in Kyiv in the period from February 24, 2022, during 2022. 69.2 of psychiatrists working in Kyiv during the war have manifestations of EB of varying intensity and clinical variability. All of them have signs of professional maladaptation (PM), deterioration of well-being, somatovegetative and dyssomnia disorders, deformation of social ties and decrease in motivation to work. In 47.5%, the formation of symptoms of tension, resistance and exhaustion are observed, 21.7% have clinically complicated and formed all manifestations of EB and PM.

The leading diagnostic and prognostic marker of EB is PM, the manifestations of which are the first consequence of the imbalance of the processes of performing professional duties and internal resources, which will ensure their optimal implementation.

A mathematical model of the development and forecast of PM, as a leading descriptor of EB, was developed, which considers the state of socio-demographic characteristics (age, work experience, and the total quality of life indicator), affective indicators (objective and subjective manifestations of depression and anxiety) and psychosocial features (social-psychological adaptation). The use of this model makes it possible to determine 4 risk groups for the development of PM (low, moderate, high, very high), based on which personalized approaches to the diagnosis, therapy and prevention of EB among psychiatrists during the war have been developed.

Conclusions: The implementation and further evaluation of these approaches proved their effectiveness in eliminating the manifestations of EB and PM, normalizing the mental state with the levelling of psychopathological symptoms, improving the socio-psychological adaptation and quality of life of psychiatrists.

EPP0541

"Emotional Intelligence, Psychological Distress, and Conflict Resolution Among Healthcare Professionals"

M. Theodoratou^{1*} and A. Papadopoulos¹

¹Social Sciences, Hellenic Open University, Patras, Greece

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.1737

Introduction: Emotional Intelligence (EI) plays a substantial role in shaping the behavior, overall well-being, and performance of individuals. In the context of healthcare, where professionals frequently confront a demanding work environment, there is a notable prevalence of high Psychological Distress (PD). Consequently, conflicts are a recurrent phenomenon within healthcare settings, exerting impacts on healthcare professionals, patients, and their families.

Objectives: Aims:

1. Investigate the link between Emotional Intelligence (EI) and conflict management among healthcare professionals.
2. Examine how Psychological Distress (PD) relates to conflict management in healthcare.
3. Explore age, specialization, and experience's influence on EI dimensions.
4. Analyze EI's impact on healthcare professionals' conflict resolution choices.
5. Assess how demographics affect conflict resolution preferences among healthcare workers.

These aims explore EI, PD, demographics, and conflict management in healthcare, informing skill enhancement and improved conflict resolution practices.

Methods: This study involved 143 healthcare professionals from diverse regions of Greece. Electronic surveys gathered demographic data and assessed Emotional Intelligence (via a dedicated questionnaire), Psychological Distress (using the Kessler K6+ questionnaire), and Conflict Resolution strategies.

Results: The majority of participants were female (69.2%), with 42.7% aged 46-55 and 30.8% aged 36-45. Age was significantly associated with “Self-awareness” ($P=0.032$) and “Social Skills” ($P=0.009$ and 0.007) within Emotional Intelligence dimensions. Negative correlations emerged between Psychological Distress and Emotional Intelligence dimensions (-0.46 to -0.19). Additionally, Psychological Distress showed negative correlations with several Conflict Resolution dimensions: ‘Atmosphere’ (-0.20), ‘Doables’ (-0.28), ‘Mutual Benefit Agreements’ (-0.18), ‘Needs’

(-0.23), and ‘Extra Considerations’ (-0.27). Participants below 35 had higher scores in “Power” ($p=0.002$), while those aged 46 and above scored higher in “Options” ($p=0.002$ and 0.009) for conflict resolution.

Conclusions: In summary, this study underscores EI’s relevance in healthcare, especially its influence on PD and conflict resolution. Developing EI competencies offers promise for improving healthcare professionals’ emotional well-being and conflict-handling abilities, ultimately benefiting patient care and staff satisfaction. Further research and tailored interventions are warranted to advance this field at an academic level.
