EUROPEAN PSYCHIATRIC ASSOCIATION

Led by Stirling Moorey

Introduction to Cognitive Behavioural Therapy

This course will allow you to understand the varieties of Cognitive Behaviour Therapy (CBT), their evolution, the application of CBT to various disorders, its key clinical features and the place of this important therapy in psychiatry today.

Led by Guy Undrill

Introduction to Motivational Interviewing

A unique opportunity to learn more about the spirit of Motivational Interviewing, the crucial relational foundation, the key techniques and how to use the techniques to steer consultations in the direction of positive change.

Led by Allan Young & Roland Zahn

Understanding and Treating Major Depressive Disorder

The topics range from epidemiology and pathophysiology to affective neuroscience and treatment paradigms. Led by world leading clinician scientists, this introduction to clinical depression is a must see for all those who seek to understand clinical depression better.

The role of Europe in Global Psychiatry

P. Falkai

Psychiatry, University of Munich, Munich, Germany

doi: 10.1192/j.eurpsy.2024.28

Abstract: The burden of mental illness in Europe: High individual and societal burden, but only 2% spent on mental health. The tradition of European Psychiatry needs to be strengthened in care, research and teaching. Within the long-term Strategic Mental Health Plan of the EPA the improvement of clinical care research, the “mapping excellence” and “developing core treatment guidelines” require further action. Researching the influence of environmental stressors on the development and maintenance of mental illness and fostering stepped care approaches to improve resilience are none the less important. Furthermore, to improve the reliability and especially validity of diagnoses of mental disorders by introducing (bio)markers and defining dimensions of mental illnesses using big data and predictive sciences are just as important as an enforced research on reducing stigma and discrimination of mental disorders.

The impact of climate change on mental health

A. Heinz

Department of Psychiatry and Psychotherapy, Charité - Universitätsmedizin Berlin, Berlin, Germany

doi: 10.1192/j.eurpsy.2024.29

Abstract: Climate change has a profound impact on mental health, supported by meta analytic evidence. For every degree temperature increase, there is a statistical increase in mental health problems by about 0.9%. The direct association between catastrophic events such as hurricanes or flooding and traumatization or negative mood states is evident. However, there are also interactions between pollution or heat islands in urban contexts and stress associated mental disorders, and there are indirect interactions e.g. between loss of agricultural space, poverty, displacement and mental health challenges. We provide an overview regarding direct and indirect effects of climate change on mental health and discuss possible interventions on the health care system.

The Experience sampling method in psychiatry: a state-of-the-art lecture

I. Myin Germeys

Dept of Neurosciences, KU Leuven, Leuven, Belgium

doi: 10.1192/j.eurpsy.2024.30

Abstract: Psychiatric problems occur in people's normal daily life, in a dynamic interaction with the context people are in. Yet, we have very few techniques to assess this dynamical nature of symptoms, nor do we have good insights in how people actually function in their ordinary life. Ambulatory assessment techniques such as Experience Sampling Methodology (ESM) or Ecological Momentary Assessment (EMA) have been proposed as a potential clinical tool to bridge this gap. Yet, very few of these techniques have actually made it to the clinic. In my talk, I will discuss the strengths and limitations of using these digital diary techniques to open up someone's real life in clinical practice. I will discuss qualitative research identifying barriers and facilitators, identified by patients and clinicians. I also will discuss what is needed in terms of technology and data security, by demonstrating the MoMent app and MoMent Dashboard, that has been developed within the H2020 IMMERSE project. Finally, I will discuss how these digital mental health tools could help in developing a much more fine-grained understanding of how psychopathology emerges in the realm of ordinary life, making patients active partners in the clinical process.

DB0001**Suicide prevention: Precision suicidology is needed**

P. Courtet

University of Montpellier, Montpellier, France

doi: 10.1192/j.eurpsy.2024.31

Abstract: Suicidal behavior is a public health challenge that resists the various efforts made toward its prevention and treatment. Indeed, suicide rate have not significantly changed in the past decades. Then one may wonder if precision psychiatry could be the solution?

Advances towards precision suicidology will be detailed from detection to opportunities for treatment.

First, current suicide risk assessment methods are unable to detect suicidal risk with sufficient accuracy and while thousand of risk factors for suicide have been identified, they are no more accurate in predicting suicidal behavior than flipping a coin. Second, we are lacking specific and effective evidence based strategies for suicide prevention.

The aim of precision psychiatry is tailoring efficient preventive and therapeutic approaches to the unique characteristics of each patient. It assumes that the determination of a reliable medical diagnosis is unfeasible if based on symptomology alone and it must integrate genomics data, clinical dimensions, biomarkers, and environmental and lifestyle factors and this amount of data analysed by artificial intelligence would give us “biosignatures” that would yield a more appropriate diagnosis, treatment and prognosis.

We will cover advances in genomics, imaging, inflammatory markers and digital health that witness the realistic possibility to change the field of suicide prevention.

Best of 2023 in psychosomatic medicine: the contribution to the rest of psychiatry

S. Ferrari

University of Modena & Reggio Emilia, Modena, Italy

doi: 10.1192/j.eurpsy.2024.32

Abstract: The field of psychosomatics has experienced many waves of “celebrity” since its origin. Its historical origin is impossible to precisely locate in time, one may argue that medicine since its very beginning has been psychosomatic in nature. In very recent times, many clinicians and researchers even from different backgrounds than psychosomatic medicine or psychiatry have expressed disappointment and worry about the excessive fragmentation of medical sciences, providing evidence in support and advocating towards the so-called holistic approach and integrated care. The old lesson of psychosomatic medicine, then, appears more contemporary than ever. This is also because it has been able to stay coherent but at the same time integrate the enormous progresses in the understanding of physiology and pathophysiology that medical sciences have witnessed in the last decades.

The presentation will focus on the most striking scientific production of 2023 in the field of psychosomatics, to show the contributions in its three souls of research, training and clinical activities and to outline the stimulating though sometimes difficult dialogue between this area of behavioural sciences and the rest of psychiatry.

BO20230002

Special Session Best of 2023: Care of the elderly

R. Perneczky

Department of Psychiatry and Psychotherapy, LMU Hospital, LMU Munich, Munich, Germany

doi: 10.1192/j.eurpsy.2024.33

Abstract: In the field of Alzheimer’s disease disease-modifying therapy, there has been a shift in diagnosis from the later dementia stages towards the earlier stages, with the potential for pre-symptomatic diagnosis. The development of truly ‘disease-modifying’ therapies that target the underlying mechanisms of Alzheimer’s disease has reached late stages of human clinical trials. The primary targets include beta-amyloid, whose presence and accumulation in the brain is thought to contribute to the development of Alzheimer’s disease, and tau protein which, when hyperphosphorylated, results in the self-assembly of tangles of paired helical filaments also believed to be involved in the pathogenesis of Alzheimer’s disease. Therapeutic strategies aimed at preventing A β formation, blocking its aggregation into plaques, lowering its soluble levels in the brain, and disassembling existing amyloid plaques are among the main strategies employed to slow the progression of AD. First anti-amyloid antibody treatments have proven effective in late-stage clinical trials and are now being approved for clinical use in some countries, initiating a new era of treatment. In terms of blood-based early diagnosis, the development of in vivo biomarkers has shifted the diagnosis of Alzheimer’s disease from the later dementia stages of disease towards the earlier stages and has introduced the potential for pre-symptomatic diagnosis. Recent study shows promising results for blood tests that could be used to identify Alzheimer’s changes in the brain before the onset of any symptoms, which could result in preventative treatments being used before any memory loss. This presentation will highlight the most exciting development of the past year in the Alzheimer’s disease therapy and diagnosis arena.

Dysregulated metabolic sensing of appetite in anorexia nervosa: implications of LEAP-2 regulation

C. Tezenas Du Montcel^{1,2*}

¹Genetic and epigenetic vulnerabilities to addictive and psychiatric disorder, Inserm UMR 1266 and ²Cliniques des Maladies mentales et de l'Encéphale, GHU Paris Psychiatrie et Neurosciences, Paris, France

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.34

Abstract: Growing interests on the role of metabolic sensors in anorexia nervosa led to implicate metabolic sensing as consequences of anorectic sensing but also in the perpetuation of the disorder. Ghrelin is an orexigenic peptide secreted by the fundic cells of the stomach in situation of fasting and known to initiate food intake through its activity on hypothalamic and motivation aspect of food intake. A body of evidence previously showed that patients suffering from anorexia nervosa display high plasma levels of ghrelin correlated with the nutritional status but this orexigenic signal do not seem to modify restrictive behavior. LEAP-2 (Liver Expressed Antimicrobial Peptide 2) is a recently discovered endogenous ghrelin antagonist, increased during overnutrition and that decreases food intake in humans and animals.

We explored changes of ghrelin and LEAP-2 in a longitudinal cohort of 30 patients suffering from anorexia nervosa during a 4 months refeeding program. We show abnormal regulation of LEAP-2 in patients with higher levels in acute stages that decrease with refeeding. This abnormal regulation was associated with early relapse in patients. This abnormal regulation could counteract with the orexigenic signal of ghrelin in patients.

We discuss these results in light with recent evidence on the consequences of LEAP-2 increase of food intake and hedonic feeding relevant in understanding anorexia nervosa.

Potential Neurobiological and clinical markers in Extreme Weight Conditions: from Anorexia to Obesity

F. Fernandez-Aranda^{1,2,3*}, S. Jimenez- Murcia^{1,2,3} and Psychoneurobiology of Eating and Addictive Behaviours Group, Neuroscience Program, IDIBELL

¹Clinical Psychology, University Hospital of Bellvitge-IDIBELL; ²CIBERObn, Instituto Salud Carlos III and ³Clinical Sciences, University of Barcelona, Barcelona, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.35

Abstract: Extreme eating and weight conditions (EWC) are a construct that emerges as a dimensional and theoretical model that identifies individuals who exhibit inappropriate eating behaviours and abrupt weight fluctuations. According to this spectrum of

EWC, one extreme can be represented by individuals with anorexia nervosa (AN), characterised by excessive food restriction and an extremely low body mass index (BMI), whereas the other end of this continuum is represented by individuals with obesity (OB), characterised by a BMI above 30. In addition to AN and OB, some eating disorders (EDs), namely bulimia nervosa and binge eating disorder, are also part of this continuum, given the high risk of falling into one of the extremes, especially that of higher BMI. Studies have described similar changes at the psychological and neurobiological levels associated with their abnormal eating patterns, delineating vulnerability pathways related to the neurobiological basis.

Based on previous literature, individuals suffering from EWC would show dysfunctional brain activity in regions associated with emotional reward processing and cognitive control compared to healthy controls (HC). Similarly, neuroendocrine alterations in EWC are expected to influence clinical symptomatology. It will also be discussed how impairments in executive function and differential brain activity observed in individuals with EWC may negatively impact their clinical course and treatment outcome.

(Ir)reversibility of structural and functional brain alterations in severe anorexia

L.-K. Kaufmann

Radboud University, Donders Institute for Brain, Cognition and Behaviour, Nijmegen, Netherlands

doi: 10.1192/j.eurpsy.2024.36

Abstract: Anorexia nervosa is characterized by profound structural and functional brain alterations, particularly during the phase of acute underweight. Understanding the reversibility of these changes upon weight normalization is an important question in the pursuit of recovery and relapse prevention. This talk shares findings from recent neuroimaging studies, focussing on the dynamic processes of brain recovery observed during and after inpatient treatment in individuals with severe anorexia nervosa.

The problem of treatment gap in alcohol use disorder (AUD)J. G. Bramness^{1,2*}¹Dep. of drug research, Oslo University Hospital, Oslo and ²Psychiatry, UiT The Arctic University of Norway, Tromsø, Norway

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.37

Abstract: Alcohol use and alcohol use disorder (AUD) is related to numerous somatic and psychiatric disorders resulting in a high contribution to global burden of disease and premature death. The need to identify and treat alcohol use disorder is high. Yet there is a large treatment gap. Too few people with AUD are recognized and are being offered treatment. In some countries well under 10 percent of those with a treatable AUD are ever offered treatment. Furthermore, there is a dearth of effective treatments and relapse rates remain high. This symposium will address some topics that may change this situation.

Disclosure of Interest: None Declared

JS0005

Sodium oxybate – new views on an old candidate This presentation will outline the outcome of a clinical development program, including a Phase 3 study, on sodium oxybate in the treatment of alcohol dependenceJ. Guiraud^{1,2*}¹Department of Psychiatry, Amsterdam UMC, University of Amsterdam, Amsterdam, Netherlands and ²Vergio, Paris, France

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.38

Abstract: Sodium oxybate (SMO) has shown efficacy in the treatment of alcohol withdrawal syndrome (AWS) and in the maintenance of abstinence in alcohol dependent (AD) patients in a series of pilot randomized controlled trials. SMO is marketed in these indications in Italy and Austria since 1991 and 1999, respectively. To expand access to SMO for the treatment of AD in other EU countries and since regulatory standards have evolved, a clinical development and research project in accordance with regulatory guidelines has been initiated in the maintenance of abstinence to further support the already available data. Phase 2 and 3 studies in AD patients were conducted. Results of this development program showed efficacy of SMO in the maintenance of abstinence in AD patients. Since heterogeneity of SMO treatment effect between studies was identified, various analyses explored the potential moderators of SMO efficacy. SMO efficacy was larger in high-severity AD population and with longer treatment duration. SMO was well tolerated both in regular clinical use and in clinical trials.

Training curriculum psychiatry: an European perspective

A. Szulc

Department of Psychiatry, Medical University of Warsaw, Warsaw, Poland

doi: 10.1192/j.eurpsy.2024.39

Abstract: Training in psychiatry varies greatly from country to country in Europe - there are differences in the duration of training, the content of training, etc. Different perspectives on training will be presented, especially as far as common features are concerned. We will also present proposals and directions leading to a common European curriculum in psychiatry. Further work is needed in the direction of developing a European curriculum and organizing a European exam in psychiatry.

The perspective of psychiatric nurses by the European Psychiatric Nurses (Horatio)

N. Kilkku*

European Psychiatric Nurses (Horatio) and European Psychiatric Nurses (Horatio)

Faculty of Health Sciences, VID Specialized University, Oslo, Norway

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.40

Abstract: In the health care system, nurses are often the biggest professional group and therefore their role is important in the development of service system to meet the current needs of support and help in mental health. Novel solutions are needed, solutions which are not only developed between the professionals, but in collaboration with the people seeking for help, family members, other social networks, and different service providers, like NGOs. Human rights and community-based approaches are guiding this development together with the principles of recovery approach. At the same time there are challenges to overcome, like the shortage of professionals, which also demand new kind of collaboration and solutions to make the field of mental health attractive for future professionals and to support the retention of those who are working in practice at the moment. In the joint symposium the viewpoint of mental health/psychiatric nurses on these issues will be presented.

JS0008

Mental health in challenging times: Psychological perspectives for practitioners and society

C. Steinebach

EFPA, Brussels, Belgium

doi: 10.1192/j.eurpsy.2024.41

Abstract: In general, resilience is a process in which the interplay of risk and protective factors of the system itself and its environment is balanced in such a way that positive development opportunities open up. The resilience of a person, a system and a profession is therefore reflected in the ability to shape conditions in such a way that positive coping with challenges and crises is possible as a basis for positive further development. The time of the pandemic and the war in Ukraine has led to a large number of adjustments to psychology as a science, as a profession and as a perspective on life. This is associated with opportunities for positive further development of the discipline. European psychology has so far mastered the challenge of the pandemic and the war in Ukraine very well. The task now is to harness its successes as a multifunctional hub for other sciences, professions and society as a whole. The aim is to develop an identity that strengthens the unity of psychology in its diversity. With wisdom and resilience, psychology is also increasingly facing up to the challenges expressed in the United Nations Sustainable Development Goals (UN SDGs). In the discussion of social and professional change, the possibilities for a joint positive development of all professions in these stressful times become clear.

Community mental health services in Europe: the state of art

M. Rojnic Kuzman

Zagreb University Hospital Centre and the Zagreb School of Medicine, Zagreb, Croatia

doi: 10.1192/j.eurpsy.2024.42

Abstract: In Europe there is significant variability of attitudes, procedure and strategies in clinical care between psychiatrists and settings across different regions and countries. However, there is a significant overrepresentation of data from mental health services from Western and Northern European countries, due a lack of data from Eastern and Central European countries as it has been suggested the Eastern and Central European regions are a “blind spot on the global mental health map”. In respect to community mental health services, Northern and Western countries introduced a large array of multidisciplinary community-based services for people with mental health problems and reorganized the mental health care services towards the community mental health care, replacing largely large hospitals and hospital-based care following recovery-oriented care models with introduction of numerous services which supported full recovery, including supported employment and housing. This process is only in the beginning in the majority of countries in the South and East of Europe. Here we present the data from these countries including the results of the RECOVER-E study (Large-scale implementation of community based mental health care for people with severe and enduring mental ill health in Europe), which incorporated the implementation of community mental health services in five South-eastern European countries.

CRS0002

Opportunities and challenges of community mental health centers in Türkiye

E. Mutlu

Hacettepe University, Ankara, Türkiye

doi: 10.1192/j.eurpsy.2024.43

Abstract: In 2011, Türkiye restructured the mental health care system in community-based settings following the announcement of the National Mental Health Action Plan. Community mental health centers (CMHCs) are the major element of this approach. As of now, the total number of CMHC have reached 186, and the service users have almost reached 100.000.

Mental health care system gained significant advantages through CMHCs, such as 1) improvement in the conditions of mental health services, 2) better follow-up of patients with chronic severe mental disorders, 3) capability of in-home services, 4) decrease in the number of hospitalizations, 5) increased social involvement of patients with severe mental disorder. CMHCs also played a significant role in promoting social rehabilitation, including employment status, development of social relationships, and redress of stigmatization. All these advantages were put into practice by community mental health teams comprising a psychiatrist, psychologists, nurses, social workers and ergotherapists, if available.

Community mental health centers come with severe challenges and shortcomings despite their ameliorations. First, CMHCs need trained mental health professionals. However, only 52% of the CMHC teams completed the CMHC trainings currently. Second, standardized work flow algorithms should be developed for CMHCs. Third, there should be a strong relationship between CMHCs, primary health care system and inpatient units as a complementary part of essential mental health care. In addition, hospital administration should be trained in terms of CMHC policy since every CMHC is affiliated with a state hospital. For instance, the ongoing issue of defining quality standards for CMHCs contributes to a misconception, portraying these centers as profit-making units rather than dedicated rehabilitation facilities.

In conclusion, community-based settings and CMHCs significantly advance mental health services despite the challenges confronted in practice. To optimize the effectiveness of community mental health care facilitated by CMHCs, it is imperative to review the implementation process with the active involvement and support of non-governmental organizations, including patient-driven organizations and national psychiatric associations.

CRS0003

Microdosing psychedelics in the treatment of ADHD and comorbid disorders

K. P. Kuypers

Neuropsychology and Psychopharmacology, Maastricht University, Maastricht, Netherlands

doi: 10.1192/j.eurpsy.2024.44

Abstract: Microdosing psychedelics has garnered considerable attention within both nonprofessional circles and the scientific community in recent years. This method involves taking small, non-hallucinogenic doses of substances like LSD or psilocybin over weeks or months, purportedly to enhance specific behaviors, emotions, or address psychiatric conditions.

Exploring these assertions is crucial given the potential therapeutic value of microdosing, especially in conditions that respond positively to full psychedelic doses, such as depression. The full psychedelic experience might not always be suitable due to various factors like age, capacity to consent or comprehend the experience (e.g., dementia), or individual personality traits that might hinder surrendering to the experience. Microdosing could potentially serve as a maintenance therapy post-full dose administration, aiding specific psychological or biological processes during therapy or therapeutic exercises.

Recent studies in healthy individuals highlight that small psychedelic doses have nuanced effects on pain perception, mood, neuroplasticity, sleep duration, brain connectivity, and default mode network synchronicity. However, some parameters show null effects after both single and repeated administration.

Our survey research uncovered that individuals with ADHD reported symptom relief through microdosing, deeming it more effective than their conventional treatments. Subsequently, we conducted a naturalistic study following individuals with ADHD across a 4-week microdosing period. Our findings indicated a reduction in symptoms over time, an increase in trait mindfulness, and a decrease in neuroticism compared to baseline. While these results are intriguing, they necessitate validation in a clinical trial. We have recently concluded such a trial and are currently analyzing the data to further explore these effects.

Disclosure of Interest: K. Kuypers Grant / Research support from: The author is a principal investigator on a research project that is sponsored by Mindmed, a company that is developing psychedelic medicines.

CRS0004

Easy access to youth mental health services in the Netherlands

T. Van Amelsvoort

psychiatry& neuropsychology, maastricht university, maastricht, Netherlands

doi: 10.1192/j.eurpsy.2024.45

Abstract: Mental health problems have increased following the pandemic and are associated with considerable health, economic and societal outcomes, particularly affecting youth. In co-creation with young people several European prevention and early intervention strategies to promote mental wellbeing of youth are currently being developed. The development and implementation of easy-access youth mental services across Europe will be presented and discussed. In addition pilot data of online, hybrid treatment platforms and self-management ecological momentary intervention apps will be presented. Ultimately the aim is: 1) to develop clinical guidelines, best practices, and policy recommendations to

mitigate the youth mental health challenges and 2) improve (cost-) effectiveness of early intervention strategies for promotion and prevention in mental health, including enhancing mental health literacy, resilience and self-management, while 3) actively involving young people in the process of these innovative developments. To amplify the reach, campaigns designed in co-creation with young people, to increase awareness, literacy, wellbeing and help-seeking among young people, targeting schools, further-education colleges, universities and other specific settings will need to be developed, specifically paying attention to high-risk groups within this young population, including children of parents with mental disorders, migrants, young people growing up in poverty, those in/leaving care, and the LGBTQ+ community, with coordination across domains: schools, general practitioners, and specialized mental healthcare facilities.

Changes in brain structure and function in youth at familial risk for schizophrenia or bipolar disorder: implications for early intervention

G. Sugranyes^{1,2*} and BASYS Working Group

¹Department of Child and Adolescent Psychiatry and Psychology, Hospital Clinic Barcelona and ²Clinical and Experimental Neuroscience, FCRB-IDIBAPS, Barcelona, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.46

Abstract: The evaluation of child and adolescent offspring of patients with schizophrenia or bipolar disorder seeks to understand changes taking place in the brain in individuals at heightened risk for disease during a key developmental period. In this session I will present findings from the BASYS (Bipolar And Schizophrenia Young offspring Study) cohort, which has recruited young offspring of patients with schizophrenia or bipolar disorder ages 6 to 17 years, using clinical, cognitive and brain imaging measures for over 15 years in Spain. I will begin by reviewing our baseline and 2 year findings using structural magnetic resonance imaging (MRI) measures, where we found whole brain and regional cortical grey matter volume and surface area reductions, specifically in offspring of patients with schizophrenia relative to controls, but not in offspring of patients with bipolar disorder, which I will compare with results from the ENIGMA relatives working group analyses. Within our cohort I will explain the relevance of baseline brain structural findings to clinical and cognitive outcome over time. I will then present longitudinal analyses of structural and functional MRI measures at up to 8 year follow-up, examining the influence of development of psychotic spectrum symptoms over time and cognitive and functional outcomes, on longitudinal brain imaging measures. I will finish the talk explaining avenues for future research in the field, which include incorporating other imaging modalities and validating our findings in other cohorts, while I will also present avenues for increasing understanding of the neurobiological changes underpinning our MRI findings.

This project has received funding from Instituto de Salud Carlos III (PI151500467; PI1700741; PI1800696; PI1800976, PI2100330), Fundació Marató TV3 (091630, 202232-30-31), the Catalonia Government (2021SGR01319), PERIS (SLT006/17/00346), Fundació Clínic Recerca Biomèdica (Ajut a la Recerca Pons Bartran), co-financed by ERDF Funds from the European Commission and CIBERSAM.

Brain developmental trajectories in offspring of parents with schizophrenia or bipolar disorder

N. Van Haren

Child and adolescent psychiatry/psychology, Erasmus Medical Center, Rotterdam, Netherlands
doi: 10.1192/j.eurpsy.2024.47

Abstract: Early diagnosis and intervention are essential for managing and improving long-term outcomes of severe mental illness, highlighting the need for reliable early biomarkers. This longitudinal study explores whether the development of the brain during childhood and adolescence differs between offspring of parents with and without schizophrenia or bipolar disorder. Moreover, we will assess if the age-dependent change over time in brain volume, cortical thickness and surface, structural network indices, and cortical gyrification are related to the presence and severity of psychiatric symptoms and level of IQ.

We obtained 286 T1-weighted MRI scans of 184 offspring (aged 8–18 years at baseline) of at least one parent diagnosed with bipolar disorder (n=78) or schizophrenia (n=52) and offspring of parents without severe mental illness (n=54); 102 offspring underwent a follow-up scan (on average 3.9 years between scans).

Group comparisons and the associations with clinical and cognitive measures were analysed with linear mixed-effects models. To correct for multiple comparisons, we applied a Benjamini-Hochberg false discovery rate (FDR) correction ($q=0.05$).

A significant effect of age was found on most of the included brain features, with suggestive evidence for subtle deviations in trajectories in the cortical thickness, structural network indices but not in gyrification index, sulcal depth, length and width or surface area in offspring of parents with schizophrenia. Interestingly, these deviations in brain development in schizophrenia offspring remained significant after taking the presence of a diagnosis or level of IQ into account. These findings suggest the aberrant brain development in familial high-risk youngsters is associated with being at familial risk and not with (also) being at clinical high-risk.

Catalyst effect of human body odours in social anxiety treatment – a pilot study.

E. Vigna^{1*}, V. Carli¹ and

C. Cecchetto, E. Dal Bò and C. Gentili from the Department of General Psychology, University of Padova, Padova, Italy. E. Eliasson, G. Hadlaczky and D. Wasserman from the National Centre for Suicide Research and Prevention of Mental Ill-Health, Karolinska

¹National Centre for Suicide Research and Prevention of Mental Ill-Health, Karolinska Institutet, Solna, Sweden

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.48

Abstract: POTION is an EU funded project (No. 824153) within the Horizon2020 initiative that aims at understanding the nature of chemosignals in humans and their sphere of influence on social interaction. The emotional state of one person can be transmitted to another through volatile molecules contained, for example, in the sweat. These molecules, or chemosignals, are processed by the receiver who is not only able to identify the feelings of the sender but also to respond accordingly.

Within this project, we conducted a study with the aim of exploring the possible catalyst effects of body odour on social anxiety. We hypothesized that subjects exposed to human chemosignals, while undergoing mindfulness treatment, would show an enhanced reduction in anxiety symptoms in comparison to the control group (exposed to clean air).

To this aim, a study including 96 women aged between 18 and 35 years with symptoms of social anxiety was conducted. After recruitment, subjects were randomly allocated to one exposure group (happiness, fear or neutral human body odour or clean air) and followed a mindfulness intervention while being exposed to one of the odour or clean air. The same intervention was repeated twice, over two consecutive days. The main outcome was change in the State-Trait Anxiety Inventory (STAI) scores for which data was collected before and after treatment at each day. Mixed model analysis revealed significant changes in STAI scores in all groups during both days of trial. However, a greater decrease in anxiety symptoms was observed in subjects exposed to fear chemosignals during both days. A post-hoc comparison of the group exposed to clean air and the group exposed to fear chemosignals showed a trend level time x odour interaction during the second day of trial ($F(1,45)=3.74, p=0.07$).

In conclusion, our pilot study indicated a potential use of human body odours as a catalysts of social anxiety treatment. While the small sample size restricts the generalizability of our findings, the observed trends offer a promising foundation for future research.

Neurobiological markers of early stressful events in psychosis

M. Aas

Social, Genetic and Developmental Psychiatry Centre, Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom

doi: 10.1192/j.eurpsy.2024.49

Abstract: New data from the MRC funded project "Integrating psychological models with biological pathways in psychosis" will be presented. The overall objective of this project is to use both environmental and genetic data to understand the biological pathways in patients with schizophrenia and bipolar disorders. Specifically, to find out if polygenic risk and childhood adverse events increase the relative risk of mental illness above that of its individual case-control explained variance, and secondly, the effect of both polygenic risk and childhood adverse events on clinical characteristics and ageing processes. Both data from new unpublished systematic reviews and original data will be presented.

The link between early life stress and psycho-cardio-metabolic multi-morbidity: Findings from The EarlyCause Consortium

C. Cecil*

EarlyCause Consortium

Child and Adolescent Psychiatry, Erasmus MC, Rotterdam, Netherlands

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.50

Abstract: In this talk I will present new findings from EarlyCause, a European consortium which aims to better understand the link between early life stress and the development of psycho-cardiomatobolic (PCM) comorbidity across the lifespan, leveraging data from large-scale pediatric and adult population studies. I will discuss findings regarding the effect of (prenatal and postnatal) early life stress on PCM health outcomes and their comorbidity, potential moderating and mediating factors, as well as evidence for causality.

Childhood trauma in adult depressive and anxiety disorders: immuno-metabolic evidences in the NESDA cohort

Y. Milaneschi

Amsterdam UMC, Amsterdam, Netherlands

doi: 10.1192/j.eurpsy.2024.51

Abstract: Childhood trauma and depression are both associated with increased risk of metabolic disorders, but their joint effects and underlying mechanisms are not well understood. This talk will present recent findings from large-scale epidemiological and biobank studies that explore the metabolic signature of childhood trauma, depression, and their interplay. For example, using longitudinal data from the NESDA cohort, we investigated the association of childhood trauma with metabolic syndrome in ~3000 adults, including patients with depression and/or anxiety and healthy controls, over 9 years of follow-up. The talk will also describe preliminary results from an individual patient data meta-analysis pooling >160,000 subjects from the Early Cause European Consortium. In this study, we examined the differences in markers of obesity and dyslipidemia across individuals with neither childhood trauma nor depression (controls), those with childhood maltreatment, those with depression, those reporting both of these conditions. The findings described in the talk shed light on the complex interplay between early life stress, mood disorders, and metabolic health.

Brain imaging studies in Internet Gaming Disorder (IGD) and problematic social network site use

A. Weinstein

Psychology, Ariel University, Ariel, Israel

doi: 10.1192/j.eurpsy.2024.52

Abstract: Gaming disorder is characterized by ICD 11 as persistent or recurrent gaming behavior manifested by impaired control over gaming, increasing priority given to gaming over other life interests and daily activities; and continuation or escalation of gaming despite the occurrence of negative consequences. IGD shares to a large extent neurobiological alterations seen in other addictions, such as activation in brain regions associated with reward, reduced activity in impulse control areas and impaired decision-making; and reduced functional connectivity in brain networks that are involved in cognitive control, executive function, motivation and reward. Moreover, there were structural changes, mainly reduction in gray matter volume and white matter density. Comorbidity studies indicate that executive control networks in ADHD may increase the susceptibility to develop IGD. Problematic SNS use has been associated with an increased rate of depression, anxiety, stress, obsessive-compulsive disorder (OCD), attention-deficit/hyperactivity disorder (ADHD), and propensity to excessive alcohol use. It may also lead to vulnerability to aggression, cyberbullying and fear of missing out (FOMO). There is little evidence for cognitive impairments, but there is some preliminary event-related potentials (ERPs) evidence for inefficiency in allocating and monitoring resources and inhibitory control. There is evidence for reduced sleep quality and quantity, longer sleeping latency and more sleep disturbance. Brain imaging studies showed impaired inhibitory-control mechanism, reduced gray matter volumes in the nucleus accumbens, amygdala, and the insula, suggesting rewarding effects of SNS use on the brain.

SP0006

Predictors of Adherence and Response to Exercise Interventions in Schizophrenia

L. Röll

Psychiatry and Psychotherapy, LMU Hospital, Munich, Germany
doi: 10.1192/j.eurpsy.2024.53

Abstract: Exercise can be considered a feasible and efficient add-on treatment in schizophrenia. However, there remain two major challenges with regard to feasibility and efficiency: First, drop-out rates during exercise programs appear to be relatively high, ranging between 30 to 80 percent. Second, only between 30 and 50 percent of patients clinically respond to exercise interventions. Hence, we aimed to identify factors that predict adherence and response to exercise programs in people with schizophrenia. Based on data from 180 patients with schizophrenia enrolled in the Enhancing Schizophrenia Prevention and Recovery through Innovative Treatments (ESPRIT) C3 study, we examined clinical baseline characteristics that may predict study completion and number of attended trainings (adherence), as well as clinically relevant improvements in symptomatology and functioning (response). We found that only levels of functioning at baseline, but not symptom severity, cognitive functioning, or physical health, predicted adherence. Further, we provide preliminary evidence suggesting that patients with higher cognitive abilities and higher education who performed regular exercise already prior to the study participation were more likely to respond. To conclude, our findings indicate that exercise is particularly helpful for a subgroup of patients characterized by higher levels of functioning, higher cognitive abilities and education, and more pronounced affinity to exercise. Future studies should additionally include environmental, genetic, and neural data to predict adherence and response to exercise.

Telepsychiatry as catalysts for equitable Mental Health Care in Intellectual Disabilities

K. Krysta

Department of Rehabilitation Psychiatry, Medical University of Silesia, Katowice, Poland
doi: 10.1192/j.eurpsy.2024.54

Abstract: Telepsychiatry has emerged as a transformative force in the field of mental health care, addressing disparities in service delivery and increasing access to care. This exploration focuses on the role of telepsychiatry in achieving equitable mental health care for individuals with intellectual disabilities (ID). Intellectual disabilities affect millions globally, posing significant public health challenges. This vulnerable population encounters numerous barriers in accessing quality mental health care, including geographical isolation, limited transportation options, and a shortage of specialized providers. Telepsychiatry offers a promising solution,

leveraging technology to overcome these challenges. The presentation reviews the current landscape of mental health care for individuals with intellectual disabilities and the specific barriers they encounter. It highlights the potential benefits of telepsychiatry, including increased availability of specialized care, reduced geographical barriers, and enhanced caregiver support. Ethical considerations and best practices associated with implementing telepsychiatry in the context of intellectual disabilities are discussed. Case studies and success stories illustrate how telepsychiatry positively impacts individuals with intellectual disabilities and their families. In conclusion, telepsychiatry plays a promising role in promoting equitable mental health care for individuals with intellectual disabilities. Embracing technology and adopting best practices pave the way for a more inclusive and accessible mental health care system, leaving no one behind.

Teleassistance Telerehabilitation Services for urgent mental health needs of people with Intellectual and Developmental disabilities

M. O. Bertelli

CREA (Research and Clinical Centre), San Sebastiano Foundation, Misericordia di Firenze, Florence, Italy
doi: 10.1192/j.eurpsy.2024.55

Abstract: Persons with intellectual disability (PwID) and/or autism spectrum disorder with high support needs (ASD-HSN) have resulted to be among the most vulnerable populations to COVID-19 and distress factors associated to the measures for containing its spread. Many health, rehabilitation, and assistance needs were managed through the use of telemedicine, specifically teleassistance (TA) and telerehabilitation (TR), with regard to the prevention and treatment of the epidemic illness as well as the continuity of care required for the condition of developmental disability and co-occurring physical or mental disorders. TA and TR can function either directly or indirectly with the PwID/ASD; in the latter case, a family member, a regular caregiver, or a technician provides local mediation. This paper examines the most common TA and TR activities, along with their requirements, applications, and goals. All of these activities should be in line with the overarching goal of each customized therapy and rehabilitation plan, which is to enhance and support the quality of life for people with intellectual and developmental disabilities.

Studies on TA and TR efficacy for PwID/ASD are limited, especially concerning adulthood. The scant research that is currently available demonstrates efficacy in maintaining or marginally enhancing cognitive, adaptive, and vocational skills. In addition to managing both routine and unusual activities as well as critical episodes, family members and other caregivers reported feeling more empowered about their educational and interpersonal abilities with the PwID/ASD. The primary benefits over traditional in-person services have been found to be greater

accessibility and availability as well as a reduction in both physical and psychological distance. The primary limits include the absence of all elements of the therapeutic alliance pertaining to face-to-face communication, possible poor ability to use technology, accessibility of the technology itself, concerns regarding privacy, and variables that divert attention connected to the household setting.

Even while telemedicine has proven to be feasible and beneficial thus far, it is doubtful that traditional techniques will be able to be replaced, at least not anytime soon. Telemedicine could, nonetheless, serve as a useful addition, integration, or short-term substitute. Future studies should provide light on the indications, contextual deployment, efficacy evaluation, and operational stability over time of certain TA and TR activities in addition to the use of artificial intelligence, machine learning, and interactive avatars.

DefiGame, a serious game to discover neurodevelopmental disorders

C. Bonnet*, C. IMMESOETE and

Specialists and parents affiliated to the french rare disease network DéfiScience - Professeur Vincent des Portes, Mme Marie-Pierre Reymond, Mme Caroline Immesoete, Mme Fanny Forel, Mme ANTOINE Odile, Mme AUPETIT Laure, Mme BENOIT Céline, Docteur BROSSEA

Filière DéfiScience, LYON, France

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.56

Abstract: Défigame is a training tool designed in collaboration with parents and specialists from the French Rare Diseases Network DéfiScience.

In this serious game, you take on the role of a general practitioner treating four young patients whose developmental trajectories raise questions. Interactively and with the help of concrete tools, you'll learn about the recommendations for coordinating an appropriate course of prescription, care and support for a family, from the search for a diagnosis to early management of a Neurodevelopmental Disorder (NDD).

WHO IS DEFIGAME FOR?

- Any European doctor questioning the etiology of a neurodevelopmental disorder, prescribing genetic tests or wishing to update their knowledge in the field of NDD, particularly in relation to a rare disease.
- Any other healthcare professional concerned with etiological diagnosis or support for people with NDD and their families.

Patients' perceptions and preferences regarding telemedicine for addictive disorders

S. Achab

Psychiatry, Clinical and Sociological Research Unit, Faculty of Medicine, Geneva University, Geneva, Switzerland

doi: 10.1192/j.eurpsy.2024.57

Abstract: Telemedicine is an emerging treatment option having been heavily used during covid lockdowns, in order to maintain treatment access including for addictive disorders.

In the present talk, we first present data published on the challenges met at ReConnecte the treatment facility for Addictive behaviors during pandemic.

We second, present results of a survey we conducted on preferences of telemedicine use in patients and doctors in our Geneva University Hospitals.

We finally illustrate findings by clinical cases of patients suffering from addictive behaviors and their specific needs and preferences in terms of telemedicine (phone or Visioconsultation).

Preferences and health tools elicited depended of their psychosocial profiles, their specific needs and expected benefits from online sessions of psychotherapy.

One of the ingredients of successful psychotherapy for addictive behaviors, is the purposeful use of telemedicine as an integrated treatment modality.

How digital technology can contribute to timely and effective recognition and response to opioid overdose events

A. M. Baldacchino*

DigitAS St Andrews

Medicine, St Andrews University, St Andrews, United Kingdom

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.58

Abstract

Objectives: To discuss novel approaches in the development early detection, response and interventions of drug overdoses.

Rationale: There is an urgent need to research and develop novel strategies to rapidly and accurately detect, respond, and treat them with the ultimate goal of reducing drug deaths secondary to fatal drug overdose incidents. This should be additional to supporting communities and networks able to intervene utilizing novel public health approaches.

Methods: We will describe technologies and associated systems that are able to accelerate detection and result in a timely response to potential overdose with effective and timely intervention to these

occurrences using digital technologies and therapeutics. This will be contextualised around novel public health approaches.

Results: We will describe 11 prototypes as part of a £5 million UK initiative. The themes will include:

- Use of discrete digital technology for easy use by people who use drugs in clinical and non-clinical settings
- Simple alert / responder pathways that created effective responses to potentially fatal overdose events
- Enhance innovative therapeutics as antidotes to overdose episodes
- Novel public health approaches

Conclusion: The use of remote monitoring devices like wearables and smartphone applications, paired with artificial intelligence and innovative therapeutics is an emerging field of research. This needs to be balanced around novel public health approaches.

A study exploring regional level predictors of suicide rates across time in Sweden

E. T. Eliasson^{1*} and V. Carli¹

¹National Centre for Suicide Research and Prevention (NASP), Karolinska Institute, Solna, Stockholm, Sweden

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.59

Abstract

Introduction: In Sweden, four lives are lost to suicide each day. Hence, identifying relevant risk factors to inform effective prevention strategies is key. Such strategies can range from individual ('micro') -level prevention methods, to broader national suicide prevention policies.

Objectives: Whilst a range of studies have explored individual-level risk factors, highlighting municipal, regional, or national-level predictors can be valuable to identify broader social and contextual determinants. This study will therefore aim to go beyond proximal predictors of suicide by looking through a wider national- and regional-level lens in Sweden.

Methods: This project will be conducted utilizing routinely collected and publicly available data and applying longitudinal modelling to investigate potential predictors of changes in suicide rates across time in Sweden. More specifically, the study will explore whether regional data on economic (e.g. proportion of state benefit recipients), socio-demographic (e.g. educational level) and health-care related variables (e.g. trust in the healthcare system) are associated with suicide rates over time.

Results: This is an ongoing project and results will be available and presented at the time of the conference.

Conclusions: Utilizing publicly available data to explore potential predictors of suicide rates is not only cost-effective, but adding such findings to existing knowledge of individual-level risk factors can also be important when targeting wider policy and ensuring effective coordination and implementation of regional suicide prevention strategies.

How good is the clinical diagnosis in schizophrenia? Reliability and validity

P. Falkai

Psychiatry, University of Munich, Munich, Germany

doi: 10.1192/j.eurpsy.2024.60

Abstract: Several changes to the classification of mental disorders have been made during the past half century to increase the reliability, clinical use and validity of the diagnostic classification. Despite the high expansion of knowledge about mental disorders, understanding of their components and processes still requires fine-tuning. This symposium identifies key issues on different classification systems with different purposes relevant to understanding and classifying mental disorders. We discuss how key issues such as ICD-11, RDoC or Biomarkers correspond or diverge because of their different purposes, and constituencies. Although these approaches have varying degrees of overlap and distinguishing features, they share the goal of reducing the burden of suffering due to mental disorder.

Disclosure of Interest: None Declared

A Case of Electroencephalography and Machine Learning in Early Diagnosis of Psychotic and Affective Disorders

E. Sarisik^{1,2*} and D. Popovic^{1,2}

¹Max Planck Institute of Psychiatry and ²Department of Psychiatry and Psychotherapy, LMU University Hospital, Munich, Germany

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.61

Abstract: Electroencephalography (EEG) serves as a non-invasive, cost-effective, and robust tool, directly measuring in-vivo neuronal mass activity with high temporal resolution. Using state-of-the-art machine learning techniques, EEG recordings have the potential to generate in silico biomarkers for severe mental disorders. In this study, we developed EEG-based classification models for schizophrenia and depression taking into account physiological and pathological aging processes.

From a cohort (N=735, 51.6% male) that is acquired in LMU Hospital, Department of Psychiatry and Psychotherapy, comprising healthy control individuals (HC, N=245) and patients with schizophrenia (SCZ, N=250) or major depressive disorder (MDD, N=240), we extracted power spectrum density and connectivity measures based on 60 second resting-state EEG recordings with 19 channels. The support vector machine models were trained to 1) classify patients with SCZ or MDD and HC individuals, and 2) predict age in HC individuals using ten-by-ten repeated nested-cross validation. The age-predicting model was applied to patient groups to calculate EphysAGE (Electrophysiological Age Gap Estimation) by subtracting chronological age from chronological age. The links between diagnosis, medication, and EphysAGE,

i.e., accelerated aging, were then further explored with univariate analyses.

The EphysAGE Model had an explained variance of 46% (MAE=8.7 years, $T=14.31$, $P_{1000}<0.001$). The patients with SCZ had a significantly higher EphysAGE (mean[SD]=0.61[10.32]) than the patients with MDD (mean[SD]=-1.10[10.49], $p=0.04$). The classification models discriminated SCZ from HC (Balanced Accuracy, BAC=72.7%, $p<0.001$), MDD from HC (BAC=67.0%, $p<0.001$), and SCZ from MDD individuals (BAC=63.2%, $p<0.001$). Higher EphysAGE was associated with an increased likelihood of being misclassified as SCZ in HC and MDD ($\rho_{HC}=0.23$, $p<0.001$; $\rho_{MDD}=0.17$, $p=0.01$) based on percentile rank scores from the SCZ Model. Moreover, in the Differential Diagnostic Model, higher EphysAGE is positively correlated with being misclassified as SCZ in patients with MDD ($\rho_{MDD}=0.14$, $p=0.03$).

Machine learning models can extract electrophysiological signatures of MDD and SCZ for potential clinical use. However, the impact of aging processes on diagnostic separability calls for timely application of such models, possibly in early recognition settings.

The clinical role of rTMS in difficult-to-treat depression

B. Baune

Department of Psychiatry, University of Münster, Münster, Germany
doi: 10.1192/j.eurpsy.2024.62

Abstract: Several meta-analyses demonstrated the efficacy of unilateral High-Frequency Left-sided (HFL) repetitive Transcranial Magnetic Stimulation (rTMS) for individuals with Major Depressive Disorder (MDD); however, results are contradictory due to heterogeneity of the included studies. Empirical evidence on the relative efficacy of rTMS treatment compared with standard pharmacotherapy in Treatment-Resistant Depression (TRD) is presented. Random effects models were used to assess the effects of rTMS on response and remission rates. In 19 randomized double-blinded sham-controlled studies were included for quantitative analysis for response ($n = 854$ patients) and 9 studies for remission ($n = 551$ patients), the risk ratio (RR) for response and remission are 2.25 and 2.78, respectively for patients after two treatment failures using rTMS as add-on treatment compared to standard pharmacotherapy. The presentation will conclude, that rTMS is significantly more effective than sham rTMS in TRD in response and remission outcomes and may be beneficial as an adjunctive treatment in patients with MDD after two treatment failures. This finding is consistent with previous meta-analyses; however, the effect size was smaller than in the formerly published literature.

SP0016

Recovery in schizophrenia: conceptualization and factors implicated

A. Vita

Department of Experimental and Clinical Sciences, University of Brescia, Brescia, Italy

doi: 10.1192/j.eurpsy.2024.63

Abstract: Schizophrenia has a heterogeneous range of possible outcomes. A portion of patients with schizophrenia significantly improves over the long term, with both clinical and functional remission. Recovery has been differently conceptualized by clinicians and service users, the former focusing on clinical and functional outcomes, the latter more underlying issues as the building a trail of personal meaning and subjective well-being. Besides the “clinical” and “personal” recovery, attention is now put on a wider perspective of “societal” recovery. The frequency of recovery achievement depends on which of these perspectives is considered. Many factors, demographic, clinical, contextual and treatment-related are involved in modulating the probability to meet these objectives. Both pharmacological and psychosocial interventions, and their integration, and attention to environmental and social circumstances could substantially improve the outcome of schizophrenia and achievement of specific recovery goals.

SP0017

Recovery in schizophrenia: the role of antipsychotic treatment

I. Bitter

Psychiatry and Psychotherapy, Semmelweis University, Budapest, Hungary

doi: 10.1192/j.eurpsy.2024.64

Abstract

Introduction: Comprehensive care programs, which include individually planned pharmacotherapy are associated with higher rates of recovery¹ and better long-term prognosis². However, there are barriers to individually optimised antipsychotic treatment both from both the patients and treatment teams perspectives.

Objectives: To summarize the potential contribution of adequate long-term antipsychotic treatment to recovery or better outcomes in schizophrenia.

Method: Review of research data.

Results A shorter duration of untreated psychosis, a lower number of relapses, and the absence of a chronic course of psychosis are associated with higher rates of recovery and a better prognosis. The OPUS early intervention program was associated with better outcomes for up to 10 years, but not for more than 20-years³. Second generation antipsychotics are associated with

lower mortality rates, including suicides in young people with schizophrenia.⁴

Higher doses of antipsychotics are associated with poorer outcomes and with potential structural brain changes, while adequate (lower) doses of antipsychotics are associated with lower side effect burden and better overall outcomes⁵. A significant proportion of patient may benefit from polypharmacy (combination of 2 antipsychotics)⁶. Antipsychotic treatment discontinuation strategies are associated with the development of treatment resistance.

Conclusions: Adequate (low dose) antipsychotic treatment is part of the complex early intervention programs and long term treatment of schizophrenia, which are associated with higher rates of recovery and good outcomes. The role of polypharmacy (combination of 2 antipsychotics) may need a reconsideration in the treatment guidelines of schizophrenia.

Recovery in Schizophrenia: The Role of Psychosocial interventions

T. Wykes

Psychology, King's College London, London, United Kingdom
doi: 10.1192/j.eurpsy.2024.65

Abstract: Recovery in Schizophrenia: The Role of Psychosocial interventions Recovery is individual and so needs individual responses from the mental health services. Different interventions are useful at different stages and of course they only “work” for some people. The paper will describe some psychosocial interventions and the role they might play in the patient’s journey to their expected recovery. Three main strategies are often referred to – reducing symptoms, reducing barriers to recovery, and extending and maintaining recovery to achieve some stable and acceptable (to the patient) optimal level of functioning. Psychosocial intervention strategies are beneficial for each of these often thought of as independent, but they are inter-related with one type of therapy leading to reductions in the need for other therapies. The process of considering which one to start with is a choice and this paper will describe some decision making to ensure that patients have the best options.

Does war increases the risk for psychoses?

P. Falkai

Psychiatry, University of Munich, Munich, Germany
doi: 10.1192/j.eurpsy.2024.66

Abstract: The [World Health Organization](#) (WHO) has stated that in situations of armed conflict, “Around 10 percent of the people who experience traumatic events will have serious mental health problems, and another 10 percent will develop behavior that will hinder their ability to function effectively.” Problems include post-traumatic stress disorder, anxiety, depression, substance misuse, and possibly precipitation of psychosis. War has a catastrophic effect on the health and well being of nations. Studies have shown that conflict situations cause more mortality and disability than any major disease. Only through a greater understanding of conflicts and the myriad of mental health problems that arise from them, coherent and effective strategies for dealing with such problems can be developed.

SP0020

Mental Health Policy Name: War and mental health (Croatian experience)

M. Rojnic Kuzman

Zagreb University Hospital Centre and the Zagreb School of Medicine, Zagreb, Croatia
doi: 10.1192/j.eurpsy.2024.67

Abstract: War represents one of the major traumatic events for humans and comes with enormous consequences for individuals and society over a long period of time. War causes acute psychological trauma, but also results in subacute, chronic psychiatric disorders for all those experiencing or witnessing direct war trauma and to those experiencing indirect war trauma resulting from losing the safety of home and financial income, to losing family members and close ones. Therefore, acute reaction to trauma may result in maladaptive disorders and PTSD within days of experiencing trauma and with chronic posttraumatic stress conditions even years after the traumatic experience. Chronic PTSD is associated with higher morbidity of somatic conditions, including hypertension, hyperlipidemia, metabolic syndrome, all resulting in cardiovascular and cerebrovascular disorders. Additionally, according to reports from World Health Organisation (WHO), it has been projected that in emergencies, on average, the percentage of people with a severe mental disorder increases by 1 per cent over and above an estimated baseline of 2–3 per cent. In addition, the percentage of people with mild or moderate mental disorders, including mood and anxiety disorders (including PTSD), may increase by 5–10 per cent above an estimated baseline of 10 per cent. Furthermore,

research indicate the possibility of a transgenerational effect of trauma, via maternal psychosocial stress and socioeconomic disadvantage during pregnancy but also through adverse parenting practices, as parenting style may change when exposed to war traumas.

As war affects mental health of different population groups dramatically and long-term, establishment of long term and coordinated mental health care is necessary. In the presentation, examples of practices from Croatia will be discussed.

Mental health needs of defendants with intellectual disabilities presenting at court

J. McCarthy^{1,2*}, E. Chaplin³, D Harvey, K Marshall-Tate, S Ali and A Forrester Professor

¹King's College London, London, United Kingdom; ²University of Auckland, Auckland, New Zealand and ³London South Bank University, London, United Kingdom

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.68

Abstract

Background: Studies in different countries of defendants with mild to borderline intellectual disability found they have distinct characteristics from other defendants. The aim of this study was to examine several characteristics among defendants with intellectual disability comparing to those defendants without intellectual disability presenting to court services in London, England.

Method: This was a retrospective data analysis of routine administrative data collected by the Liaison and Diversion services across five Magistrates courts in London, England. Data were analysed on defendants identified through screening to have an intellectual disability and compared to defendants without an intellectual disability.

Results: 9088 defendants were identified and of these 349 (4%) had an intellectual disability. Defendants with intellectual disability were over four times more likely to have comorbid attention deficit hyperactive disorder and over 14 times more likely to have autism spectrum disorder. There was an increased odds ratio of self-reported suicidal/self-harming behaviour for those defendants with intellectual disability compared to those without intellectual disability.

Conclusion: This study has highlighted the increased vulnerability of defendants with intellectual disability for other neurodevelopmental disorders.

Clinical / Therapeutic Name: Care and treatment of prisoners with intellectual disabilities

V. Tort Herrando^{1*} and Forensic Psychiatric Section

¹Penitentiary Psychiatry, Parc Sanitari Sant Joan de Deu, Sant Boi de Llobregat (Barcelona), Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.69

Abstract: Care and treatment of prisoners with intellectual disabilities I will describe what is the care, from different points of view when an offender with intellectual disabilities entry in the penitentiary system. As a vulnerable population, people with intellectual disabilities have to be treated in a more specific manner, and both prison managers and clinical staff have to be aware of that. This prisoners, sometimes, also belongs to another vulnerable population (illegal immigration, females, ethnic groups, etc) that make this cases as a complex ones. The care have to be as a comprehensive, with the highest standards of care and avoid negligence in treating this cases. We have to emphasize about rehabilitation and a good coordination with the intellectual disability community services to avoid relapse and recidivism

Essential components of pre-electroconvulsive therapy assessment

S. Medved

Department of Psychiatry and Psychological Medicine, University Hospital Centre Zagreb, Zagreb, Croatia

doi: 10.1192/j.eurpsy.2024.70

Abstract: A thorough pre-electroconvulsive therapy (ECT) assessment is an integral part of ECT preparation. Usually, the assessment encompasses elements such as medical history, cognitive assessment, laboratory tests, imaging diagnostics, and consultation with an anesthesiologist. However, there is currently no universally standardized minimal or optimal pre-ECT evaluation at the international level. Recent results show a high variability of the pre-ECT evaluation practice across Europe. Establishing a standardized approach to pre-ECT evaluation would be of great interest for both patients and practitioners.

Electroconvulsive therapy improves somatic symptoms before mood in patients with depression: a directed network approach

K. Hebbrecht

Psychiatry, University Psychiatric Hospital KULeuven, Leuven, Belgium

doi: 10.1192/j.eurpsy.2024.71

Abstract: The recent network perspective of depression conceptualizes depression as a dynamic network of causally related symptoms, this in contrast with the traditional view of depression as a discrete latent entity that causes all symptoms. Electroconvulsive therapy (ECT) is an effective treatment for severe depression, but little is known about the temporal trajectories of symptom improvement during a course of ECT. We will present the results of a study that investigates the temporal trajectories of individual symptoms during treatment with ECT.

Anti-amyloid therapies: are they effective and safe?

R. Perneczky

Department of Psychiatry and Psychotherapy, LMU Hospital, LMU Munich, Munich, Germany

doi: 10.1192/j.eurpsy.2024.72

Abstract: After numerous unsuccessful attempts to create a therapy that could alter the course of Alzheimer's disease, first monoclonal antibodies targeting amyloid- β in the brain have finally shown consistent evidence of clinical effectiveness. These therapies not only slow the progression of the disease, but also show positive results in secondary clinical outcomes and reduced amyloid- β levels on PET scans. This presentation will examine the main features of the previous failed trials and explore possible reasons for their lack of success in developing a treatment for early-stage Alzheimer's disease. It will also compare the safety profiles of various antibodies and point out precautions that should be taken when using them in regular clinical practice. Furthermore, it will be discussed how blood-based biomarkers can revolutionize the clinical care pathway, making it easier to adopt antibody treatments. A comprehensive model that integrates case-finding and treatment across various healthcare sectors will be proposed. In conclusion, we may have made a significant breakthrough by demonstrating that reducing amyloid- β levels leads to clinical benefits, not just changes in biomarkers. As the new generation of drugs becomes more commonly used, we will see whether their statistical effectiveness translates into meaningful clinical changes. This could mark the start of a new phase in the development of drugs for Alzheimer's disease.

New treatment perspectives for negative symptoms

I. Bitter

Psychiatry and Psychotherapy, Semmelweis University, Budapest, Hungary

doi: 10.1192/j.eurpsy.2024.73

Abstract

Introduction: Persistent negative symptoms of schizophrenia are generally considered difficult to treat or treatment resistant. A large number of investigational drugs developed and/or tested for the treatment of persistent negative symptoms failed to show efficacy leading to pessimism in treatment and disinvestment in treatment research of negative symptoms.

Objectives: 1. To demonstrate, that available treatment methods – both pharmacological and non-pharmacological – are in fact effective for the treatment of negative symptoms of schizophrenia 2. To shortly summarize new drug research in this field.

Method: Review of research data.

Results: The overall estimate for the placebo effect had a medium effect size, with a Cohen's d value of 0.6444 ($SE = 0.091$).¹ The estimates for the placebo effect were similar in the add-on and monotherapy studies. Amisulprid was superior to placebo, cariprazine was superior to risperidone, and “direct comparisons of antipsychotics in patients with predominant negative symptoms indicated no significant difference between amisulpride and olanzapine and between asenapine and olanzapine...”² Various non-pharmacological interventions improved negative symptoms in randomized controlled trials relative to treatment as usual (e.g. social skills training, music therapy, non-invasive brain stimulation, mindfulness, and exercise-based interventions)³ There is a progress in research with non-dopaminergic agents for the treatment of negative symptoms (e.g. pimavanserin, roluperidon, ulotaront).

Conclusions: For medication classes other than antipsychotics and antidepressants, we found no reliable support for evidence-based recommendations for using these agents in the treatment of negative symptoms in clinical practice. Effect sizes for psychosocial interventions range from small to moderate. The use of placebo has shown a clinically significant positive effect on negative symptoms, a finding that warrants further research and provides a sense of optimism regarding potential therapeutic benefits.

Cardiovascular and metabolic issues in the treatment of schizophrenia: focus on the management of negative symptoms

P. Falkai

Psychiatry, University of Munich, Munich, Germany

doi: 10.1192/j.eurpsy.2024.74

Abstract: Mortality from cardiovascular disease is increased in people with mental health disorders in general and schizophrenia in particular. The causes are multifactorial, but it is known that antipsychotic medication can cause cardiac side-effects beyond the traditional coronary risk factors. Schizophrenia itself is a contributor to an increased risk of cardiovascular mortality via cardiac autonomic dysfunction and a higher prevalence of metabolic syndrome, both contributing to a reduced life expectancy.

Overall, management of cardiovascular risk within this population group must be multifaceted and nuanced to allow the most effective treatment of serious mental illness to be conducted within acceptable parameters of cardiovascular risk; some practical measures are presented for the clinical cardiologist.

Validation of the rating scales for negative symptoms: new strategies

S. Leucht* and S. Wehr

Psychiatry and Psychotherapy, Technical University of Munich, School of Medicine and Health, Munich, Germany

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.75

Abstract: Negative symptoms of schizophrenia are linked with poor functioning and quality of life. Therefore, appropriate measurement tools to assess negative symptoms are needed. The NIMH-MATRICS Consensus defined five domains for negative symptoms. We used the COSMIN guidelines for systematic reviews to evaluate the quality of psychometric data of negative symptom scales as Clinician-Rated Outcome Measure (ClinROM). COSMIN assesses risk of bias, so called updated criteria of measurement properties, a modified GRADE approach and a final judgement on the rating scale. In the lecture the process will be described using the Brief Negative Symptom Scale and the Clinical Assessment Interview for Negative Symptoms (CAINS) as examples.

Digital treatments for affective disorders: an integrated overview

U. Volpe

Department of Clinical Neurosciences/DIMSC, Università Politecnica delle Marche, Ancona, Italy

doi: 10.1192/j.eurpsy.2024.76

Abstract: Affective disorders represent a category of psychiatric syndromes with high prevalence and associated disability. While effective, both pharmacological and psychosocial, treatments are available for depression and bipolar disorder, the many therapeutic needs of affected patients are far from being properly addressed under routine conditions. Along the past decade, several digital treatments, tools and approaches have been developed and tested in clinical settings, showing an highly promising potential to fill the treatment gap of affective psychopathology. In more detail, reviewed here will be telepsychiatry solutions for affective disorders, also encompassing the available officially approved digital therapies for major depression and bipolar disorder. Furthermore, the impact of artificial intelligence, serious gaming, social media and virtual/augmented reality in the treatment of mood disorders will be also discussed, in the light of the most recent research evidence on these topics.

Tackling adversity through innovation: A pilot study exploring VR as a tool to identify and diagnose depression

S. Sutori^{1*} and

Karolinska Institutet: E. Eliasson, G. Hadlaczy, I. Todorov, V. Carli; University of Padua: F. Mura, V. Cardi; Polytechnic University of Valencia: V. Ortiz, M.A. Raya; University of Pisa: A.L. Alfeo, V. Catrambone, G. Valenza

¹National Centre for Suicide Research and Prevention (NASP), LIME, Karolinska Institutet, Solna, Sweden

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.77

Abstract

Introduction: The final aim of the EXPERIENCE project is to enable individuals to record and share extended-personal realities in Virtual Reality (VR) - which entails the consideration of a person's neurophysiological, psychological, and cognitive states. One prospective application is using this technology to aid in assessing symptoms of affective disorders.

Objectives: The objective is to test the ability of a pre-designed VR environment to differentiate between individuals with depressive symptoms and healthy controls (HCs) via machine learning algorithms.

Methods: Conducted as a pilot study in Italy, we recruited 100 volunteers, comprising 50 HCs and 50 individuals with moderate depressive symptoms assessed via the PHQ-9. Through a 40–60-minute VR engagement, comprehensive data on cognitive (inc. cognitive flexibility, sustained attention, working memory, processing speed), behavioral (exploration, attentional bias), and physiological (heart-rate variability, skin conductance) variables was collected. Subsequently, an explainable artificial intelligence model (xAI) was trained on data from 80% of the sample and tested on the remaining 20% in terms of accuracy for between-group classification.

Results: Following an iterative process that considered both the importance assigned to each variable in the different models and

the theoretical relevance of these variables to depression the final model achieved an average accuracy of 71% (with individual trials ranging from 64.5% to 77.1%). Key predictors included exploratory behaviors and heart-rate variability during both exploration and cognitive tasks.

Conclusions: These results are comparable, however remain below the levels of accuracy achieved based on fMRI and DTI data alone (around 80%). Nonetheless, the EXPERIENCE system, slated for refinement beyond this pilot phase, shows potential in integrating multimodal data for evaluating affective disorder symptoms, aiming for a more objective screening and diagnostic approach at a lower cost.

Acknowledgement: The EXPERIENCE project is funded by the European Commission H2020 Framework Program, Grant No. 101017727.

Effectiveness and usability of an e-health system on depression among patients with somatic disorders

T. Vitcheva^{1*}, N.G. Petros, G. Hadlaczky and V. Carli

¹Karolinska Institutet, Stockholm, Sweden

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.78

Abstract

Introduction: An increase in the prevalence of depressive symptoms can be seen in patients with severe somatic conditions, with a reduction in quality of life, an increase in sleep disturbances and an increased risk of suicide as some of the most serious consequences. However, few evidence-based interventions have been developed with the aim of reducing this comorbidity. The NEVERMIND system aims to address this issue by collecting psychometric and biomedical data via a smart shirt and a mobile app, which are used to predict patients' depressive symptoms. Patients are then directed to personalised lifestyle behavioural advice, mindfulness-based therapy, and cognitive behavioural therapy.

Objectives: The primary objective was to evaluate the effectiveness of the NEVERMIND system in reducing depressive symptoms in patients with somatic conditions compared to treatment as usual. Secondary objectives included the system's effectiveness in preventing depressive symptoms, sustaining the effects at 24 weeks post-baseline, and reducing suicide ideation. Besides these, the usability, acceptability, and satisfaction of the system were examined in patients with breast or prostate cancer.

Methods: For this pragmatic randomised controlled trial, 425 patients diagnosed with myocardial infarction, breast or prostate cancer, kidney failure, or lower limb amputation were recruited from hospitals in Turin, Pisa and Lisbon. Data collection occurred at baseline, 12 weeks, and 24 weeks, with the primary outcome being depressive symptoms at week 12, measured by the Beck Depression Inventory II. Regarding the usability, acceptability and patient satisfaction, data from 288 patients was used.

Results: The intervention group included 213 and the control group 212 patients, with the sample's mean age being 59.41 (SD=10.70). Patients who used the system reported having statistically significant lower depressive symptoms at 12 weeks (mean difference=-3.05, $p=0.004$; 95%CI -5.12 to -0.99) compared to controls, with a clinically relevant effect size (Cohen's $d=0.41$). Furthermore, significant reductions were found for suicide ideation (mean difference=-0.61, $p=0.020$; 95%CI -1.13 to -0.10) and incidence of depressive symptoms at week 12 (OR=0.43, $p=0.019$; 95%CI 0.22 to 0.87). The decrease in depressive symptoms was sustained at week 24 (mean difference=-1.34, $p=0.015$; 95%CI -2.41 to -0.26). The system was found to have good usability, with women rating the system more favourably than men and valuing its emotional support, while men used the system more frequently than women and valued the self-awareness that the system encouraged.

Conclusions: The NEVERMIND system was shown to be superior to standard care in reducing and preventing depressive symptoms among the studied sample. A new project will be launched in the near future to continue the examination of the system's effectiveness.

Inflammatory based psychotic symptoms: when psychosis means encephalitis

M. Rojnic Kuzman

Zagreb University Hospital Centre and the Zagreb School of Medicine, Zagreb, Croatia

doi: 10.1192/j.eurpsy.2024.79

Abstract: Schizophrenia, as one of the most common disorders from the psychotic spectrum is most commonly detected in the phase of first psychosis and may pose a diagnostic challenge, as commonly comprise a heterogeneous group of schizophrenias, with distinct clinical presentations. If it detected in its prodromal phase without clearly developed psychotic symptoms, the diagnosis is even more unreliable, as the transition to full blown psychosis in the next two years happens in 15-40% of more, depending probably on a variety of cumulative environmental risk factors (including childhood trauma, the use of high-potency cannabis, urbanicity, season of birth). Moreover, the first episode psychosis may underlie for example the first manic episode, brief intermittent psychotic symptoms in persons with borderline personality disorders, acute reaction to trauma, the use of cannabis and psychostimulants and different organic causes, such as endocrinologic disorders and autoimmune encephalitis. Therefore, in everyday clinical practice, the diagnosis of first episode psychosis always requires an assessment of possible causes of psychosis, and also factors that may influence prognosis and treatment. Usual assessment include detailed anamnestic and heteroanamnestic data, physical examination, standard blood laboratory findings, drugs in urine/ blood, EEG and CT/MR scan. The absence of typical risk factors for schizophrenia, as well as the absence of premorbid symptoms and developmental course typical for schizophrenia, abrupt course of psychotic symptoms, symptoms such as disorientation,

catatonia, speech disturbances, alteration of consciousness, neurologic signs, autonomic dysfunction and laboratory aberrations may be especially indicative for organic cause and possibly encephalitis and require further confirmation with the analysis of cerebrospinal liquor with antineuronal antibodies.

Childhood trauma as a predictor of social cognition disturbances across psychosis spectrum: Data from the PREGAP Study

C. Aymerich^{1,2,3,4*} and A. Catalan^{1,2,3,4}

¹Psychiatry, Basurto University Hospital; ²Psychiatry, Biobizkaia Health Research Institute, Bilbao; ³Neurosciences, Basque Country University (UPV/EHU), Leioa and ⁴GCV22/1/SAM, CIBERSAM, Madrid, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.80

Abstract

Introduction: Childhood trauma is a severe form of stress that has been strongly related to both the appearance of a psychotic disorder and the existence of social cognition disturbances. We hereby hypothesize childhood trauma might be a transdiagnostic marker of social cognition disturbances across the psychosis spectrum, regardless of the main diagnosis.

Objectives: To investigate the effect of different forms of childhood trauma in social cognition impairments in first-episode psychosis, at-risk mental states for psychosis and healthy controls.

Methods: Using cross-sectional data, we will examine the relationship between different kinds of childhood trauma (measured with the Childhood Trauma Questionnaire, CTQ) and several social cognition domains, including facial emotion recognition, theory of mind (assessed using the Movie Assessment for Social Cognition, MASC, The Hinting Task, and the Faux-Pas Questionnaire). Intra and inter-group differences be studied for three study groups, including patients with first-episode psychosis (n=60), subjects with at-risk mental states for psychosis (n=60), and healthy controls (n=60).

SP0034

Childhood trauma as a transdiagnostic risk factor: clinical implications and preventive interventions

R. J. Bou Khalil

Psychiatry, Saint-Joseph University, Beirut, Lebanon

doi: 10.1192/j.eurpsy.2024.81

Abstract: Abstract: This presentation seeks to explore the interplay between various types of psychological traumas and their potential correlation with the development of distinct types and severities of

eating disorders. Emphasis will be placed on elucidating the underlying biological underpinnings and psychological and developmental factors that contribute to the manifestation of diverse eating disorder phenotypes in individuals who have experienced childhood maltreatment.

Drawing upon existing research and novel insights, I will present some data from studies investigating the notion that the observed variations in eating disorder presentations may be linked especially to environmental influences. Contrary to the conventional focus on genetic determinants, our findings suggest that the differential ecophenotypic expression of eating disorders may not solely be attributed to DNA variants but rather to the complex interplay between genetic predispositions and environmental contexts.

In particular, I will expose the concept of an ecophenotype characteristic of eating disorders associated with childhood maltreatment, positing that the unique ecological context in which an individual is raised significantly influences the trajectory and severity of their eating disorder. This exploration extends beyond a mere examination of genetic markers, shedding light on the environmental and ecosystemic factors that shape the development of an individual's relationship with food and body image.

How is trauma a transdiagnostic risk factor? A biopsychosocial model of risk and protective mechanisms following childhood trauma

H. Kerbage^{1,2*} and D. Purper-Ouakil^{1,2}

¹University Hospital Center of Montpellier (CHU de Montpellier), Montpellier and ²Center for Epidemiology and Population Health (CESP), Paris, France

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.82

Abstract: Traumatic exposure is a common global problem across nations. It is currently well established that childhood trauma is associated with increased risk for psychopathology transdiagnostically, with children having experienced trauma being twice as likely to develop a mental health condition compared to those who have never experienced trauma. According to population-based studies, this heightened risk for the emergence of mental health disorders persists throughout adolescence and adulthood. The risk for psychopathology seems to be most marked in children exposed to interpersonal violence (child emotional and physical abuse, neglect, sexual violence). In this presentation, we will summarize the results of an increasing number of published studies that have examined the mechanisms underlying vulnerability to psychopathology following childhood trauma and protective factors that buffer this risk. Specifically, we will highlight the role of emotion dysregulation and interpersonal difficulties, related to disrupted threat processing following trauma exposure, in mediating the impact of trauma on internalizing and externalizing symptoms. Research studies have also identified protective factors across the lifespan that might mitigate these outcomes, including social support and emotional skills building. Based on this review, we will suggest a conceptual transdiagnostic and biopsychosocial model of risk and resilience, which can provide opportunities and targets for early interventions and treatment, at the

primary and secondary healthcare levels, as well as the social, public health and community levels. Our model is based on a socioecological and multisystemic paradigm of risk and resilience, where resilience is conceptualized as an interaction between individuals and resourceful environments and communities.

Life narratives of individuals with psychosis in ethnic minority and migrant communities in Canada and the Netherlands

I. Jansen

Vrije Universiteit Amsterdam, Amsterdam, Netherlands
doi: 10.1192/j.eurpsy.2024.83

Abstract

Background: Increased psychosis risk has long been reported for some migrant and ethnic minority populations, a finding has been replicated in different parts of the world, with risk seeming to persist for further generations. Several explanations such as genetic liability or selective migration, higher cannabis-use or higher exposure to neurodevelopmental risk factors were considered unlikely explanations. Rather, exposure to adversity experiences found to be a determinant of psychotic disorders, such as parental separation, social and economic disadvantage, discrimination, social exclusion and marginalization. Additionally, migrants often live in cities, where high population density, low social cohesion and social fragmentation and deprivation, combined with lack of green space and urban stress increase the psychosis risk. Although previous research work has emphasized the quantitative exploration of social-environmental determinants of psychosis, qualitative studies allow for the generation of innovative, rich and nuanced understandings about a given phenomenon, being an ideal approach in face of complex social dynamics and contexts. Concretely, the associations are established, however, the underlying mechanisms and experiences remain largely unknown.

This study aims to address several research gaps identified in research on the issues of psychosis, socio-environmental determinants of mental health, migration and ethnicity, and inequalities by exploring the life narratives and experiences of service-users with first psychosis with distinct ethnic, racial and migrant backgrounds.

Methods: Participants aged between 18 and 35 years old, who have been diagnosed with a first psychosis are recruited in Montreal, Canada, and in the Netherlands. The aim is to recruit at least 20-25 individuals from each site, but recruitment is still ongoing. Qualitative interviews of about an hour are being held, and transcripts will be analyzed with Nvivo, software for qualitative data. Categories and clusters will be formed from the narratives, resulting in common themes that are important to the patients, in their understanding of the development of their psychosis, and the help they have received.

Results: Preliminary data show that the patients have predominantly African or (Eastern)European background, moved around a lot, and experiences inequities. Help and care were not always available for them, not always beneficial. Participants experiences a lot of isolation and displacement, together with socio-economic

disadvantages. Common themes as to by which mechanisms these aspects play a role will further be explored.

Discussion: These findings will be discussed in light of the quantitative data already existing. Implications for prevention and interventions will be discussed.

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.84

Abstract: According to the latest Intergovernmental Panel on Climate Change (IPCC) Report (2022), climate changes (e.g. rising sea levels and temperatures and) are noticeable and intensifying on the entire planet. Extreme weather events or ecological disasters are occurring with increased frequency and intensity. Anthropogenic climate change has been called “the defining issue of our time” (United Nations, 2022) and “the greatest threat to global health in the 21st century” (World Health Organization, 2015). Health impacts from climate change may include increased morbidity and mortality from worsening cardiopulmonary health, and greater risk of infectious diseases and mental illness. During this lecture, we will discuss environmental aspects that clearly have a negative impact on the mental well-being of the general population and, more specifically, the psychiatric population. The focus will primarily delve deeper into climate anxiety.

the Working Group on Updating Code of Ethics-Section for Human Rights and Ethics/ Psychiatric Association of Türkiye and (Ayşe Ceren Kaypak, Ayşegül Yay, Berna Uluğ, Gonca Aşut, İbrahim Fuat Akgül, Raşit Tükel, Simavi Vahip)

¹Psychiatry, Ege University, Izmir, Türkiye

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.85

Abstract: *Science, Ethics, Solidarity...* These three words are mottos of Psychiatric Association of Türkiye (PAT), since its foundation in 1995. In accordance, PAT has Code of Ethics for more than 20 years. There are many developments and changes both in practicing psychiatry and in the community in the last couple of decades. As a result, many new ethical questions, dilemmas and

approaches arise for psychiatry. PAT had decided to update the Code of Ethics about two years ago and the updating process is almost on the edge of finalization.

In this presentation, main points of the updated and newly written principles will be summarized with special references to recent developments in the world and updated or newly written international Code of Ethics such as, EPA, WPA, and several national associations' documents.

One of the most important outcome and benefit of such an updating process is modelling the project on a participatory base, having wide feedback and inputs from experts (as many as possible, enriched by diverse interests of related disciplines) and reaching as many colleagues as possible from different working conditions. A six step project with this perspective was prepared and implemented, and will be summarized in the presentation for international exchange of experiences.

Energy metabolism disturbance, altered neuronal development and glutamatergic signalling in human derived neuronal cell models of ADHD

S. D. Kittel-Schneider^{1,2*} and AG McNeill/Kittel-Schneider

¹Department of Psychiatry and Neurobehavioural Science, University College Cork, Cork, Ireland and ²Department of Psychiatry, Psychotherapy and Psychosomatic Medicine, University Hospital of Wuerzburg, Wuerzburg, Germany

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.87

Abstract: Despite major advances in research into the neurobiological basis of mental illness, there have been hardly any new developments in new drug therapies. As there are approximately 30% of affected individuals that do not respond sufficiently to available treatments, there is a significant unmet medical need for new therapeutic approaches. About 90% of novel substances that have shown promise in animal studies are not effective in clinical trials. Recent research on human induced pluripotent stem cells (hiPSC) could lead to the use of more human-tailored models in this field. iPSC-derived cell models and organoids may be very attractive for preclinical screening and bridge the gap between in vitro and in vivo studies, reducing animal testing. However, the next steps must first demonstrate the validity and reproducibility of the initial functional results from the hiPSC models of mental illness. In our own studies on neuronal cell models of patients with attention-deficit/hyperactivity disorder (ADHD) with rare PARK2 gene variants, we were able to show evidence of mitochondrial dysfunction and impaired energy metabolism. Additionally, we have first hints at a oxidative dysbalance which could be as well targeted by medication. In a model of cortical development of ADHD patients with common variants in the ADGRL3 gene, we found first evidence for altered neuronal maturation as well as abnormalities in calcium metabolism and glutamatergic functionality compared to cells from healthy controls. In summary, these first results are promising that hiPSC models can contribute new insights into cellular pathomechanisms of mental and neurodevelopmental disorders and the development of new, individualised therapeutic approaches.

Disclosure of Interest: S. Kittel-Schneider Grant / Research support from: The studies are funded by IZKF Wuerzburg and BBRF fund (to SKS and RMcN). SKS received speaker's honoraria from Takeda, Medice and Janssen.

Liaison Psychiatry model intervention in Switzerland

D. Georgescu

Department of Consultation-Liaison Psychiatry, Old Age Psychiatry and Neurodevelopmental Psychiatry, Aargau Psychiatric Services, Windisch, Switzerland

doi: 10.1192/j.eurpsy.2024.88

Abstract: Consultation and liaison psychiatry (C-L psychiatry) in Switzerland can look back on a long tradition. It began in French-speaking Switzerland back in the 1960s and gradually spread throughout the country. Currently, C-L services are present throughout the country, although they differ greatly in terms of their services and dimensions. University hospitals and larger cantonal hospitals have extensive and differentiated services, while smaller hospitals in peripheral regions only offer basic services. There are also major differences in the financing models, which are decisive for the range of services offered. The question of funding, which has not yet been resolved satisfactorily despite various models and strategies, including at national level, is highly relevant for the further development and even the continued existence of C-L services. The introduction of the subspecialization in C-L

psychiatry in 2010 and the lively training and CPD activities are of great importance for quality of the delivered services.

G. Mattei

Association for Research in Psychiatry, ARPSY, Castelnovo Rangone, Italy

doi: 10.1192/j.eurpsy.2024.89

Abstract: The birth of Consultation-Liaison (CLP) in Italy was made possible thanks to Act 180/1978, which started a 20-year-process that led to closing asylums and fostered the implementation of small psychiatric units within the general hospitals. In the meantime, Italian CLP grew steadily, fostered also by the enactment of two “Objective Mental Health Care” Plans (1994-1996 and 1998-2000), that led to the implementation of the organizational model of the mental health department (MHD).

As far as psychiatric referrals are concerned, the first Plan states that the MHD covers all territorial and hospital-based activities, in order to assure, among other services, the integration with hospital (with special attention paid to the Emergency Department and to consultation activity in non-psychiatric hospital wards) and general medicine (as well as other sectors, including mother and child health care).

With respect to psychiatric referral, the Second Plan states that “In the 24 months following the entry into force of the Plan, MHDs will adopt guidelines and procedure concerning several issues, including consultation-liaison activity in non-psychiatric hospital wards (which also includes mental health care for “psychiatric” patients hospitalized for non-psychiatric disease in the general hospital) and in Department of Addictions (for alcohol and other substances use disorders. According to the second Plan, Community Mental Health Services (CMHCs) provide, among other performances, CLP activity for general practitioners. Inside general hospitals, psychiatric referrals to non-psychiatric wards are provided by inpatient psychiatric units, when CLP Services are not available.

Since a standard definition of psychiatric consultation is not available, the one provided by the Italian region Emilia-Romagna will be used. The Region includes “consultation” among mental health services provided by CMHCs, and defines it as follows: “Psychiatric or psychological assessment carried out upon request from other [non psychiatric] Departments. The consultation includes both clinical interview with the patient and the medical report for the department that referred the patient.” The ways to identify consultation as one among other types of services provided by the MHD are defined, to count the overall number of consultations and monitor the clinical activity of health professional working in the different branches of the MHD. The following types of consultations are reckoned: consultations requested by general practitioners (who work within the Primary Care Department); consultations requested by the Department of Addiction (a branch of the MHD); and consultations requested by the Department of Child-

Adolescent Psychiatry (which, as the previous one, is a branch on the MHD).

Models of liaison psychiatry in different countries and the role of liaison psychiatrists as promoters of public and community mental health

F. Novais^{1*} and D. Telles-Correia¹

¹Faculdade de Medicina, Universidade de Lisboa, Lisboa, Portugal

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.90

Abstract: Consultation-Liaison (CL) psychiatry is the branch of psychiatric practice developed to offer support to patients with concomitant non-psychiatric diseases. In Portugal, most hospitals follow a model delivered by teams with Psychiatrists and Psychologists that support the medical team in wards. They act by advising directly other specialties’ colleagues after the observation of the patient and/or discussion of the case.

Bigger units, such as Santa Maria Hospital, in Lisbon, have tried a model of proximity to the community medical centers participating in local medical meetings, training of family doctors, discussing clinical situations directly and even doing psychiatric consultations, in community centers. This approach intends to extend primary mental health interventions and promote treatment in the community.

Sex differences in addiction: gonadal hormones and substance use effects in women

F. Fonseca^{1,2,3*}

¹Addiction Section, Hospital del Mar; ²Addiction Research Group, Hospital del Mar Research Institute and ³Medicine and Life Sciences, Universitat Pompeu Fabra, Barcelona, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.91

Abstract: Substance use disorders (SUD) affect differentially women and men. Although the prevalence has been reported higher in men, those women with addictive disorders present a more vulnerable profile and are less likely to enter treatment than men. The aim of this presentation is to present an overview of how gonadal hormones may influence in response to substances, clinical differences in the addictive disorders and implications in treatment response. Ovarian steroid hormones (estrogen, progesterone), the metabolites of progesterone, and negative allosteric modulators of the gamma-aminobutyric acid A (GABA-A) receptor, such as dehydroepiandrosterone (DHEA) may influence the behavioral effects of drugs.

Women with internet related disorders- illustration of an in-depth clinical assessment and personalized treatment approach

S. Achab

Psychiatry, Clinical and Sociological Research Unit, Faculty of Medicine Geneva University, Geneva, Switzerland
doi: 10.1192/j.eurpsy.2024.92

Abstract: Towards a personalized response to public health issues of PIU in women, understanding female profiles of problematic internet users and their underlying psychosocial characteristics is a crucial preliminary step.

Mobile Problematic Internet Use (PIU) is most likely present in young females, with heavy pattern of use being specifically associated to some online activities including communication, buying, video gaming and video watching.

The present talk will introduce epidemiological data on female with PIU in Europe, and will afterwards describe clinical assessment and treatment of a young female suffering from mobile PIU.

Assessment found heavy social networks (SNs) use, being mainly explained by dysfunctional coping to low self-esteem and traumatic sexual experiences in her biography.

Psychotherapy consisted in CBT for excessive time devoted to SNs, relocating life-priorities and cognitive remediation targeting self-esteem, self-compassion, and assertiveness.

Behind quantitative data on PIU in female, each patient has specific needs for treatment that should be identified in order to address PIU. Care process model used at ReConnecte since a decade allows for a comprehensive assessment of each PIU.

Diagnosis & Treatment Options in Depression with comorbid Dementia

A. Young

Psychological Medicine, King's College London, Institute of Psychiatry, Psychology & Neuroscience, London, United Kingdom
doi: 10.1192/j.eurpsy.2024.93

Abstract: Depression and Dementia Professor Allan H Young, Head of Academic Psychiatry, Maudsley Hospital and King's College London UK. allan.young@kcl.ac.uk

Mood Disorders are common, encompass cognitive impairments and occur in later life including first onset after the age of 50 years of age. There is a considerable overlap between depression and dementia. The relationship between depression and dementia will be reviewed and the implications for diagnosis and treatment will be discussed. Novel agents targeting alternative neurotransmitter pathways and inflammatory processes are promising potential treatment options. Neurostimulation treatments play a role with ECT at present having the best utility for late onset depression.

Key words: depression, dementia, antidepressants; pharmacotherapy

Do antidepressants lead to weight-increase? Antidepressant therapy and long-term changes in body mass index, waist circumference and fat mass - A prospective, population-based study

M.-P. Strippoli* and M. Preisig

Psychiatry, Lausanne University Hospital and University of Lausanne, Prilly, Switzerland

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.94

Abstract: The presentation will focus on long-term weight changes in patients with major depressive disorder who use antidepressants. Research studying weight change over periods of more than 12 months is scarce and the effects of depressive episodes and antidepressants on weight changes have rarely been assessed simultaneously. Using data of a prospective population-based CoLausPsyCoLaus study, data on the associations of antidepressant use prior to baseline and during a 5.5-year follow-up with

changes in adiposity markers and multiple adjustments including for the effects of depressive episodes will be presented. The cohort included 2479 randomly selected 35 to 66 year-old white residents (mean age 49.9 years, 53.3% women) of an urban area who accepted the physical and psychiatric evaluations at baseline and follow-up (76.8% participation at the follow-up). Diagnostic information on mental disorders, treatment use including psychotropic drugs was elicited using a semi-structured interview. Independently of the effect of antidepressants used during the follow-up and the effects of depressive episodes, the number of any antidepressant compounds used prior to baseline was associated with lower increase of body mass index (BMI), whereas the use of antidepressants during the follow-up was associated with steeper increase in BMI and waist circumference. Within AD classes, the use of tricyclic AD (TCA) and selective serotonin reuptake inhibitor (SSRI) prior to baseline was associated with lower increase, the use of SSRI during follow-up was associated with steeper increases in BMI. Similarly, the use of SSRI prior to baseline was associated with lower increase, the use of TCA and SSRI during the follow-up was associated with steeper increase in waist circumference. Finally, the use of SSRI during follow-up was also associated with steeper increase in fat mass. The findings support unfavorable obesogenic effects of sustained treatment not only with TCAs but also with SSRIs, suggesting that the benefit of long-term administration of these AD classes should be carefully weighed against the potential risk of weight gain.

Gender Diversity-Related Mental Health Care: Evidence, Trends, Obstacles

K. Başar

Department of Psychiatry, Hacettepe University, Ankara, Türkiye
doi: 10.1192/j.eurpsy.2024.95

Abstract: Gender identity may be experienced within a broad spectrum beyond the binary understanding of sex concerning genital characteristics. In people with gender identities not congruent with the gender culturally associated with the sex assigned at birth, distress related to biopsychosocial correlates of this condition may arise. In current diagnostic systems, this is considered within the framework of “Gender Incongruence” (ICD-11) and “Gender Dysphoria” (DSM 5). Although this diversity is known to be present throughout the ages, the terms related to gender identity were introduced to medical literature a hundred years ago. They were popularized with the advances in medical procedures that assist individuals in acquiring physical features aligning with their gender identity and expression. There has been an increase in research interest with increasing numbers in medical centers working on gender-affirmative medical procedures. Starting from the 1970s, international organizations prepared guidelines on the standards of care for trans and gender diverse (TGD) individuals. Despite all the progress in the gender-affirming medical care provided to TGD individuals and the changes in the legal recognition of gender, health inequalities persist globally. The discrepancy in mental and physical health

conditions has long been shown to be associated with “minority stress.” The minority stress perspective suggests that distal and proximal chronic stressors arising from society are associated with adverse health outcomes for TGD individuals. Resilience against these stressors is more robust with better coping styles and social support. Lately, structural stigma and discrimination have been shown to be an important source of inequality. Therefore, much more progress is still required with respect to societal inequalities, human rights, and structural transphobia for the improvements in medical care to impact the global health condition of TGD people. However, lately, there have been attempts to restrict TGD individuals’ access to medical care and their legal rights, even if they were not close to the level they ought to be. This backlash mostly sits on the discussion on the management of TGD adolescents and children. Models of care for these age groups have been developed for decades, and despite evidence of the protective and beneficial effects on health and development, in many countries, there are attempts to block their access to medical care. Growing debate on TGD care turned into a political combat, where scientific evidence and human rights perspectives are often ignored. These tendencies present a strong challenge for public health and the professional identity and practice of healthcare professionals.

Investigating LGBTQ affirmative attitudes and needs for better practice among Hungarian healthcare professionals

G. Vizin

University Budapest, Budapest, Hungary
doi: 10.1192/j.eurpsy.2024.96

Abstract: Introduction: LGBTQ (lesbian, gay, bisexual, transgender, queer) people often do not seek health care and do not identify as LGBTQ people because of fear of judgment, stereotyping, and discrimination by health professionals. All of this is a particularly worrying phenomenon, because various mental difficulties, risky behaviors, and certain types of somatic and psychosomatic diseases may appear in a higher proportion among them.

Objectives: Attitudes related to LGBTQ people were examined in several areas in Hungary. Most of our data comes from psychologists, however, a comprehensive examination of health professionals’ attitudes towards LGBTQ people has not yet been carried out.

Methods: In a cross-sectional online survey, we ask healthcare professionals (medical doctors, nurses, other graduate healthcare professionals and medical university students) to fill out our questionnaire. The participants complete the Modern Homonegativity Scale and the Lesbian, Gay, Bisexual and Transgender Clinical Skills Development Scale.

Results: We assume that the majority of Hungarian healthcare professionals have a neutral or positive attitude towards LGBTQ people, but they struggle with a significant lack of affirmative skills. We will present our results in detail in the presentation of the symposium.

Conclusions: There is an urgent need to provide the appropriate affirmative knowledge material to Hungarian healthcare workers.

Treatment recommendations and predictors in Eating DisordersF. Fernandez-Aranda^{1,2,3*}

Eating Disorders Section and Eating Disorders Section

¹Clinical Psychology, University Hospital of Bellvitge-IDIBELL;²CIBERobn, ISCIII and ³Clinical Sciences, University of Barcelona, Barcelona, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.97

Abstract: Eating disorders are severe mental disorders with a high mortality rate - suicidality - and a high incidence in adolescence and early adulthood, especially in women. The course of these disorders is uncertain and treatment outcomes are limited, with successful outcomes in 50-75% of cases. For bulimia nervosa (BN) and binge eating disorder (BED), several factors, such as duration of the disorder, eating and general psychopathology, dysfunctional personality traits and cognitive impairment, have been found to be associated with treatment adherence and response. In anorexia nervosa (AN) and atypical ED (OSFED), treatment response is poorer, with higher dropout rates and longer duration and chronicity. In this presentation, we will describe recent prospective observational studies in large samples of EDs analysing clinical, personality and cognitive predictors of treatment response in eating disorders, as well as potential associated neurobiomarkers. Optimisation of health care resources and transitions, as well as early and effective personalised treatments, can change the trajectory of EDs.

Disclosure of Interest: F. Fernandez-Aranda Grant / Research support from: We thank CERCA Programme/Generalitat de Catalunya for institutional support. Treatment strategies in eating disorders with comorbid conditions and in under-represented clinical populations

G. Paslakis

University Clinic for Psychosomatic Medicine and Psychotherapy, Ruhr-University Bochum, Campus East-Westphalia, Luebbecke, Germany

doi: 10.1192/j.eurpsy.2024.98

Abstract: Eating disorders (EDs) have long been thought to be conditions that only or mainly affect women, especially young, affluent, skinny girls and women in Western cultures. Mostly over the last decade, we have come to realize that EDs may affect individuals of all genders, ages, sexual orientations, ethnic, and socio-economic backgrounds. This, in turn, has implications for ED presentation and assessment, and the necessity for adjustments in the provided care according to diverse treatment needs. Here, we present and discuss current advances in ED-related research in underrepresented groups as well as the need to further incorporate diversity aspects in clinical care and research within the ED realm.

Reconceptualising depression along the endogenous-reactive spectrum: are different genes involved in depression depending on presence vs absence of exposure to stress?

X. Gonda

Department of Psychiatry and Psychotherapy, Semmelweis University, Budapest, Hungary

doi: 10.1192/j.eurpsy.2024.99

Abstract: Depression is a complex and highly heterogeneous disorder with an omnigenic and multifactorial background. This diversity is obvious not only in its symptomatic manifestation but also in its neurobiological underpinnings which is one potential factor contributing to the high observed rate of treatment resistance. Thus, subtyping depressions, understanding their distinct neurobiological and genetic background, and potentially developing biomarkers aiding their differential diagnosis may bring us one step closer to more effective treatment. The present talk will overview the different etiological factors contributing to the emergence of depression along an endogenous-reactive continuum, the contributory roles of different types of stress, different genes involved in distinct processes, and the potential consequences of conceptualising, diagnosing and treating depressions developing in the context or independently of current stress.

Is bipolar mixed depression associated with a good response to psychotropic augmentation?

Z. Rihmer

Psychiatry and Psychotherapy, Semmelweis University, Budapest, Hungary

doi: 10.1192/j.eurpsy.2024.100

Abstract: Is bipolar mixed depression associated with a good response to psychotropic augmentation? Zoltán Rihmer Department of Psychiatry and Psychotherapy, Semmelweis University, Budapest

and at the National Institute of Mental Health, Neurology and Neurosurgery, Budapest, Hungary.

Introduction: Suboptimal response to antidepressant pharmacotherapy (nonresponse or partial response but no remission) is the most challenging issue in the treatment of depressive disorders. Open and controlled clinical studies show that augmentation of the given antidepressant with lithium, atypical antipsychotics, antiepileptics and thyroid hormones are effective in 30-40% in such cases.

Objectives: To explore the possibility whether bipolar mixed depression is the ideal subject of good response to psychotropic augmentation.

Method: Literature review.

Results: Studies consistently indicate that in contrast to unipolar MDE (=MDD) the rate of antidepressant-resistant depression is higher not only in bipolar I and II depression but also in MDE with subthreshold bipolarity (bipolar mixed depression). However, lithium, atypical antipsychotic and antiepileptic (but not thyroid) augmentation works much better in bipolar depression and in unipolar MDE with subthreshold bipolarity (mixed depression) than in unipolar MDE without subthreshold bipolar features. In addition to this, almost all clinical predictors of good response to lithium/atypical antipsychotics/antiepileptics are classical bipolar markers (familial bipolarity, early onset, intradepressive hypomanic symptoms, agitation, cyclothymic temperamental, shorter episodes, more than three depressive episodes, and suicidality).

Conclusion: Considering that lithium, atypical antipsychotics and antiepileptics, but not thyroid stimulating drugs have more and less antimanic effect, these results suggest that treating intradepressive hypomanic symptoms in bipolar mixed depression is a new (if not the only) explanation among the several previously proposed mechanisms of action of successful psychotropic augmentation of antidepressants in patients with MDE.

Suicidal behavior in combat veterans with mood disorders

L. Sher^{1,2,3*}

¹James J. Peters VA Medical Center; ²Icahn School of Medicine at Mount Sinai and ³Columbia University Vagelos College of Physicians and Surgeons, New York, United States

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.101

Abstract: Introduction. Military conflicts are ubiquitous. There are many combat veterans around the world. The combat environment is characterized by violence, physical strains, separation from loved ones, and other hardships. Mood disorders and suicidality in combat veterans are a large and important issue.

Objectives: To discuss the pathophysiology and prevention of suicidal behavior in combat veterans with mood disorders

Methods: A review of the literature on suicidal behavior in combat veterans with mood disorders including own publications.

Results: Combat deployment may lead to multiple emotional, cognitive, psychosomatic symptoms, mood disorders, suicidal ideation and behavior. Pre-deployment, deployment and post-deployment adversities may increase risk of mood disorders and suicide in combat veterans. The act of killing in combat is a stressor which may raise suicide risk. Combat-related injuries are associated with significantly increased depression and suicide risk. Post-deployment difficulties of reintegrating into civilian life may lead to depression and suicidality. Studies suggest that suicidal behavior in combat veterans may have a neurobiological basis. Prevention of mood disorders and suicide among combat veterans should include pre-deployment screening to exclude individuals with psychiatric disorders; psychological support and prevention of harassment and/or abuse during deployment; psychosocial support after deployment; diagnosing and treating psychiatric and medical disorders including neurological disorders; frequent depression and suicide screening; education of mental and non-mental health clinicians, war veterans, their families and friends regarding signs/symptoms of mood disorders and suicidality; and restriction of access to lethal means.

Conclusion: Combat veterans are a unique population. They are frequently exposed to psychological, physical, and biological factors which are unusual for civilians or non-combat military veterans. We need to study the specific psychobiology of combat veterans to understand how to develop effective depression and suicide prevention interventions for this population.

Antipsychotics and delirium: When to start and what to select

G. Stoppe

MentAge, Basel, Switzerland

doi: 10.1192/j.eurpsy.2024.102

Abstract: Antipsychotics are among the substances that are very frequently used for elderly people and dementia patients in particular. This is known from studies both in outpatient care and in nursing homes. They are often part of a polypharmacy. This group of substances is discussed in the context of the increased risk of falls, increased mortality and also - as here - in the context of the development of delirium.

On the other hand, antipsychotics are drugs for the treatment of delirium, whereby the question of their significance in modern delirium treatment is being asked anew. In the past, butyrophenones in particular have played a role here, partly because of their variable form of administration and also because of their low cardiac impact.

In the context of delirium prevention, the aim is to reduce the number of drugs on the one hand and the anticholinergic load of the drugs on the other. Algorithms and recommendations exist for this.

In the treatment of delirium, the focus is rightly placed primarily on non-pharmacological management. The use of antipsychotics should be reserved for severe states of agitation or agitation in the context of delirium. In other cases, careful judgement is required.

CBS0002

Medication related problems in elderly patients treated with antipsychotics

M. Stuhc

Clinical Pharmacology, Medical Faculty, Maribor University & Ormoz Psychiatric Hospital, Maribor, Slovenia

doi: 10.1192/j.eurpsy.2024.103

Abstract: Elderly patients treated with antipsychotics are often prescribed multiple medications simultaneously (polypharmacy), leading to an increased risk of various medication-related problems, including irrational polypharmacy, drug-drug interactions, and potentially inappropriate medications (PIMs). Polypharmacy may be rational with clear indications and benefits, but it becomes irrational when better alternatives are available. This irrational polypharmacy is associated with poorer clinical and economic outcomes, including a higher mortality rate. Antipsychotic polypharmacy in elderly patients with schizophrenia is not well-studied and, therefore, is not generally recommended. Long-term antipsychotic use in patients with dementia has also been linked to a higher mortality rate. PIMs, representing a greater risk than benefit, are prevalent in mental health institutions at all healthcare levels, with a prevalence ranging from 40% to 60%. Antipsychotics, along with benzodiazepines, are among the most commonly included in PIMs and polypharmacy in these institutions. Moreover, antipsychotics are frequently implicated in potential severe drug-drug interactions in elderly patients with mental disorders, particularly with antibiotics and antiarrhythmics.

Unfortunately, the existing treatment guidelines and meta-analyses mostly do not cover these aspects, which represent a gap between the 'real clinical' pharmacology and treatment guidelines. The speaker will summarize the medication-related problems in this population and present practical recommendations for daily clinical practice.

CBS0003

Introduction and overview of offenders with intellectual disabilitiesK. Goethals^{1,2*}¹University Forensic Centre, Antwerp University Hospital, Edegem and ²CAPRI, University of Antwerp, Wilrijk, Belgium

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.104

Abstract: Intellectual disability (according to the DSM-5) or intellectual developmental disorder (according to the ICD-11) is a disorder with onset during the developmental period that includes both intellectual and adaptive functioning deficits in conceptual, social and practical domains. The term learning disability (LD) is also used, although this term shows more specifically deficits in the domain of learning. The term learning difficulties is often used for specific or generalized intellectual impairment that does not meet all of the criteria of LD.

The prevalence of learning disability in prisoners is about 10%. Up to 60% of male prisoners have learning difficulties. Prevalence rates for offending behaviour in patients with LD is higher than in the general population and show a large range, from 2-40%.

The main explanatory factor underlying the link between intelligence and offending is the lack of ability to manipulate abstract concepts. Poor academic performance, common in persons with LD, is also linked to offending.

With regard to sexual offending, some persons with LD may not have learnt the rules that define acceptable and unacceptable behaviour. Sexual offences may amount to inappropriate, impulsive expressions of emotion rather than premeditated violent acts. Violent behaviour in the LD population may be due to frustration, impulsivity or poor problem solving skills. There is no significant difference in the frequency of violent or property offences between individuals with LD and those without. However, sex offences and fire-setting are frequently seen in individuals with LD.

Persons with LD are vulnerable suspects and may also be disadvantaged by the criminal justice system because of a lack of appropriate support and legal representation from early stages in the process.

In this introductory paper these themes will be addressed.

The psychiatric assessment including fitness to participate in court proceedings for defendants with intellectual disabilities

J. McCarthy

King's College London, London, United Kingdom

doi: 10.1192/j.eurpsy.2024.105

Abstract: The very brief presentation will describe the initial approach to the psychiatric assessment of the case presented including the issue of fitness to participate in court proceedings.

The use of screening tools at court to identify people with intellectual disabilities will be highlighted along with what support can be provided for vulnerable offenders in attending court. The potential disposal options for the court such as prison or hospital or community will be outlined. Variation in practice across European countries needs further discussion to ensure the rights of defendants with intellectual disabilities are safeguarded during their participation in court proceedings

Case-based Workshop: Presentation of offenders with intellectual disabilities: towards an open and inclusive treatmentF. Saeedzadeh Sardahae^{1,2,3*}¹Psychiatry, St Olav University Hospital; ²Psychiatric clinic, Lukasstiftelsen and ³Psychiatric clinic, Advansmedical, Trondheim, Norway

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.106

Abstract: Legal frameworks and the challenges for treatment and rehabilitation of offenders with intellectual disabilities Speaker: Farzaneh Saeedzadeh Sardahae, MD, PhD, Consultant psychiatrist St. Olav University Hospital, Trondheim, Norway

Lack of timely diagnostic and treatment for mild intellectual disability amongst offenders presents special challenges to clinicians and prison system alike. On the one hand, appropriate treatment for their psychiatric symptoms may not be implemented as they can be mislabeled primarily as behavioral issues. Different approaches to such perceived behavioral issues within judiciary (or prison) system and health care system is a potential conflict area. On the other hand, treatment and rehabilitation of offenders with intellectual disability require both resources and expertise that may not be readily available in prison systems, pre- or past sentencing. Furthermore, the scope of such challenges varies greatly based on different legal frameworks for sentencing offenders with intellectual disability within Europe.

In the first section an overview of Norwegian legal framework for offenders with intellectual disability is briefly presented. Then using the example of a young female offender with mild intellectual disability, drug dependence and multiple psychiatric morbidities, the speaker examines complexities of dual diagnoses, interdisciplinary and multiagency cooperation follow-up and challenges faced in the recovery process. A brief introduction to the current Norwegian follow-up system for offenders with intellectual disability is discussed before examining recent changes in legal framework for sentencing offenders with intellectual disability in Norway, and its ramifications, as well as potential benefits for treatment and future rehabilitation of offenders. Finally, the speaker reflects on points for further improvement, especially considering the multi-agency nature of treatment and rehabilitation of offenders with intellectual disability.

The “Hector” case and the community rehabilitation of offenders with Intellectual Disability and psychiatric disorders

J. Santambrogio*, Emma Francia, Antonino Giancontieri, Massimo Clerici and Alessandro Santarone

ADELE BONOLIS AS.FRA. FOUNDATION, VEDANO AL LAMBRO, Italy

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.107

Abstract: Hector, 44 years, with mild Intellectual Disability and impulse control disorder, committed serious sexual offences against two children of his partner. Considered “socially dangerous”, he was put in prison, then with a deferment of the enforcement of the prison sentence in the forms of home detention he was hospitalized in a psychiatric facility due to his depressive condition. Upon entering the Community, he presented a deflected mood as a reaction to the discomfort from the custodial experience, which was not cognitively integrated. Both psychotropic and rehabilitation treatments started. He has been involved in a gardening activity, too. After a first period of high degree of denial of the facts and a defensive mode marked by stolidity and fatuity, revealing his poor cognitive resources, during the psychiatric sessions he became even more conscious of his crime and the suffering of the victims. Services/pathways available for offenders with ID and psychiatric disorders will be presented.

doi: 10.1192/j.eurpsy.2024.109

Abstract: The first psychotic episode is often a moment of utmost importance for the patients and their families, as well as for the treating professionals who need to address several dilemmas. Findings suggest that Self-Disorders (SD) specifically aggregate within schizophrenia spectrum disorders, pointing to the possibility that they could be a central phenotypic marker of schizophrenia spectrum disorders across the different severity of their clinical manifestations. We will present and discuss a case report involving a patient's first admission, where diagnostic uncertainties exist. The goal is to enhance our comprehension of the significance of contemporary clinical and phenomenological psychopathology, with a specific focus on SD, in order to achieve a more accurate and precise assessment of incipient schizophrenia.

A case of misdiagnosis and mismanagement in forensic psychiatry

F. Saeedzadeh Sardahae^{1,2*}

¹Psychiatric clinic, Lukasstiftelsen and ²Psychiatric clinic, Advansmedical, Trondheim, Norway

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.110

Abstract: A case of misdiagnosis and mismanagement in forensic psychiatry Speaker: Farzaneh Saeedzadeh Sardahae, MD, PhD, Consultant Psychiatrist, Trondheim, Norway
Timely diagnosis and treatment for psychiatric illnesses in first time offenders in forensic psychiatry remains a challenge. Presenting a young male first-time offender with recent onset psychosis, ADHD and anxiety disorder, the speaker reflects upon the complexities around making the right diagnosis in a prison with very limited resources for clinical observation. Minting the term “Psychosis Incognito”, the speaker goes on to explore a complex multiagency follow up process faced by this offender and his treating team, as well as many medical complications including malnutrition and Korsakoff syndrome.

Abstract: Geographical differences of the offender-patient pathways across Europe

In this part of the workshop, I will make an approach of how will be treated an forensic psychiatric complex case from Spain point of view, and differences with another countries. Different pathways from detention to be admitted in a psychiatric facility will be described. Also the approach from standard care to a more complex medical situation (from clinical, social and psychological view) in a penitentiary (forensic) resources, including rehabilitation. And finally, the follow-up / after care of a mentally ill offender, when discharge to the community.

K. Krysta

Department of Rehabilitation Psychiatry, Medical University of Silesia, Katowice, Poland

doi: 10.1192/j.eurpsy.2024.112

Abstract: Telepsychiatry has emerged as a transformative force in the field of mental health care, addressing disparities in service delivery and increasing access to care. This exploration focuses on the role of telepsychiatry in achieving equitable mental health care for individuals with intellectual disabilities (ID). Intellectual disabilities affect millions globally, posing significant public health challenges. This vulnerable population encounters numerous barriers in accessing quality mental health care, including geographical isolation, limited transportation options, and a shortage of specialized providers. Telepsychiatry offers a promising solution, leveraging technology to overcome these challenges. The presentation reviews the current landscape of mental health care for individuals with intellectual disabilities and the specific barriers they encounter. It highlights the potential benefits of telepsychiatry, including increased availability of specialized care, reduced geographical barriers, and enhanced caregiver support. Ethical considerations and best practices associated with implementing telepsychiatry in the context of intellectual disabilities are discussed. Case studies and success stories illustrate how telepsychiatry positively impacts individuals with intellectual disabilities and their families. In

conclusion, telepsychiatry plays a promising role in promoting equitable mental health care for individuals with intellectual disabilities. Embracing technology and adopting best practices pave the way for a more inclusive and accessible mental health care system, leaving no one behind.

Disclosure of Interest: None Declared**Workshops****WS0001****Predictors of relapse in bipolar disorder: an overview of the available evidence**I. Pacchiarotti^{1,2*}¹Institute of Neurosciences, Hospital Clínic of Barcelona and ²Bipolar and Depressive Disorders Unit, IDIBAPS, Barcelona, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.113

Abstract: After the introduction of all the speakers, the main aim of this workshop will be mentioned, which consists of identifying and highlighting those clinical, sociodemographic, environmental and other factors that might predict an increased risk of overall, depressive, manic or mixed relapses in bipolar disorder, which is crucial for the identification of high-risk individuals. Dr. Pacchiarotti will present main results from a systematic review performed recently by the work group aimed at collecting the available evidence regarding different factors that increase rates of mood recurrences or relapses for different polarities in bipolar disorder.

Disclosure of Interest: None Declared**WS0002****Readmission predictors at three years after a manic episode.**A. Giménez-Palomo^{1,2*}¹Bipolar and Depressive Disorders Unit, IDIBAPS and ²Institute of Neuroscience, Hospital Clínic de Barcelona, Barcelona, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.114

Abstract: In this section, the speaker will present the results from a recent longitudinal study performed by the work group, in which a cohort of 265 patients admitted with a manic episode were followed up during three years after hospital discharge to identify acute readmissions due to affective relapses. The study of different socio-demographic and clinical variables potentially implicated in a higher risk of readmission over three years is presented, including adherence to treatment, substance use, number of previous episodes, family history, predominant polarity, treatments used and number of visits to the Emergency Department.

PAD: a UK Perspective - Contemplating Change is Challenging!

J. Wise

CNWL, London, United Kingdom

doi: 10.1192/j.eurpsy.2024.117

Abstract: Physician assisted dying is not new, neither historically, nor globally. What has changed in the UK however, is the perspective of society. In the UK, the British Medical Association is both a union and a professional organisation representing doctors and liaising with governments departments in matters of healthcare. As with various specialties within medicine, there are those in favour of

change and those against. There are matters on which there is common ground, and a consensus of experts has identified principles, which, if legislation is to change, would be sensible to follow. A profession has united around the idea that if change is coming, it is better to inform the debate proactively and ensure that the interest of patients and doctors are promoted. This session will look at how potential change in the UK has been approached and hopefully well managed.'

Disclosure of Interest: None Declared

Physician assisted dying : A French Perspective - a new revolution?

P. Courtet

University of Montpellier, Montpellier, France

doi: 10.1192/j.eurpsy.2024.118

Abstract: The debates on euthanasia and assisted suicide (EAS) are topical in Europe. The extension of EAS for psychiatric reasons, already legalized in some countries, raises ethical and clinical issues, given the proximity between suicidal patients and patients who request or have accessed EAS. How can EAS be reconciled with the promotion of suicide prevention, which kills nearly 10,000 people per year in France? We will raise here several key questions that deserve a clear answer before considering going further in the social debates: how to ensure the irreversibility of psychological suffering? how to ensure that patients requesting EAS have full decision-making capacity? how to judge therapeutic futility? It seems crucial to protect the most vulnerable patients by ensuring that psychiatry benefits from scientific progress and can offer new solutions to suffering patients.

These issues will be discussed viewing the proposed law on EAS in France, which is supposed to come in February 2024...

Disclosure of Interest: None Declared

WS0007

Physician assisted suicide: A Swiss perspective - a liberal view

G. Stoppe

MentAge, Basel, Switzerland

doi: 10.1192/j.eurpsy.2024.119

Abstract: Switzerland is a country in which the liberal tradition is cultivated and every citizen's free decision is honoured. Associations such as EXIT or Dignitas, which advocate the right to self-determined death, were formed here early on. They see themselves as completing the Age of Enlightenment, where the end result is an individually self-determined death. The Swiss federal government is therefore reluctant to define criminal offences. However, it is regulated that active euthanasia is prohibited. The organisations mentioned are also not allowed to act for their own benefit.

Meanwhile, the number of assisted suicides is higher than the number of suicides. The extent to which the one phenomenon is related to the other is open to debate.

The topic is controversial among the general public and the medical profession. Nevertheless, the Swiss Academy of Medical Science has published guidelines on dealing with dying and death, which also deal with physician-assisted suicide.

Various associations, including the umbrella organisation for suicide prevention in Switzerland, Ipsilon, are in favour of special protection for vulnerable groups. Some of them also recommend that civil law provisions be made for the process of assisted suicide.

The Impact of cognitive remediation combined with mindfulness and social skills training on social functioning and neural plasticity in early psychosis: preliminary results from a randomized clinical multicentric trial in Italy

C. Perlini^{1,2*}

the research group on "The impact of cognitive remediation on social functioning and neural plasticity in early psychosis: a randomized clinical trial"

¹Department of Neurosciences, Biomedicine and Movement Sciences, Section of Clinical Psychology, University of Verona and ²Clinical Psychology Service, Verona University Hospital, Verona, Italy

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.120

Abstract: Affective and non-affective psychoses are characterized by deficits in neuro and social cognition, which strongly impact the patient's psychosocial functioning and health and social system. Recent literature suggests that such deficits could benefit from the innovative combination of evidence-based interventions.

This lecture aims to describe an Italian multisite (Verona, Milano, Pavia), longitudinal randomized controlled trial funded by the Italian Ministry of Health investigating the impact of Cognitive Remediation (CR) alone or combined with other approaches (namely, Mindfulness and Social Skills Training (SST)) on clinical, neuropsychological, social and brain-related outcomes in patients with a DSM5 diagnosis of affective or non-affective psychosis.

In our study, patients underwent clinical and neuropsychological evaluation at baseline (T0), end of treatment (T1), and six months post-treatment (T2), which consisted of nearly four months of CR, CR+ Mindfulness, or CR + SST. The cognitive assessment included the Brief Assessment of Cognition for Schizophrenia (BAC-S) or Affective Disorders (BAC-A) and the Executive and Social Cognition Battery (ESCB), specifically designed to identify impairments in social cognition and executive functions in patients' real life. Participants underwent a 3T multimodal MRI, including structural and functional sequences at T0 and T1. We also recruited healthy controls for comparative brain mapping at T0.

The present lecture will provide an overview of the research project, along with some preliminary findings on the effect of CR alone or combined with other interventions on clinical and social functioning and brain plasticity, with a focus on the degree of durability and generalization of CR effects to patients' real life. The study's

outcomes have the potential to inform clinical and rehabilitative settings and tailor combined therapeutic interventions.

Utility of risky cannabis use concept and the role of standard units for achieving an operational definition

H. Lopez-Pelayo^{*} and C. Oliveras

Hospital Clínic Barcelona, Barcelona, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.121

Abstract: Over the past decade (2010-2019), the number of people admitting to using cannabis in the European Union (including the United Kingdom, Norway, and Turkey) increased by 27%, from 3.1% to 3.9%. Notably, Portugal, Spain, and Luxembourg topped the list with the highest percentages of daily cannabis users among those who had consumed the substance in the last month.

With the relaxation of recreational cannabis laws in various European countries, such as Germany, Malta, and Luxembourg, there is a growing need for a public health-oriented and preventative approach. Drawing parallels with alcohol-related strategies, this session aims to explore this evolving landscape from a clinical perspective.

The focus will be on the World Health Organization's definition of risky substance use, aiming to make it practical and applicable. Two existing proposals from Canada and Spain will be reviewed, with an emphasis on the role of standardized cannabis units in defining risk and the quest for consensus in this regard.

Additionally, the session will examine the similarities between alcohol and cannabis consumption, looking at the effectiveness of the Standard Drink Unit in early intervention and prevention of alcohol-related problems. Insights from the alcohol domain will be discussed, offering valuable lessons for preventing cannabis-related harm.

Moving forwards with the Standard THC Unit: what are the next steps?

V. Lorenzetti^{1*}, iCannToolkit Working Group, T. Freeman² and iCannToolkit Working Group

¹Neuroscience of Addiction and Mental Health Program, Healthy Brain and Mind Research Centre, Australian Catholic University, Melbourne, Australia and ²Psychology, University of Bath, Bath, United Kingdom

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.122

Abstract: Current metrics of cannabis use are inconsistent. This issue prevents the integration of the literature to date and to robustly measure the health risks and benefits associated with

specific levels of cannabis consumption. This talk will overview a number of international initiatives to improve the current metrics of cannabis use.

The Standard THC Unit was created to objectively measure cannabis potency across all products, mode of administration, jurisdictions, contexts and over time.

To build upon the notion of the Standard THC Unit, additional multidisciplinary, international consensus based frameworks have been created.

One such ongoing initiatives, seeks to reach expert consensus on how cannabis potency should be reported in cannabis products in order to clearly and effectively inform consumers. The talk will overview preliminary results of the Delphi.

A similar Delphi methodology was used to establish internationally agreed-upon minimum standards to measure cannabis consumption in research (iCannToolkit), the results of which will be outlined.

Overall, it is imperative for cannabis researchers to join forces with multidisciplinary experts in order to improve metrics of use to inform consumers, general practitioners, researchers and public health experts on the harms and benefits associated with cannabis use.

Implementation of the self-sufficiency matrix (SSM) to support diagnosing people with complex social needs at the Social Services of Catalonia

C. Salrach^{1,2,3*}

¹Avedis Donabedian Research Institute, Barcelona; ²Universitat Autònoma de Barcelona (UAB), Sant Cugat del Vallès and ³Network for Research on Chronicity, Primary Care, and Health Promotion (RICAPPS), Barcelona, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.123

Abstract: The Department of Social Rights of the Generalitat de Catalunya considered using a unique tool to identify people with complex social needs at Social Services centres and to support the diagnosis processes. After conducting a thorough search and selection process for various tools, the self-sufficiency matrix (SSM), a Dutch tool, was ultimately chosen.

The tool was adapted to the Catalan context through a transcultural translation process, which included a pilot and validation process. This resulted in the creation of the Catalan matrix (SSM-CAT).

A comprehensive implementation program was defined to start the adoption of the tool at basic social services. This program included training trainers and providing online training with practical cases. The implementation process was accompanied by support and monitoring to ensure success.

Through this process, over 3,468 professionals (including 334 trainers) received training on the self-sufficiency matrix, and 31,354 individuals who received basic social services in Catalonia were evaluated. In Barcelona, a more thorough monitoring of the implementation was conducted, assessing a representative sample of the care provided (6,916 individuals attended) generating a more

accurate description of the situation of the people attended by social services in the city of Barcelona.

Innovation in the treatment, interventions and systems of care for opioid use disorder: opportunities to understand multimorbidities

A. M. Baldacchino

Medicine, University of St Andrews, St Andrews, United Kingdom

doi: 10.1192/j.eurpsy.2024.124

Abstract

Introduction: Opioid use disorder is still the main presenting illicit substance use disorder that patients present within Addiction and Mental Health Services even though the majority of the patients are polysubstance users. Innovation in the field will allow providers to understand better how systems work to support a population with physical and psychological morbidities

Method: We will present novel narratives in describing:

1. Standards and principles
2. Pharmacology
3. Delivery systems
4. Neuroscience based interventions
5. Systems and implementation

Results and Discussion: The above descriptors will allow a landscape that is less stigmatising and better in responding to the needs of the people who are highly stigmatised and multidisadvantaged.

Organized professional response to a large-scale disaster: Earthquakes in Türkiye

K. Başar

Department of Psychiatry, Hacettepe University, Ankara, Türkiye

doi: 10.1192/j.eurpsy.2024.125

Abstract: In February 2023, a series of earthquakes with high magnitudes affected 11 cities in Türkiye, a region with a population of over 13 million. With more than 50000 recorded deaths and more than 3 million survivors replaced, rescue and recovery efforts were challenging. The Psychiatric Association of Türkiye (PAT) immediately launched a “Disaster and Crisis Management,” which urgently formed and installed a program for psychosocial support and psychiatric care. The program included immediate, medium, and long-term actions. Hundreds of recruitments followed a call for volunteers for on-site and online support. An online “Earthquake and Mental Health” library was launched immediately, and a series

of webinars on psychological first aid and disaster psychiatry were organized in the first two weeks. Furthermore, in three major cities, separate interactive meetings where question and answer sessions with trauma experts have been possible were held weekly with smaller groups. Almost a hundred volunteer PAT members served in the region in the first few months after the earthquake. All colleagues in the field, including those who survived the earthquakes, benefited from the resources of the PAT for their needs in housing, food, and mobilization. Starting from the first days, the PAT organized regional centers for coordination, which required financial resources and staff. The demand was high and could only be met with close collaboration with the Turkish Medical Association and the financial support obtained from international agencies, WPA, and other national psychiatric associations. The PAT started an online support system with technical support from a professional company, targeting healthcare professionals and first responders in the earthquake area. Volunteering psychiatrists provided appointment slots, rendering the system available 12 hours a day, seven days a week. With time, as the national healthcare delivery recovered, the PAT activities transformed into coordination, education, and supervision. Furthermore, the psychiatry residency training, which was interrupted due to the disaster, has been supported through a nationwide mentorship program launched by the PAT. The experience of the Psychiatric Association of Türkiye with disasters paved the way for an organized response, which was made possible through national and international solidarity.

WS0014

The impact of natural disaster on mental health and how to deal with it?

M. Rojnic Kuzman

Zagreb University Hospital Centre and the Zagreb School of Medicine, Zagreb, Croatia

doi: 10.1192/j.eurpsy.2024.126

Abstract: Natural disasters are and will continue to represent a great challenge in addressing mental health issues globally. The most devastating recent (earthquakes on 6th February 2023 in Turkey and Syria) caused death of more than 55,000 people, injury of about 100,000 people and loss of property, overall affecting millions of people. Moreover, in the last several years in Europe, they came in a form of double disasters (for example coupled with the COVID-19 pandemic) and pointed out the unpreparedness of the health (including mental health) sectors for the emergency situations.

However, in going through these experiences, we also learnt some of the practices that proved effective – including the fast creation of collaborative networks on a larger scale that also allowed fast spread of good practices and practical organisation of help. As a practical example of it - verbalized by the mental health professionals from Turkey through the Council of National Psychiatric Associations of the European Psychiatric Association, we organized a webinar delivered by experienced clinicians, trauma experts and experts with lived experience in the earthquake zones. However, structural -implementation of mental health policies that focus on prevention and improving crisis response in care delivery are important to support populations affected by natural disasters to prevent the trauma sequel.

Understanding females with attention deficit and hyperactivity disorder

O. Kilic

Department of Neurosciences, Bezmialem Vakif University, Institute of Health Sciences, Istanbul, Türkiye

doi: 10.1192/j.eurpsy.2024.127

Abstract: The predominant association of attention deficit and hyperactivity disorder (ADHD) with males, often leads to underdiagnosis or misdiagnosis in females. Recent studies have highlighted marked differences between genders in the manifestation, symptoms, and outcomes of ADHD. Understanding these differences is essential for accurate identification, diagnosis, and tailored interventions for affected individuals, particularly females. The multifaceted nature of ADHD demands a nuanced examination of its impact on females, considering how societal expectations, hormonal influences, and a range of symptom presentations may contribute to the variation in the manifestation of this disorder across genders. This presentation aims to contribute to a more comprehensive understanding of ADHD, fostering improved recognition and tailored strategies to support both males and females who suffer from this condition.

ECP0002

Principles of ADHD diagnosis in adults The diagnosis of ADHD in adults poses unique challenges due to the subtlety of symptoms and the presence of comorbidities

A. Todzia

Polish Psychiatric Association, Warsaw, Poland

doi: 10.1192/j.eurpsy.2024.128

Abstract: Attention-Deficit/Hyperactivity Disorder (ADHD) is commonly associated with childhood, yet its prevalence and impact extend into adulthood. The diagnosis of ADHD in adults poses unique challenges due to the subtlety of symptoms and the presence of comorbidities.

The workshop aims to provide early career psychiatrists with a comprehensive understanding of the unique challenges associated with adult ADHD, emphasizing evidence-based approaches to diagnosis and effective management.

The management of adult ADHD involves a multimodal approach encompassing psychoeducation, pharmacotherapy, and psychosocial interventions. The integration of cognitive-behavioral therapy (CBT) and coaching strategies proves beneficial in addressing executive function deficits and enhancing adaptive skills.

Pharmacological interventions are a key component in the management of ADHD. These interventions aim to alleviate symptoms, improve cognitive functioning, and enhance overall functioning. The two main classes of medications commonly used for ADHD treatment are stimulants and non-stimulants.

Young Adults On Mental Health Instagram and TikTok: Self-Care, Self-Diagnosis and Performances of The Mentally Healthy Self

A. Bailie

Politics and International Relations, University of York, York, United Kingdom

doi: 10.1192/j.eurpsy.2024.130

Abstract: My PhD research critically examines the contemporary U.K politics of mental health and illness and mental illness amongst young adults via social media.

This presentation examines the way in which social media, like Instagram and Tiktok allows young adults to explore, express and share their selfhood and identity around ideas of mental health and illness through videos, posts and online interactions. I will briefly explore how young adults use social media content to learn, experience and criticise their lived experiences, care for and treatment of mental health and illness. Arguing that these new developments in language and social practices around mental health and illness via social media need to be further explored, acknowledged and addressed in social science and this can be supported by work in the field of psychiatry.

To illustrate this, I will share empirical data from interviews conducted in 2021 and 2022 with young adults who speak about their mental health and illness online and have engaged with psychiatric services, for example, in-patient settings. Instagram and Tiktok have become important arenas for young adults because of the informative role they play in young adults' understanding of what a healthy person looks like, or their ideas of *the mentally healthy self*. A concept I introduce in my research of which I will explain and explore through the presentation. In young adults' understandings of mental health and illness there is a movement towards social practices that are intended to achieve (an idea of) mental health and this is created in a powerful digital environment that is affected by capitalism, neoliberal discourse and exists in a context of multiple political and health crises in the U.K and globally. Overall, the

presentation argues that these mental health and illness social practices have transformed young adults's experiences by responsabilisation in self-care that both isolates and empowers their experiences.

Navigating Information Technologies in Everyday Psychiatry Practice: A Guide for Early Career Psychiatrists

K. Vasilchenko

Human Artificial Control Keren (HACK) lab, Bar-Ilan University, Safed, Israel

doi: 10.1192/j.eurpsy.2024.131

Abstract: This presentation provides an overview of the impact of information technologies on contemporary psychiatric practice, focusing on resources and strategies beneficial for early career psychiatrists. Considering the increasing role of digital technologies in diagnosing and treating mental disorders, the presentation emphasizes the practical applications of artificial intelligence (AI) and machine learning. These technologies offer novel approaches for analyzing large volumes of clinical data, enhancing diagnostic accuracy, and personalizing treatment.

The presentation further examines ethical and legal issues associated with using digital technologies in psychiatry, including ensuring data confidentiality and complying with patient rights. The importance of developing competencies in information security and ethical principles when using digital tools is highlighted.

The talk concludes with an overview of the current and future trends in the use of digital technologies in psychiatry, including the development of virtual therapeutic environments and mobile applications for monitoring and supporting mental health. Examples of successful integration of these technologies into clinical practice are presented, emphasizing their potential to improve the quality of patient care.

Overall, the presentation underscores the importance for early career psychiatrists of mastering information technologies, highlighting their role in enhancing diagnosis, treatment, and patient care, as well as discussing the challenges and opportunities they present.

User involvement in psychiatric research: shifting from traditional research paradigms to collaborative partnerships

D. Cavaleri

Department of Medicine and Surgery, University of Milano-Bicocca, Monza, Italy

doi: 10.1192/j.eurpsy.2024.132

Abstract: In recent years, there has been a growing recognition of the importance of involving people with lived experience of mental

health issues in psychiatric research. User involvement in research goes beyond being merely instrumental and is deeply intertwined with ethical and political considerations. Shifting from traditional research paradigms to collaborative partnerships with users is seen as a crucial step in ensuring that research is more relevant, meaningful, and respectful of the diverse perspectives within the mental health community. While there is a growing interest and responsibility regarding this matter, there is still a need to better understand the differences between participation, engagement, and user-led research alongside a respectful integration of user perspectives. In this presentation, the state-of-the-art regarding user involvement in psychiatric research will be reviewed and possible ways to practically implement such practice will be discussed.

ECP0007

How can clinical trials expedite the process of answering treatment-related questions and reduce the number of participants needed?

R. Emsley

Institute of Psychiatry, Psychology and Neuroscience, London, United Kingdom

doi: 10.1192/j.eurpsy.2024.133

Abstract: Patients and the research community need better and more cost-effective randomised trials. These are the ‘gold standard’ way of seeing if a new treatment works or not, and take years of effort involving lots of patients and funding. However, around half of trials fail to show that the new treatment is better than what it is being compared with. In cancer, this problem has been recognised. They use trial designs which test multiple treatments, and find out quicker answers to more questions. These ‘efficient trials’ are able to involve patients at a faster rate and to improve the chances of patients receiving a treatment that works. In mental health, the whole toolbox of trial designs is not being used. Sometimes there are valid reasons for this, but sometimes it is simply that researchers do not know about them – this talk will expand on the concept of ‘efficient trials’ in mental health, and present the opportunities and challenges to using these.

How can electronic health records serve as a tool for clinical trials?

R. Stewart^{1,2*}

¹Department of Psychological Medicine, King's College London and ²PMOA, South London and Maudsley NHS Foundation Trust, London, United Kingdom

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.135

Abstract: Increasing volumes of information are being collected via electronic health records and there is growing multi-site expertise in utilising these for research. This emerging field of healthcare data science is not only concerned with the technical challenges associated with complex data, but also with the need for effective security and governance in the use of sensitive information with robust structures for stakeholder input and guidance. To date, most of the focus has been on supporting observational cohort studies nested within clinical records data - particularly investigating research questions around treatment response and course/prognosis. It is likely that electronic health records will become increasingly integrated with clinical trials, providing opportunities for pre-study feasibility scoping, targeted recruitment, and enhanced and extended follow-up. In addition, there is interest in emulated trials using routine data. For mental health data science, key challenges lie in the quality and quantity of data made accessible, with a particular need for natural language processing to derive structured data from extensive clinical text. Many of the challenges have been addressed for observational research, creating exciting prospects for a transformed trials landscape.

Virtual Insanity: Perspectives from a Political Digital Ethnographer of Young Adults Using Social Media for Mental Health

A. Bailie

Politics and International Relations, University of York, York, United Kingdom

doi: 10.1192/j.eurpsy.2024.136

Abstract: To contribute to this debate I offer perspectives from my PhD research which critically examines the contemporary U.K politics of mental health and illness amongst young adults via social media. My work examines the way in which social media, like Instagram and Tiktok allows young adults to explore, express and share their selfhood and identity around ideas of mental health and illness through videos, posts and online interactions. Through this work I have engaged with digital services, psychologists and medical professionals on the subject of using technology for the treatment, engagement of and knowledge of mental health and illness. I have additionally engaged with some work on the role of the Metaverse for treating mental illness, and how this could work, but also the limitations of virtual spaces. Exploring debates in digital sociology adds evidence to these arguments and can support the understanding of the political ramifications of using technologies in the clinical space. Arguing that these new developments in language and social practices around mental health and illness via social media need to be further explored, acknowledged and addressed in social science and this can be supported by work in the field of psychiatry. Overall, my contribution to the debate will be to offer political and digital social perspectives on the use of technology and highlight some of the biases and drawbacks of utilising AI to treat mental health and illness.

Pro to AI/metaverse implementation: a review on the potential of metaverse in psychiatry

L. F. Fontenelle

Department of Psychiatry and Legal Medicine, Federal University of Rio de Janeiro (UFRJ) and D'Or Institute for Research and Education (IDOR), Rio de Janeiro, Brazil
doi: 10.1192/j.eurpsy.2024.137

Abstract: The metaverse, a term first employed in Neal Stephenson's 1992 novel "Snow Crash", is a digital environment delivered via artificial intelligence in which multiple users can use avatars to engage in social, economic and cultural activities. Broadly speaking, metaverse encompasses technologies as diverse as augmented reality (AR), "lifelogging" (smart watches, smart phones and other wearables), "mirror" worlds (e.g. Google Earth, Waze, ...) and virtual reality (VR). There is a pressing need to understand the potential of metaverse for medicine in general and psychiatry in particular. The therapeutic use of VR technologies is already a reality in clinical practice, particularly in terms of online treatments and exposure and response prevention for anxiety disorders, obsessive-compulsive and related disorders, and trauma-related disorders. Avatar integrated therapies may increase treatment seeking via anonymity, decrease in physical and communication barriers, and facilitation of expression. In terms of research, the metaverse allows manipulation of the therapeutic environment in order to answer specific questions.

Challenges that early career psychiatrists can face on compulsory treatment

E. Chumakov

Department of Psychiatry and Addiction, St Petersburg State University, St Petersburg, Russian Federation
doi: 10.1192/j.eurpsy.2024.138

Abstract: The delivery of mental health care worldwide often involves compulsory treatment, a practice encountered by early career psychiatrists from the outset of their training. Despite its prevalence, little research has explored the challenges faced by trainees and early career psychiatrists when compelled to administer treatment without patient's consent. This presentation will synthesize research data and offer personal reflections on the author's experiences.

Challenges that early career psychiatrists can face regarding compulsory treatment can be categorized into personal, professional, and institutional. Personal challenges encompass the emotional stress associated with applying coercive measures, coping with negative emotions, and managing service users' attitudes toward treatment without consent. There is also concern that compulsory treatment may elevate the risk of emotional burnout. Professional challenges involve the administrative burden associated with organizing compulsory treatment, often exacerbated by the formalization of the process as a bureaucratic procedure in many European countries. Additionally, dealing with legal processes, including interactions with lawyers and courts, can pose significant difficulties, even though it is clearly done to protect the rights of the persons receiving care. Institutional challenges encompass the overall policy of providing compulsory psychiatric care in the psychiatrist's home country and the specific practices of coercive measures in a given treatment facility. Furthermore, the lack of dedicated time for ethics of coercion during training is a common issue.

In the current landscape of mental health care, early career psychiatrists must undergo training to handle coercive measures. While these measures are sometimes unavoidable, ethical principles must guide their administration. Additionally, access to supervision/mentoring is crucial for early career professionals facing challenging cases.

Experiences and attitudes of early career psychiatrists towards ECT – an international study

C. Tapoi^{1,2*}

¹Department of Psychiatry, Prof. Dr. Dimitrie Gerota Emergency Hospital and ²Department of Psychiatry, Prof. Dr. Alexandru Obregia Clinical Psychiatry Hospital, Bucharest, Romania

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.139

Abstract

Introduction: Electroconvulsive therapy (ECT) is a psychiatric intervention that has proven effectiveness and safety in various psychiatric conditions, such as major depressive disorder, prolonged or severe manic episodes and catatonia. Despite positive scientific evidence, ECT was always seen as controversial by patients, caregivers, and even some psychiatrists, which lead to a decrease in its use over the years.

Objective: To investigate the way young psychiatrists view the place of ECT in modern psychiatry by assessing their knowledge, attitude and access to training opportunities in ECT.

Methods: An anonymous survey was disseminated online among early career psychiatrists and psychiatric trainees. The questionnaire consisted of 36 multiple-choice and Likert scale questions.

Results: Most of our respondents consider ECT both an effective and a safe treatment option and would recommend ECT to their patients when indicated. Early career psychiatrists who had access to ECT training are more knowledgeable about the indications, precautions and side effects of this method, but more than half of the participants mentioned ECT training was unavailable during their residency programme. Almost all respondents stated that they are interested in enhancing their theoretical and practical competencies in ECT.

Conclusions: Early career psychiatrists have a positive attitude towards ECT but express the need of targeted education aimed at improving levels of knowledge about ECT.

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.140

Introduction: Panic disorder (PD) and agoraphobia (AG) are highly comorbid anxiety disorders with an increasing prevalence that have a significant clinical and public health impact but are not adequately recognized and treated. Although the current functional neuroimaging literature has documented a range of neural abnormalities in these disorders, primary studies are often not sufficiently powered and their findings have been inconsistent.

Objectives: This meta-analysis aims to advance our understanding of the neural underpinnings of PD and AG by identifying the most robust patterns of differential neural activation that differentiate individuals diagnosed with one of or both these disorders from age-matched healthy controls.

Methods: We conducted a comprehensive literature search in the PubMed database for all peer-reviewed, whole-brain, task-based functional magnetic resonance imaging (fMRI) activation studies that compared adults diagnosed with PD and/or AG with age-matched healthy controls. Each of these articles was screened by two independent coding teams using formal inclusion criteria and according to current PRISMA guidelines. We then performed a voxelwise, whole-brain, meta-analytic comparison of PD/AG participants with age-matched healthy controls using multilevel kernel density analysis (MKDA) with ensemble thresholding ($p < 0.05$ – 0.0001) to minimize cluster size detection bias and 10,000 Monte Carlo simulations to correct for multiple comparisons.

Results: With data from 34 primary studies and a substantial sample size ($N=2138$), PD/AG participants, relative to age-matched healthy controls, exhibited a reliable pattern of statistically significant, ($p < 0.05$ – 0.0001 ; FWE-corrected) abnormal neural activation in multiple brain regions of the cerebral cortex and basal ganglia across a variety of experimental tasks.

Conclusions: In this meta-analysis we found robust patterns of differential neural activation in participants diagnosed with PD/AG relative to age-matched healthy controls. These findings advance our understanding of the neural underpinnings of PD and AG and inform the development of brain-based clinical interventions such as non-invasive brain stimulation (NIBS) and treatment prediction and matching algorithms. Future studies should also investigate the neural similarities and differences between PD and AG to increase our understanding of possible differences in their etiology, diagnosis, and treatment.

Early-onset obsessive-compulsive disorder: sociodemographic and clinical characterization of a large outpatient cohort

B. Benatti^{1,2*}, N. Girone¹, M. Vismara¹, C. Bucca¹ and B. Dell'Osso^{1,2,3}

¹Department of Mental Health, Sacco University Hospital; ²Center for Neurotechnology and Brain Therapeutic, Aldo Ravelli Center, University of Milan, Milan, Italy and ³Department of Psychiatry and Behavioral Sciences, Bipolar Disorders Clinic, Stanford University, Stanford, United States

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.141

Introduction: Obsessive-compulsive disorder (OCD) is a prevalent and disabling condition characterized by a wide variety of phenotypic expressions. Several studies have reinforced the hypothesis of OCD heterogeneity by proposing subtypes based on predominant symptomatology (Mataix-Cols et al., 2005), course (Tukel et al., 2007), and comorbidities (Mahasuar et al., 2011). Early-onset OCD could be considered a neurodevelopmental subtype of OCD, with evidence of distinct neurocircuits supporting disease progression (Park et al., 2022).

Objectives: The aim of the present study is to evaluate the socio-demographic and clinical differences between the early-onset and late-onset subtypes in a large patient cohort.

Methods: Two hundred and eighty patients diagnosed with OCD were consecutively recruited from the OCD Tertiary Clinic at Luigi Sacco University Hospital in Milan. Sociodemographic and clinical variables were analyzed for the entire sample and compared between the two subgroups (EO: early-onset, age <18 years [40%]; LO: late-onset, age ≥ 18 years [60%]).

Results: The EO group showed a higher frequency of male gender (65.5% vs 34.5%, $p < .001$, see Figure 1a), a higher presence of lifetime psychiatric comorbidities (75.7% vs 24.3%, $p = .025$), and higher rates of Tic and Tourette disorders (7.2% vs 0%, $p = .006$) compared to the LO group. Additionally, in the EO subgroup, a longer duration of untreated illness was observed (9.05 ± 10.0 vs 5 ± 7.17 ; $p < .001$, see Figure 1b), along with a lower presence of insight (33.3% vs. 66.7%, $p = .024$). No significant differences emerged in the Yale-Brown Obsessive-Compulsive Scale scores between the groups.

Image:

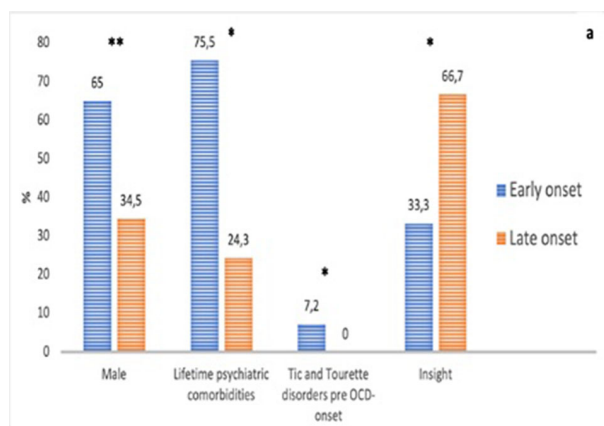

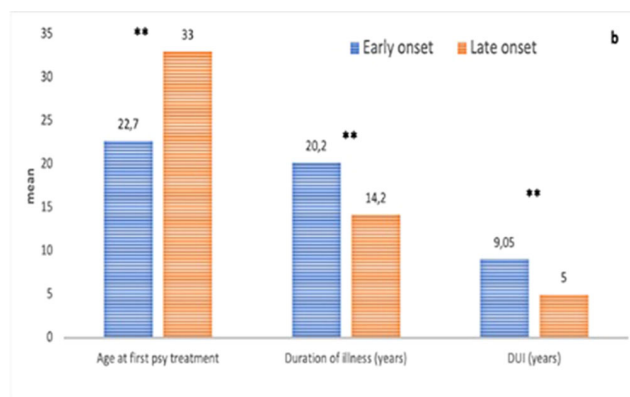

Image 2:

Conclusions: The early-onset OCD subtype highlights a more severe psychopathological profile compared to the late-onset group. Exploring distinct manifestations and developmental trajectories of OCD can contribute to a better definition of homogeneous subtypes, useful for studying risk factors and defining targeted therapeutic strategies for treatment.

A multivariate meta-analysis of peripheral cytokine levels in obsessive compulsive disorder

Y. Chen^{1,2*}, Q. Li^{1,2}, Y. Wang^{1,2}, Y. Wang^{1,2}, F. Long^{1,2} and F. Li^{1,2}

¹Huaxi MR Research Center (HMRRC), Department of Radiology, West China Hospital of Sichuan University and ²Research Unit of Psychoradiology, Chinese Academy of Medical Sciences, Chengdu, China

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.142

Introduction: Obsessive-compulsive disorder (OCD) is a common psychiatric disorder. It is considered that dysregulation of cytokine levels is related to the pathophysiological mechanism of OCD. However, the results of previous studies on cytokine levels in OCD are inconsistent.

Objectives: To perform a meta-analysis assessing cytokine levels in peripheral blood of OCD patients.

Methods: We searched in PubMed, Web of Science, and Embase from inception to March 31, 2023 for eligible studies. We conducted multivariate meta-analysis in combined proinflammatory cytokines (interleukin-6 [IL-6], IL-1 β , IL-2, tumor necrosis factor- α [TNF- α], and interferon- γ [IFN- γ]) and combined anti-inflammatory cytokines (IL-10 and IL-4) respectively, and calculated the same meta-analysis in each cytokine. We also performed sensitivity analysis and publication bias tests, as well as subgroup

analysis (i.e. different age groups, varied cytokine measurement methods, medication treated or naïve, and presence of psychiatric comorbidities) and meta-regression analysis (variables including patients' sex ratio, age, age at symptom onset, illness duration, scores of Y-BOCS, family history of psychiatric disorders, and BMI).

Results: 17 original studies (13, 13, 10, 5, 4, 3, 2 studies for IL-6, TNF- α , IL-1 β , IL-10, IL-2, IL-4, and IFN- γ , respectively), 573 patients (mean age, 25.2; 50.3% female) and 498 healthy controls (HC; mean age, 25.3; 51.4% female) were included. The results showed that the levels of combined pro- or anti-inflammatory cytokines and each single cytokine were not significantly different between OCD patients and HC (all $P > 0.05$), with significant heterogeneities in all analyses (I^2 from 79.1% to 91.7%). We did not find between-group differences in cytokine levels in all subgroup analyses. Meta-regression analysis suggested that age at onset ($P = 0.0003$) and family history ($P = 0.0062$) might be the source of heterogeneity in TNF- α level. Sensitivity analysis confirmed that all results were stable, except for IL-4 where different cytokine measurement methods may be the contributing factor. Egger test did not find publication bias.

Conclusions: Our study showed no difference in cytokine levels between OCD patients and HC, but age at onset and family history may affect TNF- α level. Confounding factors such as age at onset, family history, and cytokine measurement methods should be controlled in future studies to further explore the immune mechanism of OCD.

Exploring predictors of Treatment Attendance in Patients with PTSD and Comorbid Personality Disorders: Secondary Analysis of a Randomized Controlled Trial

A. van den End^{1,2}, A. Snoek^{1,3*}, I. Aarts^{1,4}, N. Lommerse⁵, J. Dekker^{5,6}, A. T. F. Beekman² and K. Thomaes^{1,2,4,7}

¹Sinai Centre, Amstelveen; ²Psychiatry, Vrije Universiteit Medical Centre, Amsterdam; ³Psychiatry, Vrije Universiteit Medical Centre, Amstelveen; ⁴Anatomy and Neurosciences, Vrije Universiteit Medical Centre; ⁵Arkin; ⁶Clinical Psychology, Vrije Universiteit, Amsterdam and ⁷Arkin, Amstelveen, Netherlands

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.143

Introduction: Posttraumatic stress disorder (PTSD) and personality disorders (PD) often co-occur and treatment dropout remains a challenging problem for both disorders. The literature on predictors of treatment dropout is highly mixed and few reliable predictors have been identified for both PTSD and PD treatments separately, let alone for concurrent PTSD and PD treatment.

Objectives: The aim of the present study was to identify predictors of treatment attendance among a wide range of variables in patients

with PTSD and comorbid PD who received trauma-focused treatment with and without concurrent PD treatment.

Methods: Data were used from the prediction and outcome study in comorbid PTSD and personality disorders (PROSPER), a study consisting of two randomized clinical trials (RCT) testing the effectiveness of trauma-focused treatment (eye movement desensitization and reprocessing or imagery rescripting) with versus without concurrent PD treatment (dialectical behavior therapy or group schema therapy). 256 patients with PTSD and comorbid personality disorder participated in the study. The potential predictors included demographic (e.g. work status), patient severity (e.g. PTSD severity), patient-therapist (e.g. working alliance) and therapist (e.g. therapist experience) variables. The ordinal outcome variable was treatment attendance (0, 1-7, 8-11, 12+ trauma-focused treatment sessions). Relevant predictors were identified by a series of ordinal regression analyses (threshold for inclusion $p < .10$). Relevant predictors were then entered together in a final ordinal regression model. Multiple imputation was used to handle missing data.

Results: The final model included ten predictor variables and provided a good fit for the data (pooled $R^2_{\text{Nagelkerke}} = .29$). Higher education level (OR = 1.22, $p = .009$), self-rated PTSD severity (OR = 1.04, $p = .036$) and working alliance (OR = 1.72, $p = .047$) were associated with a larger number of attended sessions. Higher levels of inadequate social support from a friend (OR = 0.90, $p = .042$) and being randomized in the concurrent treatment condition (OR = 0.52, $p = .022$) were associated with a smaller number of attended sessions.

Conclusions: In terms of treatment attendance rates, the results suggest that trauma-focused treatment is preferred over concurrent trauma-focused and personality disorder treatment for patients presenting with PTSD and PD. Clinicians should further be aware of the risk of lower treatment attendance for patients with a lower educational background and those reporting inadequate social support. Enhancing working alliance may protect against early treatment termination. Finally, patients with higher levels of PTSD severity at baseline may need a larger number of treatment sessions.

Assessment of Cognitive Performance and Psychophysiological Signals in Mental Patients by a Novel Method

M. Fűzi^{1*}, B. Petró², P. Barna² and K. Kósa¹

¹Department of Behavioural Sciences, University of Debrecen, Faculty of Medicine, Debrecen and ²Aviatic Ltd., Budapest, Hungary

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.144

Introduction: Mental disorders often manifest broad cognitive deficits that detrimentally affect daily functioning. Stress indicated by heart rate variability (HRV) has been linked to these cognitive functions.

Objectives: We aimed to develop a new method to assess cognitive performance and simultaneous measurement of psychophysiological signals related to stress and relaxation levels.

Methods: 20 adult patients with mental disorders in a rehabilitation program were recruited along with 21 healthy volunteers. A test protocol was carried out with a purpose-developed computerized psychophysiological device. The protocol consisted of a relaxation period; digitized questionnaires on pathological distress (GHQ) and sense of coherence (SOC); gamified cognitive tasks to assess working memory, attention, and decision-making; and a final relaxation period. Acute stress was assessed by heart rate variability measured by a wireless ECG sensor. The inter-beat interval's root mean square of successive differences (RMSSD) was calculated as an inverse stress measure. Relaxation levels were assessed by the relative power of the alpha frequency band measured by a commercial 4-channel EEG headband. Stress and relaxation levels were compared to the first relaxation period as a baseline.

Results: Patients scored worse than the reference group both regarding distress ($d=7$, $p=0.004$) and sense of coherence ($d=-8$, $p=0.047$). The cognitive performance of patients was significantly lower ($p<0.001$) than the reference group for all tasks. RMSSD at baseline tended to be lower for patients ($d=-12.69$, $p=0.098$), reflecting a higher level of physiological stress; 61% of patients started at an elevated stress level compared to 25% of the reference group. In addition, relative alpha levels at baseline were also lower ($d=-5.8\%$, $p=0.007$) for patients.

Compared to baseline, RMSSD decreased on average to 94% during cognitive assessments in patients and decreased to 91% by the end of the final relaxation. RMSSD decreased to 76% in the reference group and reached a final value of 78% of the baseline. Alpha levels slightly increased among patients during the tasks (103.4%) and then returned close to baseline (99.1%). For the reference group, alpha decreased during the tasks (95.5%) and then slightly increased (97.3%).

Conclusions: Patients displayed heightened distress, reduced sense of coherence, and inferior cognitive scores compared to controls. While starting with higher stress, patients exhibited less elevation in stress during tasks, coupled with alterations in alpha levels, suggesting diminished engagement or focus. Our innovative method could aid in the diagnostics of cognitive performance in mental patients after further measurements for validation.

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.145

Introduction: Given the negative impact of anxiety and depression on society and the shortage of new antidepressants, it is of paramount importance to make the best use of available treatment options. Therapeutic drug monitoring (TDM) in escitalopram treatment can potentially be clinically useful, as underexposed patients show reduced efficacy of escitalopram treatment and as adverse drug reactions (ADRs) of escitalopram are dose-dependent.

Objectives: This prospective cohort study aimed to investigate whether escitalopram treatment efficacy or safety are associated with escitalopram dose adjustment based on TDM readouts.

Methods: 89 included patients aged between 15 and 65 years who suffered from depression were enrolled in the study before starting treatment with escitalopram. Patients were assessed one day before starting treatment with the recommended dose of 10 mg/day escitalopram (baseline, visit 0) and at follow-up after four and eight weeks. Dose adjustment at four-week follow-up was based on the measured escitalopram plasma level two weeks after treatment initiation; patients who required dose increase to 15 or 20 mg/day comprised comparator group, patients who did not required dose increase comprised control group, while patients who did not reach optimal exposure at eight-week follow-up were characterized as non-compliers. Treatment efficacy was approximated by the relative change on the Hamilton Depression Rating Scale (HAMD), while safety was approximated based on the changes on the Scandinavian UKU side effect rating scale and ECG readouts. Changes in HAMD, UKU score and QTc interval were compared between groups by one-way ANOVA or chi-square tests.

Results: Compared to baseline, significant reductions in HAMD scores of 36% (95%CI, 30%-43%) and 53% (95%CI, 47%-60%) were observed at four- and eight-week follow-up, respectively; however, there were no significant differences between groups ($p > 0.1$). In the groups adjusted to 15 and 20 mg, 15/26 and 19/33 patients, respectively, reported adverse effects, compared with 6/17 patients in the control group and 6/13 in the non-complier group ($p>0.1$). A significant mean QTc prolongation of 6.40 ms (95%CI, 3.27-9.53) was observed between the baseline and eight-week follow-up ($p=0.0013$), without significant differences in QTc interval prolongation between groups ($p > 0.1$).

Conclusions: Escitalopram dose adjustment resulted in optimal drug exposure and solid treatment response in the majority of patients; however, no differences in efficacy were found between the patients who required dose adjustments, the ones who did not, and the ones who ultimately did not achieve optimal exposure. In addition, the selective increase of the dose to the patients who did not reach optimal drug exposure on the recommended dose of

10 mg/day did not lead to significant increase in adverse drug reactions and QTc prolongation.

Multicausal disruption of complement system activity in schizophrenia: abnormal transcription of C4, complement control proteins and microglia specific genes in brain and blood

R. Rey^{1*}, A. Fiorito², E. C. Ibrahim³, E. Fakra², G. Sescousse², R. Tamouza⁴ and M. Leboyer⁴

¹Schizophrenia Expert Center of Lyon, CH Le Vinatier; ²PSYR2 team, Centre de Recherche en Neurosciences de Lyon, Bron; ³Institut de neurosciences de la Timone, Marseille and ⁴Fondation FondaMental, Créteil, France

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.146

Introduction: The *synaptic pruning* process is based on the joint action of the complement system and microglia. In schizophrenia, accumulating evidence support that abnormal synaptic pruning during adolescence may be due to an altered Complement system activity. While this hypothesis is supported by C4 overexpression in various brain regions of individuals with schizophrenia, such alterations should be replicated and extended to other brain regions. Moreover, transcriptional studies of genes encoding regulators of the complement system activity (complement control proteins, CCP) and microglia-specific genes are lacking. Furthermore, it remains unknown whether brain and peripheral expression of such genes are related.

Objectives: To explore expression of C4 as well as 4 CCP encoding genes and 10 microglia-specific genes at the brain and peripheral levels in individuals with schizophrenia as compared to healthy controls.

Methods: We analyzed candidate gene expression from 9 Gene Expression Omnibus datasets obtained from 333 individuals with schizophrenia and 306 healthy controls (HC). We first compared expression of the candidate genes between individuals with schizophrenia and HC in postmortem brain samples from 7 different brain regions. Then, the same comparison was made in 4 different peripheral tissues.

Results: Regarding the complement system, we observed C4 overexpression in the DLPFC, parietal, temporal cortex and associative striatum of individuals with schizophrenia. We report distinct altered expression patterns of CCP genes in the DLPFC, hippocampus and cerebellum of individuals with schizophrenia. Only CD46 expression was altered in the blood of individuals with schizophrenia. Regarding microglia, we report an underexpression of several microglia-specific genes in the cerebellum, associative striatum, hippocampus and parietal cortex of individuals with schizophrenia vs. HC. At the peripheral level, we observed a mixed

altered expression pattern in the whole blood of individuals with schizophrenia.

Conclusions: Firstly, our results suggest that the CCP-mediated regulatory mechanisms of the Complement system are impaired in the brain of individuals with schizophrenia, potentially contributing to an excessive Complement system activity (CSA). Secondly, our results support the hypothesis of a widespread underexpression of microglia-specific genes in brain tissues of individuals with schizophrenia. Functionally, the observed transcriptional alterations may be related to the synaptic pruning impairment. Alternatively, they may translate a compensatory mechanism for neuroinflammation. In the whole blood, the altered transcriptional pattern may represent a potential peripheral signature of SZ.

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.147

Introduction: An early and comprehensive neurobiological characterization of severe mental disorders could elucidate mechanistic pathways, aid the development of novel therapeutics, and therefore enable timely and targeted intervention in at-risk youth and young adults. Therefore, we present an unsupervised transdiagnostic machine learning approach to investigate shared and distinct patterns of early-stage depressive and psychotic disorders on multiple clinical and neurobiological levels.

Objectives: To derive multi-level neurobiological and clinical signatures of early-stage affective and psychotic disorders in adolescents and young adults.

Methods: From the multicenter prospective European PRONIA cohort, we acquired data from 678 individuals (51% female) comprising young, minimally medicated in- and outpatients with clinical high-risk (CHR) states for psychosis, with recent-onset depression (ROD) or psychosis (ROP), and healthy control (HC) individuals. Within repeated nested cross-validation frameworks, we employed Sparse Partial Least Squares Analysis to detect associations between blood markers and grey matter volume (GMV), followed by support vector machine prediction of these signatures using biographical, clinical, neurocognitive, proteomic, and functional data.

Results: Our results demonstrated a psychosis staging signature separating ROP from CHR individuals via GMV patterns in the

cortico-thalamo-cerebellar circuitry with a blood marker set of elevated of IL-6, TNF- α and CRP ($\rho = 0.272$; $P = 0.002$). A depression signature separated ROD from HC individuals via altered GMV in the limbic system with a blood marker set of elevated IL-1 β , IL-2, IL-4, S100B and BDNF ($\rho = 0.186$; $P = 0.021$). Only the psychosis staging signature showed a distinct proteomic enrichment regarding innate immune response, abnormal neutrophil function, cellular senescence, and anti-inflammatory drugs (Balanced Accuracy (BAC) = 87.73%; Area Under the Curve (AUC) = 0.94). Childhood trauma differentially predicted psychosis and depression signatures, while past level of functioning, personality and quality of life was predictive of both signatures (BAC = 67.19-78.00%; AUC = 0.71-0.83).

Image:

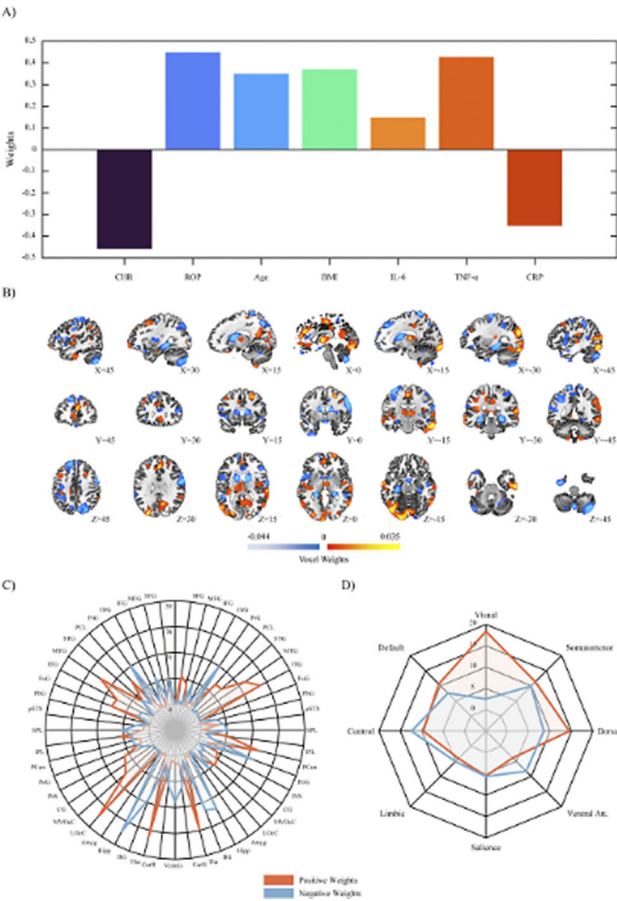

Image 2:

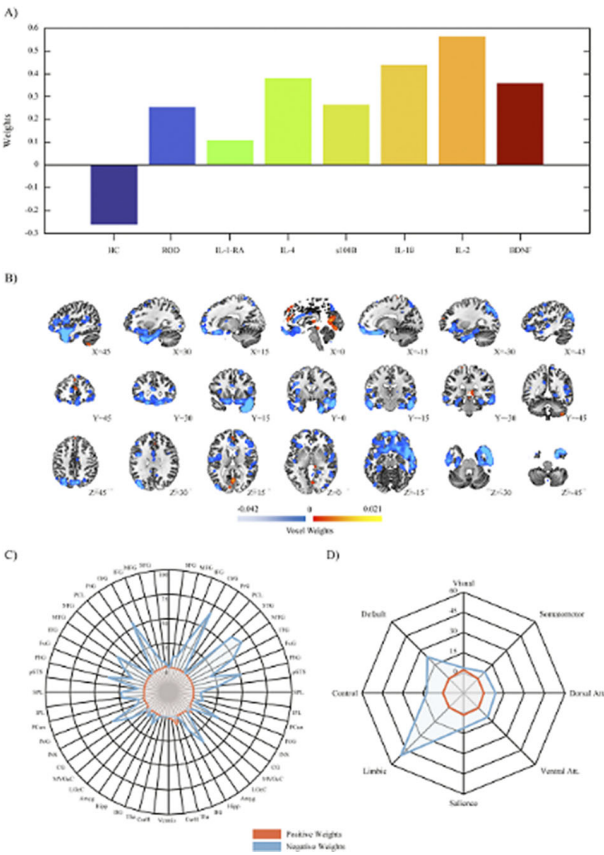

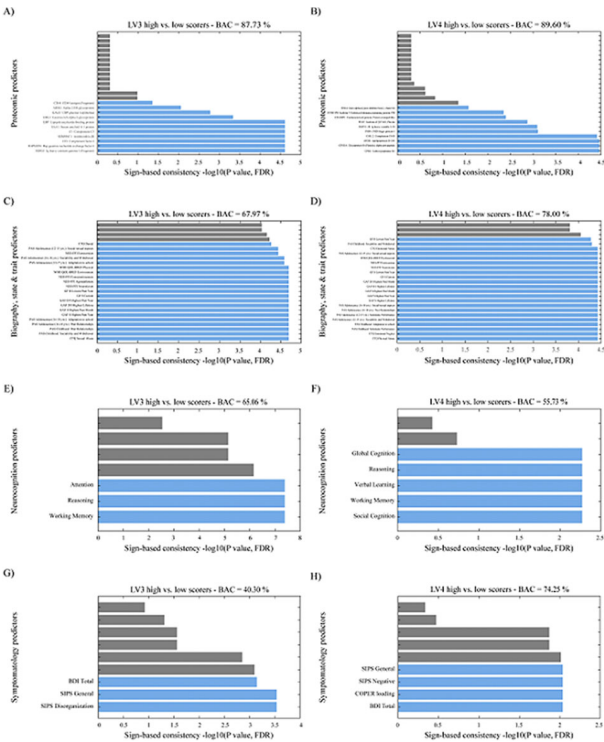

Image 3:

Conclusions: Psychosis and depression exhibit distinct multi-level signatures evident in early disease stages. Enhanced insight into these signatures could help delineate individual trajectories and potentially new mechanisms for pharmacological treatment.

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.148

Introduction: Previous research has implicated herpes simplex virus 1 (HSV1) and cytomegalovirus (CMV) in severe mental illness (SMI) with conflicting results. Both pathogens have high universal seroprevalence, are neurotropic and after the primary infection typically establish a persistent latent infection with periodic reactivations. Increased immunoglobulin G (IgG) concentrations are considered to be attributable to an increased infection severity with more frequent reactivations or host immune system alterations.

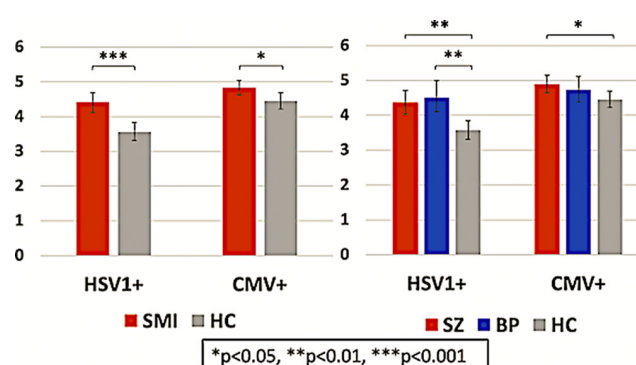

Objectives: We assessed the HSV1 and CMV IgG concentrations in previously infected (seropositive) patients with SMI and healthy controls (HC). We hypothesized that seropositive patients would show higher IgG concentrations than seropositive HC.

Methods: We included 765 patients, 515 with schizophrenia (SZ) and 250 with bipolar disorder (BP), and 541 HC. HSV1 and CMV IgG seropositivity and concentrations were measured with immunoassays. 355 patients, mean age 33 years, 45% females, and 238 HC, mean age 35 years, 44% females, were HSV1 seropositive (HSV1+) while 447 patients, mean age 33 years, 50% females, and 296 HC, mean age 34 years, 47% females, were CMV seropositive (CMV+). In our main analysis among seropositive participants, we investigated the main effect of patient/control status on HSV1 and CMV IgG concentrations.

Results: There were no significant differences in CMV or HSV1 seropositivity frequencies between patients with SZ, patients with BP and HC. Among seropositive participants, patients had higher HSV1 ($p<0.001$) and CMV ($p=0.018$) IgG concentrations than HC; stratifying by diagnosis, both patients with SZ ($p=0.001$) and patients with BP ($p=0.001$) had higher HSV1 IgG concentrations than HC, while patients with SZ, but not BP, had higher CMV ($p=0.045$) IgG concentrations than HC (Image). For HSV1, higher IgG concentrations were associated with higher general ($p=0.017$),

negative ($p=0.041$) and positive ($p=0.028$) psychotic symptom scores.

Image:

Conclusions: Seropositive patients with SMI showed higher HSV1 and CMV IgG concentrations than seropositive HC suggesting that patients suffer a more severe infection or exhibit an altered immune response when contracting the pathogens. For HSV1, higher IgG concentrations were linked to more psychotic symptoms.

Significant beneficial effects of 12-weeks add-on yoga therapy on antipsychotic-stabilized schizophrenia patients through epigenetic modulation: novel findings from a randomized controlled study

M. Debnath^{1*}, T. Mullapudi¹, R. Govindaraj², P. Raj³ and S. Varambally³

¹Human Genetics; ²Neurophysiology and ³Psychiatry, National Institute of Mental Health and Neurosciences, Bangalore, India

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.149

Introduction: Complementary and alternative therapy, especially yoga, is emerging as an important treatment modality for various complex disorders. Yoga therapy has reportedly been demonstrated to exhibit clinical benefits in schizophrenia. However, the modulatory effects of yoga therapy on the pathobiological pathways of schizophrenia are inadequately explored. Immune dysregulation is a widely recognized etiopathological construct of schizophrenia. It is not precisely known whether yoga therapy can modulate the expression of immune molecules by regulating gene expression and epigenetic processes in schizophrenia.

Objectives: To understand the impact of 12-weeks add-on yoga therapy on the immune-inflammatory pathway in schizophrenia

by examining plasma levels and gene expression levels of cytokines and complement proteins as well as by profiling promoter DNA methylation pattern of genes coding for cytokines and complement proteins.

Methods: Fifty-seven schizophrenia patients fulfilling DSM-V criteria were recruited into the study and randomized into Yoga therapy (n=28) and waitlist control (n=29) groups. Plasma levels of IL-1 β , IL-6, IL-10, IL-17, C1q, C2, C3, C4, C5, C5a, Factor B and Factor H by Multiplex Suspension Assay, quantification of gene expression of *Il1b*, *Il6*, *Il10*, *Il17*, *C3*, *C4* and *C5* genes by quantitative PCR and promoter DNA methylation of *Il1b*, *Il6*, *Il10*, *Il17*, *C3*, *C4* and *C5* genes by pyrosequencing were carried out in all the study participants.

Results: Plasma levels of IL-1 β (Z score= 2.42, p=0.02) dropped significantly and C2 (Z score= 2.24, p=0.03) levels increased after 12-weeks of yoga therapy. The expression of *Il1b* (Z score=2.45, p=0.01) and *Il6* (Z score=2.07, p=0.04) genes were significantly downregulated, while the levels of *C4* (Z score=2.23, p=0.03) gene was upregulated in schizophrenia patients of yoga therapy group. Two CpG sites in the promoter region of *Il1b* (all p \leq 0.05) and *Il6* (all p \leq 0.05) genes and three CpG sites in the promoter region of *C4* (all p \leq 0.05) gene were hypermethylated, while two CpG sites in the gene body of *Il6* (all p \leq 0.05) gene and two CpG sites in the promoter region of *Il10* (all p \leq 0.05) gene were hypomethylated after 12-weeks of yoga therapy in schizophrenia patients.

Conclusions: Our findings provide important insights into the mode of action of yoga therapy in schizophrenia. This study for the first time reports the epigenetic effects of yoga therapy on immune-inflammatory pathway in schizophrenia.

doi: 10.1192/j.eurpsy.2024.150

Introduction: Exploring the positive psychological and behavioural dimensions of people living with mental disorders can establish a firm ground in a therapeutic alliance for setting up positive life goals.

Objectives: The present study aimed to explore whether the strength of the mental health capacities and the severity of mental disorder symptoms and the interaction of the two differ in the strength of their associations with several dimensions of well-being on Hungarian adult psychiatric and non-clinical community samples.

Methods: The psychiatric sample (129 patients (44 male, 85 female)) was collected in four Hungarian healthcare facilities using a cross-sectional design. The non-clinical community sample (253 adults (43 male, 210 female)) was collected online using a cross-sectional design. All the respondents completed the Mental Health Test, six well-being and mental health measures, and the Symptom Checklist-90-Revised.

Results: Including both the mental health competencies and mental disorder symptoms variables in one regression model in both samples can predict patients' well-being even more accurately. Mental health competencies related positively; mental disorder symptoms connected negatively to subjective well-being. In all models and both samples, mental health competencies were found to be a stronger determinant of well-being than the mental disorder symptoms. The interaction of mental health functioning and mental disorders is no more predictive of well-being in either psychiatric or non-clinical samples than when the effects of each are considered separately.

Conclusions: The assessment of mental health competencies has an important predictive value for well-being in the presence of psychopathological symptoms and/or mental disorders.

doi: 10.1192/j.eurpsy.2024.151

Introduction: Autism Spectrum Disorder (ASD) is characterized by impairments in social interaction and restricted interests. It has been reported that oxytocin may improve processing of social cues and emotions in adults with ASD.

Objectives: The aim of this study was to evaluate the therapeutic effects and safety of intranasal oxytocin in this population.

Methods: Thirty-nine patients with ASD were randomly assigned to two groups: one group received intranasal oxytocin and the other group received a placebo, with 24 units administered every 12 hours for 8 weeks. The patients were evaluated using the Autism Quotient (AQ), Ritvo Autism Asperger Diagnostic Scale – Revised (RAADS-R), Social Responsiveness Scale (SRS), Clinical Global Impression (CGI), and World Health Organization Quality of Life-BREF (WHOQL-BREF) questionnaires at weeks 0, 4, and 8.

Results: The intervention group showed clinical improvements in RAADS-R ($P=0.010$), social communication subscale of SRS ($P=0.002$), CGI ($P=0.000$), physical ($P=0.004$), psychological ($P=0.006$), and social relationships ($P=0.046$) domains of WHOQL-BREF. Improvements reached their maximum at week 4 and were maintained until week 8 (Table 1).

Table 1. Effect of group, time time-group interaction and the effect size

Challenges of Sexuality Expression in Individuals with Autism Spectrum Disorder

M. M. Figueiredo^{1*}, P. Afonso² and V. Vila Nova²
¹Psiquiatria and ²Centro Hospitalar Setúbal, Setúbal, Portugal
*Corresponding author.
doi: 10.1192/j.eurpsy.2024.152

Introduction: Sexuality, although an essential component of human health, remains a controversial topic shrouded in stigma, particularly in the context of neurodiversity, which includes autism

spectrum disorder (ASD), where the expression of sexuality presents unique challenges. Autism and sexuality is a complex and multifaceted topic that involves understanding the unique ways in which individuals on the autism spectrum experience and express their sexuality.

Objectives: The purpose of this work is to address the complexity of the biopsychosocial sexuality components of people with autism, promoting a shift in the medical perspective, societal attitudes, and supporting greater inclusion of these individuals in current discussions regarding this area of human behavior and experience.

Methods: Evidence-based review, through research conducted on PubMed and selection of the most relevant studies on this topic, published in the last decade.

Results: Sexuality in autism is now recognized as a normative and integral aspect of development and functioning. Existing research suggests that most individuals with ASD display a clear interest in sexuality and relationships, with a study revealing that 96% of the ASD sample expressed an interest in sexuality. Individuals with high autistic traits tended to identify themselves more times as bisexual or presented a sexuality not definable within the categories of heterosexual. The relationship between autism and gender dysphoria is an area of ongoing research and discussion. Studies have suggested a higher prevalence of gender diverse identities and experiences within the autism community compared to the general population. Various hypotheses have been proposed to explain the increased gender and sexual diversity among individuals with autism. People with ASD may face unique challenges when it comes to their sexuality. The impairments in social skills and communication central to ASD potentially impact an autistic individual’s expression and experience of sexuality by affecting their abilities to understand and interpret social cues, emotions, and nonverbal behaviors of others. Importantly, such individuals may be more vulnerable, as they may have different or even limited understanding of boundaries and consent. To address these challenges, it is important to acknowledge and respect the diversity of sexual experiences and desires among individuals with neuro(bio)logical differences. This can be done by providing accurate and inclusive sex education, creating safe spaces for such individuals to explore and express their sexuality, and working to address discrimination and abuse in intimate contexts.

Conclusions: Recognizing and respecting this diversity and fostering inclusive and accepting environments, we can help individuals with neurological differences to fully express and explore their sexuality and have satisfying sexual lives.

doi: 10.1192/j.eurpsy.2024.153

Introduction: In the last decades, growing evidence suggests, that young adults and even adolescents consume more and more pornographic content, which might lead to behavioural addictions. Excessive pornography use was found to be associated with higher rates of sexual dysfunctions, such as genital dysfunction or disorders related to desire, arousal, orgasm and pain. The role of attachment style on sexual function has still rarely been investigated.

Objectives: To examine associations between sexual dysfunction, problematic pornography use and attachment styles in a Spanish-Hungarian sample.

Methods: A cross-sectional comparative study was carried out in 2023 which included a Hungarian (N=447; 63% female; age: 30,5 ±9,8) and a Spanish sample (N=201; 72% female; age: 40,7±14) from the general population. In the online survey, we used the Arizona Sexual Experiences Scale (ASEX) to measure sexual dysfunction, the Problematic Pornography Use Scale (PPCS) to assess pornographic content consumption within the theoretical framework of addiction and the Relationships Questionnaire to explore the attachment styles of the subjects.

Results: 13% of the Hungarian sample and 19% of the Spanish sample reported severe sexual dysfunction (ASEXTotal >19). The Hungarian sample reported more problems related to orgasm (climax and satisfaction). Overall, 7% of the Hungarian sample and 1% of the Spanish sample reported very severe problems (PPCSTotal >76) with pornography use. We found significant differences in every subscale and the Hungarian sample reportedly showed more difficulties in every aspect, especially in salience and mood change. Regarding attachment styles, the samples also showed significant differences (Hungarian: 31% secure, 26% anxious-ambivalent, 20% avoidant, 23% disorganized; Spanish: 53% secure, 11% anxious-ambivalent, 23% avoidant, 13% disorganized). In the combined sample, secure attachment style was associated with the least difficulties in sexual functioning, whereas subjects with anxious-ambivalent style reported more problems in sexual drive, arousal and erection. Disorganized attachment style was associated with the most severe dysfunction in orgasm (climax and satisfaction). The association between problematic pornography use and attachment styles was more consistent. Secure attachment style showed the least of problems, whereas subjects with anxious-ambivalent and disorganized attachment styles reported the most, especially in salience and mood change.

Conclusions: Our findings showed significant intercultural differences between the two samples and highlighted the potential role of attachment styles in sexual functioning and problematic pornography use. A more profound understanding of the relationship between attachment and sexual functioning could facilitate potential treatment of sexual dysfunctions by addressing attachment issues in psychotherapy.

Mindfulness possibilities in the treatment of chronic headaches

D. Perczel-Forintos* and D. Sal

Clinical Psychology, Semmelweis University, Budapest, Hungary

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.154

Introduction: Headache is a very common health problem worldwide and in our country due to the increasing environmental damage and daily stress. The proportion of patients with headache in general practice is 4-5%, in neurology up to 30%. Chronic headache as a persistent stressor exhausts the body through central sensitisation, which can lead to the consolidation of maladaptive coping strategies such as avoidance, feelings of loss of control, catastrophising pain. This can lead to a deterioration in quality of life and depression also. The effectiveness of pharmacotherapy in coping with chronic pain is limited, so attention should be paid to modifying maladaptive pain behaviour, as recommended by the NICE guidelines. The international literature shows that mindfulness-based cognitive therapy (MBCT) has been shown to be effective in the management of chronic headache, primarily in improving quality of life, increasing self-efficacy and reducing pain catastrophisation and depression (Hunt et al., 2022).

Objectives: Our first objective was to introduce mindfulness-based cognitive therapy in Hungary to patients suffering from chronic headache. Secondly, we wanted to measure the impact of the method on quality of life, coping with pain and depression.

Methods: N=28 patients, suffering from chronic headaches (tension headache and migraine) participated in the study at the Department of Clinical Psychology, Semmelweis University (BNO: G430, G431, G442). Selection criteria were: referral from a neurologist, age 18-65. The intervention was an 8-session mindfulness-based cognitive therapy for pain (Day, 2017) led by an MBCT teacher and a clinical psychology resident. Before the intervention, all patients had an individual first interview and filled in the questionnaires. *Measures:* Beck Depression Questionnaire, Pain Catastrophizing Scale, Comprehensive Headache-related Quality of life Questionnaire, Five Facet Mindfulness Questionnaire, Cognitive Emotion Regulation Questionnaire.

Results: After the intervention, there was a significant reduction in the negative impact of pain on quality of life ($p < 0.05$, Cohen's $d = 0.6$), pain catastrophization ($p < 0.01$, Cohen's $d = 0.74$), and depression ($p < 0.001$, Cohen's $d = 0.84$). In addition, several sub-factors of mindfulness increased, including non-reactivity and being non-judgemental ($p < 0.05$, Cohen's $d = 0.57$), as well as adaptive cognitive emotion regulation strategies ($p < 0.05$, Cohen's $d = 0.49$).

Conclusions: We can conclude, that in line with international findings, MBCT has been shown to be effective in reducing the negative impact of depressive symptoms, pain catastrophisation and headache on quality of life, and in helping people to cope with pain more adaptively, primarily through the acquisition of mindfulness skills.

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.155

Introduction: Generalized anxiety disorder (GAD) is one of the most common mental disorders in adults. Psychotherapies are among the most recommended treatment choices for GAD, but which should be considered as first-line treatment still needs to be clarified.

Objectives: To examine the most effective and accepted psychotherapy for GAD both in the short and long-term, via a network meta-analysis.

Methods: We searched MEDLINE, Embase, PsycINFO, and the Cochrane Register of Controlled Trials – CENTRAL, from database inception to January 1st, 2023, to find randomized controlled trials (RCTs) of psychotherapies for GAD. Eight psychotherapies (behaviour therapy, cognitive-behaviour therapy, cognitive restructuring, psychoeducation, psychodynamic therapy, relaxation therapy, supportive psychotherapy, and third-wave CBTs) were compared with each other and two control conditions (treatment as usual, waiting list). We followed Cochrane standards when extracting data and assessing data quality and used PRISMA guidelines for the reporting. We conducted random-effects model pairwise and network meta-analyses. We assessed risk of bias of individual studies through the second version of the Cochrane's Risk of Bias tool and used the Confidence in Network Meta-Analysis (CINeMA) to rate certainty of evidence for meta-analytical results. Severity of GAD symptoms and acceptability of the psychotherapies were our outcomes of interest.

Results: We analysed data from 66 RCTs. Effect size estimates on data from 5,597 participants suggest third wave cognitive-behavioural therapies (standardized mean differences [SMDs] = -0.78; 95%CI = -1.19 to -0.37; certainty=moderate), cognitive-behavioural therapy (CBT) (SMD = -0.68; 95%CI = -1.05 to -0.32; certainty=moderate), and relaxation therapy (SMD = -0.54; 95%CI = -1.04 to -0.05; certainty=low) reduced generalized anxiety symptoms more than treatment as usual (TAU). Relative risks for all-cause discontinuation signalled no differences compared with TAU for all psychotherapies. When excluding studies at high risk of bias, relaxation therapy lost its superiority over TAU. When considering anxiety severity at three to twelve months after completion of the intervention only CBT remained significantly more efficacious than TAU (SMD = -0.58; 95%CI = -0.93 to -0.23).

Image:

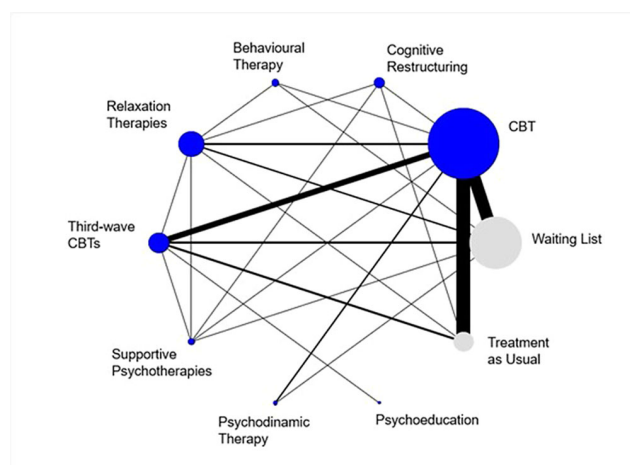

Figure 1. Network plot of evidence for efficacy. The thickness of lines is proportional to the precision of each direct estimate and the size of circles is proportional to the number of studies including that treatment. Psychotherapies are represented as coloured circles, while controls are in grey.

Conclusions: Given the evidence for both acute and long-term efficacy, CBT may represent the reasonable first-line psychological treatment for GAD. Third-wave CBT and relaxation therapy have short-term efficacy and may also be offered. Results from this investigation should inform patients, clinicians, and guidelines. This project is funded by the European Union's HORIZON EUROPE research programme under grant agreement No 101061648.

Nature-Adventure based experiential methods for enhancing psychotherapeutic efficacy

E. Kenézli^{1*}, N. Rákár-Szabó², D. Szabó¹, E. Lévy¹, G. Szabó², A. Szegő¹, B. Hajduska-Dér¹, I. Seres¹, I. Császár¹, J. Hordósi¹, K. Zseli¹, J. Réthelyi¹ and Z. S. Unoka¹

¹Psychiatry and Psychotherapy, Semmelweis University and ²Kétté Alapítvány, Budapest, Hungary

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.156

Introduction: A complex, Nature-, and Adventure Therapy - integrated Schema Therapeutic program (N-ABST) and a related efficacy study was launched in 2022 April at the Psychotherapy Department, at Semmelweis University. The participants had the opportunity of having outdoor, experience based group processes – seven full days in a month - in addition to the classic Schema Therapy (ST) sessions. According to the study design, 4-week long traditional thematic ST programs and 4-week long N-ABST programs were taken place alternately.

Objectives: Our aim was to compare the efficacy in a randomized, controlled design, short and medium terms. The participants of the programs and thus the target group of the research were adults, diagnosed mainly with Borderline Personality Disorder, inpatients in psychiatry.

Methods: This methodological innovation also meant the integration of two therapeutic teams in practice. When establishing the collaboration, we put emphasis on finding common points and understanding how N-AT contributes to schema therapy goals. During our joint work, it became clear that the elemental need for contact with nature enriched the schema therapy approach with a new basic need that was not included in it before. Measurements were taken before the start of the entire program and at the end of the 4-week cycle. Preliminary results are presented based on the Personality Inventory for DSM-5 - Hungarian Short Form (PID-5-HSF), and the Derogatis Symptom Checklist (SCL90).

Results: In the N-ABST group (n=23) the PID5 "Dysinhibition" scale ($p < .01$, Cohen's $d = .636$), and the "Negative Affectivity" scale ($p < .05$, Cohen's $d = .388$) showed significantly lower scores after therapy. In the case of the "Detachment" we have found a tendency to decrease after the therapy. Regarding the comparison of the effectiveness of N-ABST and classical Schema Therapy - with the current state of analysis - there was a significant difference in the PID5 values for "Suspiciousness" and "Manipulativeness". The former characteristic was reduced to a greater extent by the schema therapy, and the latter by the N-ABST therapy. Based on the SCL90, the N-ABST program resulted in a significant symptom reduction measured by the following subscales: somatization, obsessive compulsive, interpersonal sensitivity, depression, phobia. Global symptom severity also decreased significantly ($p < .05$, Cohen's $d = .588$).

Conclusions: According to our results, Nature- Adventure Therapy enhanced Schema Therapy seems to be an innovative and efficient method in the psychotherapy of personality disorders. Besides the effectiveness, there is a great challenge to design programs that are sustainable and therefore serves therapy long term as well.

This study was supported by the National Research, Development and Innovation Office grant K 129195.

Existential Therapy within Palliative Care: Searching for Meaning

F. Cunha*, I. Santos, N. Castro, R. Andrade, E. Almeida, J. Abreu, J. Martins, R. Vaz and S. Borges

Centro Hospitalar Tondela-Viseu, Viseu, Portugal

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.157

Introduction: Irvin D. Yalom defines existential psychotherapy as a dynamic therapeutic approach that focuses on concerns rooted in existence with the four ultimate concerns being death, isolation, meaning in life, and freedom. Patients in advanced stages of cancer often experience elevated levels of psychological distress, encompassing conditions such as depression, anxiety, and a sense of spiritual hopelessness. Recently, interest in spiritual well-being has prompted a new wave of interventions that directly target this

population, namely logotherapy and other existential interventions based on existential principles.

Objectives: In this review, the primary focus was to comprehend the current evidence on the application of existential psychotherapy for individuals coping with advanced cancer and give an overview of the therapy approaches used.

Methods: Narrative review of scientific literature using Pubmed search engine.

Results: Terao and Satoh identified nine types of existential psychotherapies which were investigated using randomized controlled trials for patients with advanced cancer or in terminal care: Meaning-Centered Group Psychotherapy (MCGP), Individual Meaning-Centered Psychotherapy (IMCP), Meaning-Making intervention (MMi), Meaning of Life Intervention, Managing Cancer and Living Meaningfully (CALM), Hope Intervention, Cognitive and Existential Intervention, Dignity Therapy, and Life-Review Interviews. All deal with the issues pointed by Yalom. Existential or spiritual well-being improvements were validated in MCGP, IMCP, Meaning of Life intervention, and Life-Review intervention.

Conclusions: Current evidence is still based on a very limited number of studies. Additional research is needed to delve into the impact of existential psychotherapy on individuals facing advanced cancer.

Comparing The Effectiveness Of Mentalization-Based Therapy And Dialectical Behavior Therapy In An Adult Population With Cluster B Personality Disorders To Reduce Hospital Service Use

P. Yin¹, F.-S. Lahaie¹, A. Allery², F. Pérusse^{2,3}, L. Caillhol^{2,3*} and S. Poirier^{2,3}

¹Faculty of Medicine, University of Montreal; ²Service des Troubles relationnels et de la personnalité, Institut Universitaire en Santé Mentale de Montréal and ³Department of Psychiatry and Addictology, University of Montreal, Montreal, Canada

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.158

Introduction: Mentalization-based therapy (MBT) and dialectical behavior therapy (DBT) are two treatments known to be effective for borderline personality disorder (BPD). However, head-to-head comparisons between those two treatments are scarce and their effectiveness in naturalistic clinical services, where BPD is often comorbid with other cluster B personality disorders (PD), needs to be further explored.

Objectives: The study's goal was to answer the following question: Is there a difference in emergency department visits, hospitalizations and dropout rates after one year of treatment in MBT compared to DBT for a clinical adult population with cluster B PD?

Methods: We compared the effectiveness of MBT and DBT in 288 patients between 2015 and 2019 with at least one cluster B PD by measuring their emergency services use and hospitalizations one year before and one year after beginning therapy. Drop-out rates for those two treatment modalities are also compared. Image 1 illustrates the patient distribution for the study.

Results: In terms of reducing emergency room use, patients in each treatment group experienced a significant decrease with medium effect sizes ($p < .001$ for both, $d = .768$ for MBT and $d = .640$ for DBT). In terms of reducing hospitalizations, the MBT group had a significant decrease ($p < .05$) with a medium effect size ($d = .568$) whereas the DBT group had a non-significant decrease ($p = .595$) with a negligible effect size ($d = .140$).

When we compare both therapies, no significant differences were found between them in terms of reductions in emergency room use ($p = .358$) and hospitalizations ($p = .195$), as well as dropout rates ($p = .743$). Image 2 further illustrates the dropout trends in the first year of treatment for both groups in intervals of 3 months.

Hospitalizations were rare in our population, which may hinder the validity of results containing this variable. In absolute numbers, total emergency room visits decreased from 119 to 37, whereas hospitalizations were reduced from 24 to 12. Drop-out rates before entering treatment were high (20.6%), as it was during treatment for both therapies (around 30% in the first year of treatment).

Image:

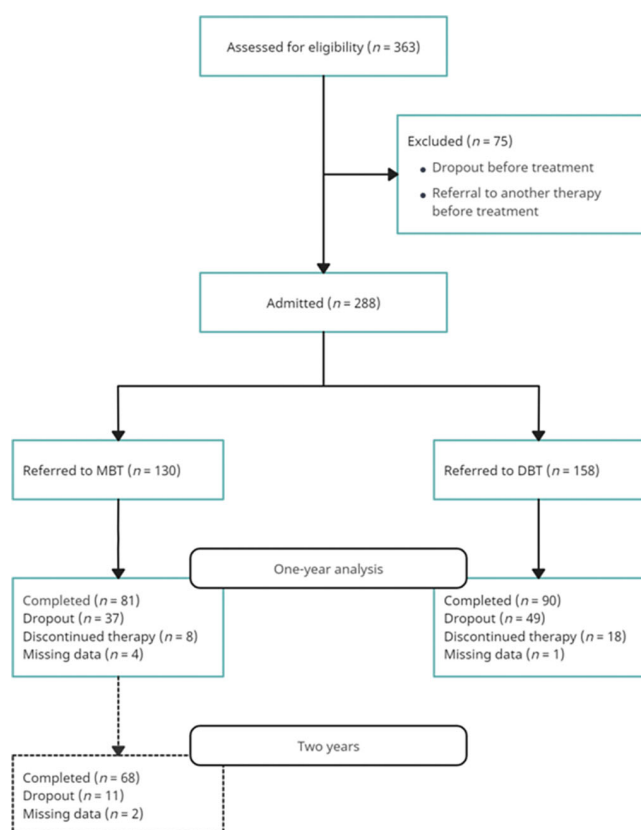

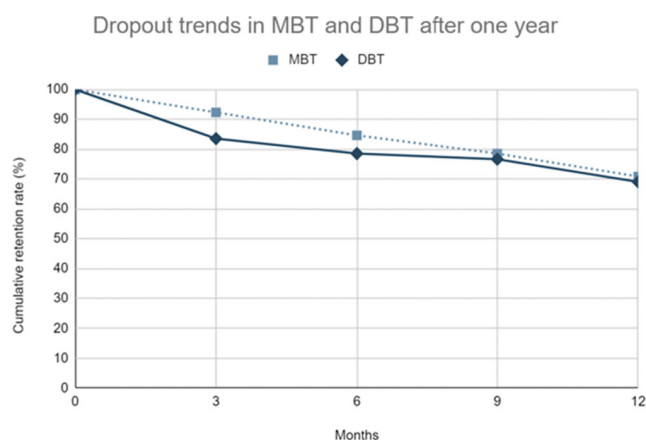

Image 2:

Conclusions: This study emphasizes that both DBT and MBT are linked to a reduction in service use over time. Dropout rates in both treatments are also similar to other studies. Therefore, future research should investigate the factors that can help clinicians guide individuals with PDs towards the type of therapy that is most suitable for them.

The improvement of mental and physical health of people with severe mental disorder: one-year efficacy of a lifestyle experimental intervention

M. Carbone*, L. Mario, M. Di Vincenzo, B. Della Rocca, C. Toni, S. Cipolla, F. Martinelli, G. Sampogna and A. Fiorillo

Department of Psychiatry, University of Campania Luigi Vanvitelli, Naples, Italy

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.159

Introduction: Patients with severe mental disorders have a significantly reduced life expectancy than the general population, often resulting from the increased prevalence of cardiovascular and metabolic diseases. Reasons include unhealthy lifestyle behaviours, reduced access to screening programs and adverse effects of many psychotropic drugs.

Objectives: Our goal is to assess the efficacy of a psychosocial group intervention promoting healthy lifestyle behaviors compared to a brief psychoeducational group intervention in terms of improvement of severity of psychiatric symptoms and perceived quality of life, and a series of anthropometric and hematological parameters.

Methods: This is a multicenter randomized controlled trial. Patients between 18 and 35 years of age with a diagnosis of schizophrenia and other primary psychotic disorders, unipolar depression and bipolar disorder were recruited. Exclusion criteria

were inability to perform moderate physical activity, pregnancy and breastfeeding and impaired cognitive functions.

Results: 401 patients were recruited and randomly assigned to receive the experimental intervention (LIFESTYLE) or a behavioural control intervention. About 57% of the sample were female, with a mean age of 45.8 ± 11.8 , and BMI of 32.5 ± 5.5 . All of them were receiving almost one psychotropic drug. At one year, we observed a reduction in HOMA-IR index (from 4.3 ± 5.5 to 3.1 ± 2.9 , $p < 0.01$) and triglycerides (from 162.5 ± 78.1 mg/dL to 131.4 ± 76.0 mg/dL, $p < 0.001$), as well as an increase in HDL (from 46.2 ± 14.6 mg/dL to 50.9 ± 26.7 mg/dL, $p < 0.05$). Moreover, a reduction in the values of BPRS "Affectivity" (from 8.7 ± 3.0 to 7.2 ± 2.5 , $p < 0.001$), "Activity" (from 4.7 ± 1.9 to 4.2 ± 1.3 , $p < 0.01$) and "Negative Symptoms" subscale (from 7.7 ± 3.1 to 7.0 ± 2.7 , $p < 0.001$) was also observed, along with an improvement in perceived quality of life (MANSA total score from 4.0 ± 1.0 to 5.3 ± 0.8 , $p < 0.01$).

Conclusions: The results support the evidence that the LIFESTYLE intervention has long-lasting positive effects on physical and mental health of people with mental disorders. More efforts need to be done in order to increase the availability of these treatments in routine clinical settings.

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.160

Introduction: The *European Alliance for Sport and Mental Health* (EASMH) is a partnership of scientific institutions, charity associations and sport organizations, funded by EU-Erasmus+. It aimed at developing good clinical practice in psychiatric rehabilitation through sport-based interventions as an integration of pharmacological and psychological therapies. Within the framework of the EASMH projects, several actions have been promoted including an assessment of the dissemination of sport-based interventions, a training course for specialized coaches and the implementation of pilot actions in four European Countries.

Objectives: To briefly describe EASMH pilot actions performed in Finland, Italy, Romania and United Kingdom, where trained coaches delivered sport-based interventions to patients with severe mental disorders.

Methods: After completing pilot actions, charity associations and sport organizations belonging to EASMH network described general and specific aims, sport activities, composition of staff, timing and tools for assessing the outcomes.

Results: In Italy, "Crazy for Rugby", including adolescents and young patients, and "Not only headshots", a football project for adults with severe mental disorders were performed. In UK, a football-based activity called "Imagine Your Goal" and a walking-football program for participants aged more than 40 were delivered. In Romania, two courses including gymnastics, yoga and pilates called "Get fit!" were provided. Different team sport-based activities were implemented in Finland, where "Multiple Sport Group" and "Rehabilitating Sports" aimed at increasing patients' autonomy. Assessment of psychopathological, social, cognitive and sport/fitness outcomes confirmed the overall beneficial effects of sport on mental health.

Conclusions: Pilot actions represent the final step of EASMH project, which showed improvement of mental health outcomes by also delivering sport-based rehabilitation to patients with severe mental disorders. Institutions and stakeholders are now called to promote the implementation of such initiatives on a broader scale.

Geographical variation in compulsory mental health care: cause for concern and source of causal inference

T. Hofstad

Haukeland University Hospital, Bergen, Norway

doi: 10.1192/j.eurpsy.2024.161

Introduction: Compulsory mental health care remains a controversial practice. The many difficulties in performing Randomised Controlled Trials (RCT) on the topic means there is limited evidence to support its effectiveness. For ethical and legal reasons, compulsory mental health care should only be used when necessary. Yet, geographical variations, which can indicate both overuse and underuse, have been observed. In the funded research project "Controversies in Psychiatry" we intend to use this variation as a source of knowledge production. We propose that this naturally occurring variation mimics randomisation, and can therefore permit causal inference from registry data.

Objectives: We will estimate the causal effect of compulsory inpatient mental health care on a range of outcomes, including injuries, self-harm, and all-cause mortality; violent crime; employment vs benefit allowance; rehospitalisation and outpatient commitment.

Methods: Observed variation in register data on all episodes of compulsory inpatient mental health care in Norway between 2015-2016 ($N \approx 300\,000$), will serve as a source of as-random variation. Provider-preference for compulsion usage will be used as an instrumental variable (IV).

Results: Outcomes will be observed from 2017-2025. If assumptions underlying IV-analysis do not hold, the project will still provide important and complete descriptive data on long-term outcomes for a whole population.

Conclusions: Geographical variation is a cause for concern if people are treated differently depending on area of residence. But it also presents an opportunity to use differences in service provider's preference for using compulsory care as an instrumental variable to estimate the causal effect of compulsory care on multiple short and long-term outcomes. This approach can help resolve controversies that are difficult or even impossible to investigate through RCTs. After presenting the project plan we invite to a discussion of the feasibility of using an instrument variable approach to explore if relatively low versus high rates of compulsory care produce favorable outcomes for patients.

What influence mothers' mental health and health care seeking behaviors for their malnourished children in Nepal: building evidence for a broader perspective

K. Le Roch^{1*}, B. Tonon² and O. Acharya³

¹Mental Health and Psychosocial Support; ²Nutrition and Health, Action contre la Faim, Montreuil, France and ³Nutrition and Health, Action contre la Faim, Kathmandu, Nepal

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.162

Introduction: Implementing research projects on community-based health care interventions in low-resource settings is feasible with specific methods and applications. In order to critically understand all ins and outs of influencing factors involved in health care pathways for children and their mothers, we must consider to implement more than one research in the same context.

Objectives: The objective of this presentation is to showcase the continuum of research projects starting from the assessment of the effectiveness of a combined nutrition and psychosocial intervention and its economic evaluation, and how that led to exploring social representations of malnutrition in order to better understand the link with health care seeking behaviours.

Methods: The FUSAM cluster randomized control trial included 427 were severe acutely malnourished (SAM) children and their mothers. They were divided in two groups receiving the standard nutrition treatment while the intervention group benefited from five psychosocial sessions. A battery of tests for child development and maternal mental health was administered pre and post intervention. For the economic evaluation, a data collection was conducted with 98 community members and District Public Health Office personnel in Saptari and 17 Action contre la Faim and government personnel in Kathmandu. Finally, a mixed-method study comparing social representations of malnutrition included 376 adults in Saptari and Nuwakot district. Data analysis was performed according to the study design: a multivariate model analysis for the CRCT, a micro-costing methodology to cost data collection and analysis was favored. For the mixed-method analysis, descriptive and inductive analysis were performed.

Results: Regarding the child development, children in the intervention group showed higher scores than children in the control group at all time points. And the economic evaluation showed that the costs of adding psychosocial counselling to an existing CMAM program was approximately EUR 28,788 for 6 centers per year.

However, referrals of children through the community-based screening were not optimal. The findings related to health seeking behaviors showed that different meaning categories were simultaneously resorted to by community members leading to different representations of SAM children and that relevant health advises were neither systematically nor uniquely associated to medical categories but are linked to different meaning categories depending on the cultural context.

Conclusions: Multiplying research projects is crucial to mitigate the limitations of the studies often facing numerous contextual challenges and ultimately to leverage further opportunities.

doi: 10.1192/j.eurpsy.2024.163

Introduction: Fat plays an important role in brain function; 60% of the brain's dry weight is fat. Among fats, omega-3 fatty acids, which are long-chain fatty acids, have been reported to reduce depressive symptoms. On the other hand, there are few studies on short-chain fatty acids (SCFAs), and those that do exist are mostly animal studies, with only a few human studies (about 100 cases). This is the first study to examine the association between fecal short-chain fatty acids and depressive symptoms on a large scale in the general population.

Objectives: We examined the association of fecal SCFAs with depressive symptoms. In addition, we analyzed the associations stratified by age and examined differences in the associations.

Methods: This study was conducted using data from the Dynamics of Lifestyle and Neighborhood Community on Health Study (DOSANCO Health Study). The target population was all residents of the city of Suttu, Hokkaido, Japan, excluding residents of special nursing homes (n=2638). 579 individuals (22% of the target population) aged 18 years and older who were able to measure fecal SCFA participated in this study with written informed consent. Approval was obtained from the Ethics Committee of Hokkaido University School of Medicine (15-002 and 15-045). Fecal SCFA was measured by high-performance liquid chromatography. We examined the association of fecal concentrations of SCFA subtypes (i.e., acetate, butyrate, and propionate) and total SCFA concentrations (mg/g wet weight as a continuous variable) with total Patient Health Questionnaire-9 (PHQ-9) scores using multiple regression analysis. We adjusted for age, sex, habitual exercise, total energy intake, and total dietary fiber intake. We performed additional

multiple regression analyses with stratification by age group (18-59 years and 60 years or older). Two-tailed tests were used for all analyses with a significance level of $P < 0.05$.

Results: The mean age (standard deviation) of the study participants ($n=534$) was 58.3 (16.0) years. Among them, 48% were 18-59 years old and 54% were female. Fecal propionate concentration was significantly associated with total PHQ-9 score ($\beta=0.62$, $p<0.01$). Other SCFAs and total SCFA were not significantly associated with total PHQ-9 score. In addition, using stratification analyses by age group, the associations between fecal propionate concentration and total PHQ-9 score showed a different trend by age group ($\beta=0.18$, $p=0.62$ for 18-59 years; $\beta=0.80$, $p<0.01$ for 60 years or older).

Conclusions: The study showed an association between higher concentrations of fecal propionic acid and higher levels of depressive symptoms. The association was particularly pronounced in older people, those aged 60 years and older. The results suggest that improving dietary habits to reduce fecal propionic acid may be effective in preventing depression in the elderly.

Physical activity reduces cardiovascular risk and mortality in people with severe mental illness: a cohort study using accelerometry

Y. Y. Liang*, J. Du and Y. Zhou

Center for Sleep and Circadian Medicine, The Affiliated Brain Hospital of Guangzhou Medical University, Guangzhou, China

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.164

Introduction: Cardiovascular disease (CVD) is a leading cause of excess mortality in people with severe mental illness (SMI). Physical activity (PA) is widely acknowledged with multiple health benefits, but associations of PA with incident CVD, all-cause and CVD mortality in people with SMI remain unclear.

Objectives: To determine dose-response and intensity-specific associations of PA with incident CVD, all-cause and CVD mortality in people with SMI.

Methods: This prospective cohort study was conducted on 6313 SMI participants with accelerometry data from UK Biobank (mean age 61.05 years) from February 2013 to November 2021 (median 7-year follow-up). Moderate-to-vigorous PA (MVPA) was categorized by meeting the guideline level or not, while total PA and light-intensity PA (LPA) were grouped by tertiles. Incident CVD, all-cause and CVD mortality ascertained by hospital and death registries were main outcomes.

Results: PA was inversely associated with the risk for incident CVD ($P_{\text{overall}} < 0.05$ for total PA and MVPA, $P_{\text{nonlinearity}} > 0.05$ for all PA), all-cause mortality ($P_{\text{overall}} < 0.05$ for all PA, $P_{\text{nonlinearity}} < 0.05$ for total PA and LPA), and CVD mortality ($P_{\text{overall}} < 0.001$ for total PA

and LPA, $P_{\text{nonlinearity}} < 0.05$ for all PA). Performing guideline-recommended volume of MVPA was associated with a reduced risk of 19% for incident CVD (95% CI, 0.67-0.98), 42% for all-cause mortality (95% CI, 0.43-0.79), and 50% for CVD mortality (95% CI, 0.31-0.82). A combination of recommended MVPA and a moderate volume of LPA was associated with the lowest risk, mitigating 21% risk for incident CVD, 59% for all-cause mortality, and 78% for CVD mortality.

Conclusions: Primary engagement of guideline-recommended MVPA, supplemented with moderate amount of LPA, was associated with lower risks for incident CVD, all-cause and CVD mortality among people with SMI.

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.165

Introduction: Stigma towards mental health has been described as a major obstacle to seek help and access to mental health services. This could result in a worsened Quality of Life (QoL). There is a little evidence of stigma in Mental Health Professionals and its consequences, especially in Early Career ones (ECMPH), who can be a more vulnerable group. There is even more lack of studies with multicultural approaches. Exploring stigma, support systems and access to these, and the link of these factors with QoL is essential to develop effective strategies to support ECMHP, for both their own mental health and providing care to patients.

Objectives: This study aims to explore the association between ECMHP's stigma towards mental health and their QoL, and to identify predictors of QoL among this population.

Methods: In this cross-sectional study, we designed an online survey to collect data among ECMHP, identified as having completed training since less than 7 years. QoL was assessed using the WHO-QoL. Stigma towards mental health was measured with the Opening Minds Stigma Scale for Health Care Providers (OMS-HC). Other general sociodemographic data were also collected. Descriptive results are resumed in absolute and relative frequencies for categorical variables. Student's t-test and ANOVA were used to analyse scores in WHO-QoL and OMS-HC according to categorical variables. Pearson's correlation coefficient was used to assess the association between WHO-QoL and OMS-HC. Simple and multiple linear regression were used to study the effect of stigma on QoL, taking into account potential confounders.

Results: We collected data from 277 ECMHP from Europe (54.15%) and Asia (45.85%). Only 20% of our sample knew that their workplace has staff dedicated for mental health practitioners support, and among those, only 44% had visited it. OMS-HC total scores were significantly higher ($p < 0.05$) in nurses and practitioners without a sufficient support system and without a mental disorder. WHO-QoL total scores were significantly higher in participants with sufficient support systems, and without a mental or physical illness. There was a negative correlation between OMS-HC and WHO-QoL total scores. Univariate analysis showed that OMS-HC total scores predicted WHO-QoL total scores. In the multivariate analysis, OMS-HC total scores, having a mental illness and having sufficient support, independently predicted WHO-QoL total scores, even when adjusted for sociodemographic variables.

Conclusions: Stigma towards mental health is related to QoL in ECMHP. Also, having sufficient support in the workplace improves QoL in this population. More studies are needed to help clarify the relationship between stigma and QoL using a longitudinal design.

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.166

Introduction: Psychotic disorders present a significant lifetime risk for suicide. Past estimates suggest that up to 25-50% of individuals with schizophrenia (SCZ) may attempt suicide during their lifetime. A growing body of literature indicates that the level of cognitive performances may be associated with a differing level of lifetime suicide attempts, albeit inconsistently depending on the diagnostic category and study setting. However, the vast majority of the literature in the field is composed of cross-sectional studies, limiting the overall interpretation of the available evidence.

Objectives: In the present study, we probed the possible association of BDNF plasma levels, cognitive functions assessed through the Brief Assessment of Cognition in Schizophrenia (BACS) and lifetime suicide ideation and/or attempts (LSI+LSA). More specifically, we tested whether such association would persist during the 2 years follow-up divided in 5 different timepoints at 6-month intervals, if present.

Methods: The present study represents a secondary analysis of a previously described cohort (Manchia et al. Brain Sci. 2022 Dec 4;12(12):1666). The sample comprised 105 subjects with SZC or schizoaffective disorder. We employed the 1) Wilcoxon test for non-parametric data 2) linear modelling to test the possible association of BACS-defined cognitive task performances with LSI+LSA. We also investigated if either BDNF plasma levels or four tested BDNF SNP genes would mediate this association.

Results: From a total of 105 subjects, data relevant to the analysis were available for 89 subjects. We observed a significant association between BACS-Letter fluency task (BACS-LF) with LSI+LSA, persisting even when adjusting for gender, duration of untreated psychosis, total Positive and Negative Syndrome Scale score, age, chlorpromazine equivalents of antipsychotic therapy and for the effect of time. The association remained significant even when adjusting with the Bonferroni-Holms method for multiple comparisons ($p=0.002$). No association was found either for BDNF plasma levels or the tested BDNF genes for the tested outcomes.

Conclusions: In our sample, higher BACS-LF performances appeared to be associated with a higher lifetime risk of LSI+LSA. This report adds to the previous literature suggesting that different cognitive performance levels may represent one of the many chronic risk factors associated with LSI+LSA, and that may ultimately complexly interact with more proximal ones.

Examination of Speech Analysis to Predict Suicidal Behavior in Depression

S. YÜNDEN^{1*}, M. AK¹, M. SERT², S. GICA¹, O. ÇINAR³ and Y. A. ACAR⁴

¹Psychiatry, Necmettin Erbakan University Meram Faculty of Medicine Hospital, Konya; ²Computer Engineering, Başkent University Faculty of Engineering; ³Emergency Service, Acıbadem Ankara Hospital, Ankara, Türkiye and ⁴Emergency Service, Mercer University School of Medicine, Macon, United States

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.167

Introduction: Suicide is one of the leading causes of preventable deaths worldwide. The psychiatric disorder that is most strongly

associated with suicide is depression. It is crucial to develop clinical tools that can provide objective data to assess suicide risk in clinical settings. Depression and high suicide risk may lead to physiological changes that can affect the speech pattern. Prior research has indicated that the acoustic and prosodic characteristics of speech may hold potential clues for assessing suicide risk. Additionally, specific speech parameters may serve as discriminators for identifying individuals at risk. In recent years, deep learning-based models have yielded successful results in identifying such alterations in speech signals.

Objectives: The aim of our study was to examine specific voice analysis parameters between control, depressive and high suicide risk groups. We also aimed to investigate the effect of voice-related variables in predicting suicidal behavior in patients with depression using an artificial intelligence model. The results of voice analysis are intended to serve as a starting point for the development of future artificial intelligence algorithms.

Methods: The study sample consisted of 30 near-term suicidal patients, 30 patients with major depression and 30 healthy controls. The participants were presented with a pre-determined text and a voice recording was carried out. Feature extraction and model training for three tasks, namely depression or not, suicide or not, and depression or suicide were carried out. Mel-Frequency Cepstral Coefficients (MFCCs), deep learning-based (VGGish), formant and prosodic features were extracted to analyze the sound characteristics of the participants. The Support Vector Machine was used as the machine learning algorithm for classification and the three models were trained for each task. A 10-fold cross-validation was carried out and presented by metrics including accuracy, precision, sensitivity and specificity.

Results: Among the metrics examined, MFCCs for the “Suicide or not” task were found to be more successful with rates of 0.90, 0.88, 0.93 and 0.86 for accuracy, precision, sensitivity, and specificity, respectively. MFCCs were also more successful for the “Depression or suicide” task with rates of 0.68, 0.66, 0.76, and 0.60 for accuracy, precision, sensitivity, and specificity, respectively. Among the metrics examined for the “Depressed or not” task, VGGish was more successful with rates of 0.73, 0.81, 0.70, and 0.76 for accuracy, precision, sensitivity, and specificity, respectively.

Conclusions: To the best of our knowledge, our study is the first to compare the VGGish and other features of speech (MFCCs, prosodic, formant features) between high suicide risk, depression and control groups. Classification parameters developed using the VGGish and MFCCs features of speech could be useful in predicting suicide risk in future studies.

O0035

Deliberate self-harm and suicide in people with immigrant background: how can reason for immigration and country of origin differentiate the risks?

P. Qin

National Centre for Suicide Research and Prevention, University of Oslo, Oslo, Norway
doi: 10.1192/j.eurpsy.2024.168

Introduction: A growing body of research have devoted into suicide and deliberate self-harm in immigrant population, but no study has examined how reason for immigrating to the host country differentiates the risks.

Objectives: To gain firm insight into suicide and deliberate self-harm among people with immigrant background.

Methods: Norwegian registers were interlinked to identify all individuals who died by suicide in 1992-2018 and who received emergency treatment for non-fatal deliberate self-harm (DSH) in 2008-2018, and to construct the respective databases via a nested case-control design. Rates and relative risks of suicide and DSH were assessed according to immigrant background, country of birth and reasons of immigration, and in the context of personal socioeconomic status.

Results: People with an immigrant background accounted for 11.6% of all suicides in 1992-2018 and 17.9% of all DSH incidents treated in hospital emergency departments in 2008-2018. The rates of both suicide and DSH were highest in people born abroad with two Norway-born parents (mean rate: 19.4/100 000 for suicide and 280.9/100 000 for DSH) and lowest in the second-generation immigrants. Compared with the native Norwegians, suicide risk was significantly higher for those foreign-born with two Norway-born parents (HR=1.50) and those born in Norway with 1 one foreign-born parent (HR=1.20), but was significantly lower for the first- and second-generation immigrants. The associated risks remained almost unchanged when the data were adjusted for personal differences in education, marital status, income and place of residence in Norway. The analyses on deliberate self-harm exhibited similar patterns of results as for suicide, although the estimated reduced risks in the first- and second-generation immigrant is somewhat smaller. Evidently, the risks for suicide and DSH varied significantly by reason of immigration and country of origin. Immigrants coming for education had the lowest risk for suicide and self-harm, and those coming for work the second lowest. The risks for immigrants coming for family unity were lower than the natives, but significantly higher than counterparts coming for job or education from the same country. Among immigrants coming to Norway as a refugee or asylum seeker, the risk of suicide was comparably high as those coming for work, but the relative risk for self-harm was significantly higher. The increased risks associated with the mixed immigration background tended to be slightly higher in females than in males, and were likely confined to adoptee population.

Conclusions: Risks for suicide and deliberate self-harm in people with an immigrant background differs significantly by reason of immigration and country of origin. The findings should be taken into account in efforts of mental healthcare and suicide prevention targeting immigrant population.

Prospective mortality in patients with non-fatal deliberate self-harm: a national cohort study

P. Qin

National Center for Suicide Research and Prevention, University of Oslo, Oslo, Norway
doi: 10.1192/j.eurpsy.2024.169

Introduction: Deliberate self-harm (DSH) is a strong indicator of psychological distress and constitutes a significant risk factor for subsequent mortalities.

Objectives: In this study we want to gain insights into cause-specific mortalities in self-harming patients and to disentangle important factors differentiating the risks so that to inform follow-up care and mortality prevention.

Methods: Retrospective data from nationwide registries were inter-linked to follow all patients presenting to specialist healthcare with non-fatal DSH from January 2008 through December 2018. Data on cause of death, personal socioeconomic status, clinical features of DSH and other medical covariates were retrieved. The Fine and Gray competing risks model was used to identify significant factors impacting subsequent mortality risk by specific causes of death in the cohort.

Results: The cohort of 43153 DSH patients comprised 24286 females and 18867 males, with 45.3% being 10-34 years old, 38.1% being 35-64 years old and 16.6% above 65 years old at index DSH episode. Of these patients, 7041 died during the follow-up period, including 2290 within the first 1-year, corresponding to a mortality rate of 31.9 per 1000 person-years in the follow-up period and 54.9 per 1000 person-years in the first year. Common causes of death included suicide (n=911), other external causes (n=1020), cancer (n=896), cardiovascular diseases (n=1523), respiratory disease (n=787) and mental and substance misuse disorders (n=463), but the causes of death varied greatly by age groups and other factors. The risk of dying by suicide was highly associated with middle-age, male gender, tertiary education, psychiatric history, and DSH by injury, clear intent of self-harm, comorbid affective or personality disorder, referral to psychiatric treatment, as well as DSH repetition during the period of follow-up. Significant risk factors for death by other external causes included male gender, old or middle age, single marital status, lowest quartile income, history of psychiatric treatment, and DSH by injury and comorbid substance misuse. For death by natural causes, the relative risk was highest among the elderly and the middle-aged, with other significant risk factors including male gender, single marital status, low education, lowest quartile income, and comorbid substance misuse. Attendance in psychiatric treatment after DSH appeared to be beneficial reducing the risk for mortality by suicide, other external causes and natural causes as well.

Conclusions: Patients with DSH represent a high-risk group for suicide, other external and natural cause mortalities. Mental healthcare is essential in follow-up care and personalized care should take into account patients' socio-demographic background and clinical features of self-harm.

Co-design of a digital violence prevention and management tool for psychiatric inpatient care: focus on supporting integration into electronic health record system

T. Lantta^{1,2*}, T. Rautiainen¹, M. Anttila¹, J. Anttila^{1,3} and M. Ameen^{1,3,4}

¹Department of Nursing Science, University of Turku, Turku, Finland;

²Centre for Forensic Behavioural Sciences, Swinburne University of

Technology, Melbourne, Australia; ³Hospital District of Helsinki and Uusimaa and ⁴University of Helsinki, Helsinki, Finland

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.170

Introduction: Violence in psychiatric inpatient settings is a global challenge. Several methods have been developed and tested to help staff prevent the occurrence of violence on the wards. One novel and effective method is eDASA+APP, originating from Australian forensic psychiatric settings (Maguire *et al.* Int J Ment Health Nurs 2019; 28:1186-1197, Griffith *et al.* Psychiatr Serv 2021; 72:885-890). This electronic method contains an instrument (DASA) to assess the risk for imminent violence and includes evidence-based violence risk management methods for risk levels. It is important to ensure that this electronic intervention is integrated into daily clinical practice. This can be done in co-design between all that are involved e.g., staff and experts by experience, and by encouraging them to achieve a common goal and gain benefits by working together.

Objectives: This prevention gives an overview of how the Finnish version of eDASA+APP was co-designed with healthcare staff and experts by experience, focusing on integration into the electronic patient health record system. The presentation is part of a larger research project testing eDASA+APP in Finnish psychiatric inpatient care.

Methods: Co-design workshops focusing on three major themes: 1) identifying current practices and how eDASA+APP would fit in those, 2) producing a linguistically and culturally appropriate version of eDASA+APP, and 3) preferred use of eDASA+APP in an electronic patient health record system. Notes were kept during the workshops by researchers. Qualitative material were analysed with deductive content analysis. Results from the third theme are shared in this presentation.

Results: Staff and experts by experience described that integration of eDASA+APP in electronic patient health record system is supported if it 1) brings clear and fast information to the staff about the violence risk of a patient, 2) is a visible measure that is concretely in sight in electronic patient health record system, 3) provides information about which violence prevention and management interventions have worked with a patient, 4) involves patient preferences, and 5) consist of joint decisions that have been agreed multi-professionally.

Conclusions: Integration of eDASA+APP in the electronic patient health record system has the potential to succeed if it is realized in cooperation with staff and experts by experience, is technically easy to use, and the users have an understanding of its benefits to everyone involved.

Guidance on how to involve people with lived experience in research on digital mental health interventions

I. Wells*, E. Thelwell and D. Giacco

University of Warwick, Coventry, United Kingdom

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.171

Introduction: Digital technologies and interventions (defined as patient-facing or self-administered interventions delivered through a digital platform) have an increasing role in mental health care. It is key to ensure that appropriate patient and public involvement (PPI) is not overlooked when developing new digital mental health interventions (DMHIs). The unique perspective offered by those with lived experience can improve study conduct and design as well as ensure that interventions meet the needs of users, which may improve their quality and acceptability.

Objectives: To develop guidance for the involvement of people with lived experience of severe mental illness in designing and conducting research on DMHIs.

Methods: Four co-production workshops were arranged online with people who have lived experience of severe mental illness. Initial ideas were formulated in the first workshop and were then prioritised in the second workshop using the nominal group technique. The prioritised ideas were then refined in workshops three and four. Minutes were generated from each workshop and were validated by the those who took part. These minutes were analysed using thematic analysis.

Results: Nineteen people with lived experience participated in the co-production workshops overall. Six people took part in one workshop only and 13 took part in multiple workshops. Two main themes were identified in this study: why do people become and remain involved in PPI?; and what areas should be discussed within PPI consultations? Three subthemes associated with the second theme were also identified. These are: areas related to specific types of DMHI; areas related to any type of DMHI; and what can make a difference within DMHIs? To ensure that people become and remain interested in PPI around DMHIs, it is important to provide a non-judgemental space for people with lived experience to discuss any concerns and ensure they feel valued during consultations. Aspects to consider discussing in PPI consultations around the development of DMHIs include the provision of safety and security within DMHIs, issues around digital exclusion and the potential impact of people's symptoms on DMHI use. Finally, points that were identified as important to consider when developing DMHIs include offering encouragement throughout the DMHI, accommodating for individual and collective needs within DMHIs and developing a structure within the DMHI which includes adding in attainable goals.

Conclusions: If used, the information provided from this study can generate positive and productive PPI consultations where those with lived experience can make significant contributions to the development of DMHIs. Such contributions will increase the acceptability and efficacy of the DMHIs developed.

The Online Support System for Mental Health Problems After the Earthquake: A Prompt Response from The Psychiatric Association of Turkey

I. G. Yilmaz-Karaman^{1*}, B. R. Erim², H. Karas² and E. Mutlu³

¹Psychiatry, Eskişehir Osmangazi University, Eskişehir; ²Psychiatry, Private practise, Istanbul and ³Psychiatry, Hacettepe University, Ankara, Türkiye

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.172

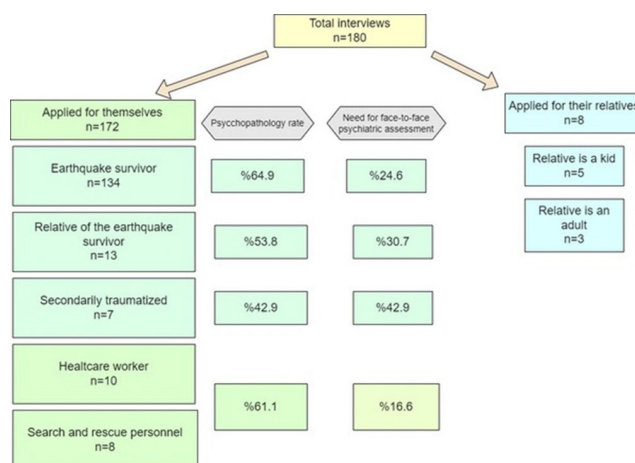

Introduction: Previous research demonstrated that disasters have adverse mental health outcomes. Preventive mental health interventions in the golden hours/days after a disaster may reduce psychological harm by getting in the way of emerging mental disorders or alleviating existing ones. The widespread use of smartphones and broad internet access enabled remote mental health interventions during disasters. After the 2023 Turkey earthquake, observing the mental health burden of the earthquake, The Psychiatric Association of Turkey conducted an online platform for psychological first aid. The aim was to unite volunteer psychiatrists and disaster survivors.

Objectives: This study presents the organization of an online mental health service during a disaster while reporting the characteristics of the service users.

Methods: The Psychiatric Association of Turkey called its members to volunteer for an Online Support System for Mental Problems After the Earthquake. The group regularly united to set standards of care. An action plan and algorithm were set up for applicants with acute suicidal, homicidal risk, or active psychotic symptoms in collaboration with local institutions and field volunteers. Volunteer psychiatrists were asked to collect information on the applicant's sociodemographic characteristics, disaster experience, and mental health status.

Results: Volunteer psychiatrists collected data on 180 applications. Most cases applied for themselves (%95.5), and some asked for advice to care for their relatives (%4.5). Earthquake survivors have the highest psychopathology rate (%64.9), followed by healthcare workers and search and rescue personnel (%61.1). Figure 1 summarizes the subgroups of the service users. The earthquake survivors group had a mean age of 34.45, % and 76.1 of them were female. Only %15.7 of them had lower educational levels than high school. %75 cases reached safe places on the 5th day of the disaster. Applicants reported discrimination and aggression after the catastrophe, related to experiencing mental health problems, owning a pet, looting, and being seen as less traumatized since their relatives are alive.

Image:

Conclusions: The present experience of the Psychiatric Association of Turkey is an example of a fast and collaborative response to a disaster regarding mental health. Our results also represent the characteristics of online mental health service users during a disaster.

Artificial Intelligence in Psychiatry: A Comprehensive Literature Review

M. Gerantia

Addiction, Center of Mental Health and addiction prevention, Tbilisi, Georgia

doi: 10.1192/j.eurpsy.2024.173

Introduction: The incorporation of artificial intelligence (AI) in healthcare, especially in mental health services, offers potential advancements in efficiency and personalization. As AI technologies like machine learning and natural language processing (NLP) continue to evolve, it's vital to evaluate their applications in psychiatry comprehensively.

Objectives: This review aims to summarize and characterize studies that used AI, particularly machine learning and NLP, in mental health. Additionally, it endeavors to understand how these technologies may enhance diagnostic tools, symptom monitoring, and delivery of personalized treatment in psychiatry.

Methods: Adhering to PRISMA guidelines, a systematic search was executed across multiple medical databases, including PubMed, Scopus, ScienceDirect, and PsycINFO. Keywords encompassed machine learning, data mining, psychiatry, and mental health. Exclusion criteria included non-English papers, anonymization process descriptions, case studies, conference papers, and other reviews. Data from various segments in the provided information were synthesized to capture the broader picture of AI's application in psychiatry.

Results: From the 327 articles initially identified, 58 were chosen for detailed review. Studies predominantly revolved around three main populations: patients in medical databases, emergency room visitors, and social media users. The primary applications of AI entailed symptom extraction, illness severity classification, therapy effectiveness comparison, and psychopathological insights derivation. Data sources mainly included medical records and social media, with Python emerging as the preferred platform for most studies.

Conclusions: While AI shows immense promise in revolutionizing mental health care, its current applications largely confirm existing clinical hypotheses. Ethical concerns, such as patient privacy and data biases, remain paramount. Future work should delve deeper into these challenges while further exploring AI's potential in clinical psychiatry practice.

Text4Hope: An e-Mental Health Tool for Mitigating Psychological Symptoms among Young Adults

A. Belinda^{1*}, R. Shalaby¹, W. Vuong², S. Surood², A. Greenshaw¹, A. Gusnowski², Y. Wei¹ and V. I. O. Agyapong^{1,3}

¹Department of psychiatry, University of Alberta; ²Addiction and Mental Health, Alberta Health Services, Edmonton and ³Department of psychiatry, Dalhousie University, Halifax, Canada

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.174

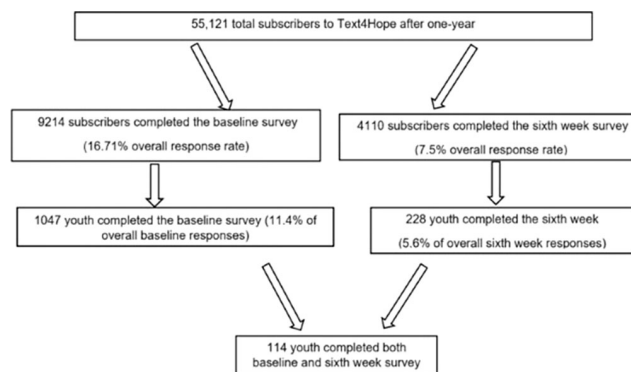

Introduction: Chronic stress, anxiety, and depression can interfere with young adults' everyday function, academic achievement, and interpersonal relationships. Interventions aimed at preventing the deterioration or possibly onset of these mental disorders among young people are timely.

Objectives: To assess the impact of a supportive text messaging program (Text4Hope) on the psychological well-being of young adults.

Methods: This study adopted both longitudinal and naturalistic controlled trial designs. Longitudinal study: compared baseline and 6th week outcomes in the same group of young adult subscribers. Naturalistic controlled study: compared clinical parameters in two groups of Text4Hope young adult subscribers: (i) intervention group (IG), subscribers who received once-daily supportive text messages for 6-weeks and completed 6th-week evaluation between 26 April and 12 July 2020, and (ii) control group (CG), subscribers who joined Text4Hope the same time frame, completed a baseline survey and were yet to receive text messages. The prevalence and severity of moderate-high stress, anxiety, and depression was measured using standardized scales. Inferential statistics, including the t-test, McNemar test, chi-square, and binary logistic regression analyses, were used to evaluate the differences in the prevalence and severity of the psychological symptoms.

Results: Longitudinal study: subscribers who completed both the baseline and 6th-week surveys, had significant reduction in the prevalence of moderate-high stress (8%) and likely GAD (20%) from baseline to six weeks. The largest reduction in mean scores was for the GAD-7 scale (18.4%). Naturalistic study: significantly lower prevalence for likely Moderate Depressive Disorder (25.2%) and suicidal thoughts/thoughts of self-harm (48.4%), with a small effect size in the IG compared to CG.

Image:

Conclusions: TheText4Hope program has been demonstrated as an effective e-mental health tool for mental health support for young adult subscribers. This is particularly encouraging, as young adults have already adapted to SMS text messaging and texting. Therefore, this mode of intervention can be used to supplement existing treatments for psychological problems impacting young adults. In addition, the cost effectiveness and easy scalability of supportive text message interventions mean that policymakers and governments can quickly implement similar programs as part of national youth suicide prevention strategies.

A pragmatic randomised controlled non-inferiority trial of open-door policy versus treatment as usual in urban psychiatric inpatient wards

A.-M. R. Indregard^{1,2}, M. S. Tesli^{3,4}, J. Gather⁵, M. C. Småstuen^{6,7}, H. M. Nussle¹, P. O. Vandvik^{7,8} and N. Kunøe^{7,9*}

¹Psychiatry, The Lovisenberg Diaconal Hospital; ²Health Services Research, Oslo Metropolitan University; ³Mental Health and Suicide, Norwegian Institute of Public Health; ⁴Regional Center, SIFER National Research Centre on Security, Prisons and Forensic Psychiatry, Oslo, Norway; ⁵Psychiatry, Psychotherapy and Preventive Medicine, LWL University Hospital, Ruhr University Bochum, Bochum, Germany; ⁶Nursing and Health Promotion, Oslo Metropolitan University; ⁷University of Oslo; ⁸Department of Medicine and ⁹Department of Psychiatry, The Lovisenberg Diaconal Hospital, Oslo, Norway

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.175

Introduction: Open-door policy (ODP) is an approach to reduce coercion in psychiatric wards recommended by the World Health Organization and the Council of Europe. Observational studies from Switzerland and Germany have shown promising results in reducing coercion, but no RCTs have been conducted. Skeptics have been concerned the observational evidence could mask that ODP could increase risks and harms and / or increase the use of coercive measures staff use to assist patients with psychoses, while proponents have argued that de-escalation and alliance-building will result in no such increase.

Objectives: To evaluate open-door policy in an openly randomised, ethical-board approved trial of all patients referred to ward care at the Lovisenberg Diaconal Hospital in Oslo, Norway.

Methods: A 12-month pragmatic, randomised-controlled non-inferiority trial comparing two ODP and three TAU acute psychiatric wards. The trial was pre-registered (ISRCTN16876467) and conformed to CONSORT. Ethical committee exemption enabled waiver of consent rules for the study, meaning all regular patients were included. Patients were randomly assigned (2:3 ratio) by a clinical admissions team using an open list. The non-inferiority margin was 15 % on the primary outcome: the proportion of patient stays with one or more coercive measures, including involuntary medication, isolation/seclusion, and physical and mechanical restraints. Primary and safety analyses were based on intention-to-treat. Safety analyses included suicides and violent events against staff. Secondary outcomes were individual coercive measures, intensive care, resource use, and patient feedback.

Results: N=556 patients were included and randomised and were similar on all pre-admission demographics: Around 75% of patients were diagnosed with a psychotic disorder and were involuntarily admitted. Primary outcome: Use of coercive measures was within the non-inferiority margin (see table 1). Safety outcomes: No suicides occurred during ward care in any group. Violence against staff did not differ between study wards. Secondary outcomes: Use of intensive care ('skjerming') and number of days admitted was significantly less on open-door policy wards. Patients on open-door policy wards rated their experience of coercion and ward atmosphere better than patients on control wards.

Table 1. Absolute and relative risk of being subjected to coercion on open-door policy or usual-treatment wards.

Main outcome	Number (%)		Relative Risk (95% CI)	Risk Difference (95% CI)	Primary hypothesis confirmed
	Absolute Risk ODP wards (n=245)	Absolute Risk TAU wards (n=311)			
One or more coercive measures during the admission	65 (26.5%)	104 (33.4%)	1.3 (0.97 to 1.6)	6.9% (-0.7 to 14.5)	Yes

Conclusions: This first RCT found open-door policy does not increase use of coercion or resource use. It does not harm staff or patients and is experienced as better by patients.

 doi: 10.1192/j.eurpsy.2024.176

Introduction: Mental health-related stigma occurs not only within the public community but is also an issue among healthcare professionals. The relationship between national culture and provider stigma remains yet to be empirically attested.

Objectives: We performed a cross-sectional multicentre study across 32 European countries to investigate the attitudes of psychiatrists towards patients with mental health problems. We aimed to examine the relationship of attitude with country-specific indicators.

Methods: We measured stigmatizing attitudes using the Opening Minds Stigma Scale for Health Care Providers (OMS-HC) within an online survey among specialists and trainees in general adult, child and adolescent psychiatry. Its total score was correlated with the Human Development Index (HDI), the Democracy Index (DI), the Social Progress Index (SPI), the number of psychiatrists per 100,000 people, and the Hofstede dimensions. Latent class analysis was done to find subgroups of countries according to the stigmatizing attitudes of psychiatrists and the six Hofstede dimensions.

Results: Altogether, n=4245 participants completed the survey. The total score of the OMS-HC significantly correlated with the long-term orientation ($r=0.453$, $p=0.015$) and indulgence dimensions ($r=-0.629$, $p<0.0001$) and with the HDI ($r=-0.503$, $p=0.005$), DI ($r=-0.418$, $p=0.024$), SPI ($r=-0.348$, $p=0.040$). The latent class analysis separated high- and low-stigma countries. High stigma was associated with high power distance and uncertainty scores.

Conclusions: Findings from this study not only expand knowledge of factors related to stigmatizing attitudes of healthcare professionals, but also enlighten the cultural aspects of the stigma that could contribute to the further development of anti-stigma programs.

Physical activity and treatment adherence in patients with mental disorders: a randomized controlled trial

R. Silvestro*, V. Dello Stritto, P. Catapano, M. Di Vincenzo, B. Della Rocca, M. V. Lapadula, C. Toni, R. Bello, M. Luciano, G. Sampogna and A. Fiorillo

Psychiatry, Università degli studi della Campania "Luigi Vanvitelli", Naples, Italy

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.177

Introduction: Lack of adherence to pharmacological treatment is considered a multifactorial phenomenon, remarkably frequent in clinical practice. Non-adherence is associated with increased number of relapses, poor clinical and functional outcomes, and worsening of patient health status, with a resulting increase in healthcare costs, particularly in people with severe mental disorders (SMD). Treatment adherence rates remain extremely low, highlighting the need to develop innovative and integrated strategies; one of these is represented by the promotion of healthy lifestyle behaviours, including regular physical activity.

Objectives: The aim of this study is to assess how the rates of treatment adherence vary in patients with SMD after receiving a psychosocial intervention, focusing on the positive relationship between treatment adherence and physical activity.

Methods: LIFESTYLE is a randomized controlled trial comparing the efficacy of a structured psychosocial lifestyle intervention involving moderate physical activity exercises over a brief psychoeducational intervention. Levels of physical activity was assessed thorough the IPAQ scale, while treatment adherence was evaluated by the Morisky Medication Adherence Scale (MMAS).

Results: The sample includes 401 patients, with a mean duration of illness was 16.3 (± 17.8) years. All patients were receiving a pharmacological drug treatment; in particular, 59.6% (N=239) were treated with a second-generation antipsychotic and 54.9% (N=220) with a mood stabilizer. Our results show that moderate physical activity improves rates of treatment adherence. After 6 months, adherence to treatment increased from 35.8% at baseline to 47.6% at baseline in the experimental group, along with improvement in clinical health parameters (reduction in BMI, weight, and metabolic parameters). Another significant inverse correlation was found between adherence and quality of life (Rho di Person: $-.140$, $p<.005$). Furthermore, this study indicates that having a diagnosis of major depression, a better cognitive functioning, a shorter duration of illness and contact time with the local mental health centre are factors that positively influence treatment adherence. Remarkably, treatment adherence was not influenced by symptom severity and type of pharmacological treatment.

Conclusions: Moderate physical activity can represent a valid strategy to increase treatment adherence in patients with SMD.

Therefore, promoting physical activity exercises in our clinical practice may be associated with better outcomes. However, further studies that evaluate patients with acute mental disorders are needed.

Individual Placement and Support for persons with mental disorders and disability pension: Randomized controlled trial and follow up

W. Kawohl^{1,2,3,*}

¹Clenia Schlössli AG, Oetwil am See; ²Psychiatry, Psychotherapy and Psychosomatics, University of Zurich, Zurich, Switzerland and ³University of Nicosia Medical School, Nicosia, Cyprus

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.178

Introduction: Individual Placement and Support (IPS) is a supported employment method used for the vocational inclusion of individuals with mental disorders. There is vast evidence that IPS is effective for finding jobs. However, evidence concerning the applicability of IPS for persons with mental disorders receiving a disability pension and concerning the sustainability of IPS is scarce.

Objectives: The aim of the studies included in this report was to a) control for the applicability of IPS for persons receiving a disability pension and b) to gain insight in the sustainability of IPS in this context.

Methods: A randomized controlled trial with 250 participants was conducted. The participants in the intervention group received job coaching according to the IPS standard. Members of the control group received no organized support but were allowed to seek assistance on their own. The initial phase of the study lasted 24 month. Job coaching was delivered only in the first phase of the study and discontinued after 24 month. A follow up was performed six years after the start of the study to clarify the further course (number of employment relationships, degree of employment, duration of employment, salary).

Results: In the first phase of the study, the overall dropout rate was 32%. 114 participants (46% of the original number of participants) took part in the follow-up survey. The intervention was superior to the control condition in the first phase. There were no significant differences between the groups in terms of number of employment relationships, degree of employment, length of employment, and salary in the follow up.

Conclusions: The effect of a clear superiority of the IPS intervention with regard to the number of employment relationships, which was measured during the originally planned duration of the study, was only slightly detectable six years after the start of the study and up to four years after the end of the intervention and was no longer statistically significant. This result underlines the importance of continuing job coaching for an unlimited period of time, as called for in the IPS concept, in order to perpetuate the positive effects such as finding and maintaining a job in the primary labor market.

Prenatal Cannabis Use Disorder and Risk of Neurodevelopmental Disorders in Offspring: A Linked Data Cohort

A. W. Tadesse^{1*}, B. A. Dachew¹, G. Ayano², K. Betts¹ and R. Alati¹

¹School of Population Health, Curtin University, Perth, Australia and

²School of Population Health, Curtin University, Perth, Austria

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.179

Introduction: Cannabis use has been increasing among women of reproductive age in the last few decades. In-utero cannabis exposure could be associated with an increased risk of neurodevelopmental disorders such as attention deficit hyperactivity disorder (ADHD), autism spectrum disorder (ASD), and intellectual disability (ID) during childhood and adolescence; however, existing evidence was generated based on maternal self-report of cannabis use in pregnancy. We conducted a large-scale with data linkage cohort study, in which both exposure and outcome of interests were confirmed using diagnostic tools, ICD-10-AM.

Objectives: This study aimed to examine the association between prenatal cannabis use disorder (CUD) and neurodevelopmental disorders in offspring using a large-scale cohort study.

Methods: We conducted an administrative health data-based cohort study of 222,569 mother-offspring pairs using linked data obtained from health registries in New South Wales (NSW), Australia. Data were drawn from the NSW Perinatal Data Collection (PDC), which included all live births in the Australian state of NSW between January 2003 and December 2005. These were linked with the NSW in-patient and ambulatory data collections for mothers and offspring. The prenatal cannabis use disorder (exposure) and neurodevelopmental disorders in offspring (outcomes of interest) were measured by using ICD-10-AM. Generalized linear regression with a binomial family model was used to explore the association. We also carried out a modification/interaction effect of low birth weight (LBW), smoking and premature births (PTB), which enhanced the methodological robustness of the study.

Results: This study found that offspring from mothers with prenatal CUwD had a 98%, 94% and 46% increased risk of ADHD [aRR = 1.98: 95 % CI 1.36 – 2.88], ASD [aRR = 1.94: 95 % CI 1.34 – 2.82], and ID [aRR = 1.46: 95 % CI 1.01 – 2.63] compared to those non-exposed offspring, respectively. We observed a significant interaction effect between CUD during pregnancy and maternal smoking on the risk of childhood ADHD, ASD and ID [CUD*smoking: RR = 5.62: 95 % CI 3.77 – 8.39, RR = 2.72: 95 % CI 1.78 – 4.18, and RR = 2.84: 95 % CI 1.54 – 5.22, respectively]. Furthermore, we also found significant associations between PCUD and ADHD, ASD and ID when interacting with LBW, and PTB.

Conclusions: Maternal prenatal CUD is associated with a higher risk of ADHD, ASD, and ID in offspring. The effect of maternal CUD on neurodevelopmental disorders was also found to be stronger when mothers also reported smoking during pregnancy, compared to the individual effects of cannabis use or smoking alone. The findings highlight the importance of implementing preventive strategies to reduce cannabis use in pregnancy.

Assessment of anorexia nervosa according to the DSM-5 alternative personality model using the SCID-5-AMPD diagnostic interview system

J. Bognár^{1*}, D. B. Pólya², G. Purebl³, J. Réthelyi⁴, K. Bai-Nagy³, S. Hamvas⁴ and J. Biliczki⁴

¹Department of Pediatrics; ²Semmelweis University, Budapest, Hungary; ³Institute of Behavioural Sciences and ⁴Department of Psychiatry and Psychotherapy, Semmelweis University, Budapest, Hungary

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.180

Introduction: Anorexia nervosa (AN) is a chronic disease that significantly impairs the quality of life, with a low (less than 50%) remission rate, the incidence of which is increasing and it appears at younger and younger ages.

Objectives: Our aim is to facilitate effective and targeted therapy for anorexia nervosa by identifying personality traits and endophenotypes that aid diagnosis and identification of psychotherapeutic targets.

Methods: AN patients aged 18-45 years (N=14 female patients in the current study) completed online questionnaires on personality traits (PID-5), eating disorder (EDI-1), emotion regulation style, mentalization (MZQ), dissociation (DIS-Q), current emotional and mood state (SCL-90, PHQ-9), and past traumatic events (CTQ) after MINI and SCID-5-AMPD interview. Results were compared with a matched healthy control sample.

Results: Apart from AN, the most common comorbidity was depressive episode, and anxiety disorders were also present. In the SCID-5-AMPD interview, high scores were obtained for several domains describing personality dysfunction in the AN group. Among self-report questionnaires, we observed significant differences in scores on the SCL-90-R, and no difference in CTQ in the AN patients compared to healthy controls.

Conclusions: Based on the results of our study, the AN group showed more severe personality trauma, especially in the functional domains of identity and intimacy, and more psychological distress. The above may help to identify personalised psychotherapeutic treatment targets in AN patients, which may significantly improve effectiveness and reduce the time spent in therapy.

Perceived parental bonding and cortisol awakening response in people with eating disorders

N. Attianese^{1*}, M. Battipaglia¹, S. Donato¹, R. Ceres¹, R. Cerra¹, G. Cascino², P. Monteleone² and A. M. Monteleone¹

¹University of Campania "L. Vanvitelli", Naples and ²University of Salerno, Salerno, Italy

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.181

Introduction: Early life experiences may have an impact on hypothalamic–pituitary–adrenal (HPA) axis functioning in eating disorders (EDs). Parental bonding is defined as the parental contribution of care and control to parent–child relationships. We evaluated whether perceived care and protection of parental bonding in childhood and adolescence were associated with HPA axis functioning in adult patients with EDs. The activity of the HPA axis was assessed by measuring the salivary cortisol awakening response (CAR).

Objectives: We evaluated whether parental care and control in childhood and adolescence were associated with HPA axis functioning in adults with EDs. On the basis of literature data on healthy participants, we hypothesized that people with high levels of parental care would show a reduced CAR compared to people with low levels of parental care.

Methods: We admitted patients according to the following inclusion criteria: (a) female sex, (b) age > 18 years, (c) current diagnosis of AN or BN according to DSM-5 criteria, (d) absence of severe physical disorders, (e) no history of endocrine disorders, psychoactive substance use, schizophrenia or other psychoses, bipolar disorders or head trauma. Participants completed the Italian version of the Parental Bonding Instrument (PBI). To measure the CAR, participants were instructed to collect saliva samples at awakening and 15, 30, and 60 min after awakening.

Results: 64 women with EDs participated in the study: 37 with AN and 27 with BN. 28 participants reported low levels of both maternal and paternal care while 12 participants reported high levels of care from both parents; 31 participants reported high levels of both maternal and paternal control, while 12 participants reported low levels of control from both parents. When maternal care was entered as between factor in the analysis, the repeated measures 3-way ANOVA showed a significant time effect ($F_{3, 180} = 2.81, p < 0.05$) and a significant maternal care X time interaction ($F_{3, 180} = 2.99, p < 0.05$), while, when paternal care was entered as between factor, the repeated measures 3-way ANOVA did not show significant effects for time and no significant paternal care X time interaction.

Conclusions: Our results show an association of perceived maternal care with the time pattern of CAR in female patients with ED, while perceived parental control was not associated with any CAR feature in EDs. Maternal control, paternal care and paternal control were not associated with any difference in the CAR.

Updating the WHO Model Lists of Essential Medicines to promote global access to the most cost-effective and safe medicines for mental disorders

D. Papola^{1,2*}, G. Ostuzzi¹, C. Gastaldon¹ and C. Barbui¹

¹Neuroscience, Biomedicine and Movement Sciences, University of Verona, Verona, Italy and ²Global health and Social Medicine, Harvard Medical School, Boston, Massachusetts, United States

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.182

Introduction: Since its first publication in 1977, the World Health Organization's (WHO) Model List of Essential Medicines (EML) has guided the national procurement of medicines deemed essential to

inform public health policy worldwide. Aiming to include the most effective, safe, and cost-effective medicines for priority conditions, WHO updates the EML every two years. However, over the past 45 years, updates to the mental health section of the EML have been infrequent, mostly involving the addition of individual medicines. A comprehensive revision of the entire section was never attempted.

Objectives: The aim of this project was to update the mental health section of the EML to identify the most effective and safest medicines for mental disorders in the light of the most up-to-date evidence base.

Methods: A series of nine evidence-based applications were submitted to the WHO Expert Committee on the Selection and Use of Essential Medicines in December 2022, recommending a substantial revision of the entire mental health section.

Results: All of our applications were accepted by the WHO Expert Committee. For psychotic disorders, aripiprazole, olanzapine, paliperidone, and quetiapine were added as therapeutic alternatives to risperidone; short-acting intramuscular chlorpromazine was replaced by short-acting intramuscular olanzapine; first-generation antipsychotics were limited to oral haloperidol and chlorpromazine. For bipolar disorder, the list now includes second-generation antipsychotics such as quetiapine, aripiprazole, olanzapine, and paliperidone. Tricyclic antidepressants for depressive disorders were limited to amitriptyline alone. Treatment options for anxiety and obsessive-compulsive disorder are now expanded to include SSRIs. For anxiety disorders, diazepam and lorazepam became the only benzodiazepines recommended, with the specific caveat that they should only be used for short-term emergency treatment of acute and severe anxiety symptoms. Finally, chlorpromazine and haloperidol are no longer considered essential medications for psychotic disorders in children under 13 years of age.

Conclusions: The WHO released the 23rd EML in July 2023. After decades of minimal and inconsistent updates, groundbreaking changes have been made to its mental health section. The updated mental health section provides a compelling opportunity to improve the quality of medicine selection at the country level, with the goal of increasing the availability of the safest and most effective psychotropic medicines worldwide.

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.183

Introduction: Mental Health problems and substance misuse during pregnancy constitute a serious social problem due to high maternal-fetal morbidity (Cook et al, 2017; JOCG, 39(10) ,906-915) and low detection and treatment rates (Carmona et al. Adicciones. 2022;34(4):299-308)

Objectives: Our study aimed to develop and test the feasibility and acceptability of a screening and treatment clinical pathway in pregnancy, based on the combination of e-Health tools with in-person interventions and, secondly, describe the prevalence of mental illness and substance use problems in this population.

Methods: 1382 pregnant women undergoing her first pregnancy visit were included in a tailored clinical pathway and sent a telematic (App) autoapplied questionnaire with an extensive battery of measures (WHO (Five) Well-Being [WHO-5], Patient Health Questionnaire [PHQ-9], General Anxiety Disorder [GAD-7], Alcohol Use Disorders Identification Test [AUDIT], Drug Abuse Screening Test [DAST], Columbia Suicide Severity Rating Scale [C-SSRS] and specifically designed questions on self-harm and psychopharmacological drugs).

Patients who did not respond to the questionnaire on their own received a counseling call.

Based on the screening results, patients were classified into five groups according to severity (Figure 1) and assigned a specific action pathway (Figure 2) that included a range of intervention intensity that goes from an individual psychiatric appointment to no intervention.

Results: Of the 1382 women included in the clinical pathway, 565 (41%) completed the evaluation questionnaires. Of these, 205 (36%) were screened as positive (Grades III,IV or V. Table 1) and 3(0.5%) were classified as needing urgent care. Of the patients offered on-line groups (100), 40% (40) were enrolled in them. Concerning prevalence rates, 73 (12,9%) patients endorsed at least moderate anxiety according to GAD-7 (≥ 10), 65 (11,5%) endorsed at least moderate depression according to PHQ-9 (≥ 10), 17 were positive on DAST (3%) and 63 (11%) patients scored above the threshold in AUDIT-C(≥ 3) for alcohol use.

Table 1: Grade distribution of those screened as positives

Grade III	97 (17,2%)
Grade IV	105 (18,6%)
Grade V	3 (0,5%)

Image:

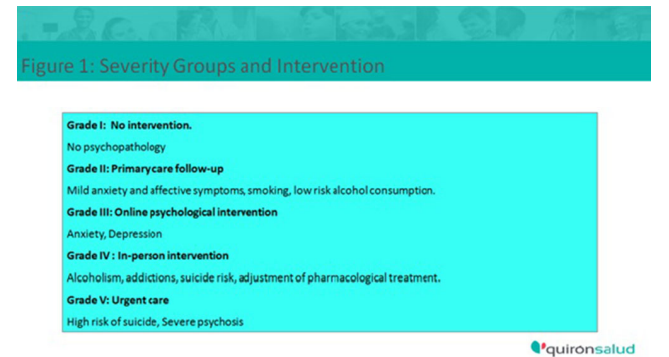

Image 2:

Figure 2: Action Pathway

Conclusions: High prevalence rates suggest that effective detection and treatment mechanisms should be integrated into usual care. The use of standardized clinical pathways can help with this aim, allowing better clinical management and referral to treatment, but still face challenges to increase retention. The use of e-health tools offers the opportunity to improve accessibility and therapeutic outcomes through online interventions.

The association between prenatal cannabis use and congenital birth defects in offspring: A systematic review and meta-analysis

A. W. Tadesse^{1*}, G. Ayano², B. A. Dachew¹, B. S. Tusa¹, Y. Damtie¹, K. Betts¹ and R. Alati¹

¹School of Population Health, Curtin University, Perth, Australia and

²School of Population Health, Curtin University, Perth, Austria

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.184

Introduction: A body of research has examined the association between prenatal cannabis use and congenital birth defects in offspring; however, these studies have not been synthesised. We performed a comprehensive synthesis of existing research to test whether there is an association between prenatal cannabis use and congenital birth defects in exposed offspring.

Objectives: The aim of this study was to conduct a comprehensive systematic review and meta-analysis of existing evidence to synthesise the association between prenatal cannabis use and congenital birth defects in exposed offspring.

Methods: In line with the preregistered protocol (PROSPERO: CRD42022368623), we systematically searched PubMed/Medline, CINHAL, EMBASE, Web of Science, ProQuest, Psych-Info, and Google Scholar for published articles until 4 April 2023. The methodological quality of the included studies was appraised by the Newcastle-Ottawa Quality Assessment Scale (NOS). A meta-analysis was carried out to report the pooled effect estimates from the included studies. We further performed subgroup, leave-one-out sensitivity, and meta-regression analyses, which increased the robustness of our findings.

Results: Thirty observational studies (i.e., fifteen case-control and fifteen cohort studies) with 229,930 cases of birth defects and 26,826,741 controls (healthy babies) were included in the final analysis. We found that offspring exposed to maternal prenatal

cannabis had a 56%, 69%, 47%, 23%, and 13% increased risk of any birth defects (irrespective of specific body system) [RR = 1.56: 95 % CI 1.28 – 1.92], defects of the gastrointestinal [RR = 1.69: 95 % CI 1.37 – 2.09], cardiovascular/heart [RR = 1.47: 95 % CI 1.09 – 1.97], central nervous systems [RR = 1.43: 95 % CI 1.09 – 1.89], and facial/oral cleft [RR = 1.13: 95 % CI 1.08 – 1.18], respectively.

Conclusions: The findings from the current study suggest that maternal prenatal cannabis exposure is associated with a higher risk of birth defects in offspring. The findings highlight the importance of promotive and preventive strategies to reduce cannabis use during pregnancy that contribute to minimising the risk of birth defects in offspring.

Traits of narcissistic vulnerability in adults with Autism Spectrum Disorders without intellectual disabilities

G. Broglio^{1*}, V. Nistico^{1,2,3}, B. Di Paolo¹, R. Faggioli⁴, A. Bertani⁵, O. Gambini^{1,3,4} and B. Demartini^{3,3,4,4}

¹Health Science Department, University of Milan; ²Department of Psychology, University of Milan Bicocca; ³Aldo Ravelli Research Center for Neurotechnology and Experimental Brain Therapeutics, University of Milan; ⁴UO Psichiatria 51 e 52 and ⁵Centro Giovani Ettore Ponti, ASST Santi Paolo e Carlo, Presidio San Paolo, Milan, Italy

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.185

Introduction: The relationship between Autism Spectrum Disorders (ASD) and Narcissistic Personality Disorder (NPD), considering the dimensions of narcissistic grandiosity and vulnerability, represents an important differential diagnosis and potential ground of comorbidity, since both conditions show high grades of pervasiveness, a life-long course, ego-syntonic traits, and difficulties in building up and sustaining interpersonal relationships. Although the co-diagnosis rates, according to the categorical criteria in use, are limited (0%–6.4%), it is common to encounter diagnostic doubts in clinical practice.

Objectives: Here we aimed to explore both the dimensions of narcissistic vulnerability and grandiosity in a group of adults diagnosed with ASD without intellectual disabilities.

Methods: 87 individuals with ASD completed the Pathological Narcissism Inventory-52 Items (PNI-52). The mean scores of our sample were compared with the normative distribution available in the literature. Participants also underwent a detailed sociodemographic and anamnestic interview, along with an assessment for autistic traits, comprising the “Ritvo Autism and Asperger Diagnostic Scale-Revised” (RAADS-R) and the Autism Quotient (AQ). **Results:** Individuals with ASD scored significantly higher than neurotypical controls at the Total Score and at the Vulnerable Narcissism subscale, but not at the Grandiose Narcissism subscales. Demographic features did not influence these results. Vulnerable narcissism was significantly associated with the RAADS-R subscale Social Relatedness.

Conclusions: Our findings could potentially be indicative of a greater comorbidity rate between the two disorders with respect

to the one reported to date, possibly because DSM-5 criteria are mainly focused on the grandiose dimension. Potential explanatory links between ASD phenomenology and vulnerable narcissism, such as the personality dimension of neuroticism, are discussed, together with the possible role of narcissistic vulnerability in mediating internalizing symptoms (e.g., anxiety, depression) in individuals with ASD.

Mental Disorders in patients hospitalized due to Neurologic Disorders: a nationwide study

M. Gonçalves-Pinho^{1,2*}, B. Martins³, A. Costa³, J. Pedro Ribeiro², A. Freitas⁴, E. Azevedo¹ and L. Fernandes^{1,5}

¹CINTESIS@RISE, Department of Clinical Neurosciences and Mental Health, Faculty of Medicine, University of Porto, FMUP, Porto; ²CHTS, Penafiel; ³Department of Clinical Neurosciences and Mental Health, Faculty of Medicine, University of Porto; ⁴CINTESIS@RISE, MEDCIDS, Faculty of Medicine, University of Porto, FMUP and ⁵Psychiatry Service - Centro Hospitalar Universitário de São João, CHUSJ, Porto, Portugal

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.186

Introduction: The presence of psychiatric comorbidity significantly impacts the quality of life for patients and often goes unnoticed within the realm of neurology.

Objectives: This study's objective was to elucidate and characterize psychiatric comorbidity among patients hospitalized for neurological disorders in mainland Portugal.

Methods: This retrospective observational study analyzed hospitalizations categorized with a primary diagnosis of neurological disorders, defined by Clinical Classification Software (CSS) for ICD-9-CM codes 76, 77, 79-85, 95, and 109, occurring in adult patients (≥ 18 years) between 2008 and 2015. Psychiatric comorbidity was determined by the presence of secondary diagnoses falling under CCS categories 650-670.

Results: A total of 294,806 hospitalization episodes were documented with a primary diagnosis of neurological disorders in adult patients between 2008 and 2015 in Portuguese public hospitals. Approximately 26.9% ($n=79,442$) of these episodes were associated with documented psychiatric comorbidity (22.1% for female hospitalizations and 32.2% for male hospitalizations). Patients with recorded psychiatric comorbidity were younger (66.2 ± 16.2 vs. 68.6 ± 17.2 for those without psychiatric comorbidity, $p < 0.001$), exhibited a lower overall in-hospital mortality rate, and experienced significantly longer mean hospital stays. Among these comorbidities, 'Delirium, dementia, amnesic, and other cognitive disorders' were documented in 7.4% ($n=21,965$) of hospitalizations, followed by alcohol-related disorders in 6.5% ($n=19,302$) and mood disorders in 6.1% ($n=18,079$). Epilepsy/seizures had the highest recorded psychiatric comorbidity rate among neurological disorders (39.9%).

Conclusions: Psychiatric comorbidity is present in more than a quarter of hospitalizations with a primary diagnosis of neurological disorders. The prevalence of psychiatric comorbidity varies across

different neurological disorders and is associated with distinct demographic and clinical characteristics.

Evidence-Informed Approach to De-Prescribing of Atypical Antipsychotics (AAP) in the Management of Behavioral Expressions (BE) in Advanced Neurocognitive Disorders (NCD): Results of a Retrospective Study.

A. S. Luthra^{1*}, R. LinBin Gao², P. Carducci³, J. Sue⁴ and S. Remers⁵

¹Department of Psychiatry and Behavioural Neurosciences, McMaster University; ²Department of Pharmacy, St. Peter's Hospital, Hamilton; ³School of Pharmacy, University of Waterloo, Waterloo; ⁴Clinical Neuropsychologist, St. Peter's Hospital, Hamilton and ⁵Homewood Health Inc, Guelph, Canada

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.187

Introduction: Diagnosis of behaviors in advanced neurocognitive disorders (aNCD) is one of exclusion, and the framework has been laid out in DSM-V. However, clinical assessments in aNCD become increasingly unreliable, and commonly used psychometric tools for clinical assessments lack reliability and validity, thereby making outcomes unreliable. Consequently, the syndromic and symptom management approaches for behaviors in aNCD behaviors have yielded poor results. To address this, the focus has shifted towards understanding the 'meaning' of behaviors in aNCD, recognizing them as a 'mode of communication'. To date, there are no existing frameworks to ascribe 'meaning' to behaviors in aNCD.

Objectives: LuBAIR™ paradigm is the first step in offering such a framework for understanding the 'purpose' and 'meaning' of behaviors in NCD. The 'meaning' ascribed to each behavioral category was used to guide the use of atypical antipsychotics in their management. De-prescribing was attempted on patients who qualified to enter this retrospective study. De-prescribing was defined as successful if individuals were completely withdrawn from AAP and remained off them for 60 days without the re-emergence of behaviors.

Methods: The data collected on the second occasion, in the successful and failed de-prescribed groups, were compared in this retrospective study. MANOVA, Chi-Square paired *t*-test statistical analyses were used to detect the differences in the behavioral categories between the two cohorts. Cohen *d* was used to measure effect size.

Results: Patients who did not have Mis-Identification and Goal-Directed Expressions were more likely to successfully de-prescribe: X2 (1, $N = 40$) = 29.119 $p < 0.0001$ and X2 (1, $N = 40$) = 32.374, $p < 0.0001$, respectively. Alternatively, the same behavioral categories were more likely present in patients who failed de-prescribing: MANOVA and paired *t*-test ($p < 0.0001$). Atypical antipsychotics, in their role as an antipsychotic and mood stabilizer, may be used to manage Mis-Identification and Goal-Directed Expressions, respectively.

Conclusions: LuBAIR paradigm has the potential to guide the development of specific behavioral care plans and the use of AAP in managing individual behavioral categories. AAP use can be justified for managing Misidentification and Goal-Directed Expressions. Vocal expressions may warrant the use of AAP, pending further study. The LuBAIR paradigm offers guidance for de-prescribing AAP for all other behavioral categories in the LuBAIR Inventory. This study is also a preliminary step in validating the psychological theories used to support the individual categories. This workshop will educate the participants on the LuBAIR paradigm and its application in developing person-centered interventions for behaviors in a NCD.

A thematic analysis of the introduction of smart-hub technology to a rural Psychiatry of Old Age Service during Covid-19 lockdowns.

S. Patel^{1,2*}, A. Gannon³, M. Cryan⁴, C. Dolan⁴, C. McDonald^{2,5}, C. Houghton⁶ and G. McCarthy^{4,7}

¹Liaison Psychiatry, University Hospital Galway; ²School Of Medicine, University Of Galway, Galway; ³Sligo Leitrim Mental Health Services, Sligo, Ireland; ⁴Psychiatry of Old Age, Sligo Leitrim Mental Health Services, Sligo; ⁵Psychiatry, University Hospital Galway; ⁶School of Nursing and Midwifery, University Of Galway, Galway and ⁷School Of Medicine, University of Galway, Sligo, Ireland

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.188

Introduction: The use of smart technology in supporting older adults is a growing field of research. However, there is little qualitative research on the experiences of patients utilizing this technology, particularly those attending psychiatry services.

Objectives: To explore the experiences of staff and patients utilizing smart-hubs implemented during the Covid-19 pandemic to provide remote audio/visual communication and smart AI personal assistant technology for the management of patients in a rural Psychiatry of Old Age service.

Methods: Smart hubs were installed in patient homes and in the Psychiatry of Old Age base during the Covid-19 pandemic when lockdown restrictions limited in-person service provision. Patients and staff utilized the smart hubs for its assistive technology and to engage with each other. Semi-structured qualitative interviews were conducted of 10 staff and 15 patients at 6-12 months following the introduction of the smart hubs and thematic analysis was conducted to generate themes.

Results: Three themes were generated from the thematic analysis: 1) Openness to SMART hub technology, 2) Getting set-up and 3) Keeping SMART. The majority of participants did not have much experience using smart technology prior to the intervention. However, many participants reported that they would be comfortable using technology. The Covid-19 pandemic contributed to the rapid adoption of this intervention within the service with mixed views regarding the smart hub prior to implementation. The role of key individuals such as staff and family was highlighted in supporting older persons with setting-up the smart hub. Technical needs included the need for a strong internet connection and technical

limitations were driven by privacy, cost and regional considerations. Many patients were able to utilize the smart hub independently to access interests, therapeutic activities and as a memory aid. The smart hub offered a novel way to connect to services and families and was also seen as a companion by some patients and staff to help address loneliness and isolation. The majority of participants found the use of smart hubs acceptable and were willing to utilize the smart hub in the future as an adjunct to face to face psychiatric interventions. However, suggestions for future use included the need for additional training as users felt that there was more they could do with the smart hub, continued support to manage any challenges and improved information leaflets to better engage users.

Conclusions: Smart hub technology offers an alternate means of providing remote and inclusive psychiatric care to older patients unable to access services in person and at risk of deterioration without intervention in the community.

Temporal Dynamics of Depressive Symptoms and Cognitive Decline in the Oldest Old: Dynamic Time Warp analysis of the Leiden 85-plus Study

A. J. van der Slot^{1*}, A. S. Bertens^{1,2}, S. Trompet³, S. P. Mooijaart³, J. Gussekloo^{3,4}, F. van den Bos³ and E. J. Giltay^{1,5}

¹Department of Psychiatry, Leiden University Medical Center; ²Mental Health Service Rivierduinen; ³Department of Internal Medicine, Section of Gerontology and Geriatrics; ⁴Department of Public Health and Primary Care, Leiden University Medical Center, Leiden and ⁵Health Campus, Leiden University, The Hague, Netherlands

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.189

Introduction: The prevalence of depressive symptoms and cognitive decline increases with age, reducing quality of life. However, the temporal relationship between the two remains elusive.

Objectives: We aimed to explore the temporal relationship between depressive symptoms and cognitive decline in individuals aged 85 years, during up to 5 years follow-up.

Methods: Participants eligible for this study were selected from the Leiden 85-plus Study, who participated for at least 3 follow-up measurements. Depressive symptoms were assessed at baseline and at follow-up in a period of 6 yearly assessments, utilizing the 15-item Geriatric Depression Scale (GDS-15). Cognitive decline was measured through various tests including the Mini Mental State Exam (MMSE), Stroop Test, Letter Digit Coding Test, and immediate and delayed recall using the 12-word learning test. Dynamic Time Warping (DTW) analysis was employed to model their temporal dynamics, in undirected and directed analysis, to ascertain whether depressive symptoms precede cognitive decline, or vice versa.

Results: The study included a total of 325 (54.2%) of 599 patients, of whom 68.0% were female, 45.0% with intermediate to higher education, and all aged 85 years. Depressive symptoms and cognitive functioning significantly covaried in time, and directed analyses showed that depressive symptoms preceded most of the parameters of cognitive decline in the oldest old. Of the 15 GDS

symptoms, those with the strongest outstrength were worthlessness, hopelessness, low happiness, dropping activities/interests, and low satisfaction with life (all $p < .01$).

Conclusions: We found a strong temporal link between depressive symptoms and subsequent cognitive decline in a population of the oldest old. This highlights the importance of a holistic approach that considers both mental and cognitive well-being in the aging population. As depressive symptoms were an early indicator of cognitive decline, it is of importance that healthcare professionals recognize and address depressive symptoms early to allow for appropriate interventions and support, to potentially mitigate the impact on cognitive decline.

Prevalence of depressive disorders in breast cancer patients

R. A. Starostin^{1*}, S. V. Kuzmina² and I. G. Gataullin³

¹LLC «Druzhkov Clinic»; ²FBElOHE KSMU MOH Russia and ³KSMA - Branch Campus of the FSBEIFPE RMACPE MOH Russia, Kazan, Russian Federation

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.190

Introduction: Breast cancer is the most common type of cancer and the leading cause of death from malignant neoplasms in women in Russia and in most countries in the world (Lima *et al.* *EClinicalMedicine* 2021; 38 100985). According to an analysis of the incidence and mortality from 36 cancers in 185 countries (Sung *et al.* *CA Cancer J Clin* 2021. 3 209-249) in 2020, 2261419 new cases of breast cancer were identified in the world in both sexes, which is accounted for 11.7% of the total cancer incidence. Mortality from breast cancer in 2020 amounted to 684996 cases. Patients with comorbid depression and anxiety disorders experience more severe symptoms, have longer recovery time, use more healthcare resources and have poorer outcome compare to those with cancer alone (Katon *et al.* *Gen Hosp Psychiatry* 2007; 2 147-155).

Objectives: Analytical review of data on the impact of depressive spectrum disorders as comorbid conditions on the survival of breast cancer patients and their quality of life.

Methods: The following databases were searched for publications: PubMed, Embase, CINAHL, PsycINFO, Scopus, Science Citation Index/Social Sciences Citation Index, Cochrane Evidence Based Medicine database. The searches were limited to English language and studies with more than 100 subjects with diagnosed breast cancer where this information was mentioned. The analyzed period is between 1977 and 2018.

Results: The reported prevalence of depression in breast cancer patients, according to researches, varies 4,5 to 38%. In patients with I-III stage breast cancer depression increased hazards of all-cause mortality by 50% compared to non-depressed patients. Stage-specific analyses demonstrated a 2–2.5 fold increase in breast cancer-specific and all-cause mortality in patients with stage I

and II disease (Vodermaier *et al.* *Breast Cancer Res Treat* 2014; 2 373-384.). Women with non-metastatic breast cancer who report mild to moderate depressive symptoms in the weeks after surgery have approximately 2.5 times greater risk of death 8–15 years later than women who report little or no depressive symptoms post-surgery (Antoni *et al.* *Gen Hosp Psychiatry* 2017; 44 16-21). Depression in advanced cancer not only reduces quality of life but is also an independent predictor of poorer survival (Lloyd-Williams *et al.* *J Affect Disord* 2009; 113 127-132.).

Conclusions: Depression and anxiety both have adverse effects on recurrence and all-cause mortality in patients with breast cancer. Untreated depression leads to significant increase in incidence and mortality. Depression can debut at any stage of cancer, including the stage of diagnosis. It proves the necessity for affective disorders screening in patients with cancer on the stage of diagnosis. Patients with diagnosed affective disorders should be observed not only by oncologist, but also by a psychotherapist in order to receive the necessary treatment to improve the quality of life and reduce the risk of mortality.

Combined effects of psychological and life style factors on pain intensity and/or disability in patients with chronic low back pain: A cross-sectional study

E. Tsatsaraki¹, I. Bouloukaki², G. Kontakis³, A. Vakis⁴, A. Miliaras⁵ and M. Basta^{5*}

¹Surgery; ²Social and Family Medicine; ³Orthopaedics and Traumatology; ⁴Neurosurgery and ⁵Psychiatry, University of Crete, School of Medicine, Heraklion, Greece

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.191

Introduction: Chronic Lower Back Pain (CLBP) is a frequently encountered health issue in primary care settings, leading to global disability and imposing a considerable economic burden.

Objectives: This study aimed to: (1) compare socio-demographic, health, lifestyle (sleep, physical activity) and psychological factors (depression, anxiety) between people with and without CLBP; and (2) quantify the correlations between these psychological and life-style factors, and clinical outcomes (intensity of CLBP and CLBP-related disability) in people with CLBP after considering other confounders.

Methods: A cross-sectional study was undertaken at the neurosurgery and orthopedic outpatient department of Heraklion University Hospital between 2019-2021. Two hundred fifty three volunteers with CLBP and 116 without CLBP provided socio-demographic information, daily habits, medical history, subjective sleep/ sleep complaints, low back pain intensity and disability using a 10-point numeric Visual Analogue Scale pain rating scale and Quebec Back Pain Disability Scale, as well as questions assessing impact of pain on mobility, self-care, routine activities and psychological status, respectively. Participants also completed the Zung Self-Rating Scale (SDS) for self-assessment of depression and

Self-rating anxiety scale (SAS). Associations among CLBP, demographics, psychosocial or sleep disorders parameters and clinical outcomes were analyzed using multivariate models.

Results: People with CLBP exhibited a substantially greater prevalence of depressive, insomnia and obstructive sleep apnea (OSA) symptoms than controls ($p < 0.05$). CLBP diagnosis was independently correlated with female gender, older age, as well as worse physical and mental health outcomes measured by (i) higher level of sleep symptoms such as sleepiness, OSA and insomnia symptoms and (ii) higher prevalence of physician-diagnosed depression, and moderate to severe depressive symptoms. The level of functional disability for CBLP patients (based on Quebec score) was independently associated with age, physician diagnosed depression, lower educational status, moderate to severe depressive symptoms and OSA symptoms. The combination of moderate to severe depressive symptoms with OSA or insomnia symptoms was the most important predictive factor for functional disability for CBLP patients (OR 13.686, 95% CI 4.581-40.885; $p < 0.001$).

Conclusions: Depressive symptoms and subjective sleep disorders appear to relate to greater CLBP-intensity and/or CLBP-related disability in people with CLBP. To achieve the desired outcomes when treating patients with chronic CLBP, it is essential to employ a holistic approach, involving assessment and management of their psychological comorbidities, and sleep issues, that may improve quality of life in these patients.

Gene expression of protein synthesis, immunity and brain pathways specifically altered in Anorexia Nervosa

N. Ramoz^{1*}, C. Verebi¹, N. Lebrun¹, P. Duriez², P. Gorwood³ and T. Bienvenu¹

¹INSERM U1266; ²CMME and ³GHU Paris Psychiatrie et Neurosciences, Paris, France

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.192

Introduction: Anorexia nervosa (AN) is a severe and chronic psychiatric disorder, resulting from a voluntary food restriction, vomiting, use of laxatives and excessive exercises, leading in dramatic weight loss and high mortality. AN is a multifactorial disease involving genetic and epigenetic factors supporting that AN is a metabo-psychiatric disorder. The molecular mechanisms involved in the etiology of AN remain unclear. One work reported gene expression by RNA sequencing in peripheral blood before and after weight restoration in 6 AN patients (Kim 2013), and one RNA sequencing in human iPSC-derived neurons from 4 patients and 4 controls (Negraes 2017). To date, the profile of expression of genes and proteins in AN is undetermined.

Objectives: In this study, our goal is to identify specific gene expression signatures from circulating blood nuclear cells to decipher the pathophysiology of AN and characterize biomarkers that can be used for diagnostic or prognostic of AN.

Methods: All consented participants are recruited at Sainte-Anne Hospital, Paris, France, using DSM5 criteria. They had a blood draw in Paxgene tube for the collection of RNAs. Total RNA was extracted from peripheral blood mononuclear cells of 15 patients suffering of AN and 15 healthy controls. All messenger RNAs are sequenced on a Novaseq platform. Reads are aligned to the human genome 19 and statistical analyses on the read counts for differentially expressed genes are computed with DESeq2.

Results: The total RNA sequencing allows us to identify 673 dysregulates genes (p adjusted value < 0.01 , fold change > 1.5). Among them, 248 are down-regulated and 425 are up-regulated genes in AN patients compared to controls. From them, 151 transcripts are annotated as pseudogene and 45 are referenced as antisense RNA. Of the 522 remaining transcripts, 424 correspond to a transcript or protein annotated by HGNC and ENSEMBL and 93 are known pseudogenes. A large number of proteins resulting from the expression of deregulated genes interact with each other and form a statistically enriched network impacting biological processes. They are mainly increased and acting in the cellular machinery allowing protein synthesis (biological process: transcription, ribosome, spliceosome and mitochondria). In contrast, down-regulated genes present an enrichment in genes involved in immunity pathways. Finally, several genes are also expressed in the brain. We observed a significant enrichment of genes expressed in the blood and brain tissues.

Conclusions: We identify specific profiles of gene expression in AN. Several genes are both blood and brain tissue expression. Some genes are good candidates for biomarker of the diagnostic in AN that need to be investigated in a longitudinal study to evaluate their useful as prognostic biomarker of AN.

Crosstalk between Anxiety and Depression and Inflammatory bowel diseases: preliminary data on circulating miRNAs

I.-C. Matei^{1*}, M. Dobre², E. Milanese² and T. E. Manuc^{3,4}

¹Psychiatry, Clinica Nutrimed; ²Victor Babes National Institute for Pathology; ³Gastroenterology, Fundeni Clinical Institute and

⁴Gastroenterology, University of Medicine and Pharmacy Carol Davila, Bucharest, Romania

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.193

Introduction: Numerous studies have established a heightened prevalence of anxiety and depression (A&D) in individuals diagnosed with Inflammatory Bowel Diseases (IBD) when compared to the general population. Research indicates that patients with active IBD exhibit a higher frequency of anxiety symptoms and depression symptoms compared to those with inactive disease. In patients with IBD, anxiety was linked to reduced medication adherence and an increased likelihood of undergoing surgery. Furthermore, associations were identified between depression and an elevated risk of disease relapse, as well as a poorer response to treatment in IBD

patients. In both IBD and depression, there is evidence of disruptions in circulating miRNAs.

Objectives: One facet of the ongoing project titled “The brain-gut axis linking inflammatory bowel disease with anxiety and depression: the inflammation-microbiome network” (CRP/ROU21-01) involves the exploration of circulating miRNA profiles in various patient groups.

Methods: These groups encompass IBD patients with symptoms of anxiety and/or depression (IBD+A&D+), patients lacking anxiety and depression symptoms (IBD+A&D-), a cohort of individuals without IBD but experiencing depressive and anxiety symptoms (IBD-A&D+), and a control group (IBD-A&D-). Thus far, our investigation has entailed screening a comprehensive panel of 179 miRNAs in the plasma of six IBD patients and 12 non-IBD patients (CTRL) to identify a subset of highly dysregulated miRNAs. MiRNA isolation was achieved using the miRNeasy Serum/Plasma Kit, and miRNA expression levels were assessed via quantitative reverse transcription-polymerase chain reaction (qRT-PCR) utilizing the Human serum/plasma focus, MIRCURY LNA miRNA Focus PCR panel (Qiagen).

Results: Our statistical analysis revealed significant differential expression in 45 miRNAs ($p < 0.05$). Specifically, we identified 29 miRNAs with elevated expression and seven miRNAs with reduced expression. Among these dysregulated miRNAs, 15 (miR-223-3p, miR-143-3p, let-7f-5p, miR-30b-5p, miR-26a-5p, let-7a-5p, miR-339-5p, let-7d-5p, miR-221-3p, miR-191-5p, let-7g-5p, miR-24-3p, miR-107, miR-26b-5p, miR-320b) were associated with depression and/or anxiety and were previously identified as dysregulated in the plasma of patients in other studies. These miRNAs will soon undergo evaluation in the plasma of IBD-A&D+ and IBD+A&D+ patients.

Conclusions: These initial findings provide us with a panel of circulating miRNAs that warrant further investigation in the aforementioned patient groups. The miRNA profile we obtained may either be unique to IBD or linked to the intricate phenotypes of IBD occurring concurrently with anxiety and depression. A more profound comprehension of these mechanisms will aid in the development of enhanced diagnostic tools and disease monitoring strategies, as well as the exploration of innovative therapeutic approaches.

Longitudinal amygdala resting state functional connectivity develops differently in adolescents with internalising disorders compared to healthy peers

E. Roelofs^{1,2,3*}, J. M. Bas-Hoogendam^{2,3,4}, N. van der Wee^{2,3} and R. Vermeiren¹

¹LUMC-Curium, Department of Child and Adolescent Psychiatry;

²Department of Psychiatry, Leiden University Medical Center;

³Leiden Institute for Brain and Cognition and ⁴Developmental and Educational Psychology, Institute of Psychology, Leiden University, Leiden, Netherlands

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.194

Introduction: Longitudinal neuroimaging studies focused on adolescents with internalising psychopathology (i.e. with clinical anxiety and/or depression) are scarce, even though anxiety and depression are highly prevalent mental illnesses in adolescence. Often linked to comorbidity with anxiety disorders, a large proportion of depressed adolescents displays more severe symptoms and poorer response to treatment. Previous longitudinal resting-state fMRI (RS-fMRI) studies of intrinsic functional connectivity (iFC) in depressed adolescents point to dysregulation of underlying neural networks such as the corticolimbic network, including among others the amygdala and frontal regions, which are involved in emotion processing and regulation.

Objectives: This naturalistic study investigates longitudinal changes in resting-state iFC in adolescents with internalising disorders, compared with healthy peers.

Methods: 23 treatment naïve adolescent patients with clinical depression and comorbid anxiety (INT) and 24 healthy controls (HC) participated in RS-fMRI scans at baseline and after three months. Questionnaires measuring anxiety and depression were completed at both timepoints. Imaging analyses were conducted using independent component analysis (ICA) to extract 7 networks, being the default mode, frontoparietal (bilateral), affective, salience, executive control and dorsal attention network. Additional iFC of amygdala subregions, being laterobasal (LB) and centromedial (CM), was investigated using seed-based analyses. To investigate changes over time between groups, voxelwise analyses were conducted using FSL's PALM.

Results: No significant results within ICA defined networks were found. iFC between the left LB amygdala and left frontal pole significantly increased over time in patients and decreased in HC. iFC between the right LB amygdala and right pre- and post-central gyrus also significantly increased over time in patients and decreased in HC, and was significantly associated with reduction in depressive symptoms within patients.

Conclusions: This study provides initial evidence that iFC between the laterobasal amygdala and frontal regions develops differently over time in adolescents with internalising disorders compared to healthy peers and that it is associated with reduction in depressive symptoms.

doi: 10.1192/j.eurpsy.2024.195

Introduction: Attention-deficit/hyperactivity disorder (ADHD) is a highly prevalent psychiatric condition that frequently originates in early development and is associated with a variety of functional impairments. Despite a large functional neuroimaging literature on ADHD, our understanding of the neural basis of this disorder remains limited, and existing primary studies on the topic include somewhat divergent results.

Objectives: The present meta-analysis aims to advance our understanding of the neural basis of ADHD by identifying the most statistically robust patterns of abnormal neural activation throughout the whole-brain in individuals diagnosed with ADHD compared to age-matched healthy controls.

Methods: We conducted a meta-analysis of task-based functional magnetic resonance imaging (fMRI) activation studies of ADHD. This included, according to PRISMA guidelines, a comprehensive PubMed search and predetermined inclusion criteria as well as two independent coding teams who evaluated studies and included all task-based, whole-brain, fMRI activation studies that compared participants diagnosed with ADHD to age-matched healthy controls. We then performed multilevel kernel density analysis (MKDA) a well-established, whole-brain, voxelwise approach that quantitatively combines existing primary fMRI studies, with ensemble thresholding ($p < 0.05$ - 0.0001) and multiple comparisons correction.

Results: Participants diagnosed with ADHD ($N=1,550$), relative to age-matched healthy controls ($N=1,340$), exhibited statistically significant ($p < 0.05$ - 0.0001 ; FWE-corrected) patterns of abnormal activation in multiple brains of the cerebral cortex and basal ganglia across a variety of cognitive control tasks.

Conclusions: This study advances our understanding of the neural basis of ADHD and may aid in the development of new brain-based clinical interventions as well as diagnostic tools and treatment matching protocols for patients with ADHD. Future studies should also investigate the similarities and differences in neural signatures between ADHD and other highly comorbid psychiatric disorders.

Nicotinamide Riboside Attenuates Memory Impairment and Depressive-like Behavior in an Alzheimer's Disease Animal Model

A. Aytulun^{1*}, B. Cimen², Y. Sara² and S. Ö. Erden Aki³

¹Psychiatry, Kilis Prof Dr Alaeddin Yavaşca State Hospital, Kilis;

²Medical Pharmacology and ³Psychiatry, Hacettepe University Faculty of Medicine, Ankara, Türkiye

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.196

Introduction: Depression in Alzheimer's disease (AD) differs from major depression in terms of clinical features and treatment. Anti-depressants do not provide the expected benefits in depressive symptoms accompanying cognitive decline in AD, suggesting distinct mechanisms. Emerging research suggest that compromised mitophagy, the selective removal of damaged mitochondria, may contribute to the pathogenesis of AD. However boosting nicotinamide adenine dinucleotide (NAD+) to induce mitophagy reduces

amyloid β (A β) aggregation and enhances cognitive function in AD models (Kerr *et al.*, Trends Neurosci 2017;40:151-66). Nevertheless, data on NAD's impact on depression in AD remains limited.

Objectives: This study aimed to examine the impact of the NAD+ precursor nicotinamide riboside (NR) on cognitive and neuropsychiatric symptoms in a AD rat model.

Methods: To induce the AD, a single dose of 5 μ l A β 1-42 was injected into each lateral ventricle of rats (day 0), while the control group received an intracerebroventricular (icv) saline (0.9%NaCl). Four experimental groups were designed: control (icv saline+po saline), NR (icv saline+po NR), A β (icv A β +po saline), and A β +NR (icv A β +po NR). After the injection, to reduce A β clearance (Kang *et al.* Science. 2009;32 1005-7.) rats were subjected to 96 hours of sleep deprivation. Starting from day 6, rats were given either 700 mg/kg oral NR or saline, and handling test scores were recorded daily. The procedures were repeated daily until the rats were sacrificed on day 28. Behavioral experiments were randomly conducted at the end, and statistical analysis was performed using repeated measures ANOVA, followed by the Tukey post hoc test.

Results: Passive avoidance test results showed that the A β group had the shortest latency to enter the dark area. However, the A β +NR group exhibited a prolonged latency compared to the A β group ($F(3,2)=5.5$; $p < 0.05$). A β injection induced depressive-like behavior in rats, as indicated by the forced swim test (FST) for anhedonia. In AD rats treated with NR (A β +NR), A β -induced depressive-like behavior was reduced, with lower FST immobility scores ($F(3,2)=6.2$; $p < 0.05$) and increased sucrose preference in the SPT ($F(3,2)=7.5$; $p < 0.05$). There were no significant differences in anxiety-like behaviors among the groups, assessed by the time spent in the open arm in the elevated plus maze test ($F(3,2)=1.9$; $p > 0.05$). During the 28-day monitoring period, the A β +NR group of rats exhibited a more rapid decrease in aggression levels compared to the other groups in the handling test. This decrease was significant between days 7 and 10 compared to the A β group ($F(48,5)=1.5$; $p < 0.05$).

Conclusions: NR improved memory, reduced depressive behavior, and lowered aggression in AD rats. This suggests that NAD+ precursor NR effectively treats cognitive decline and neuropsychiatric symptoms in an AD model.

Treatment effect of trauma-focused treatment and/or integrated trauma-focused and personality disorder treatment on brain activation during an emotional face task

I. Aarts^{1,2,3*}, C. Vriend^{2,3,4}, O. A. Van Den Heuvel^{2,3,4} and K. Thomaes^{1,2,3}

¹Sinai Centrum, Amstelveen; ²Psychiatry; ³Anatomy and Neurosciences, Amsterdam UMC, Vrije Universiteit Amsterdam and ⁴Compulsivity, Impulsivity & Attention Program, Amsterdam Neuroscience, Amsterdam, Netherlands

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.197

Introduction: Post-traumatic stress disorder (PTSD) and personality disorders are highly comorbid. There is some evidence that

trauma-focused treatment normalises activation in brain areas involved in the fear circuit and regions involved in emotion regulation in people with PTSD. Although we assume that working mechanism of personality disorder treatments relies on improving emotion regulation and associated brain regions, there is as of yet little evidence of neurobiological effects of personality treatment on people with PTSD and comorbid PD.

Objectives: To 1) study the effect of trauma-focused and/or trauma-focused and personality disorder treatment n brain activation in participants with PTSD and comorbid personality disorders and 2) relate change in brain activation to symptom improvement.

Methods: Participants with PTSD and comorbid borderline and/or cluster c personality disorders from the PROSPER-trials (Prediction and Outcome Study for PTSD and personality disorders) were randomized to either trauma-focused treatment (TFT) or TFT with personality disorder treatment (TFT+PT). Brain activation was measured with an emotional face task during functional magnetic resonance imaging scanning before and after treatment. Regions of interest for the analyses were the amygdala, dorsal ACC, insula, ventromedial prefrontal cortex (PFC), ventrolateral PFC and dorsolateral PFC. Bayesian multilevel analyses were conducted to analyze change in brain activation. Clinical measures were clinician-administered PTSD severity, self-rated emotion regulation problems, depression severity and dissociation severity.

Results: We included 42 participants with a pre- and posttreatment scan (24 with TFT, 18 TFT+PT). Analyses on the pre-post data are currently being run and will be presented in April.

Conclusions: This is one of the first studies to conduct functional MRI analyses on treatment in participants with both PTSD and personality disorders.

A Meta-Analysis of fMRI Activation Studies of Ketamine in Healthy Participants

J. H. Shepherd^{1*}, A. Hickman¹, C. Baten¹, A. M. Klassen¹, G. Zamora¹, E. Johnson-Venegas¹, S. S. Madugula², E. Woo¹, J. A. Miller³, M. D. Sacchet⁴, D. W. Hedges⁵ and C. H. Miller¹

¹Department of Psychology, California State University, Fresno, Fresno; ²School of Medicine, Stanford University, Stanford; ³Department of Psychology, Palo Alto University, Palo Alto; ⁴Department of Psychiatry, Massachusetts General Hospital, Harvard Medical School, Boston and ⁵Department of Psychology, Brigham Young University, Provo, Provo, United States

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.198

Introduction: There has been rapidly growing interest in understanding the pharmaceutical and clinical properties of psychedelic and dissociative drugs, with a particular focus on ketamine. This compound, long known for its anesthetic and dissociative properties, has garnered attention due to its potential to rapidly alleviate symptoms of depression, especially in individuals with treatment-resistant depression (TRD) or acute suicidal ideation or behavior. However, while ketamine's psychopharmacological effects are increasingly well-documented, the specific patterns of its neural impact remain a subject of exploration and basic questions remain

about its effects on functional activation in both clinical and healthy populations.

Objectives: This meta-analysis seeks to contribute to the evolving landscape of neuroscience research on dissociative drugs such as ketamine by comprehensively examining the effects of acute ketamine administration on neural activation, as measured by functional magnetic resonance imaging (fMRI), in healthy participants.

Methods: We conducted a meta-analysis of existing fMRI activation studies of ketamine using multilevel kernel density analysis (MKDA). Following a comprehensive PubMed search, we quantitatively synthesized all published primary fMRI whole-brain activation studies of the effects of ketamine in healthy subjects with no overlapping samples (N=18). This approach also incorporated ensemble thresholding ($\alpha=0.05-0.0001$) to minimize cluster-size detection bias and Monte Carlo simulations to correct for multiple comparisons.

Results: Our meta-analysis revealed statistically significant ($p<0.05-0.0001$; FWE-corrected) alterations in neural activation in multiple cortical and subcortical regions following the administration of ketamine to healthy participants (N=306).

Conclusions: These results offer valuable insights into the functional neuroanatomical effects caused by acute ketamine administration. These findings may also inform development of therapeutic applications of ketamine for various psychiatric and neurological conditions. Future studies should investigate the neural effects of ketamine administration, including both short-term and long-term effects, in clinical populations and their relation to clinical and functional improvements.

A longitudinal study of child and adolescent psychopathology in conditions of the war in Ukraine

T. Skrypnik, I. Martsenkovsky* and I. Martsenkovska

Department of Mental Disorders of Children and Adolescents, SI «Institute of Psychiatry, Forensic Psychiatric Examination and Monitoring of Drugs of the Ministry of Health of Ukraine», Kyiv, Ukraine

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.199

Introduction: According to UNICEF, 2 million children have left the country since the beginning of the war. 2.5 million Ukrainian children are internally displaced persons. Minors often become victims or witnesses of violence.

The events of 2022-2023 are the largest military conflict in the world since World War II. The impact on the mental health of the population is characterized by the variety and mass of traumatizing factors.

Mental trauma causes PTSD, depressive disorders (DD), anxiety disorders (AD), behavioral disorders (CD), attention deficit hyperactivity disorder (ADHD).

Objectives: The aim of the study was to determine the prevalence of PTSD and its comorbidities at different stages of experiencing a traumatic experience.

Methods: 785 teen's displaced from the zone of military operations, occupied territories were surveyed. Examinations included: K-SADS-PL, PSC-17, SCARED, CATS. 260 teen's were examined during - 6, 400 – 6–12 months after traumatization.

Results: After 6 months of trauma, PTSD was diagnosed in 9.8%, ADHD – 10.2%, DD-22.3%, AD-30.8%, CD – 15.4%, 28.8%; examined 6 to 12 months after the injury, respectively: 21.9%, 12.6, 33.3%, 11.5%, 18.0%.

Conclusions: In war-affected children, PTSD is a risk factor for the subsequent development of comorbid depression, anxiety, conduct disorders, and ADHD. Female sex, secondary traumatization after displacement increase the risk of developing depression, signs of pervasive development and ADHD - the risk of destructive and self-injurious behavior. The prevalence of PTSD, DD, ADHD increases within 6-12 months after the trauma, the sensitivity of children with PTSD to secondary traumatic events increases.

The association between glucose 6-phosphate dehydrogenase (G6PD) deficiency and attention deficit/hyperactivity disorder (ADHD)

B. Krone^{1*}, J. Newcorn¹, I. Manor² and E. Merzon³

¹Psychiatry, Icahn School of Medicine at Mount Sinai, New York, United States; ²Psychiatry, ADHD Unit, Geha MHC and ³Lehumi Health Services, Tel Aviv, Israel

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.200

Introduction: Glucose-6-phosphate dehydrogenase (G6PD) deficiency is an X-linked genetic enzymopathy that impacts 4.9% of the population, with greater prevalence among Mediterranean, East Asian, and African populations. G6PD deficiency results in levels of nicotinamide-adenine dinucleotide phosphate (NADPH) and glutathione (GSH) that are insufficient for maintaining the balance of oxidation-reduction in the body. This results in elevated production of reactive oxygen species (ROS), oxidative stress on proteins and lipids, damage to DNA, and potential activation of chemokine and cytokine pathways by astrocytes and microglia. We propose that these direct and indirect effects of G6PD deficiency are associated with development of ADHD.

Objectives: This study investigated the association between G6PD deficiency and Attention Deficit/Hyperactivity Disorder (ADHD).

Methods: The study involved 7,473 G6PD-deficient patients and 29,892 matched case-controls (selected at a 1:4 ratio) from a cohort of 1,031,354 within the Leumi Health Services database. Clinical characteristics were analyzed using Fisher's Exact Tests for categorical variables and Mann-Whitney U tests for continuous variables.

Results: The average age of patients was 29.2 ± 22.3 years, with 68.7% being male. The mean follow-up duration was 14.3 ± 6.2 years. Individuals with G6PD deficiency showed a significant 16% higher risk of being diagnosed with ADHD (Odds Ratio (OR) = 1.16 [95% CI, 1.08-1.25], $p < 0.001$) on follow up. Furthermore, G6PD deficiency was associated with a 30% greater likelihood of seeking care from adult neurologists (OR = 1.30 [95% CI, 1.22-1.38], $p < 0.001$) and a 12% higher probability of

consulting adult psychiatrists (OR = 1.12 [95% CI, 1.01-1.24], $p = 0.048$). The use of stimulant medications among G6PD deficient individuals was 17% higher for methylphenidate class drugs (OR = 1.17 [95% CI, 1.08, 1.27], $p < 0.001$), and use of amphetamines elevated by 16% (OR = 1.16 [95% CI, 1.03, 1.37], $p = 0.047$).

Conclusions: This study establishes a significant association between G6PD deficiency and an increased risk of ADHD diagnoses. These findings suggest potential opportunities for the development of culturally sensitive interventions.

The bifactor model of the Hungarian self-report version of the Strengths and Weaknesses of ADHD and Normal Behaviors scale

K. Vajsz^{1,2*}, L. R. Paulina^{1,2} and M. Miklósi^{1,2,3}

¹Department of Clinical Psychology, Semmelweis University;

²Department of Developmental and Clinical Child Psychology, Eötvös Loránd University and ³Centre of Mental Health, Heim Pál National Pediatric Institute, Budapest, Hungary

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.201

Introduction: Attention Deficit/Hyperactivity Disorder (ADHD) is one of the most common neuropsychiatric conditions, maintaining its presence well into adolescence and adulthood, resulting in impaired functioning. Evaluating ADHD symptoms through self-reporting plays a crucial role in assessing individuals within these age groups. The novel self-report version of the Strengths and Weaknesses of ADHD and Normal Behaviors (SWAN) scale offers a comprehensive assessment of behaviour, extending beyond just focusing on the typical signs and symptoms of ADHD, thus providing a more holistic perspective.

Objectives: Our goal was to assess the factorial validity of the Hungarian version of the SWAN self-report by comparing a two-factor model with bifactor models with a general and 1) two specific factors (inattention, hyperactivity/impulsivity), 2) three specific factors (inattention, motor hyperactivity/impulsivity, verbal hyperactivity/impulsivity) in a community sample.

Methods: Data from 717 adolescents and young adults (mean age = 20.0 years, SD = 3.10, range: 14 - 25 years, female: N = 664, 92.6%) were analysed. Participants completed an online questionnaire including the SWAN scale after giving informed consent. Confirmatory factor analyses were conducted based on the maximum likelihood estimator (ML).

Results: The bifactor model with a general and three specific factors demonstrated the best fit to our data (CFI = .933, RMSEA = .064 [90% CI: .058 – .071], SRMR = .038). While the overall composite reliability was excellent ($\omega = .91$), the reliability of the specific verbal hyperactivity/impulsivity factor fell below acceptable ($\omega_h = .40$).

Conclusions: In line with previous studies, the fit indices of the bifactor models were superior to the non-hierarchical two-factor model. Our results support the existence of a strong general factor but suggest uncertainty in the capacity of the specific factors to consistently explain the distinct variance in observed variables,

particularly when compared to the overarching influence of the general factor.

doi: 10.1192/j.eurpsy.2024.202

Introduction: Children with parents with psychiatric diagnoses have an increased probability for not only the same condition as their parent, but also for other conditions and behavioral and psychosocial problems. Whereas many studies have focused on parental severe mental illness due to their significant impairment, less attention has been paid to more common disorders despite their higher prevalence. In addition, because most past research only included one exposure or one outcome at a time, it remains difficult to examine and compare broad patterns of intergenerational transmission.

Objectives: To examine associations between six parental psychiatric diagnoses in parents, and a broad range of psychiatric diagnoses, psychotropic medications, criminality, suicide, violent victimization, accidents, and school and labor performance in their offspring.

Methods: Based on Swedish national registers, we linked all individuals born in Sweden between 1970 and 2000 to their biological parents ($N = 3\,286\,293$). We used a matched cohort design, analyzed with stratified Cox regression and conditional logistic regressions to examine associations between six psychiatric diagnoses in the parents, and 32 outcomes in their offspring. All exposed and unexposed children were followed from their date of birth to the date of emigration from Sweden, the death, or 31 December 2013 when the offspring were 14-44 years old.

Results: In terms of absolute risk, most children who had parents with psychiatric diagnoses were not diagnosed in specialist care themselves, as the proportion of having any of the 16 types of psychiatric conditions ranged from 22.17% (exposed to parental depression) to 25.05% (exposed to parental drug-related disorders) at the end of follow-up. Nevertheless, in terms of relative risk, all six parental psychiatric diagnoses increased the probability of all 32 outcomes in their offspring, with the Hazard Ratio ranging from 1.04 to 8.91 for time-to-event outcomes, and the Odds Ratio ranging from 1.29 to 3.36 for binary outcomes. Some specificities were observed for parental psychotic and substance misuse diagnoses, which strongly predicted offspring psychotic-like and externalizing-related outcomes, respectively.

Conclusions: The intergenerational transmission of parental psychiatric conditions appeared largely transdiagnostic, even for non-psychiatric outcomes in offspring. Given the broad spectrum of associations with the outcomes, service providers (e.g., psychiatrists, teachers, and social workers) should consider clients' broader psychiatric family history when predicting prognosis and planning interventions/treatment.

The Prevalence of Attention Deficit Hyperactivity Disorder in Children and Adolescents: An Umbrella Review of Global Evidence

G. Ayano¹, L. Tsegay², Y. Gizachew³, S. Demelash⁴ and R. Alati^{1*}

¹Curtin University, Perth, Australia; ²Aksum University, Aksum; ³Bethel Medical College, Addis Ababa, Ethiopia and ⁴Maastricht University, Maastricht, Netherlands

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.203

Introduction: From recent epidemiological studies to emerging epidemiological evidence, it becomes evident that numerous primary studies have investigated the prevalence of ADHD in children and adolescents. Additionally, several systematic reviews and meta-analyses have explored this subject. The objective of this umbrella review is to offer a robust synthesis of evidence derived from these systematic reviews and meta-analyses

Objectives: To conduct a comprehensive umbrella review that synthesizes emerging epidemiological evidence regarding the prevalence of ADHD in children and adolescents, drawing insights from numerous primary studies as well as systematic reviews and meta-analyses.

Methods: We conducted a systematic search across multiple databases, including PubMed, Web of Science, PsychINFO, and Scopus, to identify relevant studies. The study was preregistered with PROSPERO (registration number: CRD42023389704). To assess the quality of these studies, we utilized the Measurement Tool to Assess Systematic Reviews (AMSTAR). We employed an inverse variance-weighted random-effects meta-analysis to combine prevalence estimates from the included studies.

Results: The final analysis incorporated thirteen meta-analytic systematic reviews, encompassing 588 primary studies and a total of 3,277,590 participants. A random-effects meta-analysis of these studies revealed that the global prevalence of ADHD in children and adolescents stood at 8.0% (95% CI: 6.0%–10%). Notably, the prevalence estimate was twice as high in boys (10%) compared to girls (5%). Among the three subtypes of ADHD, the inattentive type (ADHD-I) emerged as the most prevalent, followed by the hyperactive type (ADHD-HI) and the combined type (ADHD-C).

Conclusions: The comprehensive umbrella review findings emphasize the high prevalence of ADHD in children and adolescents, with a notable gender disparity, wherein boys are twice as likely to be affected compared to girls. These results underscore the urgency of prioritizing prevention, early identification, and treatment strategies for ADHD in children and adolescents.

Climate change and mental health. Polish perspective.

M. Gawrych

Psychology Institute, The Maria Grzegorzewska University, Warsaw, Poland

doi: 10.1192/j.eurpsy.2024.204

Introduction: World Health Organization estimates that climate changes are expected to cause an additional 250 000 deaths worldwide per year between 2030 and 2050 (1). We do not know, in what extent, population mental health will deteriorate due to climate change. Unfortunately, not all European countries, including Poland collect the evidence-based information about current and possible future risks for mental health.

(1)World Health Organization. Climate change and health; 2018. Available from who.int/news-room/fact-sheets/detail/climate-change-and-health [cited 20 October 2020]

Objectives: The aims of present study are: (1) summarize the available literature through a current review and (2) make recommendations for future actions/ prevention strategy for Poland.

Methods: Medline database (through PubMed) and Polish authorities documents was searched for records published in 2010–2024. Mental health-related descriptors (i.e. „mental health” OR “mental disorders”) and „climate change” and “Poland/ Polish” and “Europe” term were used in particular searches. The results of the screening were included in the final selection list. References of screened full-text articles and reports were manually searched for further literature. Additionally, European and worldwide publications and reports prepared by mental health and/ or climate change organizations were taken into account.

Results: Mental health risks of climate change can stem from climate-related natural disasters (e.g., extreme weather events), slower moving events (e.g., drought), or concern about the phenomenon of climate change itself. Primary mental health impact is related mostly to disasters itself and its consequences: environment of disruption, trauma and grief. Direct consequences include increased rates of high-risk behaviours. Secondary effects of climate change are due to various processes of environmental changes and ecological disruptions. They consist of damages to physical and social infrastructure, physical health effects, food and water shortages, conflict, and displacement. Long-term droughts affect food and water supplies and can subsequently affect the economic and mental wellbeing not only the land-based workers.

Conclusions: A focus on climate change impact on mental health can help enhance the understanding of factors that strengthening psychosocial resilience and adaptation. The future mental health challenges of climate change in Poland cover:

- developing scientific knowledge regarding adaptation process and resilience,
- focusing on high-risk groups (i.e. children, rural workers),
- strengthened community engagement,
- developing available locally strategies for mental health improving.

Effectiveness of AI-driven Individualized Learning Approach for Children with Autism Spectrum Disorder (ASD)

H. Atturu^{1*} and S. Naraganti²¹Dept of Psychiatry, CARE Hospitals and ²Dept of Clinical Psychology, Rainbow Children's Hospital, Banjara Hills, Hyderabad, India

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.205

Introduction: Autism Spectrum Disorder (ASD) is a condition with varying degrees of social, emotional and behavioural disability. These children require focused and individualised learning plan to facilitate social integration. Robots have been used for this purpose but are not routinely available in several parts of the world. Effective, point of care (POC) digital therapies that can be used anywhere by anyone is the need of the day.

Objectives: To evaluate the effectiveness of Artificial Intelligence (AI) driven individualised learning plans delivered through POC digital platform (CognitiveBotics) for children with ASD.

Methods: After Ethical approval and parental consent, children diagnosed with ASD (Childhood Autism Rating Scale CARS 2) aged 2 years and above were screened for study inclusion and exclusion criteria and enrolled. AI driven individualised learning plan was administered through CognitiveBotics software that could be used on either computer or a tablet. Initially, interactive questions were administered to parents by the AI tool to understand child's functioning. Based on these, an individualised learning plan was assigned. Each task is delivered using either interactive videos, chatbot and/or animated/AI games. The child's progress is captured for attention (attempted questions, retries and timeouts) and retention (first time corrects and corrects) continuously. The initial interactive questions administered to parents were repeated to assess child's progress in real life. Paired 't' test using SPSS version 26 was used to compare initial and final data.

Results: Out of 85 registered children, 41 regularly used the AI tool. Mean age was 43.93 months (range 26 to 72 months). 37 (90.24%) were boys. The baseline mean scores (ranges), were CARS 33.48 (30-39.5); Social quotient 53.4 (27.25-80.32), Developmental quotient 71.35 (45.90-93.33) and IQ 62.34 (36.58-86.83). The base line mean score of parents assessed child function was 115.24 (range 58 to 215). A mean of 15.54 tasks were given (range 5 to 48). At the time of analysis with a mean follow up of 3 months (range 2 to 5 months) the children completed a mean of 10.10 tasks (range 0 to 42). There was significant improvement in child's learning captured by the AI software based on attention and retention parameters ($p = <0.00001$). This improvement was also reflected in parent assessed child function (mean 147.15, (59 to 231)) ($p = <0.00001$). The percentage of improvement in both software captured and parent assessed child function was directly related to the amount of time spent by the child on the software.

Conclusions: AI driven individualised learning approach is effective in teaching skills and promote social integration for children with ASD. Such technology can capture the child's progress on a day-to-day basis and deliver personalised training.

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.206

Introduction: Bipolar disorder (BD) is a multifaceted illness encompassing mood, energy, cognitive and biorhythms alterations. Sleep disturbances are common in prodromic, acute and inter-episodic phases of BD. Suicidality presents a known association with sleep disturbances. However, their interplay in BD remains intricate and not fully elucidated.

Objectives: The aim of the present systematic review (SR) and meta-analysis (MA) is to summarise the available evidence and to provide an estimate of the association between sleep disturbances and suicidality, defined as presence of suicide ideation, behaviour and suicide attempts, in patients with BD.

Methods: We conducted a comprehensive literature search following the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) guidelines across PubMed, PsycINFO, and SCOPUS databases. We included all studies reporting an association between sleep problems and suicidal behaviour in BD patients. No language restriction was imposed. Effect sizes were calculated as odds ratio (OR) for dichotomic variables, standard mean difference (SMD) for continuous outcomes, and Spearman's coefficient (r) for correlations. Heterogeneity was assessed using the I² statistic. Global inconsistency was evaluated using the Q statistics with the corresponding p-value.

Results: The initial search yielded 911 unique abstracts, of which 62 underwent full-text screening. Fourteen publications were included, comprising twelve cross-sectional and two longitudinal studies. The total sample consisted of 19,601 subjects diagnosed with BD, of which 51.76% were females and 69.52% had a diagnosis of BD type 1. We found that people with BD and sleep disturbances tend to have higher suicidality, both current (SMD=0.79, 95% CI=0.53, 1.05) and lifetime (OR=1.8; 95%CI=1.41, 2.55), when compared with people with BD and no sleep disturbances. Additionally, patients with BD and a history of suicide attempts tend to have more sleep problems (OR=1.37, 95%CI=1.21, 1.55).

Moreover, a positive correlation exists between suicidality and poor sleep quality measured by the Pittsburgh Sleep Quality Index (PSQI) (r= 0.24, 95%CI=0.10, 0.36). No heterogeneity was found, except in the subanalysis of correlation (I²=66.67%, Q p-value=0.01).

Conclusions: Our SRMA outlines a positive relation between sleep disturbances and suicidality in patients with BD. The small number of included studies and the scarcity of longitudinal studies, preventing the inference of a causal relationship, represent the major limitations of this study. Also, studies with objective measures of sleep alterations are currently lacking. The prompt recognition, objective measurement, and treatment of sleep alterations could be crucial in averting or reducing suicidal attempts in BD.

Evaluation of Neurocognitive Functions of Children and Adolescents Diagnosed with Pediatric Bipolar Disorder and Disruptive Mood Dysregulation and at High Risk for Bipolar Disorder

I. Yenen Sivri^{1*}, E. Çöp², K. C. Can³ and A. S. Yenen Menderes⁴

¹Child and Adolescent Psychiatry, Osmaniye State Hospital; ²Child and Adolescent Psychiatry; ³Adult Psychiatry, Ankara City Hospital and ⁴Child and Adolescent Psychiatry, Keçiören Educational Research Hospital, Ankara, Türkiye

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.207

Introduction: Pediatric Bipolar Disorder (BPD) is a chronic psychiatric disorder that alters normal and psychological development processes among patients. Although cognitive deficits in BPD have identified in recent studies, little is known about the developmental trajectory of these deficits. DMDD is a newly defined diagnosis included in the DSM-V. Since it added a new dimension to the clinical spectrum but few studies conducted on DMDD, there are

some conflicting discussions in the literature about how to distinguish this disorder from other childhood psychiatric disorders and how to treat it.

Objectives: The aim of this study was to determine the phenomenological and neuropsychological differences between children and adolescents with a diagnosis of BPD (Pediatric Bipolar Disorder), DMDD (Disruptive Mood Dysregulation Disorder), and children and adolescents who are genetically at high risk for Bipolar Disorder (BD), and healthy controls (HCs) who do not have any psychiatric diagnosis, to investigate endophenotypes that may be predictive for BD.

Methods: Our study sample consists of four groups, the BPD group (n=30), the Risk group (n=25), the DMDD group (n=36), and the Healthy Control group (n=29). All participants were evaluated by the “Kiddie Schedule for Affective Disorders and Schizophrenia for School-Age Children—Now and Lifetime Pattern (K-SADS-PL)”, “Young Mania Rating Scale/Parent Form (YMRS-ABF), Conner’s Parent Rating Scale (CPRS-48), Child and Adolescent Behavior Rating Scale (CBCL)” scales were filled by parents, and “Child Depression Inventory (CDI), Youth Self-Report Form for 11-18 Years Olds (YSR)” scales were filled by children and adolescents. Neurocognitive test battery was applied to each participant: Continuous Performance Test (CPT), Wisconsin Card Sorting Test (WCST), Stroop Color and Word Test (SCWT), Trait Making Test A and B sections (TMT-A/B), California Verbal Learning Test-Child version (CVLT-C).

Results: While it was determined that the cases in the BPD and DMDD groups performed significantly worse in CPT, SCWT, CVLT-C, TMT A/B tests compared to healthy controls, it was found that the subjects in the Risk group performed worse at the CPT test than healthy controls. In addition, the cases in the BPD, Risk and DMDD groups reported more clinical and behavioral problems than the healthy controls.

Conclusions: There is a significant deterioration in the areas of continuous attention, processing speed, cognitive flexibility, response prevention, verbal memory and working memory in the BPD and DMDD groups, and in the continuous attention area in the Risk group compared to healthy controls. Prospective follow-up and imaging studies using larger samples and a larger neurocognitive test battery in the future will better reveal the neuropsychological characteristics of the BPD, Risk and DMDD groups.

Internalized Stigma in Patients with Bipolar Disorder: A Cross-sectional Study on Its Associations with Sociodemographic, Marital and Clinical Characteristics

S. Tanyeri Kayahan^{1*} and S. Vahip²

¹Psychiatry, Yalvaç State Hospital, Turkish Republic Ministry of Health, Isparta and ²Psychiatry, Ege University School of Medicine, İzmir, Türkiye

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.208

Introduction: Bipolar disorder (BD) is a chronic and complex affective disorder among top diseases that cause disability worldwide. Internalized stigmatization is a process including the

awareness of negative stereotypes adopted by the society, participation in and internalization of these judgements, associated with impaired social functionality. Studies examining internalized stigma and related factors in BD is limited.

Objectives: In this study, it is aimed to investigate the associations between internalized stigmatization and clinical characteristics, as well as sociodemographic and marital features of patients with BD.

Methods: This observational and cross-sectional study was conducted at a specialized affective disorders clinic in a university hospital between November 2020 and March 2021. During routine follow-up, each consecutive patient with BD was invited and a total of 118 were included in the study. Information about sociodemographic, marital and clinical characteristics of patients was collected through a prepared data form and follow-up documents. Internalized Stigma of Mental Illness Scale (ISMIS) was administered to assess internalized stigma. Statistical analysis of data was conducted by SPSS version 25 and a statistical significance level of $p < 0.05$ was determined.

Results: Mean ISMIS total score of the sample was 56.50 ± 13.65 . Multiple linear regression was used to test the predictors of higher ISMIS scores. Being currently unemployed ($p = 0.012$, $B = 0.208$), shorter BD duration ($p < 0.001$, $B = 0.302$) and presence of inter-episode residual symptoms ($p = 0.004$, $B = 0.248$) predicted higher ISMIS total. Younger age ($p = 0.002$, $B = 0.264$), being female ($p = 0.007$, $B = 0.226$) and absence of mania dominance ($p = 0.019$, $B = 0.190$) predicted higher alienation scores. Presence of inter-episode residual symptoms predicted both stereotype endorsement ($p < 0.001$, $B = 0.320$) and perceived discrimination ($p < 0.001$, $B = 0.358$). Younger age ($p = 0.001$, $B = 0.281$) and total number of depressive episodes ($p = 0.015$, $B = 0.212$) also predicted perceived discrimination. Shorter BD duration and absence of seasonality predicted higher ISMIS social withdrawal, while history of hospitalization predicted higher ISMIS stigma resistance.

Conclusions: Our study demonstrated similar mean ISMIS total scores to the findings previously reported in Türkiye, while roughly lower than results in the international literature. Considering that internalized stigmatization was increased in earlier stages of BD and in younger patients, as well as in patients with inter-episode residual symptoms, it might be important to implement psychosocial interventions for internalized stigmatization and appropriate psychoeducation programs in the earlier periods of BD. Therefore a multidimensional and holistic approach towards internalized stigmatization may positively contribute to the functionality of patients with BD.

Cariprazine add-on in resistant bipolar depression. Long-term effectiveness and safety data from a multicentric real-world experience

V. Martiadis^{1*}, E. Pessina², A. Martini², F. Raffone¹, A. Vignapiano³ and D. De Berardis⁴

¹Department of Mental Health, Asl Napoli 1 Centro, Napoli;

²Department of Mental Health, Asl Cuneo 2, Bra; ³Department of Mental Health, First Episode Psychosis Center, Salerno and

⁴Department of Mental Health, Asl Teramo, Teramo, Italy

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.209

Introduction: Persistent depressive episodes and subsyndromic depressive symptoms frequently characterize mood alterations in bipolar disorder (BD) and negatively influence quality of life and suicide risk. BD patients with predominant depressive episodes generally show significantly higher treatment resistance rates. Although not specifically approved in Italy for bipolar depression, recently published observational data suggest that the cariprazine add-on may be a potential effective short-term treatment for resistant bipolar depression. Nevertheless data on long-term cariprazine treatment are lacking.

Objectives: This study evaluated the efficacy and safety of long-term cariprazine augmentation in patients suffering from treatment-resistant bipolar depression.

Methods: 30 resistant bipolar depressed patients, whose resistance was defined according to The CINP Guidelines on the Definition and Evidence-Based Interventions for Treatment-Resistant Bipolar Disorder, were treated with cariprazine 1,5 -3 mg flexible dose for 4 weeks, added to previous mood stabilizing and/or antidepressant treatment. Psychopathology at time 0 and at 4, 8, 12, 16, 20, 24 weeks of treatment was evaluated using the Hamilton Depression Rating Scale (HDRS), the Hamilton Anxiety Rating Scale (HARS), the Young Mania Rating Scale (YMRS) and the Bipolar Depression Rating Scale (BDRS); safety and tolerability was measured by the UKU Side Effect Rating Scale. The drop-out rate was assessed throughout the study duration.

Results: Cariprazine add-on was effective in the study sample but only during the first 4 weeks of treatment. Improvement in depression scores started from the first week, reaching about 40% mean HDRS score reduction at T4; a moderate ulterior decrease (-15%) was reached at T24 but was accompanied by a significant drop-out rate; anxiety symptoms improved (mean HARS score reduction 37% at T4) mainly during the first 4 weeks. The treatment was generally well tolerated. From week 4 to 24 we observed a near 70% drop-out rate (18 total drop-outs) with maximum drop-outs between weeks 4-8 (n=7) and 18-24 (n=7). Discontinuation causes were inefficacy (5/18); clinical worsening (10/18); side effects (3/18); hypomanic shift (2/18).

Conclusions: Despite the relatively small population examined and the observational design, our results suggest that cariprazine may represent an effective and safe short-term enhancement strategy in resistant bipolar depression. Long-term treatment, in this sample, did not lead to significant improvements and was burdened by a high drop-out rate, mainly due to inefficacy/clinical worsening. Further studies on larger samples are needed to confirm these preliminary findings, both in short-term and in longer observations.

IDIBAPS, Cellex, Internal Medicine Service, Hospital Clínic de Barcelona, Biomedical Research Networking Centre Consortium on Rare Diseases (CIBERER); ³Department of Psychiatry and Psychology, Institute of Neuroscience, Hospital Clínic de Barcelona, Barcelona, Catalonia, Spain, Barcelona, Spain and ⁴Department of Pathophysiology and Transplantation, University of Milan, 20122 Milan, Italy, Milano, Italy

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.210

Introduction: Bipolar disorder (BD) is a chronic and recurrent disease characterized by acute mood episodes alternated with periods of euthymia. The available literature postulates that a biphasic dysregulation of mitochondrial bioenergetics might be observed in BD.

Objectives: We aimed to explore differences in *in vivo* mitochondrial respiration (1) intra-individually: longitudinally within patients during an acute mood episode of BD and after clinical remission, and (2) inter-individually: between patients with BD on depressive or manic episodes and healthy controls (HC).

Methods: Patients admitted to our acute psychiatric ward with a manic episode or bipolar depression were recruited. Different mitochondrial oxygen consumption rates (OCRs) were assessed during the acute episode (T0) and after clinical remission (T1) in one million of peripheral blood mononuclear cells (PBMC): Routine, Leak, ETC and Rox. They were measured as picomoles of oxygen per million cells (pmol O₂/million). This experiment was also conducted in HC. High-resolution respirometry was performed at 37°C by polarographic oxygen sensors in a two-chamber Oxygraph-2k system. Manic and depressive symptoms were assessed using standardized psychometric scales. Oxygen consumption capacity was compared (1) intra-individually, during acute episodes and after clinical remission, and (2) inter-individually, during acute manic and depressive episodes, and in HC. Statistical analyses were performed with SPSS, GraphPad and R Statistics.

Results: 20 patients with BD (15 manic, 5 depressed) and 10 HC were included. A significant increase in the maximal oxygen consumption capacity (ETC) was observed in clinical remission (27.4 ± 17.4) compared to the acute episodes (21.1 ± 11.7 , $p = 0.001$), which remained significant after subtracting Rox from the other rates ($p = 0.001$). At T1, patients admitted with a manic episode tended to show higher mean ETC (31.2 ± 18.7) compared with T0 (24.1 ± 12.0 , $p = 0.074$); the tendency persisted after Rox subtraction ($p = 0.076$). Patients admitted with a depressive episode also showed higher ETC means in T1 (16.3 ± 3.8) compared to T0 (12.1 ± 3.4), but there were not significant differences ($p = 0.231$). When HC, manic and depressive patients at T0 were compared between them, significant differences were observed in ETC ($H = 8.5$; $p = 0.014$) and Rox ($H = 13.8$; $p = 0.001$). After Rox deduction, differences in ETC remained ($H = 11.7$; $p = 0.003$). Individuals with bipolar depression showed lower ETC rates (12.1 ± 3.4) than those with a manic episode (24.1 ± 12.0 ; $t = -3.5$, $p = 0.003$), which was also found after Rox deduction ($p = 0.001$).

Conclusions: In both manic and depressive episodes in BD, mitochondrial respiration might be reduced and increase after clinical remission. Further studies with larger samples will allow to confirm these results and also to identify potential mitochondrial state-dependent biomarkers.

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.211

Introduction: People with severe mental illness (SMI), including schizophrenia and bipolar disorder, experience significant health inequalities and are more likely to develop long-term physical health conditions (LTCs), such as type 2 diabetes and cardiovascular disease. Many people with SMI rely on informal caregivers, typically friends and family, to support their health and enable them to live in the community. Informal caregivers of people with SMI experience high levels of caregiver burden, social isolation, and poor health outcomes. However, it is unclear how co-existing LTCs contribute to the caregiving experience.

Objectives: The aim of this study was to explore the lived experience of informal caregivers of people with co-existing SMI and LTCs.

Methods: We conducted a qualitative study with informal caregivers of people with co-existing SMI and LTCs in England. We recruited 12 informal caregivers and conducted five semi-structured interviews and two focus groups between December 2018 and April 2019. The interviews and focus groups were audio recorded, transcribed verbatim and thematically analysed.

Results: SMI impacts profoundly on the health and well-being of both service users and their informal caregivers. Service users were described as too unwell with their SMI to engage in self-management of their mental and physical health, with the primary responsibility for these tasks falling to informal caregivers. There were significant barriers to adequate physical healthcare for service users, therefore informal caregivers needed to advocate extensively for their loved ones to ensure access to services. Informal caregivers felt significantly under-supported and struggled with the caregiver burden associated with SMI and LTCs. This burden included the constant monitoring of risk, anxiety around the vulnerability of their loved one, repeated hospitalisations, physical health concerns, lack of respite services, lack of recognition of their role, the guilt

associated with paternalistic care, shame and stigma, and the difficulties managing the changeable nature of SMI.

Conclusions: Informal caregivers of people with SMI face an additional caregiver burden resulting from co-existing LTCs. This adds substantially to their caring role, yet they do not receive the necessary support, and therefore their own health and wellbeing are negatively impacted. Improved recognition of the role of informal caregivers and additional support, including improved provision of respite services, are needed to improve the well-being of informal caregivers.

Physical illness and multimorbidities in patients diagnosed with personality disorder

I. Simunovic Filipcic^{1*}, N. Jaksic¹, S. Levaj¹, M. Sagud¹, I. Filipcic², M. Grah² and D. Marcinko¹

¹Department of Psychiatry and Psychological Medicine, University Hospital Center Zagreb and ²University Psychiatric Clinic Sveti Ivan, Zagreb, Croatia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.212

Introduction: People with personality disorder (PD) often experience suffering, suboptimal psychiatric treatment outcomes, and early mortality due to chronic physical illness (CPI) and multimorbidity (≥ 2 CPI) (CPM). Increasing research underscores the elevated prevalence of CPI and CPM in those with PD.

Objectives: To compare the prevalence of CPI/CPM between the general population and those with PD and to explore the relationship between CPI/CPM and various aspects of PD.

Methods: This cross-sectional study enrolled 126 PD patients (70.6% female, mean age 41.22 years) based on the ICD-10 criteria, and 126 socio-demographically matched individuals from the general population. The participants completed the following instruments: the ICD-11 Personality Disorder Severity Scale (PDS-ICD-11), the Personality Assessment Questionnaire for ICD-11 (PAQ-11), Subjective Emptiness Scale (SES), the Reflective Functioning Questionnaire-Revised-7 (RFQ-R-7), and self-reported chronic physical illnesses questionnaire.

Results: The mean number of CPI in patients with PD and matched controls was 2.69 (SD=2.371) and 1.02 (SD=1.702), respectively, and this difference was statistically significant. Patients with PD also suffered more often from CPM than none or one CPI, compared to matched controls. In the multivariate logistic regression analyses among the patients with PD, higher personality disorder severity, increased trait Negative Affectivity and poorer reflective functioning/mentalizing were predictive of having CPM. These relationships were independent of age, gender, education status, income level, length of psychiatric treatment, and smoking status. Subjective emptiness was not significantly predictive of having CPM.

Conclusions: This study highlights a higher prevalence of CPI and CPM in individuals with PD compared to the general population. Factors such as higher PD severity, increased Negative Affectivity, and poorer reflective functioning were identified as predictors of CPM. These findings underscore the necessity for integrated healthcare approaches to address the multifaceted needs of PD patients, emphasizing the importance of considering both mental and physical health in treatment strategies.

Relationship between Early Maladaptive Schemas and DSM-5 Pathological Personality Traits from a Dimensional Diagnostic Approach

J. Major*, A. Matúz, B. Gács and B. Birkás

Behavioural Sciences, University of Pécs, Medical School, Pécs, Hungary

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.213

Introduction: In DSM-5 Section III, the Alternative Model for Personality disorders (AMPD), a dimensional approach for conceptualization and diagnosing complex character problems was introduced. Based on recent findings, AMPD aligns well with the theory of Young's Schema Therapy (ST). ST seems to offer a valuable clinical framework that complements the empirically based AMPD, which is not built upon a certain theory of psychopathology.

Objectives: The aim of the current study was to explore the association between early maladaptive schemas (EMSs), DSM-5 pathological personality traits and certain psychological symptoms to gain a better understanding of their relationship and highlight the connection points between AMPD and the theory of ST.

Methods: A total of 490 Hungarian participants, including 98 males, took part in the cross-sectional research, with an average age of 26.9 (SD = 9.34). All participants completed the short form of Young's schema questionnaire (YSQ-S3), the brief form of PID-5 (PID-5 BF) and the revised version of the Derogatis Symptom Checklist (SCL-90 R).

Results: Results of a series of hierarchical regression analyses found that all five schema domains were able to predict psychological symptoms and DSM-5 pathological personality traits at a statistically significant level. Moreover, in accordance with our data, specific EMS patterns are associated with different psychological symptoms and pathological personality traits. Ultimately, we identified two EMSs, namely Negativity/Pessimism and Insufficient Self-control, which predicted all of our dependent variables.

Conclusions: Our findings suggest that the relationship between EMSs and DSM-5 pathological personality traits goes beyond the established fact that EMSs, like any other indicators of personality problems are associated with psychopathological symptoms and traits. This is supported by the fact that we could link specific EMS patterns to the pathological personality traits and psychological symptoms that we investigated. We believe that our results contribute to the clinical utility of AMPD, by assisting the creation of schema profiles tailored to personality pathologies, thereby facilitate the diagnostic process and the development of

schema - focused interventions. Furthermore, it seems that the identified EMSs, Negativity/Pessimism and Insufficient Self-control play a special role in relation to pathological personality traits and psychological symptoms and should be considered with particular emphasis in terms of risk group classification and vulnerability.

The Effect of a Virtual Reality Counseling Program Based on Metacognitive Therapy in Reducing Post-Traumatic Stress Disorder among Those Recovering from Covid-19

N. S. G. Abdelrasheed* and M. M. M. Al Majali

Department of Education, Dhofar University, Salalah, Oman

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.214

Introduction: Many COVID-19 survivors who were attacked and suffered severe symptoms of the virus have suffered from post-traumatic stress disorder (PTSD) which persists for long periods. These people need treatment to alleviate the severity of these disorders. Metacognitive therapy (MCT) is one of the modern therapeutic trends in psychological counseling, which focuses on the nature of the thought rather than on identifying and changing the thought as in other cognitive therapies. It is also concerned with whether people possess an aspect of reflective awareness and aims for a broader understanding of the way the mind works. Working on the process of metacognition, that is, the individual's thinking about what he knows, being aware of his thoughts, and constantly monitoring and organizing them, helps reduce anxiety disorders and mood swings, and this will reduce psychotic disorders.

Objectives: The current study aims to identify the effect of a virtual reality (VR) counseling program based on MCT in reducing the severity of PTSD among survivors of Covid-19. It also examines the continuity of the effectiveness of this program in reducing these disorders.

Methods: The quasi-experimental method (two group design) with experimental and control groups with a pre-posttest and a follow-up test was adopted. The sample for the current study consisted of 60 COVID-19 survivors suffering from PTSD. The PTSD scale was applied online to a group of people recovering from Covid-19 from the Arab Republic of Egypt. Then those who had high scores were selected, contacted and their consent was obtained to apply a virtual reality counseling program to them. The counseling program was implemented via virtual reality technology, and consisted of 20 counseling sessions, each session lasted between 60-90 minutes. The program continued for two months, with two sessions per week.

Results: The results of the current research revealed a significant improvement in the experimental group through a significant reduction in their post-traumatic stress disorders. The results also showed the effectiveness of the counseling program based on metacognitive therapy in reducing the manifestations of post-

traumatic stress disorders in those recovering from Covid-19. The results confirmed the continuing effect of the program after the follow-up period.

Conclusions: Using metacognitive therapy has an effective effect in reducing post-traumatic stress disorder, and it can be used with many psychologically disturbed people.

Prevalence of Prolonged Grief Disorder and Related Clinical Factors During the COVID-19 Pandemic in Turkey

R. Tekdemir^{1*}, A. Kandeger², Ö. Tan², M. Aydın² and K. Altınbaş³

¹Psychiatry, Selcuk University Faculty of Medicine, Mazhar Osman Mood Clinic; ²Psychiatry, Selcuk University Faculty of Medicine, Konya and ³Freelance, Consulting doctor, Istanbul, Türkiye

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.215

Introduction: Prolonged grief disorder has recently been added to the Diagnostic and Statistical Manual of Mental Disorders 5, Text Revision. To understand the health burden and then allocate economic and professional resources, it is necessary to provide epidemiological data for this new disorder. More information on the characteristics of people suffering from PGD is also beneficial to better identify individuals at risk.

Objectives: This study, therefore, aimed to estimate the prevalence of the PGD criteria in a special period such as the Covid-19 pandemic and in a representative population-based sample, evaluate the sociodemographic, and loss-related correlates of PGD case-ness and explore possible predictors.

Methods: The study included 126 people (97 females/29 males) who lost a relative for any reason during the Covid-19 pandemic period (March 2019-January 2022) in Turkey. We used self-reported data from participants who all completed questions on socio-demographic and loss-related characteristics plus Hospital Anxiety and Depression Scale (HADS), Prolonged Grief Disorder Scale (PG-13), Multidimensional Scale of Perceived Social Support (MSPSS), Adult Separation Anxiety Questionnaire (ASA-27).

Results: Median age was 34 years, range (18-63); 12 participants were diagnosed with PGD (9.5%). No difference was detected between deaths due to COVID-19 and its complications and deaths due to other causes in terms of PGD diagnosis and PGD symptom severity. When we divide the participants into two groups according to PGD diagnosis (PGD and nonPGD): The average age of the PGD group was higher ($Z=-2.068$; $p=0.031$) and they had more additional medical conditions ($\chi^2=7.21$; $p=0.007$). Thoughts of guilt were more common in the PGD group ($\chi^2=7.92$; $p=0.005$). Additionally, HADS-total, HADS -depression, HADS -anxiety and ASA-27 were higher in the PGD group (respectively: $Z=-4.047$; $P=0.00$, $Z=-4.209$; $P=0.00$, $Z=-3.437$; $P=0.001$, $Z=-1.975$; $P=0.048$). PGD occurred most frequently after first-degree losses ($\chi^2=13.67$; $p=0.00$) and was inversely proportional to the age of the loss ($Z=-1.979$; $P=0.04$). In the nonPGD group, the rate of believing in any religion ($\chi^2=5.807$; $p=0.016$). and the level of fulfilling the requirements of the religion were

higher ($\chi^2=10.584$; $p=0.05$). In the linear regression analysis examining the predictors associated with the severity of prolonged grief; the deceased person was a first-degree relative ($t=6.23$; $p<0.001$) and younger in age ($t=-3.71$; $p<0.001$), the presence of guilt ($t=3.28$; $p=0.001$), and increased separation anxiety ($t=4.13$; $p<0.001$) and depression scores ($t=4.29$; $p<0.001$) were significant boost of prolonged grief severity.

Conclusions: Although higher PGD rates were expected in deaths due to Covid-19 compared to deaths due to other causes, we did not detect any significant difference in this study. However, this study identified some possible predictors associated with PGD.

Physical healthcare gap among patients with severe mental illness through the COVID-19 pandemic. Preliminary results from a real-world investigation in Lombardy, Italy

C. Conflitti^{1,2,3*}, M. Monzio Compagnoni^{1,2}, G. Corrao^{2,4} and A. Lora^{2,3}

¹Statistics and Quantitative Methods, University of Milan-Bicocca;

²National Centre of Healthcare Research & Pharmacoepidemiology, Milan;

³Department of Mental Health, ASST Lecco, Lecco and

⁴University of Milan-Bicocca, Milan, Italy

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.216

Introduction: Patients suffering from mental disorders tend to be less adherent to the recommended therapies. Moreover, the COVID-19 pandemic had a global impact on physical and social well-being, which turned out stronger in the most fragile patients, like those with a mental condition.

Objectives: To assess whether the COVID-19 pandemic influenced the physical healthcare gap between patients with and without severe mental illness (SMI) treated for chronic conditions.

Methods: Data were retrieved from Healthcare Utilization Databases of Lombardy region (Italy). Prevalent users of antihypertensive drugs, statins or antidiabetic drugs, receiving healthcare in Lombardy during 2020, were identified. Among them, those with a previous diagnosis of schizophrenic or bipolar disorder were selected and matched with up to 3 patients without any sign of mental disorder by sex, age and number of contacts with the NHS during the previous year. 3 cohorts (not necessarily independent) were formed.

High adherence to specific recommended drug therapies and discontinuation during 2020 were evaluated.

Association between presence of SMI and high adherence was evaluated by using a log-binomial model (risk ratios, RR with 95% CI); a Cox model (hazard ratios, HR) was used for discontinuation.

As comparison, same analyses were performed to the cohorts of prevalent users in 2019, to evaluate the impact of the COVID-19 pandemic. Results were stratified according to the type of mental disorder.

Results: 36'436, 14'136 and 12'597 prevalent users of antihypertensives, statins or antidiabetics respectively were identified, of which 25% with SMI (9'109, 3'536 and 3'152 respectively).

During the pandemic period, for all the three cohorts, patients with mental illness had 10% lower probability of being adherent to the recommended drug therapies.

The association between SMI and discontinuation was significant and varied among the three cohorts, with HR (95% CI): 1.27 (1.21; 1.33) for antihypertensives users, 1.16 (1.07; 1.26) for antidiabetics users and 1.08 (1.01; 1.16) for statins users.

Compared with 2019 the gap remained similar, except for discontinuation of antidiabetics, where the gap diminished from 34% in 2019 to 16% in 2020.

No differences between the two mental disorders were found.

Conclusions: Results show that suffering from a mental disorder in people with chronic physical conditions affects their adherence to recommended drug therapies. During the pandemic period, the restrictive measures adopted may have led to a better care by family members, counteracting any increase in the gap.

The healthcare gap in patients suffering from mental illness remains an unsolved problem of primary importance for public health.

N-acetylcysteine counteracts increased brain excitatory/inhibitory balance following maternal high-fat diet and restores emotional and cognitive profiles in adult mouse offspring

C. Musillo^{1*}, M. Samà¹, B. Collacchi¹, M. A. Ajmone-Cat², R. De Simone², K. C. Creutzberg³, M. A. Riva³, A. Berry¹ and F. Cirulli¹

¹Center for behavioral sciences and mental health; ²Dept. Neuroscience, Istituto Superiore di Sanità, Rome and ³Dept. Pharmacological and Biomolecular Sciences, University of Milan, Milan, Italy

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.217

Introduction: High-fat diet (HFD) consumption during pregnancy can shape fetal brain development, increasing susceptibility to mental disorders. Nevertheless, the mechanisms underlying these negative outcomes remain unclear.

Objectives: We hypothesize that mHFD induces inflammation and oxidative stress (OS) in the fetal brain, disrupting excitatory/inhibitory (E/I) balance in the adult brain. This results in altered hypothalamic-pituitary-adrenal (HPA) axis reactivity, emotional regulation, and cognitive function. We tested the ability of N-acetyl-cysteine (NAC) - a powerful anti-oxidant and anti-inflammatory compound - to counteract mHFD effects.

Methods: Our mHFD model consists of female C57BL/6N mice fed either HFD (fat 58%, carbohydrate 25.5%, and protein 16.4%) or control diet (CD, fat 10.5%, carbohydrate 73.1% and protein 16.4%) before and during pregnancy (13 weeks). After 5 weeks on diets, half of them received NAC (1g/kg) for 8 weeks, until delivery. Gene expression of *Il-1b*, *Cd68*, *Tmem119*, *iNOS*, and *Arg1* was measured in fetal brains. Cognitive function and emotional phenotype were assessed in adult male and female offspring through the

Morris Water Maze (MWM) and the Emergence test, respectively. HPA axis functionality was assessed by measuring plasma corticosterone levels by ELISA following acute stress. Gene expression of vesicular glutamate transporter 1 (*Vglut1*) and vesicular GABA transporter (*Vgat*) were assessed as markers of E/I balance.

Results: Exposure to mHFD induced inflammation and OS in the fetal brain of both sexes, by increasing *Il-1b* and *iNOS/Arg1*. Additionally, *Cd68* and *Tmem119* were specifically increased in females. In adulthood, mHFD reduced latency to emerge from the shelter in the Emergence test in both sexes. In females, mHFD impaired cognitive function, reducing time spent in the MWM target zone, and increased HPA reactivity in response to acute stress. Furthermore, mHFD decreased *Vgat* expression in both sexes, resulting in an imbalanced *Vglut1/Vgat* ratio towards excessive excitatory input. Maternal NAC supplementation rescued this imbalance.

Conclusions: Overall, these data show that mHFD increases inflammation and OS in fetal brains, with greater effects in female offspring, inducing alterations in the E/I neuronal balance with concomitant disruptions of the neuroendocrine system and the emotional and cognitive profiles during adulthood. The supplementation with NAC was effective in rescuing the E/I imbalance as well as the behavioral phenotype.

Depressive Symptoms and Urbanization - A Cross-Sectional Network Analysis

D. Ochnik^{1*}, B. Buława², P. Nagel², M. Budziński³ and M. Gachowski²

¹Clinical Psychology; ²Architecture and ³Project Management, Academy of Silesia, Katowice, Poland

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.218

Introduction: With increasing urbanization, more people are exposed to mental health risk factors stemming from the urban social or physical environment. However, research on urbanization and depression is not clear.

Objectives: This study aimed to explore environmental and social factors with depression symptoms in view of a network theory of mental health disorders.

Methods: The study was conducted among a representative sample of 3,296 habitants of Metropolis GZM (63% of women) – the most urbanized region in Poland. The measurements used were PHQ-9, UCLA, Neighbourhood Cohesion (Neighbourhood Belonging and Social Cohesion), REAT 2.0 (Quality of architecture in neighborhood area), distance and frequency use of green public areas, Self-Rated Health, Physical Activity, size of place of residence per person.

Results: The prevalence of depression risk in villages ($N=713$), towns under 20,000 ($N=219$), towns (under 99,000; $N=823$), and cities (under 300,000; $N=1541$) was 44.2%, 44.7%, 39.2%, and 34.9% respectively.

The depression nodes with the highest centrality degree and expected influence were PHQ9 (suicidal thoughts), PHQ2 (feeling depressed), and neighborhood belonging. Living in a more urbanized area (UA) had a smaller centrality degree in the network.

Edges between PHQ9 and environmental factors were mediated by loneliness (UCLA). Poor architectural conditions (REAT) were linked positively with neighborhood belonging and adversely with social cohesion. Living in UA was negatively related to PHQ9, PHQ5 (eating control), and PHQ2, social cohesion, and green area distance, while positively to PHQ7 (problems with being focused), poor physical health, REAT, and neighborhood belonging (Figure 1).

Conclusions: Living in a city is negatively related to the most central depression symptoms. Even though social cohesion is negatively linked to UA, neighborhood belonging is higher in more urbanized areas.

The balance between detrimental environmental factors and those that protect mental health requires a better understanding of the interaction between urban living and depression.

Brain magnetic resonance imaging outperforms clinical severity ratings in the prediction of treatment outcomes in major depressive disorder

F. Long*, Y. Chen, Q. Zhang, Y. Wang, Y. Wang, Q. Li, Y. Zhao and F. Li

Department of Radiology and Huaxi MR Research Center (HMRRC), Functional and Molecular Imaging Key Laboratory of Sichuan Province, West China Hospital, Sichuan University, Chengdu 610041, Sichuan Province, China

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.219

Introduction: Major depressive disorder (MDD) is a prevalent and disabling condition. Approximately 30-50% of patients do not respond to first-line medication or psychotherapy. Therefore, several studies have investigated the predictive potential of pretreatment severity rating or neuroimaging features to guide clinical approaches that can speed optimal treatment selection.

Objectives: To evaluate the performance of 1) severity ratings (scores of Hamilton Depression/Anxiety Scale, illness duration, and sleep quality, etc.) and demographic characteristic and 2) brain magnetic resonance imaging (MRI) features in predicting treatment outcomes for MDD. Second, to assess performance variations among varied modalities and interventions in MRI studies.

Methods: We searched studies in PubMed, Embase, Web of Science, and Science Direct databases before March 22, 2023. We extracted a confusion matrix for prediction in each study. Separate meta-analyses were performed for clinical and MRI studies. The logarithm of diagnostic odds ratio [$\log(\text{DOR})$], sensitivity, and specificity were conducted using Reitsma's random effect model. The area under curve (AUC) of summary receiver operating characteristic (SROC) curve was calculated.

Subgroup analyses were conducted in MRI studies based on modalities: resting-state functional MRI (rsfMRI), task-based fMRI (tbfMRI), and structural MRI (sMRI), and interventions: antidepressant (including selective serotonin reuptake inhibitors [SSRI]) and electroconvulsive therapy (ECT). Meta-regression was conducted 1) between clinical and MRI studies and 2) among modality or intervention subgroups in MRI studies.

Results: We included ten studies used clinical features covering 6494 patients, yielded a $\log(\text{DOR})$ of 1.42, AUC of 0.71, sensitivity of 0.61, and specificity of 0.74. In terms of MRI, 44 studies with 2623 patients were included, revealing an overall $\log(\text{DOR})$ of 2.53. The AUC, sensitivity, and specificity were 0.89, 0.78, and 0.75.

Studies using MRI features had a higher sensitivity (0.89 vs. 0.61) in predicting treatment outcomes than clinical features ($P < 0.001$). RsfMRI had higher specificity (0.79 vs. 0.69) than tbfMRI subgroup ($P = 0.01$). No significant differences were found between sMRI and other modalities, nor between antidepressants (SSRIs and others) and ECT. Antidepressant studies primarily identified predictive imaging features in limbic and default mode networks, while ECT mainly focused on limbic network.

Conclusions: Our findings suggest a robust promise for pretreatment brain MRI features in predicting treatment outcomes in MDD, offering higher accuracy than clinical studies. While tasks in tbfMRI studies differed, those studies overall had less predictive utility than rsfMRI data. For MRI studies, overlapping but distinct network level measures predicted outcomes for antidepressants and ECT.

Rapid reduction of depressive symptoms with minimal dissociation: results from the KET01-02 and KET01-03 trials with oral prolonged-release (PR) ketamine KET01

C. zu Eulenburg^{1*}, E. Papanastasiou¹, K. Schmid², A. Damyanova¹, A. Glas¹, C. Strote¹, L. Arvastson¹ and H. Å. Eriksson¹

¹HMNC Brain Health, Munich, Germany and ²Develco Pharma, Pratteln, Switzerland

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.220

Introduction: Current ketamine-based therapies for treatment-resistant depression (TRD) often induce dissociative effects. A novel oral PR ketamine formulation (KET01) results in a low and delayed peak concentration of ketamine, high hydroxynorketamine concentration, and is associated with limited dissociative properties.

Objectives: To investigate efficacy, safety, and pharmacokinetics of KET01 in TRD.

Methods: KET01-02 was a randomized, double-blind phase 2 trial in outpatients with TRD comparing adjunct 120 mg (n=42) or 240 mg (n=40) oral KET01 once-daily for 3 weeks to placebo (PBO, n=40). The primary endpoint was change from baseline in the MADRS mean score on Day 21. KET01-03 was a randomized, double-blind, cross-over phase I trial in 26 healthy volunteers comparing single doses of 240 mg oral KET01 and 84 mg an approved intranasal formulation of esketamine. The primary endpoint was maximum change of Clinician-Administered Dissociative States Scale (CADSS) score from baseline.

Results: KET01-03 trial; the mean (\pm SD) maximum change of CADSS score within 24 hours after dosing was 29.6 ± 12.5 for intranasal esketamine and 0.7 ± 1.7 for KET01 ($p < 0.000000000001$). KET01-02 trial; no differences in CADSS score (range: 0.2 to 1.3), and heart rate and blood pressure were observed between the groups on Day 1 and beyond. 10%, 12%, and 15% of patients in

the PBO, 120 mg/day, and 240 mg/day KET01 groups, respectively had CADSS score >4 and increase from baseline. At 7 hours post first KET01 dose (240 mg), plasma concentration of ketamine (38.7 ± 27.0 ng/ml) was lower than its metabolites norketamine (267.5 ± 81.6 ng/ml) and hydroxynorketamine (190.2 ± 85.5 ng/ml). 240 mg/day KET01 induced clinically relevant reduction from baseline in MADRS score already within the first 7 hours of treatment (-7.65 ; Δ vs PBO: -2.22 , n.s.), with a statistically significant separation on Day 4 (-10.02 ; Δ vs PBO: -3.66 , $p=0.020$) and Day 7 (-12.21 ; Δ vs PBO: -3.95 , $p=0.042$). MADRS score decrease was sustained throughout Day 21 (-13.15 ; Δ vs PBO: -1.82 , n.s.), and during 4-week follow-up (-12.51 ; Δ vs PBO: -3.35 , n.s.). Treatment-emergent adverse events occurred in 47.5%, 50.0%, and 62.5% of patients in the PBO, 120 mg/day, and 240 mg/day KET01 group, respectively.

Conclusions: Oral 240 mg/day KET01 induces a rapid, and clinically relevant reduction of depressive symptoms with only minimal signs of dissociation, potentially due to lower ketamine levels and increased norketamine and hydroxynorketamine levels compared to intravenous administration. Our results suggest that KET01 may be an efficacious and safe take-at-home adjunct treatment for TRD.

Working mechanisms of Cognitive Behavioral Therapy and Acceptance and Commitment Therapy: a dynamic network approach

W. A. Van Eeden

Psychiatry, Leiden University Medical Center, Leiden, Netherlands
doi: 10.1192/j.eurpsy.2024.221

Introduction: Cognitive Behavioral Therapy (CBT) and Acceptance and Commitment Therapy (ACT) seem to be similarly effective for the treatment of major depressive disorder (MDD). However, much remains unknown about the differences in underlying psychological mechanisms of change. Assessing dynamic change of depressive symptoms and treatment-specific psychological constructs over time may yield important insights.

Objectives: The current study will be the first to compare dynamic symptom networks in randomized groups of two psychotherapies by using dynamic time-warp (DTW) analyses.

Methods: We reanalyzed data from a randomized controlled trial of 82 patients suffering from MDD. Three depressive symptom subscales (mood, sleep, appetite/weight) and three treatment-related constructs (dysfunctional attitudes, decentering, and experiential avoidance) were collected at 7 time-points before, during, after treatment, and at up to 12 months follow-up. The DTW-analysis modeled the temporal dynamics of depressive symptoms and treatment-related constructs within each individual after which the findings were aggregated on the group-level. Undirected and directed networks were constructed, of which the latter

yielded in- and out-strength for each node, that were compared between treatment arms.

Results: Networks based on symptom and construct dynamics markedly differed between treatment arms. Within the CBT-arm a decrease of experiential avoidance was related to a decrease in dysfunctional attitudes ($d = 0.059$, $p = 0.008$). Within the ACT-arm a decrease of mood symptoms was related to a decrease of experiential avoidance ($d = 0.051$, $p = 0.04$) and an increase of decentering was related to a decrease in sleep symptoms ($d = 0.038$, $p = 0.02$) and appetite/weight symptoms ($d = 0.049$, $p = 0.03$).

Conclusions: DTW offers a promising alternative approach to study and compare working mechanisms of different treatment interventions. Comparing CBT and ACT revealed a decrease in experiential avoidance within CBT and an increase in the ability to decenter within ACT. However, within both treatments a change in other constructs, suggesting that a first alleviation of mood symptoms is important to activate underlying psychological change.

doi: 10.1192/j.eurpsy.2024.222

Introduction: Major depressive disorder (MDD) is a tremendous global disease burden and the leading cause of disability worldwide. Unfortunately, individuals diagnosed with MDD typically experience a delayed response to traditional antidepressants and many do not adequately respond to pharmacotherapy, even after multiple trials. The critical need for novel antidepressant treatments has led to a recent resurgence in the clinical application of psychedelics, and intravenous ketamine, which has been investigated as a rapid-acting treatment for treatment-resistant depression (TRD) as well as acute suicidal ideation and behavior. However, variations in the type and quality of experimental design as well as a range of treatment outcomes in clinical trials of ketamine make interpretation of this large body of literature challenging.

Objectives: This umbrella review aims to advance our understanding of the effectiveness of intravenous ketamine as a pharmacotherapy for TRD by providing a systematic, quantitative, large-scale synthesis of the empirical literature.

Methods: We performed a comprehensive PubMed search for peer-reviewed meta-analyses of primary studies of intravenous ketamine used in the treatment of TRD. Meta-analysis and primary studies were then screened by two independent coding teams according to pre-established inclusion criteria as well as PRISMA and METRICS guidelines. We then employed metaumbrella, a

statistical package developed in R, to perform effect size calculations and conversions as well as statistical tests.

Results: In a large-scale analysis of 1,182 participants across 51 primary studies, repeated-dose administration of intravenous ketamine demonstrated statistically significant effects ($p < 0.05$) compared to placebo-controlled as well as other experimental conditions in patients with TRD, as measured by standardized clinician-administered and self-report depression symptom severity scales.

Conclusions: This study provides large-scale, quantitative support for the effectiveness of intravenous, repeated-dose ketamine as a therapy for TRD and a report of the relative effectiveness of several treatment parameters across a large and rapidly growing literature. Future investigations should use similar analytic tools to examine evidence-stratified conditions and the comparative effectiveness of other routes of administration and treatment schedules as well as the moderating influence of other clinical and demographic variables on the effectiveness of ketamine on TRD and suicidal ideation and behavior.

Electroconvulsive Therapy (ECT): A Scotland Wide Naturalistic Study of 4,826 treatment episodes

J. Langan Martin^{1*}, M. Fleming¹, D. Varveris², S. Kelly² and D. Martin³

¹University of Glasgow; ²NHS Greater Glasgow and Clyde and ³NHS Forth Valley, Glasgow, United Kingdom

doi: 10.1192/j.eurpsy.2024.223

Introduction: Despite its apparent efficacy in the treatment of a range of psychiatric disorders, electroconvulsive therapy (ECT) is viewed by some as a contentious treatment. Although most clinicians and researchers consider ECT a safe and effective treatment, there are ongoing and significantly publicised concerns about potential side effects.

Objectives: To explore use of ECT across Scotland in a large naturalistic clinical sample across an 11-year period from 2009 to 2019. To consider the efficacy and side effects of ECT for a range of common psychiatric disorders including, depression, bipolar depression, schizophrenia, and mania.

Methods: Using data from the Scottish Electroconvulsive Therapy (ECT) Accreditation Network (SEAN), information was collected for all adults who had received ECT. Variables included age, sex, Scottish Index of Multiple Deprivation (SIMD) quintile, International Classification of Diseases, Tenth Edition (ICD-10) diagnosis, indication for ECT, Mental Health Act status, consent status, entry and exit Montgomery-Asberg Depression Rating Scores (MADRS), entry and exit Clinical Global Index Severity CGI-S) scores and reported side effects. Side effects were recorded as present if the side effect was reported at any point during the episode of treatment.

Results: 4826 ECT episodes were recorded. The majority of episodes were in women (68.4%, $n=3,301$). Average age at treatment onset was 58.52 years. Males were slightly younger ($m=58.24$ years

vs $f=58.65$ years, $p=0.20$). Mean number of treatments/episode was 9.59 (95% CI 9.32 – 9.85). Mean treatment dose delivered was 277.75mC (95%CI 272.88 – 282.63mC).

2920 episodes of treatment had CGI-S entry and exit recorded. At entry, mean CGI-S indicated marked illness (5.03 95% CI 4.99–5.07). Recipients with schizophrenia had the highest CGI-S score (5.45 95% CI 5.21–5.60), followed by those with post-partum disorders (5.38, 95% CI 4.61–6.14). At exit, mean CGI scores indicated borderline illness (2.07, 95% CI 2.03–2.11), recipients diagnosed with mixed affective state had the lowest CGI-S score (1.72, 95% CI 0.99–2.47) followed by those with schizoaffective disorder (2.01, 95% CI 1.76–2.42).

Anaesthetic complications ($n=34$) and prolonged seizures ($n=38$) were rare, occurring in $<1\%$ of treatment episodes. Cardiovascular complications were reported in 2.2% ($n=102$). Nausea was reported in 7.2% ($n=334$) and muscle aches in 12% ($n=560$). Confusion was reported in 19% ($n=879$) and cognitive side effects were reported in 26.2% ($n=1212$). One third of treatment episodes reported confusion or cognitive side effects (33.1%, $n=1545$).

Conclusions: From this large naturalistic clinical sample, ECT appears to be effective in improving illness severity as measured by CGI-S score. While some side effects (such as prolonged seizures and cardiovascular complications) were rare, others (such as confusion or cognitive side effects) were relatively common.

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.224

Introduction: In a 12-week, Phase II (NCT02832037) trial, iclertin (BI 425809), an inhibitor of glycine transporter-1, was generally well tolerated and significantly improved cognition in 509 patients with schizophrenia.

Objectives: The Phase III CONNEX programme aims to confirm the efficacy, safety and tolerability of iclertin in improving cognition and functioning across a larger cohort of patients with schizophrenia.

Methods: The CONNEX programme includes 3 randomised, double-blind, placebo-controlled parallel group trials in patients with schizophrenia (NCT04846868, NCT04846881, NCT04860830) receiving stable antipsychotic treatment. Each trial aims to recruit ~586 patients, 18–50 years old, treated with 1–2 antipsychotic

medications (≥ 12 weeks on current drug and ≥ 35 days on current dose before treatment) who have functional impairment in day-to-day activities and interact ≥ 1 hour per week with a designated study partner. Patients with cognitive impairment due to developmental, neurological or other disorders, with a current DSM-5 diagnosis other than schizophrenia or receiving cognitive remediation therapy within 12 weeks prior to screening, will be excluded. Patients will be recruited from multiple centres across 41 countries in Asia, North and South America, Europe and the Asia-Pacific Region, and randomised 1:1 to receive either iclertin 10 mg (oral administration; $n=293$), or placebo ($n=293$) once daily for 26 weeks. The primary endpoint is change from baseline in overall composite T-score of the Measurement and Treatment Research to Improve Cognition in Schizophrenia Consensus Cognitive Battery. The key secondary endpoints are change from baseline in total score on the Schizophrenia Cognition Rating Scale and change from baseline in the adjusted total time T-score in the Virtual Reality Functional Capacity Assessment Tool. **Results:** The CONNEX programme is currently recruiting (Table); the first patients were enrolled in Aug–Sept 2021 and completion is expected in Q1 2025. The presentation will describe the current study status, information relating to screening failures, and the experience of collecting these data as part of a large multi-country, multicentre study.

Table. The number of patients recruited by 31 August 2023

	CONNEX 1	CONNEX 2	CONNEX 3
Screened	565	521	493
Randomised	409	360	350
Completed trial medication	202	184	191

Conclusions: Iclertin may represent the first efficacious medication for cognitive impairment associated with schizophrenia.

doi: 10.1192/j.eurpsy.2024.225

Introduction: Evidence from observational and genetic studies suggests a bidirectional relationship between loneliness and psychosis. To our knowledge, no previous study has assessed the association between loneliness in childhood and first-episode psychosis (FEP).

Objectives: We aimed to assess the association between loneliness in childhood and the odds of FEP and clinical variables of interest (i.e., diagnosis and clinical and functional severity) in FEP and to explore gender differences in this association.

Methods: This was an observational, case-control study, based on the AGES-CM cohort, a longitudinal prospective study including patients with FEP ages 7–40, their first-degree relatives, and an age- and sex-matched sample of controls in seven university hospitals in the region of Madrid. We assessed loneliness in childhood with the question “Have you ever felt lonely for more than 6 months before the age of 12” and objective social isolation with the peer relationships item from the childhood subscale of the Premorbid Adjustment Scale. We conducted logistic and linear regression analyses to assess the association between childhood loneliness and i) the odds of presenting a FEP and ii) clinical variables of interest (diagnosis and scores on positive, negative, general, depressive, and manic symptoms and functioning), while adjusting for demographic variables.

Results: The study sample comprised 285 patients with FEP (32.6% female, age 24.50 ± 6.2 years) and 546 controls (48.7% female, age 25.93 ± 5.5 years). Loneliness in childhood was associated with increased odds of FEP (adjusted odds ratio; aOR: 2.17, 95% CI [1.40-3.51], $p=.002$). This association remained significant after controlling for objective social isolation in childhood (aOR:2.70, IC 95% [1.58-4.62], $p<.001$).

The effect of the association was stronger in females (aOR:4.74, 95% CI [2.23-10.05], $p<.001$) than in males (aOR:1.17, IC 95% [0.63-2.19], $p=.623$). In females with FEP, loneliness in childhood was significantly associated with increased odds of receiving a diagnosis of other psychosis (aOR:0.155, 95% CI [0.048-0.506], $p=.002$) relative to an SSD diagnosis. In the FEP sample, loneliness in childhood was associated with greater severity of positive and affective symptoms and worse functioning.

Conclusions: Loneliness in childhood is associated with increased odds of FEP and clinical variables of interest. This suggests the potential role of this phenotype as an early risk marker for psychosis that could help guide targeted interventions.

Transdiagnostic Analysis of Verbal Fluency across Autism Spectrum Disorder, Schizophrenia, and Neurotypical Healthy Control Groups

F. Kinga^{1*}, E. J. Zarka¹ and O. Pesthy²

¹Department of Psychiatry and Psychotherapy, Semmelweis University and ²Institute of Psychology, ELTE Eötvös Loránd University, Budapest, Hungary

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.226

Introduction: Verbal fluency, a cognitive function that reflects executive functions and the rapid retrieval of pertinent information from memory, has yielded inconsistent findings in previous research on autism spectrum disorder (ASD), however in schizophrenia (SCH) semantic fluency exhibits a more pronounced impairment compared to letter fluency.

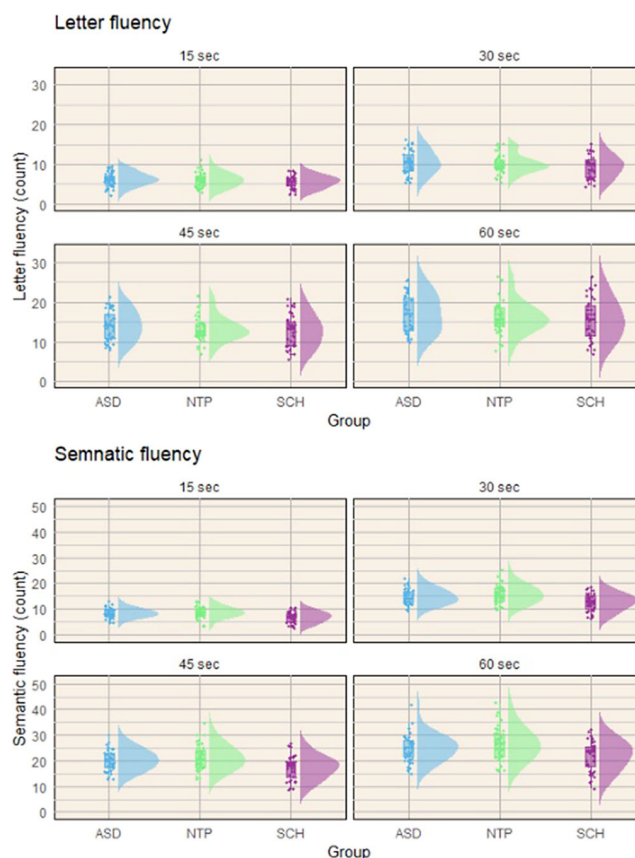

Objectives: In this study we aim to comprehensively investigate verbal fluency in ASD, SCH, and neurotypical healthy control individuals (NTP). The primary objective is to investigate disparities in novel response generation, specifically between the ASD,

SCH and NTP groups, using phonemic and semantic fluency tasks. Three central inquiries guide our research: (1) whether differences between groups (ASD, SCH, and NTP) can be identified in word productivity, clustering, errors, and perseverations; (2) whether participants with ASD and SCH exhibit different word production with elevated imageability and concreteness values; and (3) if individuals with ASD and schizophrenia demonstrate reduced productivity during the earlier phases of fluency tasks.

Methods: Forty participants with ASD (12 female, 24 male, 4 other, mean age: 30.5), 39 with SCH (10 female, 28 male, 1 other, mean age: 34.7) and 41 NTP (13 female, 28 male, mean age: 31.0) were recruited from the outpatient units of the Department of Psychiatry and Psychotherapy, Semmelweis University. Participants were requested to list as many words as they could on two phonemic and two semantic category conditions. Audio recordings were later transcribed. To assess concreteness and imageability, we employed a seven-point scale and recruited independent external raters to evaluate a total of 1481 words.

Results: Preliminary results indicate that the three study groups did not differ significantly in phonemic fluency ($F(2, 119)=0.983$, $p=0.377$), during either time period. However, a significant difference was observed in semantic fluency ($F(2, 119)=6.531$, $p=0.002$). Post-hoc tests (Tukey corrected) revealed that this difference stemmed from impaired performance in the SCH group. Participants with schizophrenia (SCH) exhibited reduced semantic word productivity compared to both neurotypical (NTP) individuals and participants with ASD (Figure 1). However, there were no significant differences between participants with ASD and NTP individuals.

Image:

Conclusions: In conclusion, our study investigated the characteristics of verbal fluency in a transdiagnostic approach. While phonemic fluency did not reveal significant differences among the three groups, our analysis of semantic fluency unveiled a distinction. Specifically, individuals with schizophrenia exhibited impaired semantic word productivity. Our study highlights the complex nature of verbal fluency impairments in different conditions and the importance of considering more nuanced methods when assessing cognitive functions.

Evaluation of The Relationship of Circular RNA With Suicide Behavior In Patients Diagnosed With Schizophrenia and Other Psychotic Disorder

M. Aydin^{1*}, S. O. Unal¹ and E. M. Ozdemir²

¹Psychiatry and ²Medical Genetics, Selcuk University, Konya, Türkiye

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.227

Introduction: Schizophrenia is a major mental disorder with a high risk of suicide, which is one of the leading causes of early death in schizophrenia patients. It is known that suicidal behavior is 20-50 times higher in schizophrenia patients compared to the general population. Clinical features makes it difficult to determine the risk of suicide in this patient group. Since genetic studies on suicides of patients with schizophrenia are limited, this area was deemed worthy of research.

Objectives: CircRNAs can potentially serve as minimally invasive biomarkers because they can freely cross the blood-brain barrier. It is aimed to define the effect of circRNA molecules on suicidal behavior in patients diagnosed with schizophrenia and other schizophrenia spectrum psychotic disorders, and to increase protective and preventive approaches by predicting possible consequences of suicidal behavior.

Methods: 104 patients followed up with the diagnosis of schizophrenia and other schizophrenia spectrum psychotic disorders were included in the study. RNA was isolated from the blood taken into a hemogram tube, and three circRNA molecules were identified using a number of RNA sequencing techniques. In addition, socio-demographic characteristics of the participants, clinical features of the disease, suicidal behavior history, current treatment status were questioned in detail. Simultaneously, the current clinical status was evaluated with clinical evaluation scales as Positive and Negative Syndrome Scale (PANSS), Calgary depression scale for schizophrenia (CDSS), Suicide Probability Scale (SPS), Beck Suicidal Intent Scale (BSIS).

Results: Three circRNA molecules were identified, chr3_196488683, chr5_69175537 and hsa_circ_0084021. No significant difference was found between these molecules and past suicide attempts. It was found that chr5_69175537 was negatively associated with the age of onset of psychotic disorder negative symptoms, and hsa_circ_0084021 was negatively associated with the age of onset of both negative and positive symptoms. When the relationship between the clinical assessment scales and suicidal behavior was evaluated, the PANSS general symptoms subscale score was significantly higher in the group with suicidal behavior

($p < 0.05$). CDSS mean scores and BSIS scores were also found to be significantly higher in the group with previous suicide attempts ($p < 0.01$).

Conclusions: Although our findings do not allow definitive conclusions due to the complex interaction between epidemiological and clinical factors and limited literature, it has shown that schizophrenia contains many risks that increase suicidal behavior. To predict suicide, circRNA molecules need to be supported by prospective studies with large sample groups and comparison with control groups.

Serum d-serine and d-amino acid oxidase (DAO) levels in schizophrenia and related psychotic disorders: a 6-month follow-up study

E. Uzun Uysal*, N. B. Tomruk, C. Çakır Şen and E. Yıldızhan

Department of Psychiatry, Bakırköy Research and Training Hospital for Psychiatry, Neurology and Neurosurgery, İstanbul, Türkiye

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.228

Introduction: D-serine and the DAO enzyme may impact the NMDA receptor and contribute to schizophrenia, but the exact role and outcomes are not fully understood due to the complexity of the disorder.

Objectives: We analyzed serum levels of d-serine and DAO in untreated individuals with schizophrenia during acute psychotic episodes. We correlated these factors with clinical characteristics and compared results to a healthy control group. We also examined any differences after six months of treatment.

Methods: The study involved 89 patients with schizophrenia or related psychotic disorders who were hospitalized due to psychotic episodes. Also, the study had 81 healthy participants matched in terms of gender, age, and smoking status with the patient group. PANSS, CGI, GAS, CDSS, and MoCA were applied to determine the severity of the disease. Serum d-serine and DAO levels were measured by ELISA kits.

Results: During an acute psychotic episode, patients had significantly lower levels of D-serine, DAO, and D-serine/DAO ratio compared to healthy individuals ($Z=6.52$, $p < 0.001$; $Z=4.54$, $p < 0.001$; $Z=2.90$, $p=0.004$). Although DAO and D-serine levels increased with symptom regression after six months of treatment, the D-serine and D-serine/DAO ratios were significantly lower in patients than in healthy individuals ($Z=3.52$, $p < 0.001$; $Z=3.44$, $p < 0.001$). There was no correlation between the change in D-serine level and the change in scale scores. However, there was a negative correlation between the change in DAO level and the change in PANSS total ($r=-0.681$, $p=0.000$), anxiety scores ($r=-0.336$, $p=0.032$), and Calgary depression score ($r=-0.547$, $p=0.000$). There was a positive correlation between the change in D-serine/DAO ratio and the change in the Calgary depression scale score ($r=0.353$, $p=0.024$) in addition to PANSS positive ($r=0.395$, $p=0.011$) and total scores ($r=0.585$, $p=0.000$). Antipsychotic doses negatively correlated with the changes in DAO level ($r=0.421$, $p=0.01$). It was found that the female patients had significantly lower levels of DAO than the female healthy subjects ($Z=-5.061$, $p < 0.001$).

No correlation was found between serum D-serine level, DAO level, and the D-serine/DAO ratio with cognitive function. D-serine level negatively correlated with age ($r=-0.265$, $p=0.012$) and age at onset of the disease ($r=-0.227$, $p=0.032$).

Conclusions: The findings support the view that D-serine and DAO may play a role in the pathophysiology of schizophrenia and related psychotic disorders. To better understand the relationship between D-serine metabolism and symptom clusters in psychosis and the effects of antipsychotic drugs on NMDAR dysfunction, further studies that directly measure DAO enzyme activity and examine cognitive symptoms in more detail are needed.

Catchment area rates of involuntary care and subsequent patient morbidity and mortality in Norway

O. Nittingnes^{1,2*}

¹Health Services Research Unit, Akershus University Hospital, Lørenskog and ²Centre for Research and Education in Forensic Psychiatry, Haukeland University Hospital, Bergen, Norway

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.229

Introduction: Mental health legislation allows for involuntary care of patients with severe mental disorders, assuming it improves health and reduces risk. Professionals have warned against potentially adverse effects of recent initiatives to heighten involuntary care threshold, such as CRPD and national coercion-reduction strategies. We have not found that the impact of high thresholds for involuntary care have been studied.

Objectives: Our aim was to use national data from Norway to test implications of the hypothesis that areas with lower levels of involuntary care show higher levels of morbidity and mortality in their severe mental disorder populations compared to areas with higher levels. We pre-specified five models of how such adverse effects could manifest in national register data.

Methods: Using national register data, we calculated standardized (by age, sex, and urbanicity) involuntary care ratios across Community Mental Health Center areas in Norway. For patients diagnosed with severe mental disorders (ICD10 F20-31), we tested whether lower area ratios in 2015 interacted with 1) case fatality over four years, 2) an increase in inpatient days, and 3) time to first episode of involuntary care over the following two years. We also assessed 4) whether area ratios in 2015 predicted an increase in the number of patients diagnosed with F20-31 in the subsequent two years and whether 5) standardized involuntary care area ratios in 2014–2017 predicted an increase in the standardized suicide ratios in 2014–2018.

Results: We included 21481 patients with either an F20-31 diagnosis, an episode of involuntary care in 2015, or both. The standardization variables age, sex, and urbanicity explained 70.5% of the variance in raw rates of involuntary care, and the remaining extremal quotient was 2.5. Age and sex predicted case-fatality, but involuntary care-rate was insignificant. Patients with F20-31 and no involuntary care episode in 2015 showed a steady reduction in inpatient days the following years, but not significantly related to the area's involuntary care rates. For the same sample, these rates

did not predict the time to an episode of involuntary care. The area's involuntary care rate in 2015 did not predict *changes* in the number of patients in treatment for a diagnosis of F20-31 from 2015-2017. Finally, the area's involuntary care rate from 2014-2018 explained 1.2% of the variance in suicides in 2014-2019 in the area.

Conclusions: In the models, we found no significant associations between low standardized catchment area rates of involuntary care and the pre-specified outcomes. This raises questions about some assumptions in mental health legislation and merits further research.

Preliminary data from the CONNEX-X extension trial examining the long-term safety of iclepterin in patients with schizophrenia who completed Phase III CONNEX trials

C. Reuteman-Fowler¹, Z. Blahova^{2*}, S. Marder³, S. Ikezawa⁴ and P. Falkai⁵

¹Boehringer Ingelheim RCV GmbH & Co. KG, Ridgefield, CT, United States; ²Boehringer Ingelheim RCV GmbH & Co. KG, Vienna, Austria;

³Department of Psychiatry and Behavioral Sciences, David Geffen School of Medicine, Los Angeles, CA, United States; ⁴Department of Psychiatry, International University of Health and Welfare, Mita Hospital, Minato-ku, Tokyo, Japan and ⁵Clinic of Psychiatry and Psychotherapy, Ludwig Maximilians University Munich, Munich, Germany

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.230

Introduction: Cognitive impairment associated with schizophrenia (CIAS) is an important unmet need as there are no effective treatments available. Iclepterin (BI 425809), a glycine transporter-1 inhibitor, has been shown to improve CIAS in Phase II trials, and Phase III trials are underway.

Objectives: The ongoing CONNEX-X extension study aims to collect additional safety data relating to iclepterin treatment in patients with CIAS.

Methods: CONNEX-X (NCT05211947/1346-0014) is a multinational, multicentre, open-label, single-arm extension study in patients with CIAS who completed 26 weeks of treatment (iclepterin 10 mg or placebo) in one of 3 Phase III CONNEX parent trials (NCT04846868/1346-0011, NCT04846881/1346-0012, NCT04860830/1346-0013). An estimated 1400 clinically stable outpatients will be treated (iclepterin 10 mg daily) for 1 year, irrespective of previous treatment (iclepterin/placebo). Patients are excluded if any of the following circumstances occur during the parent study and up to Visit 1 of CONNEX-X: suicidal behaviour or ideation (type 5 on the Columbia-Suicide Severity Rating Scale), diagnosis with moderate/severe substance use disorder, diagnosis other than schizophrenia (according to Diagnostic and Statistical Manual of Mental Disorders – Fifth Edition), development of any condition preventing participation, a haemoglobin level decrease ($>25\%$ or $<100\text{g/L}$ from baseline in parent trial) or haemoglobinopathies. The primary endpoint is the occurrence of treatment-emergent adverse events. The secondary endpoints include change from baseline (Cfb) in Clinical Global Impressions-

Severity (CGI-S) and Cfb in haemoglobin. Further efficacy end-points include Cfb in MATRICS Consensus Cognitive Battery (MCCB) overall composite T-score, Cfb in Schizophrenia Cognition Rating Scale total score and Cfb in Virtual Reality Functional Capacity Assessment Tool (VRFCAT) total times.

Results: Currently, 460 patients have been enrolled and randomised from the parent trials with 0% screening failures (-80% roll-over rate, 30 August 2023). Current study status, including recruitment, screening failures and data collection experiences, are presented.

Conclusions: Patient enrolment rates from the CONNEX trials to the CONNEX-X open-label extension study are stable. CONNEX-X will allow the exploration of long-term safety, as well as descriptive analyses of cognitive and functional endpoints of iclepertin in the treatment of CIAS.

Evaluation of Psychiatric High and Intensive Care (EPHIC-study): monitoring innovative care from a value-based approach

H. Demunter^{1*}, H. Jossa¹, K. Vandenhout¹, S. Claes¹ and R. Bruffaerts¹

¹UPC KU Leuven, Kortenberg, Belgium

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.231

Introduction: Systematic monitoring and evaluation of innovative healthcare programs are essential to develop sustainable solutions to health needs in the population (Porter & Teisberg, 2006). Development of Psychiatric High and Intensive Care Units (HIC's) in Belgium, following the Dutch Model (van Mierlo et al., 2013), is an innovative model for patients with acute and severe psychiatric illness, resulting in potential danger. HIC aims to provide intensive, need-adapted care with interventions that reduce (perceived) coercion, focusing on participative processes and continuity of care.

Objectives: (1) What are the clinical characteristics of admitted patients? (2) How does clinical symptomatology evolve during admission? (3) How do patients, relatives and caregivers experience the process of care and recovery? (4) What is the role of HIC's in the reformed mental health care?

Methods: This is an explorative, hypothesis-generating study, using a mixed-method approach, consisting of qualitative and quantitative methods against a value-based framework. Data collection lasted 18 months in the first 9 HIC's in Belgium. Results are

based on validated questionnaires completed by adult patients and their HIC caregivers at admission and discharge (N=472).

Results: We provide the first, preliminary results. Suicidality, psychotic and substance-related symptoms are the most important primary symptoms. Almost 70% have 2 or more symptoms, with psychiatric comorbidity of 50%. Substance-related- and psychotic disorders are the two most common diagnoses, followed by personality disorder cluster B and depressive disorder. 83% have been in residential care in the past, of whom 87% twice or more. The median age is 36 years, but the median age of onset of mental disorders is 21 years, which equals to 15 years in mental disorder progress and comorbidity development. Over 50% meet the criteria for Severe Mental Illness and 56% are involuntary admitted. There is a high degree of unmet needs: no outpatient care is provided for one out of five prior to admission and there is a low follow-up by mobile teams prior to and after admission (around 12% each). We found significant improvements after an average stay of 22 days for aggression, suicidality and crisis (respectively decrease of 68%, 25% and 9%); readiness to change and motivation for treatment (respectively increase of 5% and 14%) The Client Satisfaction Questionnaire scores range from 1 to 4, with an average score 3.15 out of 4.

Conclusions: Based on these preliminary results we can conclude that aggression, suicidality, crisis, readiness to change and motivation for treatment all improve significantly after a short stay of 3 weeks. Despite a vulnerable, severely distressed population, patients are generally satisfied with received care. There is a high degree of unmet needs: insufficient provided outpatient care and low follow up by mobile teams.

Involuntary Psychiatric Hospitalization of Minors Due to Court Orders: Effectiveness Assessing Through a Case Series

E. Yerlikaya Oral^{1*} and M. Tekden¹

¹Department of Child and Adolescent Psychiatry, University of Health Sciences, Bakirkoy Prof. Dr. Mazhar Osman Research and Training Hospital for Psychiatry, Neurology and Neurosurgery, Istanbul, Türkiye

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.232

Introduction: Involuntary treatments in forensic psychiatry represents a complex intersection of mental health, legal systems and ethics. Judicial authorities may compulsorily refer children to inpatient clinics for receiving necessarily treatment. Despite its importance, there is limited research on the reasons behind and effectiveness of such interventions in minors.

Objectives: The objectives of this study were to describe the clinical characteristics of minors who have risks of harming themselves and/or others so receiving involuntary treatment due to a court order. It is aimed to assess the effectiveness of involuntary treatment.

Methods: A follow-up case series was conducted on 9 minors who hospitalized by court orders in a secure inpatient child and adolescent psychiatry clinic, in the year of 2023. Data collected from medical records, including demographic information, clinical presentation, diagnosis and discharge treatment. After one, three and six month of the discharge, interviews made with the patients and their families. Current data collected on treatment regimen, compliance, behavioral outcomes and reoffending rates. All data were anonymized to maintain patient confidentiality.

Results: The case series consisted of 3 males and 6 females, with a mean age of 16.5 years at the time of admission. The most common reason to hospitalization was homicide risk 88%, followed by substance use 66%. Conduct Disorder was the most common diagnosis with the rate of 88%, followed by Substance Use Disorder (66%) and Attention Deficit and Hyperactivity Disorder (50%). 44% of minors had a history of juvenile delinquency. School dropout rates were 100%. Treatment consisted of a combination of individual and group therapy and medication. Treatment refusal rates were 88% so in terms of treatment, 88% of the minors in this sample treated with depot form antipsychotic medications, with the most common medication being risperidone. Overall all of the sample showed a significant reduction in disruptive behaviors during their hospital stay. Follow-up data collecting is still continue and preliminary statistics show us that relapse rates are low and treatment compliance is relatively high of the sample.

Conclusions: The findings suggest that involuntary hospitalization can be effective in reducing disruptive behaviors and increasing treatment compliance in minors with conduct disorders, substance abuse disorders and a history of juvenile delinquency. These results underscore the need for comprehensive, multidisciplinary approaches that integrate psychiatric treatment, psychoeducation and social support. Given the relatively small sample size and short-term follow-up, further research is needed to determine the long-term effects of involuntary treatment and to identify factors that predict treatment response.

Increasing Physical Activity in Medium Secure Mental Health Services in the UK: (IMPACT) - Preliminary Results from the Phase 4 Feasibility Study, with a highlight into the Women's Services

T. Walker

Psychology, Durham University, Durham, United Kingdom
doi: 10.1192/j.eurpsy.2024.233

Introduction: In the UK there are 3500 individuals detained in medium secure forensic psychiatry units. Service users in such settings have complex and serious mental illness (SMI), often with co-morbid physical health problems and a life expectancy of at least 10 years shorter than the general population. They often have low levels of physical activity. There is little evidence about physical activity interventions for medium secure service users in the United Kingdom.

Objectives: Our objective is to co-produce, with medium secure service users, the content and delivery of an intervention to increase physical activity. We shall assess feasibility, acceptability, and pilot

data collection methods for outcomes relevant for a future randomised controlled trial.

Methods: This is a 30-month mixed-methods project that will follow the Medical Research Council (MRC) framework Developing and Evaluating Complex Interventions. The study has 4 phases. Phases 1-2 will gather information required to co-develop an evidence-based intervention in Phase 3. Phase 4 will assess the intervention in a feasibility study, evaluating and testing the intervention for a future pilot study.

Study settings: Two NHS Medium Secure In-Patient Psychiatric Hospitals in the UK.

Results: This paper presents the preliminary findings from Phase 4 and also offers a highlight into the results from the Women's Services from both study sites. A total of thirty-three service users from both study sites participated in Phase 4 of the study and twenty-six completed the physical activity intervention, known as the IMPACT Intervention. Between both study sites, there were two Women's Standard Medium Secure Services and one Women's Enhanced Medium Secure Service, involved in this study. A total of nine female service users participated in Phase 4.

Conclusions: The preliminary findings of Phases 4 are allowing the team to move forward and evaluate the effect of the IMPACT Intervention.

War in Ukraine as a mental health challenge of Czech health care workers

M. Janoušková^{1*}, M. Kuklová¹, P. Čermáková¹, J. Pekara², J. Šeblová³ and D. Šeblová¹

¹Department of Epidemiology, Second Faculty of Medicine, Charles University; ²Department of Paramedic Science, Medical College, Prague and ³Emergency Department, Kladno Regional Hospital, Kladno, Czech Republic

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.234

Introduction: Czech health care workers recently experienced serious challenges to their mental health. After the COVID-19 pandemic that was extremely stressful, a war in Ukraine caused a flood of refugees that needed health care. Although the Czech Republic does not have borders with Ukraine, it welcomed more than 400,000 refugees in 2022.

Objectives: The aim of this study was to investigate the association between depression and working with Ukrainian refugees among health care workers and the nature of emotional burden connected with this situation.

Methods: We use data from an online survey of the Czech COVID-19 Health Care Workers (HEROES) Study collected in September - November 2022 (n=1,076). We combined quantitative binary logistic regression and qualitative content analysis of answers to an open-ended question ("How does the current situation of war in Ukraine affect your mental well-being and working conditions?"). Logistic regression estimated odds ratio (OR) of at least moderate depression, defined as ≥ 10 points on the Patient Health Questionnaire.

Results: Among our participants (75.1% women, mean age 46 (SD 11.0)), 62.1% had experience of working with Ukrainian refugees, and 13.8% reported moderate to severe depression. Logistic regression model (adjusted for potential confounders) indicated that health care workers who worked with Ukrainian refugees had slightly greater chance of having depression, but the association was not statistically reliable (OR 1.05; 95% CI 0.59-1.86). Out of all survey respondents, 867 replied to an open-ended question. As follows from qualitative analysis, three categories of psychological strain were described by the health care workers: 1) specificity of work with the refugee patients (e.g. language barrier, increased workload, opinion conflicts), 2) insecurity, threat of war and fears about future (regarding global and nuclear war, security, future of kids, economic burden, etc.), 3) grief and compassion for the suffering of refugees. It was also frequently mentioned in the responses that war is a greater threat to health care workers than the COVID-19 pandemic.

Conclusions: There is a slight association between working with refugees and depression. However, health care workers are also endangered by general fears of war and insecurity in a nearby country. In this changing world, it is of the greatest importance to pay attention to resilience building and stress prevention programs. Further, health care workers should be offered psychological support and practical resources to deal with the varying workload.

EFPT Exchange programme - Feedback results from 2012 - 2022

F. H. Kraxner

Department of Psychiatry and Psychotherapy, Hospital of Affoltern, Affoltern am Albis, Switzerland
doi: 10.1192/j.eurpsy.2024.235

Introduction: Differences in psychiatry training vary substantially across Europe. Such organisations as the European Federation of Psychiatry Trainees (EFPT), the European College of Neuropsychopharmacology, and the European Psychiatry Association, have committed to offer international experiences based on the premise that it could foster international collaboration, aid early career professionals to progress professionally and spark discussion regarding different practices across Europe. To date, there are no studies that focus exclusively on the exchange experience in mental health professionals

Objectives: I present the synthesis of the ten years answers from 2012 to 2022 to the post-exchange online evaluation form, which trainees had to fill in in order to receive an attendance certificate.

Methods: The present study analysed the answers of 202 psychiatry trainees or recent graduates who took part in the EFPT exchange program during 2012 and 2022 and filled in the internet-based evaluation form. The inclusion criteria were currently in training or recently finished training as a psychiatrist in Europe and filling in the questionnaire. The exclusion criterion was participation in the EFPT exchange program for the second or subsequent time.

All trainees were systemically asked to complete the online evaluation form after the exchange period. The form includes socio-demographic, training in host country-related, and exchange experience-related questions. Experience measures were evaluated using the 4-point Likert scale. Data was anonymized before the analysis. The study followed the principles of the Declaration of Helsinki.

Results: The majority of participants were females in the second half of their training. The average age was 29 years. The largest number of applicants were from Turkey, whereas the United Kingdom hosted the most participants. One-third of the participants had previous international exchange experience. Most trainees were exposed to both outpatient and inpatient treatment settings and were involved in educational or research activities. 96.7% of participants indicated that they were satisfied or very satisfied with the experience, 95.6% said that the exchange was useful or very useful, and 98.9% were likely or very likely to recommend exchange to colleagues.

Conclusions: To my knowledge, this study is the first to assess the experience of psychiatry trainees who went on exchange during their professional training. Vast majority of trainees were satisfied with their exchange, thought it would be useful for their clinical practice and would recommend it to their colleagues. These findings are in line with other studies that examined medical exchange experiences.

Rates of delirium referrals to the Neuropsychiatry Service in a tertiary referral centre hospital

S. M. Gunawardena*, S. Riaz and K. Murphy

Neuropsychiatry, Beaumont Hospital, Dublin, Dublin, Ireland

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.236

Introduction: Beaumont Hospital is the National Neurosurgical Centre in Ireland. Due to the high numbers of referrals from Neurology and Neurosurgery, The Department of Psychiatry established a specialist Neuropsychiatry inpatient Liaison service and a weekly Neuropsychiatry outpatient clinic. Many of the referrals that the service receive involve the management of delirium. Delirium is a common medical complication, particularly in neurosurgical settings. Delirium causes significant symptom burden which can lead to distress to all involved and impacts quality of life.

Objectives: The aim was to improve the rates of referrals for delirium presentations and referral rates overall from Neurology and Neurosurgery. The neuropsychiatry service have implemented a delirium protocol for all medical and surgical teams in Beaumont Hospital. This protocol can be accessed through the Beaumont hospital phone app, or on site on each ward. For this reason, delirium can be managed by medical teams in the first instance. If this is not successful, neuropsychiatry can be contacted for further advice or review of patients with more complicated presentations.

Methods: The neuropsychiatry service receives referrals through the Patient Information Profile Explorer system which is accessed through the Beaumont Hospital online portal. In the event of an urgent referral, neurology or neurosurgery teams can contact the neuropsychiatry service directly by phone. Referrals are logged on the team referral log book, and details of the referral are recorded along with diagnosis and management. Data was collected retrospectively from the PIPE and log book to measure the rates and reasons for referrals over a one year period. Rates and details of referrals were initially recorded between July-December 2022. An educational intervention was provided where psychoeducation was provided to junior hospital doctors during protected teaching times and further education was provided over the phone when referrals were discussed between team members. Rates and details of referrals were then recorded between January-July 2023.

Results: There was a reduction in referrals when comparing the two six month periods. There were 115 neuropsychiatry referrals from July to December 2022 and 78 referrals from January to July 2023. Rates of delirium referrals also reduced from 31% to 25% after psychoeducation was provided to junior doctors.

Conclusions: This audit highlights the importance of communication and education for medical and surgical trainees in the management of delirium. There is a high rate of turnover of junior doctors throughout the year in Beaumont Hospital. For this reason, it is imperative that continued education is provided to allow them to follow the delirium protocol independently before seeking tertiary service assistance. Ultimately, early and rapid intervention of delirium can have a positive impact on patient care and prognosis

The risk of antidepressant-induced hyponatremia: A meta-analysis of antidepressant classes and compounds

T. Gheysens^{1*}, L. De Picker^{2,3} and F. Van Den Eede^{3,4}

¹Psychiatry, AZ Klina, Brasschaat; ²SINAPS, Duffel; ³CAPRI, Antwerp and ⁴Psychiatry, Antwerp University Hospital, Edegem, Belgium

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.237

Introduction: Hyponatremia (hypoNa) is a potentially serious adverse event of treatment with antidepressants. Previous research suggests that risk of drug-induced hyponatremia differs between antidepressants.

Objectives: This meta-analysis sought to determine the risk of antidepressant-induced hypoNa, stratified by different compounds and classes.

Methods: PubMed and Web of Science were searched for studies reporting on incidence or risk of hypoNa in adults using antidepressants (PROSPERO, CRD42021269801). We modelled random-effects meta-analyses to compute overall incidence and risk of any and clinically relevant hypoNa for each compound and class, and ran head-to-head comparisons based on hypoNa incidences. We conducted subgroup analyses for geriatric populations, study context and sodium cut-off value.

Results: Thirty-nine studies (n = 8,459,033) revealed that exposure to antidepressants was associated with significantly increased odds of hypoNa (OR = 2.82 (1.79 – 4.45)). The highest event rates were

found for SNRIs (7.17%), SSRIs (5.20%), and TCAs (2.26%); the lowest for mirtazapine (1.02%) and trazodone (0.89%). The highest odds ratios were found for MAOIs (4.12 (1.92 – 8.86)), SNRIs (3.16 (1.77 – 5.67)), and SSRIs (2.78 (1.57 – 4.91)); the lowest for mirtazapine (2.82 (1.87 – 4.21)) and TCAs (1.85 (1.28 – 2.69)). Compared to SSRIs, SNRIs were significantly more likely (OR = 1.27 (1.13 – 1.42), p < 0.001) and mirtazapine significantly less likely (OR = 0.61 (0.39 – 0.96), p = 0.032) associated with hypoNa.

Conclusions: Our meta-analysis demonstrated that, while no antidepressant can be considered completely risk-free, for hypoNa-prone patients mirtazapine should be considered the treatment of choice and SNRIs should be prescribed more cautiously than SSRIs and TCAs.

Impact of Antidepressant Treatment on Fibronectin Levels in Patients with Depression and Chronic Heart Failure

A. K. Sikora^{1*} and S. Fedorov²

¹Psychiatry, Narcology and Medical Psychology and ²Ivano-FrankIskenderun National Medical University, Ivano-Frankivsk, Ukraine

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.238

Introduction: Inflammation has emerged as a critical factor in the pathophysiology of both depression and chronic heart failure (HF). Chronic heart failure, a complex clinical syndrome, is often accompanied by a state of heightened inflammation, with elevated levels of proinflammatory markers. Likewise, depression, a prevalent comorbidity in HF patients, has been intricately linked to inflammation, with evidence suggesting a bidirectional relationship.

Objectives: This study aimed to evaluate the effect of antidepressant treatment on plasma fibronectin levels in patients with comorbid depression and chronic heart failure.

Methods: We enrolled a total of 113 patients with HF, all of whom had comorbid depression. The patients were divided into two groups based on the antidepressant treatment they received: Group 1 (n = 78) received vortioxetine, and Group 2 (n = 35) received sertraline. Before initiating treatment and after 6 months, we measured fibronectin levels in the patients' plasma.

Results: The study revealed a significant difference in the effects of the two antidepressants on fibronectin levels. Patients treated with vortioxetine demonstrated a substantial reduction in fibronectin levels post-treatment, with an approximate threefold decrease compared to the pre-treatment levels (pre-treatment value ± standard deviation) µg/ml to (post-treatment value ± standard deviation) µg/ml, (p < 0.05). Conversely, patients treated with sertraline experienced a comparatively lesser reduction in fibronectin levels, with a change from (pre-treatment value ± standard deviation) µg/ml to (post-treatment value ± standard deviation) µg/ml (p < 0.05).

Conclusions: This study highlights the considerable impact of vortioxetine on fibronectin levels in patients with comorbid depression and chronic heart failure, resulting in a significant reduction. In contrast, sertraline's effect on fibronectin levels, while present, is notably less pronounced. The study emphasizes the potential

therapeutic benefit of vortioxetine in cardiac remodeling associated with depression in patients with chronic heart failure, underscoring the need for further research and exploration.

The psychosocial assessment of heart transplant candidates in Ireland

K. Corrigan^{1,2*}, G. Crudden^{2,3}, A. M. Clarke⁴, A. Doherty⁵, R. Duffy³ and Z. Azvee²

¹St Vincent's University Hospital; ²St. Vincent's University Hospital; ³Holles Street, The National Maternity Hospital, Dublin; ⁴Naas General Hospital, Kildare and ⁵The Mater Misericordiae Hospital, Dublin, Ireland

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.239

Introduction: We aim to describe the psychosocial features, including Stanford Integrated Psychosocial Assessment for transplantation (SIPAT) scores of individuals undergoing assessment for heart transplantation in Ireland.

Objectives: All potential heart transplant candidates undergo assessment of psychosocial criteria to enhance selection and improve transplant outcomes. The Mater Hospital Consultation Liaison Psychiatry (CLP) department provides this national service in Ireland. All potential heart transplant candidates should receive a biopsychosocial assessment and screening via SIPAT tool as per international best practice. The SIPAT is a psychosocial evaluation and risk assessment tool which can help to determine suitability for organ transplant and identify modifiable risk factors to optimise a patient for transplant. Lower scores represent higher rates of suitability with a score < 21 representing an *acceptable* candidate and ≥21 *minimally acceptable*.

Methods: We retrospectively examined the clinical files of all individuals referred to the national centre for heart transplant assessment over a five-year study period between January 2014 and December 2019.

Results: One-hundred and fifty four individuals were referred for heart transplant assessment with 79% (n=122/154) listed for a heart transplant. The most common indication for heart transplant assessment was non-ischaemic cardiomyopathy (48%, n=74/154). Of those listed for transplant, 74% (n=90/122) went on to receive a heart transplant. Of those undergoing assessment for heart transplant, 92% (142/154) were assessed by CLP and 94% (144/154) received social work assessment.

SIPAT scores were available for 64/154 individuals with 22% (14/64) deemed *excellent* candidates for transplant, 59% (38/64) deemed *good* candidates, 14% (9/64) *minimally acceptable* candidate and 5% (3/64) deemed *high risk*. The SIPAT domain breakdown was as follows: patient readiness (mean 3.9, SD 3.4); social support system (mean 2.9, SD 4.2); psychological stability (mean 5.1, SD 4.9); and substance use (mean 3.8, SD 2.4), with an average total score of 16 (SD 12.4).

Post-transplant, 26% (23/90) were referred and seen by CLP, 53% (48/90) were referred to social work and 32% (29/90) required psychology services. Seventeen individuals (19%, 17/90) received

a psychiatric diagnosis and 27% (24/90) were prescribed psychotropic medication in the post-transplant period.

Conclusions: This study describes for the first time the psychosocial factors and SIPAT scores of a national cohort of individuals referred for heart transplant. Psychiatric morbidity is high and this has implication for transplant suitability and post-operative course. This highlights the need for services to proactively identify and treat psychosocial factors in potential transplant recipients.

Involve fathers in family dynamics and in early interactions with children, in the face of cultural factors

E. Dozio^{1*} and I. Pueugueu²

¹Action contre la Faim, Paris, France and ²Action contre la Faim, Goma, Congo, The Democratic Republic of the

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.240

Introduction: In the first years of life, parents and a secure family environment are essential to the survival and development of young children.

Attention is focused on the undeniable importance of mothers' role in childcare. But it's also important to involve fathers, who are often sidelined from the responsibilities of this role, not least because of cultural factors linked to the separation of roles. In some situations, this is compounded by the psychological suffering that men may feel, without being able to admit it or express it, as a result of representations linked to masculinity.

Objectives: The aim of the intervention was to strengthen the psychosocial and parenting skills of men, while taking into account their distress. The objective was to reduce intra-family violence, to involve men more in family life and in the care of young children, and to work on cultural representations of the role and cultural dynamics within the family and the community.

Methods: Men, fathers and future fathers were recruited in the Mweso region in the Democratic Republic of Congo, following community psychoeducation. The group protocol took the form of five weekly sessions covering various themes linked to psychological distress, emotion management, psychosocial skills as well as gender roles and child development.

Results: Between 2021 and 2023, 727 men participated in the program. They showed an improvement in well-being (reduction in anger, symptoms of anxiety, depression and PTSD), better management of emotions and the acquisition of strategies to address cultural factors linked to fatherhood within the family unit and the community.

Conclusions: The use of this protocol allowed men to become more aware of the issues of psychological suffering and fatherhood linked to cultural factors by allowing them better inclusion in the family dynamic.

Comparison of PTSD prevalence between immigrants and locals with psychotic disorders

A. Trabsa Biskri^{1,2*}, A. Mané¹, R. Rodríguez¹, N. Zabaleta¹, L. Martínez^{1,2}, F. Casanovas¹, I. Ezquiaga¹, T. Legido¹, V. Pérez¹, B. Amann¹ and A. Moreno¹

¹Psychiatry, Institut de Salut Mental, Hospital del Mar and ²Programa doctorat psiquiatria i medicina legal, Universitat Autònoma de Barcelona, Barcelona, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.241

Introduction: Due to the global humanitarian crisis, there has been a significant increase in global immigration.(1) The migration process typically involves multiple trauma exposures that are sustained over time(2), which may result in an impact on the mental health of these individuals(3), such as posttraumatic stress disorder(3). A recent meta-analysis estimated that 25% of migrants had PTSD(15), which is significantly higher than the 0.2% to 3.8 percent prevalence data found for the general population(4). In addition, a number of meta-analyses indicate an increased risk of psychosis among immigrants(5). Despite this rise, there is a gap in trauma research in non-refugee immigrants, particularly those with psychotic disorders.

Objectives: To describe and compare PTSD diagnosis between immigrants and locals recruited from mental health services in Barcelona.

Methods: Patients who have presented, according to DSM-V criteria, one or more non-affective psychotic episodes, were recruited in Acute and Chronic inpatients units at Hospital del Mar (Barcelona) from November 2019 to June 2021, leading to a total sample of 199 patients.

Demographic characteristics of patients, clinical data and main pharmacological treatment were recorded through a questionnaire. Database information was completed with electronic medical records. Global Assessment of Posttraumatic Stress Questionnaire (EGEP-5) was used as an instrument to assess PTSD diagnosis, main trauma nature and PTSD symptoms. Comparative analysis was performed with IBM SPSS Statistics (Chicago INC) using Chi-Square Test for qualitative variables and t-Student test for continuous variables. Covariate adjustment with demographic and clinical variables was performed by ANOVA test. Study received local ethics committee approval "CEIC" (No. 2019/8398/I).

Results: From the total sample of 199 individuals, 98 were immigrants and 98 locals. From the total sample 39 individuals (19.69%) presented PTSD. 32.3% of the immigrants with psychotic disorders presented PTSD compared to 7.1% of the locals with psychotic disorders ($F_{1,199}=19.9$, $p=0.00$). Most traumatic events related to PTSD in immigrants were: "murder of relatives" (33.1%), Physical violence (21.9%) and Terrorism (15.6%) in locals were: "physical violence" (28.6%). Immigrants and locals with psychotic disorders showed similar averages of symptoms, except for avoidance symptoms where locals showed a mean of 5.1 compared to a mean of 3.5 in the immigrant group. Finally, immigrants showed one more functionality affected area by PTSD (5.1) when compared to locals (4) ($F_{7,199}=3.9$, $p=0.05$).

Conclusions: According to our results there are important differences in PTSD prevalence between immigrants and locals with psychotic disorders. These findings ought to be taken into

consideration for programs that are both clinically and sociopolitically tailored to improve assessment and treatment for this population.

Development and validation of the Illness Representation Interview (IRI)

D. Y. Kim*, H. Y. Shin and S. Choi

Clinical Psychology, Duksung Women's University, Seoul, Korea, Republic Of

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.242

Introduction: It has been several years since the World Health Organization (WHO) advocated for shared decision-making(-SDM) models when developing treatment plans for individuals with mental illnesses. It is emphasizing the importance of actively involving patients in expressing their opinions and sharing treatment-related information. However, few clinicians accept patients' subjective views in clinical practice. Given that patients' subjective beliefs about their symptoms significantly impact treatment satisfaction, prognosis, and adherence, it is essential to assess these perceptions. However, few studies have been conducted to assess patients' subjective beliefs, their mental representation, of their disease. Therefore, this study aims to develop Interview that enable the utilization of patients' cognitive representations of their mental illnesses in clinical practice.

Objectives: The primary objective of this study is to develop a semi-structured interview and a self-report scale to evaluate patients' mental representations of their illnesses. Subsequently, validate the reliability and validity of these tools as psychological assessments.

Methods: An initial structure for both the semi-structured interview and self-report scale was established through a literature review of existing disease representation measurements. Subsequently, expert panel discussions and further literature reviews were conducted to refine the structure and content of both tools. Content validity for both the interview and self-report scale was assessed by a panel of nine experts and a group of ten students. Following this, the developed interview tool was subjected to a validity analysis with clinical patients using Missick's six validity criteria(Content, Substantive, Structural, Generalizability, External, Consequential).

Results: Content validity index (CVI) values for the overall structure indicated that all subdomains scored above 0.8, demonstrating the appropriateness of the interview tool's five subdomains: symptoms, causes, temporal aspects, impact, and treatment and control. Content validity assessment for individual items revealed that some items within the "causes of the disease" subdomain, specifically stress-related factors, scored below 0.6, prompting necessary item modifications. All other factors achieved CVI scores of 0.6 or higher. Facial validity assessment yielded favorable results for all items in the self-report scale. All validity was demonstrated to be satisfactory.

Conclusions: This study has provided evidence that the developed tools are reliable and valid instruments for measuring patients'

perceptions of their illnesses, offering a trustworthy means to assess these vital cognitive representations in clinical practice.

Understanding the Occurrence of Psychiatric Disorders in Epilepsy in Brazil: An Epidemiological Investigation

L. Bardini Goulart^{1*}, A. Roloff Krüger², G. Moreno Xavier³, G. Fiorio Grando², J. Michelon³, L. F. Alves Nascimento³, J. Adames³, A. T. Konzen³, G. Pereira Bernd⁴, C. Fontes Augusto³, H. doi: 10.1192/j.eurpsy.2024.243

Introduction: Epilepsy is one of the most common serious brain illness, with symptoms influenced by multiple risk factors and a strong genetic predisposition, rather than having a single expression and cause¹. Neuropsychiatric symptoms in epilepsy can encompass manifestations such as mood alterations, anxiety, sleep disturbances, psychosis, and behavioral disorders. While the motor and sensory manifestations of epileptic seizures are widely recognized, neuropsychiatric symptoms accompanying epilepsy are

often underestimated. Therefore, it is essential to understand the most prevalent epidemiological profile of these patients to improve the diagnosis and management of these symptoms.

Objectives: Our goal was to evaluate the neuropsychiatric behavior of epilepsy patients in Brazilian over the past 3 years through hospitalization data in order to outline an epidemiological and behavioral profile.

Methods: A cross-sectional, descriptive, retrospective, and quantitative study was conducted on hospitalizations of individuals simultaneously diagnosed with epilepsy, schizotypal and delusional disorders, and mood disorders in all five regions of Brazil (South, Southeast, Midwest, North, and Northeast) between February 2020 and December 2022. Data from January 2020 were not available. The data used were collected through the Department of Health Informatics of the Brazilian Unified Health System (DATASUS) in the "Hospital Information System of SUS" section, gathering information regarding the nature of care, age range, gender, and ethnicity of the patients.

Results: The analysis covers the years 2020 to 2022, totaling 503,045 hospitalizations. In 2022, the highest number of cases occurred ($\approx 37.55\%$), followed by 2021 ($\approx 33.62\%$) and 2020 ($\approx 28.81\%$). Urgent hospitalizations represented $\approx 90.85\%$ of the total. The most affected age group was 30 to 39 years old ($\approx 18.30\%$). Men were more affected than women ($\approx 52.03\%$ and $\approx 47.96\%$, respectively), and Caucasians accounted for $\approx 36.07\%$ of the hospitalizations. The average length of stay was 19.1 days, and the mortality rate was 1.4%.

Conclusions: Thus, there is a gradual and annual increase in the number of hospitalizations during the observed period. While there is a minimal disparity between the affected genders, it is evident that the profile of male, caucasian, and adult patients is the most prevalent. Moreover, the predominantly urgent nature of hospitalizations points to an alarming scenario regarding this issue. From the analysis of the data obtained in the study, there is a clear need for interventions capable of reducing the prevalence of hospitalizations for neuropsychiatric symptoms in epilepsy patients in Brazil.

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.244

Introduction: Opioid Use Disorder (OUD) is a severe and recurrent condition that contributes to a global prevalence of disabilities. Accumulating evidence suggests a potential convergence of clinical and genetic factors underlying OUD.

Objectives: This study explores the clinical and genetic factors associated with OUD in the Lebanese population.

Methods: A cross-sectional study in the Lebanese population included three different groups of participants stratified according to the cut-off of the revised Opioid Risk Tool (ORT-OUD): (1) Low-risk group for OUD (n=513; general population; ORT-OUD score <2.5); (2) High-risk group for OUD (n=87; general population; ORT-OUD score ≥3); (3) a third group consisting of patients clinically diagnosed with OUD according to the DSM-5 (n=46). The survey included sociodemographic information and used validated scales to assess other substance use disorders, sleep disturbances, depression, and anxiety. Genotyping for the *COMT*, *MTHFR*, and *CRY2* genes was conducted for 91 patients using a real-time PCR (Roche®). Bivariate and multivariate analyses were conducted to identify the associations between OUD risk and sociodemographic, clinical, and genetic factors.

Results: This study enrolled 646 participants. Multivariate analysis showed significant associations between risk of developing an OUD and cigarette smoking (B=0.583), worse insomnia scores (B=0.074) and Alcohol, Smoking and Substance Involvement Screening Test-alcohol (B=0.053) scores, male gender (B=13.351), lack of education (B=4.159), unemployment (B=7.235), low income (B=11.285), lack of healthcare coverage (B=4.190), neuropsychiatric disorders (B=7.966). Conversely, OUD risk was negatively correlated with the morning chronotype (B=-0.372). Bivariate analysis showed that the *CRY2* AA genotype was significantly associated with a higher risk of OUD; nevertheless, none of the genetic factors remained significant in the multivariable model.

Conclusions: This study identified several sociodemographic, clinical, and genetic factors that could potentially increase the risk of developing OUD in the Lebanese population. Further research is needed to clarify risk factors and underlying mechanisms, enabling the development of more effective prevention strategies.

Cannabis addiction in Tunisia: sociodemographic profile and neuropsychological complications

E. Smaoui*, D. Mnif, R. Ouali, R. Sellami, I. Feki, I. Baati and J. Masmoudi

Psychiatry, CHU Hédi Chaker, Sfax, Tunisia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.245

Introduction: Cannabis consumption constitutes a public health problem both because of its serious repercussions and complications and the psychological and social problems it causes.

Objectives: Our objective was to assess the level of cannabis dependence in consumers receiving care at the Sfax detoxification center in Tunisia, to describe the sociodemographic profile of these consumers and the neuropsychological complications that may be caused.

Methods: We conducted a cross-sectional study, over a period of 13 months (September 2020 to October 2021), among cannabis users consulting the Sfax detoxification center in Tunisia. We used the Cannabis Abuse Screening Test (CAST) in order to detect a "problematic" cannabis use, along with a clinical information sheet to collect epidemiological and clinical data. All patients gave their free and informed oral consent to participate in the survey while ensuring anonymity.

Results: We included 38 patients. The average age was 26 years old with a median age of starting cannabis use at 17 years old. The sex ratio was 8.5 with an over-representation of men. Most of the subjects were single, lived with their family and had a secondary school education. Consumption was daily for the majority of patients (68.5%) with an average quantity of 4 joints/day. According to the CAST scale, 36 users (94.7%) had problematic cannabis use. The factors favouring cannabis consumption were stress and anxiety in 34 patients (89.5%) followed by depression and the festive atmosphere in 14 subjects (36.8%) each. Among the participants, 26.3% had a psychiatric history including depression (5.3%), a psychopathic personality disorder (10.5%) and cannabis-induced psychotic disorder (10.5%). History of psychiatric hospitalization and history of suicide attempt were found in 21.1% and 26.3% of the patients respectively. Concerning the complications caused by cannabis, 68.4% of the patients described a phenomenon of tolerance, while 63.2% reported the sensation of craving. Psychotic symptoms such as delirium and/or hallucinations were found in 6 patients (15.8%) and 8 subjects (21.1%) reported a history of overdose in the form of cannabis psychosis. Chronic complications were an amotivational syndrome (63.2%) and social disintegration (52.6%). Treatment of cannabis dependence was considered effective with total withdrawal in 31.6% of subjects. Weaning was partial in 42.1% of the patients.

Conclusions: Cannabis use is emerging as one among many interacting factors that can affect psychological and physical health, with an impact on various levels including mood, neurocognition and general health. Although studies have shown functional brain mechanisms underlying the effects of cannabis, the exact mechanisms remain unclear. Overall, treatment for substance use disorders generally prevents these complications and improves prognosis.

Extent of substance abuse among patients with psychiatric disorders in Amman, Jordan

L. N. Abbasi^{1*}, T. K. Daradkeh², M. ElWasify³ and S. Abassy⁴

¹Medicine, Al-Balqa Applied University, Salt; ²Psychiatry, Jordan University of Science and Technology, Irbid, Jordan; ³Psychiatry, Mansoura University, Mansoura, Egypt and ⁴Medicine, Yarmouk University, Irbid, Jordan

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.246

Introduction: The issue of substance abuse is increasingly being recognized as a significant global public health concern. In relation to its influence on the Arab world, scholarly investigation continues to be regarded as relatively constrained in scope.

Objectives: The primary goal of the present study was to investigate the extent of substance abuse in a sample of patients with psychiatric disorders who attended a psychiatric clinic in Amman and analyse this in relation to demographic and clinical variables.

Methods: In this prospective study, we investigated the prevalence, sociodemographic, and clinical characteristics of substance abuse among patients with psychiatric disorders who attended an outpatient private psychiatric clinic in Amman, Jordan between January and May 2023. Overall, 671 patients were enrolled. We compared demographic and clinical parameters of drug abuse and non-drug abuse patients.

Results: Among the 671 patients included in the study, 48.0% (n=322) reported substance use, while 52.0% (n=349) did not. The mean age of the patients was 32.45±10.18 years. The sample included 546 male patients (81.4%). Among the participants, 388 (57.8%) were single, 360 (53.7%) held a bachelor's degree or higher, 394 (58.7%) were employed, and 545 (81.2%) lived with their families. 506 (75.4%) were smokers, 110 (16.4%) reported having a medical illness, and 25% reported engaging in self-harm. The most prevalent psychiatric diagnosis was major depressive disorder, accounting for 30.6% of cases, followed by anxiety disorders. Additionally, 148 patients (22.1%) reported emotional abuse, 40 (6.0%) reported physical abuse, 57 (8.8%) reported sexual abuse, and 47 (7.0%) had a family history of substance use.

Conclusions: Our research findings indicate that substance abuse is more prevalent among certain demographic groups, specifically young, unemployed, male patients with a low level of education and a family history of substance use. These findings highlight the need for further research in diverse settings and populations to better understand the scope and underlying factors contributing to substance abuse in Arab countries. Additionally, targeted interventions and prevention strategies should be developed to address the specific needs of these high-risk groups and reduce the burden of substance abuse in these communities.

Trends in cannabis consumption: psychotic and anxiety symptoms among users

O. Martin-Santiago*, P. Martinez.Gimeno, M. Calvo-Valcarcel, C. Alario-Ruiz and B. Arribas-Simon

Hospital Clinico Universitario, Valladolid, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.247

Introduction: During cannabis use, some individuals may experience psychotic symptoms, such as unusual perceptions or irrational thoughts, including mild hallucinations or temporary paranoia. Anxiety is also common, characterized by excessive worry or intense fear. The occurrence of these symptoms varies based on cannabis quantity, individual sensitivity, and surroundings. Although not all users experience these effects, the link between cannabis and psychotic or anxiety symptoms highlights the need for a thorough risk assessment.

Objectives: Our goal is to analyze trends in cannabis use, as well as the psychotic and anxiety symptoms experienced by users, and to examine whether cannabis use is associated with other substances consumption.

Methods: We collected demographic and substance consumption data from two groups: 29 individuals aged 18 to 28 who had tried cannabis at least once and 19 regular consumers through a structured questionnaire.

Results: Regular cannabis consumers had a higher proportion of males than those who had tried it once ($X^2_{(1)}=4.81$; $p=0.028$). There were no significant differences in age, alcohol or tobacco consumption between the groups. Notably, regular cannabis consumers had a history of using other illegal drugs, both in the past and within the last month ($X^2_{(1)}=8.53$; $p=0.003$). Regarding cannabis effects, regular users more frequently reported sensations like euphoria, relaxation, altered time perception, tachycardia, motor coordination difficulties, and impaired clear thinking compared to one-time users ($X^2_{(1)}=10.12$; $p=0.001$). Regarding anxiety symptoms during cannabis consumption, both groups experienced a similar frequency. Finally, regular cannabis consumers reported strange ideas or perceptions more often than one-time users ($X^2_{(1)}=0.743$; $p=0.019$). However, the associated discomfort level was similar in both groups.

Conclusions: This study highlights that regular cannabis use is associated with a greater likelihood of using other substances and experiencing more pronounced effects, including psychotic symptoms. However, it doesn't necessarily lead to increased anxiety symptoms compared to one-time users. It's important to acknowledge that the relationship between cannabis and psychosis is intricate and influenced by factors like consumption quantity and individual sensitivity. These findings stress the importance of understanding cannabis's impact on mental health and its connection to the use of other substances.

The Potential Cardiovascular Benefits of Physical Exercise in Early Onset Psychosis and Bipolar Disorder

H. C. Bohman* and M. Lundberg

Neuroscience, Ki SÖS, Stockholm, Sweden

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.248

Introduction: Early onset psychosis (EOP) and bipolar disorder (EOBP), occurring before the age of 18, have been linked to early signs of atherosclerosis and an elevated risk of cardiovascular disease (CVD). Physical exercise is a well-established factor in reducing the risk of developing CVD. However, it remains unclear whether regular physical activity can mitigate cardiovascular risk factors and signs of atherosclerosis in individuals with EOP and EOBP.

Objectives: This study aimed to explore the impact of physical exercise on cardiovascular risk factors in these populations.

Methods: We assessed the physical exercise habits of 71 individuals, including 22 with EOP, 21 with EOBP, and 28 age-matched healthy controls. Participants' physical exercise routines were categorized as 0, 1, 2, or 3 or more times per week, with each session lasting at least 30 minutes. Our analysis included adjustments for conventional CVD confounders. Additionally, we used high-frequency ultrasound (22 MHz) to evaluate different layers of the arterial wall in the left common carotid artery (LCCA).

Results: Compared to the control group, adolescents with EOP and EOBP exhibited significantly thicker LCCA intima thickness (0.132 vs. 0.095 mm, $p<0.001$) and intima/media ratio (0.24 vs. 0.17, $p<0.001$). Remarkably, adolescents with EOP and EOBP who engaged in physical exercise three times or more weekly ($n=13$) displayed significantly less intima thickness (0.142 vs. 0.116 mm, $p<0.01$). However, we did not observe a significant association between exercise and other CVD risk factors. Even when considering factors such as the extent of antipsychotic medication use or the severity of the disorders in our regression analysis, the significant association between exercise and reduced intima thickness persisted ($p<0.05$).

Conclusions: Among adolescents with EOP or EOBP, those who engaged in physical exercise three or more times weekly exhibited less pronounced LCCA intima thickness compared to their less active counterparts, although it remained thicker than that of healthy controls. These findings, if replicated, suggest that regular physical exercise, specifically three or more times a week, could potentially offer protection against the future development of CVD in individuals with EOP and EOBP. Further research is warranted to confirm and expand upon these promising results.

Descriptive study of adolescents hospitalized in the Psychiatric Unit of a hospital in Madrid, Spain

P. Del Sol Calderon^{1*}, A. Izquierdo de la Puente¹, R. Fernández², M. García Moreno¹, L. Mallol¹ and I. Palanca¹

¹Psychiatry, Hospital Puerta de Hierro and ²Psychiatry, Hospital Universitario Infanta Cristina, Madrid, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.249

Introduction: An increase in suicidal behavior among the adolescent population is reflected in the literature and in clinical practice. According to a study of suicidal behavior and mental health by the Spanish ANAR Foundation, the number of cases with suicidal behavior has experienced an accentuated growth in the period 2012-2022 (1,921.3%), highlighting the increase produced in the post-COVID-19 period, between 2020 and 2022 (128%)

Objectives: To analyze the reasons for admission to the short hospitalization unit. To describe the sociodemographic characteristics of hospitalized adolescents.

Methods: Descriptive observational study of the sample of adolescents admitted to the inpatient psychiatric unit of the Hospital Universitario Puerta de Hierro between January 1, 2023 and June 30, 2023. It is carried out through the information obtained in the clinical history of the patients.

Results: During this period of time 113 adolescents were admitted, 80.2% were female. The mean age was 15.16 years. The main reason for admission was autolytic ideation, occurring in 33.3% of the patients. The second most frequent reason for admission was suicide attempt (29.7%) and behavioral disturbance (17.1%) was the third most frequent. Of the methods used in suicide attempts, drug overeating stands out among the methods used in suicide attempts. (75.8%), followed by attempted hanging (12.1%) or cutting (12.1%).

Image:

Reason for admission	Total		Male		Female	
	N	Percent aje (%)	N	Percent aje (%)	N	Percent aje (%)
Suicidal ideation	37	33,3	2	10	35	40,2
Suicide attempt	33	29,7	4	20	29	33,3
Behavioral disturbance	19	17,1	11	55	8	9,2
Self-aggressiveness	8	7,2	2	10	6	6,9
Eating disorders	3	2,7	0	0	3	3,4
Psychotic symptoms	2	1,8	0	0	2	2,3
Dissociative symptoms	1	0,9	1	5	0	0
Conversive symptoms	1	0,9	0	0	1	1,1

Conclusions: The results corroborate what is reported in the scientific literature, where self-harm and self-injury attempts have increased and are the most frequent reasons for admission. This

shows that suicide is a public health problem of the first order, where prevention and early intervention programs are necessary.

Sleep quality mediates the relationship between problematic social media use and attention-deficit/hyperactivity symptoms

L. R. Paulina^{1,2*}, I. Csejtei^{3,4} and M. Miklósi^{2,5,6}

¹Department of Psychiatry and Psychotherapy; ²Department of Clinical Psychology, Semmelweis University; ³Department of Media and Communication, Eötvös Loránd University; ⁴Fay Andras Foundation, OTP; ⁵Institute of Psychology, Eötvös Loránd University and ⁶Mental Health Center for Children and Adolescents, Heim Pál National Pediatric Institute, Budapest, Hungary

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.250

Introduction: Commencing in 2019, the onset of the COVID-19 pandemic prompted an upsurge in online engagement, drawing attention to the advantages and perils associated with the use of social media. Existing research emphasizes that elevated symptom levels of attention deficit/hyperactivity disorder (ADHD) are linked not to the extent (time) of usage but to its addictive nature. However, scant research has explored its relationship with sleep quality.

Objectives: In this study, we scrutinized the correlation between problematic social media usage, sleep quality, and ADHD symptoms in a non-clinical sample of young individuals during the third wave of the pandemic.

Methods: We administered an online survey to 139 participants (mean age: 21.37 years, standard deviation: 2.68 years, range: 15-27). The survey encompassed various assessments, including the Bergen Social Media Addiction Scale (BSMAS), the Athens Insomnia Scale (AIS), and the self-report version of the SWAN scale (Strengths and Weaknesses of ADHD Symptoms and Normal Behavior). Participants also reported on the extent of their social media use.

Results: Significant distinctions emerged in the extent of social media usage between online (M=3.12; SD=1.08) and in-person educational settings (M=2.47; SD=0.78) (t(73)=6.01; p<0.001; d=0.70). While ADHD symptom levels exhibited no correlation with the extent of social media engagement, they did exhibit a significant positive correlation with problematic usage (r=0.32; p<0.001). Likewise, the extent of social media usage displayed no correlation with sleep quality; however, problematic usage was linked to poorer sleep quality (r=0.27; p=0.002). In our mediation analysis, problematic usage correlated both directly (c'=-0.61; p=0.02) and indirectly (ab=-0.36; 95% CI: -0.60 - -0.10) with heightened ADHD symptoms through diminished sleep quality (F(1,120)=21.94; p<0.001; R²=0.27).

Conclusions: Our findings affirm that it is not the extent but rather the problematic nature of social media usage that assumes significance. Moreover, our results propose that problematic usage may

exacerbate ADHD symptoms, not only directly but also by influencing sleep quality.

Prevalence and predictors of Anxiety and Depression among Adolescents and Young Adults: Findings from the MoreGoodDays Support Program in Alberta, Canada

A. Belinda^{1*}, R. Shalaby¹, K. Hay², R. Pattison², E. Eboime³, M. Korthuis⁴, Y. Wei¹ and V. I. O. Agyapong^{1,3}

¹University of Alberta; ²Kickstand, Edmonton; ³Dalhousie University, Halifax and ⁴Glenrose Rehabilitation Hospital Foundation, Edmonton, Canada

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.251

Introduction: The COVID-19 pandemic has led to a rise in psychological disorders among adolescents and young adults. There is an increase in the prevalence of likely anxiety and likely depression among the subscribers of MoreGoodDays supportive text message program, reflecting the impact of the COVID-19 pandemic on this cohort.

Objectives: To assess the prevalence, severity, and correlates of likely generalized anxiety disorder (GAD) and likely major depressive disorder (MDD) among subscribers of MoreGoodDays program.

Methods: This study used a cross-sectional design. An online survey questionnaire was used to collect sociodemographic and clinical information from subscribers of MoreGoodDays program, a daily supportive text message program co-designed with adolescents and young adults for their peers in Alberta. Validated instruments, the Generalized Anxiety Disorder GAD-7 and Patient Health Questionnaire-9 PHQ-9 were used to collect information on likely GAD and likely major depressive disorder (MDD), respectively. Data was analyzed with SPSS version 25 using chi-squared tests and binary logistic regression analysis.

Results: 343 subscribers of MoreGoodDays participated in the survey. Overall, 117 (56.0%) respondents had a likely MDD and 97 (46.6%) had a likely GAD. Participants who would like to receive mental health counselling were 27 times more likely to experience GAD (OR = 27; 95% CI: 3.09–250.00) and 40 times more likely to experience MDD (OR = 40.03; 95% CI: 4.43–361.51) than those who did not. Respondents who had received mental health counselling in the past were 18.5 times more likely to experience MDD compared with those who had not (OR = 18.52; 95% CI: 1.55–200.00). Demographic variables, including age, education, employment, and relationship status, and clinical variables, such as history of anxiety, depression, obsessive-compulsive disorder, ADHD, and adverse childhood experience, did not independently predict presence of likely GAD or MDD in subscribers of MoreGoodDays.

Conclusions: The prevalence of anxiety and depression was relatively high among subscribers of MoreGoodDays, indicating the

long-term effect of the COVID-19 pandemic. This finding has significant implications in the broader context of mental health research and emphasizes the need for more research into innovative mental health support for this cohort. The desire to receive counselling was predictive of both anxiety and depression and is a positive sign of the openness of this cohort to receive psychological intervention. Since this group is mostly adapted to mobile text technology, government agencies and policymakers should prioritize and implement readily accessible interventions such as supportive text messages to support their psychological well-being.

The effect of prophylactic esketamine in labor and cesarian delivery on the prevention of postpartum depression (PPD): A systematic review and meta-analysis of randomized controlled trials

A. Kozhokar Mikhaylovskaya^{1*} and A. Q. Shimit²

¹Department of Medicine, Universitat Internacional de Catalunya, Sant Cugat del Vallès, Spain and ²Department of Medicine, Pontifical Catholic University of Poços de Caldas, Poços de Caldas, Brazil

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.252

Introduction: Postpartum depression (PPD) is a common psychiatric illness affecting maternal health, which can lead to poor outcomes for the infant, mother and family. Since the usual pharmacological treatment has low efficacy and a delayed onset of action, new treatment options should be explored. A recent meta-analysis demonstrated positive effects of racemic ketamine on PPD, but limited evidence is available on its more potent derivative esketamine.

Objectives: To determine the effect of esketamine administered prophylactically during labor on the risk of incidence of PPD at 1 week and 6 weeks after delivery.

Methods: PubMed, Scopus and GoogleScholar databases were searched for randomized controlled trials that studied the efficacy of esketamine that screened for PPD using the Edinburgh Postpartum Depression Scale (EPDS). Risk ratio was used to determine the effect of incidence on PPD. Heterogeneity was examined with I2 statistics. A random-effects model was used, as per moderate heterogeneity (I2=59%, p-value<0.05).

Results: We included 7 RCTs with 1287 patients, 635 having received esketamine (49.3%). Patient-controlled intravenous analgesia (PCIA) or single intravenous dose during the delivery or cesarian section were the main drug delivery methods. Follow-up ranged from 4 weeks to 6 months, and EPDS cut-off scores for depression risk differed between studies, from 9 to 13 points. Dosages varied from 0.2mg/kg to 0.5mg/kg for single-dose administration and 0.1mg/kg to 1.25mg/kg for PCIA. Incidence of PPD at one week (RR: 0.459 95%CI 0.217-0.970; p<0.05; figure 1A) and at 6 weeks (RR: 0.470 95%CI 0.273-0.810; p<0.01; figure 1B) was significantly less common in patients who received esketamine during or after labor. Risk of bias was low in 5 studies and moderate in 2 studies. Risk of publication bias is significant.

Image:

Figure 1A. Incidence of PPD was significantly reduced in puerperae receiving esketamine 1 week after delivery.

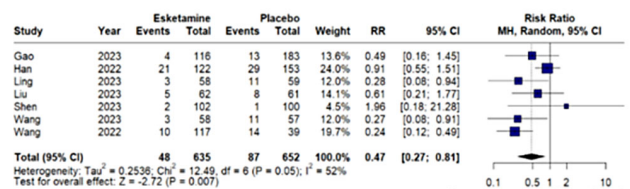

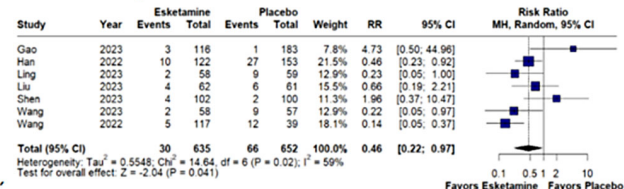

Figure 1B. Incidence of PPD was significantly reduced in puerperae receiving esketamine 6 weeks after delivery.

Conclusions: Prophylactic esketamine seems to improve EPDS scores in women at one and six weeks after birth. A more thorough analysis of the adverse effects on maternal and neonatal health are required, and long-term benefits are not fully understood. Larger multicenter studies would be a welcome addition to the issue at hand.

doi: 10.1192/j.eurpsy.2024.253

Introduction: Spravato® (esketamine nasal spray- ENS) is a new adjunctive drug for Treatment Resistant Depression (TRD), i.e. patients with major depressive disorder that failed to adequately respond despite the use of two different antidepressants. In France, a real world non-interventional post-commercialization cohort study is being conducted aiming to describe the conditions of use of the esketamine, and to observe the outcomes.

Objectives: To in-depth explore the lived experience of first administered ENS treatment among adults with TRD, we are conducting an ancillary qualitative study.

Methods: This qualitative study uses the IPSE approach (Sibeoni et al. *BMC Medical Research Methodology* 20.1(2020):1-21) and has been conducted in four French psychiatric departments. Design was based on the recruitment of patients through the Cohort study, all interviewed twice, the first time 3 to 5 weeks after the first administration of ENS, and the second time around 6 months after, whether treatment has been continued or not. Data analysis follows the IPSE analytic procedure and is conducted in two stages: three individual researchers carry out independent work and the group collectively pools data. These preliminary results are based on the sole analysis of the first interviews conducted from July 2022 to July 2023.

Results: Eighteen participants with moderate to severe TRD, including 13 women, were interviewed and two axes of experience have been produced: (1) the overwhelming experiences of the treatment, perceived differently depending on patients, as a dissociative experience, both inside – described as a *trip*- and outside of them; (2) A discordant treatment experience with both solitude and relational support from medical team.

Conclusions: These results highlight the need to better prepare the patients for the initiation of the treatment and to take into consideration the settings in which the treatment is administered, as well as the importance of the support received from the nursing staff.

The DiSCoVeR trial – Mid-study look at post-training patient motivation for an innovative treatment approach

L. Rubene^{1,2*}, L. Konošonoka¹, A. Stürmane^{1,2}, E. Dechantsreiter³, F. Padberg³, D. Bavelier⁴, F. Hummel⁵, O. Bonne⁶, Y. Benjamini⁷, M. Nahum⁸ and E. Rancāns^{1,2}

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.254

Introduction: The DiSCoVeR Project: 'Examining the synergistic effects of a cognitive control videogame and a self-administered non-invasive brain stimulation on alleviating depression' is a double-blind, sham controlled, randomized controlled trial

investigating the feasibility and efficacy of an innovative, self-applied treatment approach for patients diagnosed with major depressive disorder. The trial is conducted at three clinical trial sites (Hadassah, Israel; Riga Stradiņš University, Latvia; Ludwig-Maximilian-University, Germany). The treatment approach combines prefrontal transcranial direct current stimulation with a videogame designed to enhance cognitive and emotional control. This treatment is self-applied at home and remotely monitored. At the beginning of the intervention the patients are randomized in an active group receiving both active stimulation and videogame and the other group receiving sham stimulation and visually similar but not active videogame.

Objectives: The present interim analysis after half of the patients included examines patients' intrinsic motivation after completing the first five sessions (of 30) of the treatment. We also examine patients' interest/enjoyment, perceived competence, effort, felt pressure/tension, and perceived choice following the first week of treatment. Intrinsic motivation has been associated with enhanced learning and performance, so it can be used as one of the predictors for patient compliance.

Methods: At the end of the 5th session, the patients filled in the Intrinsic Motivation Inventory (IMI) including the following subscales: interest/enjoyment, perceived choice, perceived competence, effort/importance and felt pressure/tension (scored on a 7-point Likert scale, ranging from 1 "not at all true" to 7 "very true").

Results: This report includes the first 55 patients randomized (27 patients in the active group and 28 patients in placebo group) for the DiSCoVeR trial. Patients rated their overall interest/enjoyment at 4.50 out of 7 (SD±0.17 95% CI 4.16 to 4.84), their perceived choice at 5.55 (SD±0.16; 95% CI 5.23 to 5.87), their perceived competence at 4.52 (SD±0.15; 95%CI 4.22 to 4.82), their effort/importance at 5.07 (SD±0.16; 95%CI 4.74 to 5.40) and their pressure/tension at 3.00 (SD±0.13; 95% CI 2.73 to 3.26).

Conclusions: We conclude that overall patients were quite interested in the treatment and had inherent pleasure while doing the sessions, felt that it was their choice to do them, felt that they performed the task quite effectively, were invested in doing the sessions and the experienced pressure and tension were low. The perceived choice and competence are positive predictors of intrinsic motivation. This aligns with the previous published data of a smaller patient subset (L. Konosonoka et al *Medicina* (Kaunas) 2022;58(Supplement 1):72) with the standard deviations being smaller in our larger patient sample.

Clinical suitability of intranasal delivery of M2 macrophage soluble factors in patients with post-COVID olfactory disorders

E. Markova^{1,*}, E. Shevela¹, M. Davydova¹, I. Meledina¹, A. Ostanin¹, V. Kozlov¹ and E. Chernykh¹

¹State Research Institute of Fundamental and Clinical Immunology, Novosibirsk, Russian Federation

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.255

Introduction: SARS-CoV virus showed transneuronal penetration through the olfactory bulb resulting in the rapid intracranial spread. So, olfactory dysfunction is an early marker of COVID-19 infection. However, individuals may develop chronic olfactory impairment for more than six months in 1–10% of cases.

Objectives: The study's objective was to evaluate the efficacy and safety of intranasal immunotherapy using bioactive substances produced by M2 macrophages for the treatment of people with long-term post-COVID-19 hyposmia.

Methods: Seven individuals with long-term persistent hyposmia (7 to 24 months), associated with PCR-confirmed coronavirus infection were evaluated for olfactory function at baseline, one, and six to twelve months after therapy.

Results: The intranasal inhalation of M2 macrophage conditioned medium (one time per day for 28-30 days) was well tolerated. Furthermore, olfactometry demonstrated that the patients restored their capacity to perceive (Kruskal-Wallis H test 14.123, $p = 0.0009$) and recognize odors ($H = 11.674$, $p = 0.0029$). In addition, the subjective evaluation of smell significantly improved ($H = 11.935$, $p = 0.0026$). At the 6- to 12-month follow-up, the majority of patients (5/7) reported extremely high levels of satisfaction with the outcomes, and the remaining two patients also felt generally positive about the therapy's success.

Conclusions: Overall, our study showed that the use of intranasal inhalations as a method of delivering bioactive factors and the conditioned medium of M2 macrophages as a therapeutic agent are both safe, well tolerated and, according to preliminary data, clinically effective in the treatment of patients with long-term post-COVID-19 hyposmia.

Identifying predictors of resilient coping in students during COVID-19 lockdown

C. Laranjeira^{1,2,*}, A. I. Querido^{1,2} and M. A. Dixe^{1,2}

¹School of Health Sciences and ²ciTechCare, Polytechnic University of Leiria, Leiria, Portugal

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.256

Introduction: Although increasing resilient coping throughout life is beneficial, it is particularly important in young people. To prevent the development of mental health problems, it is crucial to understand the factors associated with resilience. However, among university students, the characteristics considered conducive to resiliency have not been sufficiently studied, particularly during pandemic times.

Objectives: The present study examined factors associated with resilient coping in Portuguese higher education students during the COVID-19 pandemic.

Methods: Data were collected from an opportunity large sample of participants during the academic year 2020/2021. Four self-report measures were utilized within the study: Herth Hope Index, Brief Resilient Coping Scale, Depression Anxiety and Stress Scale – 21 items, and Impact of Event Scale-Revised. Additionally, a demographic questionnaire was used to collect data including age, gender, have children, education level, and study area. Ethics clearance was obtained. In order to test the research question, a multiple

regression was conducted (using SPSS 28), with resilient coping as the dependent variable and the other variables entered as potential predictor variables.

Results: A total of 1522 students (75.1% women and 24.9% men) took part in this study. Most participants were single (91.2%), had no children (93%), and the ages ranged from 18 to 59, with a mean age of 22.88 ± 6.93 years. In terms of study level, the majority of students (73.7%) are at the undergraduate level and are not working (76.6%). Among the participants, 35.7%, 36.2%, and 28.5% had symptoms of stress, anxiety, and depression above the normal range, respectively. High resilience scores were found in 215 participants (14.1%). The mean hope (HHI) was 35.53 (SD = 5.92). Our results also demonstrated that hope is the only predictor of resilient coping ($p < 0.001$). A higher level of hope is expected to affect people's psychological adjustment by influencing both their appraisal of, and their coping with, the stressors confronted by them.

Conclusions: Establishing and improving protective factors should increase the likelihood of the individual successfully avoiding negative outcomes and increase their ability to function normally, thus promoting resilient outcomes. We were able to draw practical implications for developing resilience-promoting methods in a university context. These results can be used to help students build resilience by preparing for future problems.

Role of L-Arginine supplementation in Long Covid-related Fatigue and Depression in Elderly Outpatients

G. Moniello¹, I. Bonfitto², F. Simonetti³, S. Dimalta^{2*}, M. R. Rizzo³ and A. Bellomo⁴

¹Department of Geriatric Medicine and Gerontology, ASL CE, Caserta;

²Department of Mental Health, ASL FG, Foggia; ³Department of Geriatric and Internal Medicine, AOU Luigi Vanvitelli, Caserta and

⁴Department of Clinical and Experimental Medicine, University of Foggia, Foggia, Italy

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.257

Introduction: Chronic fatigue and psychiatric manifestations (depression, anxiety and sleep disturbances) appear to be key features of post-COVID-19 syndrome and increase significantly in prevalence over time (Lavienraj et al. J Neurol Sci 2022;434:120162). Several studies have suggested an association between altered levels of arginine metabolites and depression, anxiety and stress severity (Arisoy et al. J Psychiatr Res 2020;120:21-28). L-arginine supplementation has also been shown to improve walking performance, muscle strength, endothelial function and fatigue in adults with Long COVID (Tosato et al. Nutrients 2022;14(23):4984).

Objectives: To study effects of L-arginine oral supplementation on chronic fatigue and depressive symptoms reported 3 months or more after acute COVID-19 onset in elderly outpatients without severe comorbid conditions.

Methods: This is a parallel-group, double-blind, randomized controlled trial conducted on 96 over 65 non-hospitalized patients suffering from Long Covid-related fatigue and depression. The first

group included patients that received 1,66 g L-arginine twice a day in addition to a standard antidepressant therapy based on Selective Serotonin Reuptake Inhibitors (SSRIs), whereas the second group received antidepressant only. Severity of fatigue and depressive symptoms was evaluated at baseline and after 8 weeks of treatment using Fatigue Symptom Inventory (FSI) and Hamilton Rating Scale for Depression (HAM-D), respectively.

Results: At baseline, 64 patients (66,7%) reported moderate fatigue (4-6) and the remaining 32 (33,3%) reported severe fatigue (7-10). In this phase the average HAM-D score was $12,85 \pm 5,97$; among patients, 57,3% experienced mild symptoms of depression, 32,3% experienced moderate symptoms and 6,4% experienced severe symptoms. After two months, patients treated with L-arginine supplementation exhibited a 30% greater improvement in fatigue-related symptom severity ($p=0.008$) and a significantly decrease in average HAM-D score ($p=0.002$) compared to the group treated with SSRI only.

Conclusions: According to our results, adding oral L-arginine to standard antidepressant therapy in elders with Long Covid-related fatigue and depression significantly decreases severity of both physical and affective symptoms. Further studies are needed to clarify the intriguing role of L-arginine in the treatment of Post Covid-19 syndrome and its potential effects in promoting geriatric patients' health, wellbeing and quality of life.

COVID-19 Infection and Medicines in Pregnancy in Canada

A. Berard^{1*}, O. Sheehy¹, P. Kaul², S. Eltonsy³, M. Walker⁴, S. Hawken⁴, S. Bernatsky⁵, M. Pugliese⁶, O. Barrett⁷, A. Savu² and R. Dragan⁸

¹Research Centre, CHU Sainte-Justine, Montreal; ²Faculty of Medicine & Dentistry, University of Alberta, Edmonton; ³College of Pharmacy, University of Manitoba, Winnipeg; ⁴Ottawa Hospital Research Institute, Ottawa; ⁵Department of Epidemiology, Biostatistics and Occupational Health, McGill University, Montreal; ⁶Department of Epidemiology and Community Medicine, University of Ottawa, Ottawa; ⁷Alberta Health Services, Edmonton and ⁸Manitoba Centre for Health Policy, University of Manitoba, Winnipeg, Canada

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.258

Introduction: Although over 100 million pregnant women worldwide are at risk of infection with SARS-CoV-2, little data exists on the impact of COVID-19 and related treatments on maternal/neonatal health.

Objectives: 1) To quantify the prevalence of medication use in pregnancy to treat COVID-19; 2) To quantify and compare the risk of adverse pregnancy/neonatal outcomes in those with and without COVID-19.

Methods: In the Canadian Mother-Child population-based cohort (CAMCCO), two key sub-cohorts were identified using prospective data collection of medical services, prescription drugs, hospitalization archives data, and COVID-19 surveillance testing program (02/28/2020-2021). The first cohort included all pregnant women with at least one completed trimester of pregnancy during the study

period regardless of pregnancy status (delivery, induced/planned or spontaneous abortion); this cohort was further stratified on COVID-19 status. The second cohort included all non-pregnant women (aged 15-45) with a positive COVID-19 test. COVID-19 infection in pregnant or non-pregnant women was assessed using COVID-19 test results or ICD-10CM code U07.1 from hospital data. COVID-19 severity was categorized based on hospital admission. Women were considered exposed to COVID-19 medications if they filled at least one prescription for a medicine included in the WHO list in the 30 days pre- or 30 days post-COVID-19 positive test/diagnosis. Considering potential confounders, association between COVID-19 during pregnancy, treated vs not, and perinatal outcomes were quantified using log-binomial regression models.

Results: 150,345 pregnant women (3,464 (2.3%) had COVID-19), and 112,073 non-pregnant women with COVID-19 diagnoses were included. Pregnant women with COVID-19 were more likely to have severe infections compared to non-pregnant women with COVID-19 (11.4% vs 1.6%, $p < 0.001$). The most frequent medications used in pregnancy to treat COVID-19 were antibacterials (13.96%), psychoanaleptics (7.35%), and medicines for obstructive airway disease (3.20%). In pregnancy COVID-19 was associated with spontaneous abortions (adjRR 1.76, 95%CI 1.3, 2.25), gestational diabetes (adjRR 1.52, 95%CI 1.18, 1.97), prematurity (adjRR 1.30, 95%CI 1.01, 1.67), NICU admissions (adjRR 1.32, 95%CI 1.10, 1.59); COVID-19 severity was increasing these risks but COVID-19 treatment with study medications reduced all risks.

Conclusions: Severity of COVID-19 was greater in pregnancy. Antibacterials, psychoanaleptics, and medicines for obstructive airway disease were the most used overall. Severe COVID-19 in pregnancy was associated with higher risks of adverse maternal, and neonatal outcomes.

Impact Of Emotion Dysregulation On Eating Behavior Among The Tunisian General Population

A. Hadj Ali^{1*}, M. Turki¹, A. Zribi¹, N. Halouani¹, S. Ellouze¹ and J. Aloulou¹

¹Psychiatry “B” department, Hedi Chaker University Hospital, Sfax, Tunisia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.259

Introduction: Previous theoretical models and reviews have documented a strong connection between emotion dysregulation and eating disorders (ED) psychopathology among the general and clinical populations.

Objectives: We aimed to assess the link between emotional dysregulation and ED in the Tunisian general population.

Methods: We conducted a cross-sectional, descriptive and analytical study among Facebook group members, using an online questionnaire, over the period from February 17, 2023 to May 26, 2023. Emotional dysregulation was assessed via the “Difficulties in Emotion Regulation Scale” (DERS), which is composed of six sub-scores: “Non-acceptance” (N), “Strategies” (S), “Impulse” (I), “Goal” (G),

“Clarity” (C) and “Awareness” (A). The Eating Attitude Test (EAT-26) was used to assess the risk of developing ED.

Results: A total of 528 responses were included. The mean EAT-26 score was 12.36 ± 10.34 ; and 12.3% of our population were at high risk of developing an ED. The mean N, S, I, B, Cl, C and overall DERS scores were 7.78; 8.24; 7.08; 9.57; 6.46; 7.61 and 46.74, respectively.

We showed that the EAT-26 score was correlated with the overall DERS score ($r=0.260$; $p<0.001$) as well as with the N ($r=0.208$; $p=0.002$), S ($r=0.228$; $p<0.001$), I ($r=0.212$; $p=0.025$), B ($r=0.198$; $p<0.001$), C ($r=0.122$; $p=0.005$) and Cl ($r=0.136$; $p=0.002$) scores.

Conclusions: Our study showed that participants with a high risk of developing an ED seem to have more difficulties with emotional regulation. Thus, our findings call for interventions that target emotion regulation in the treatment of ED.

The Zen Garden Virtual Reality App for eating disorders: description and preliminary results

D. Gravina^{1,2*}, S. Kirupakaran^{3,4}, M. Badr⁵, A. Meaburn⁵, M. Kresojevic^{3,4}, L. Dell’Osso², J. Treasure^{1,5} and H. Himmerich^{1,5}

¹Institute of Psychiatry, Psychology and Neuroscience, King’s College London, Centre for Research in Eating and Weight Disorders, London, United Kingdom; ²University of Pisa, Department of Clinical and Experimental Medicine, Pisa, Italy; ³Digital Innovation and Technology Services, South London and Maudsley NHS Foundation Trust; ⁴Maudsley Digital Lab and ⁵Bethlem Royal Hospital, South London and Maudsley NHS Foundation Trust, London, United Kingdom

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.260

Introduction: Virtual Reality (VR) represents an emerging and promising tool to enhance standard care for patients with eating disorders (EDs). Indeed, VR provides an immersive and interactive experience in a safe and controlled environment that can simulate real-life situations, showing encouraging findings on various components of psychological treatments such as exposure therapy, psychoeducation, and emotional regulation.

Objectives: This study aims to evaluate the Zen Garden VR App in patients with anorexia nervosa (AN) in order to obtain pilot data regarding changes in mood, relaxation, anger, anxiety, and weight and shape concerns. A secondary aim was to receive feedback from participants about the VR experience, its components, and its possible application for people with AN.

Methods: Self-reported baseline and post-intervention data were collected from a sample of six female inpatients with AN recruited at the Eating Disorders Service at the Bethlem Royal Hospital of the South London and Maudsley NHS Foundation trust (SLaM). The technology used during the VR session consisted of an Oculus head-mounted display headset and two controllers which provided continuous rotational and positional tracking (Figures 1, 2 and 3).

Results: Findings showed a global improvement after the VR Zen Garden App session, mainly in reducing levels of anxiety (Cohen’s $d=1.07$) and promoting relaxation (Cohen’s $d=0.95$), with possible applications especially before and after meals when food fears are at

their highest. In addition, the music that was played during the intervention had a particularly positive effect.

Image:

Image 2:

Image 3:

Conclusions: Despite limitations, such as the small sample size and the one time point measurement, positive clinical implications have been highlighted for the Zen Garden VR App in patients with AN, although further studies are needed to confirm these preliminary findings. It is possible that VR could usefully augment and personalize care for people with an EDs. A range of interventions might be used to target the most compromised symptoms such as designing interventions that can help with triggers to eating disorder psychopathology.

EPP0023

Comparative Analysis of Impulsivity Profiles in Children and Young Patients with Anorexia Nervosa Restrictive Type, Anorexia Nervosa Binge Eating/Purging Type, Bulimia Nervosa, and Binge Eating Disorder

M. D. M. Arango^{1*} and E. Montasell²

¹Psychiatry and ²Neuropsychology, ITA Clinic, Barcelona, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.261

Introduction: High levels of impulsivity are associated with individuals suffering from eating disorders. Impulsivity is a complex and multidimensional construct, with elevated impulsivity traits posing a specific risk in relation to binge-eating and purging disorders when compared to restrictive types eating disorders.

Objectives: Our aim was to identify the difference in impulsivity profile in children and young patients with eating disorders, including anorexia nervosa restrictive type (ANR), anorexia nervosa binge eating/purging type (ANP), bulimia nervosa (BN) and binge-eating disorder (BED).

Methods: Patients aged 21 years or younger, meeting the DSM-V criteria for ANR (n=125), ANP (n=48), BN (n=38), and BED (n=37) were enrolled in the study. The participants had an average age of 16.3 ± 2.15 years. Data collection involved the administration of the UPPS Impulsiveness Scale (UPPS). Bilateral Student's t-tests were conducted to evaluate potential statistically significant differences among the diagnostic groups.

Results: Our results indicated statistically significant differences in total impulsivity between patients diagnosed with ANR and each of the other eating disorders including ANP (T-Stud $-2.19 p < .02$), BN (T-Stud $-2.17 p < .03$), and BED (T-Stud $-2.68 p < .008$) (Figure 1). However, no significant differences were observed among the other eating disorder groups. Nevertheless, it is noteworthy that heightened impulsivity traits, particularly sensation-seeking tendencies, were a common feature among all subtypes of eating disorders, regardless of their specific diagnostic category. Impulsivity and age also exhibited a statistically significant negative correlation ($r = -0.13, p = .03$) (Figure 2).

Image:

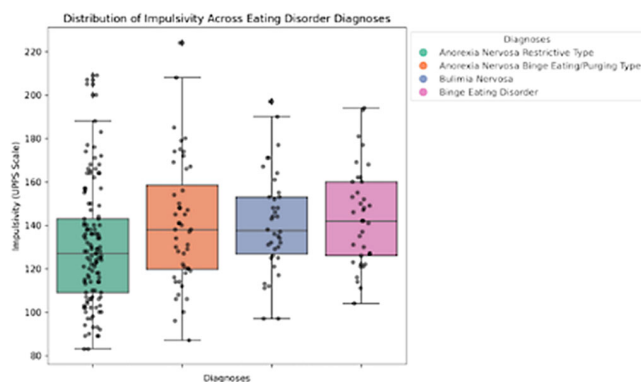

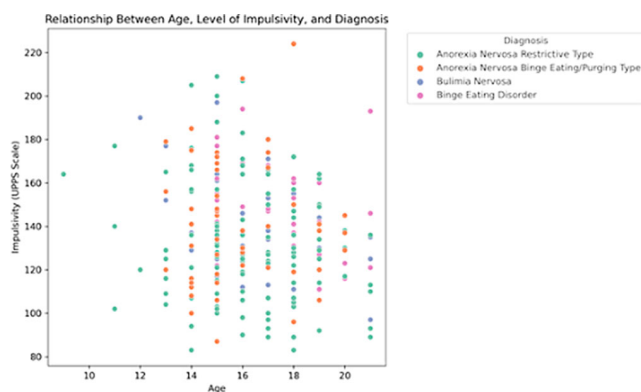

Image 2:

Conclusions: Impulsivity in individuals with restrictive and binge/purgative eating disorders differ significantly, with lower levels of impulsivity in ANR (Figure 1), except for sensation-seeking tendencies. This suggests that both groups may share a similar inclination for seeking intense emotions or engaging in emotionally arousing behaviors. As individuals age from adolescence to young adulthood, there is a tendency for impulsivity levels to decrease (Figure 2).

Comparing DSM-5 pathological personality traits in eating disorder patients and healthy control subjects using PID-5: results of a pilot study

J. Biliczki^{1*}, J. Bognár², D. B. Pólya³, S. Somogyi⁴, S. Sutori⁵, X. Gonda⁴, S. Hamvas⁴ and J. Réthelyi⁴

¹Clinical Psychology; ²Pediatrics; ³Semmelweis University, Budapest, Hungary; ⁴Psychiatry and Psychotherapy and ⁵Pharmacodynamics, Semmelweis University, Budapest, Hungary

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.262

Introduction: The presence of eating disorders is often associated with serious physical complications, self-destruction, and suicidal tendencies. Furthermore, eating disorders may often present as a symptom of or in comorbidity with personality disorders. In order to treat eating disorder patients successfully we need a more complex and individual approach taking into consideration the specific personality dysfunctions and traits present in the patient underlying symptomatic manifestations. Recently a paradigm shift in conceptualisation of personality disorders led to the introduction of a dimensional concept focusing on severity of dysfunction in both ICD-11 and DSM-5 in its Alternative Model for Personality Disorders (AMPD). In addition, DSM-5 as part of AMPD also considers the presence of 5 domains of pathological personality traits including 25 facets. This more complex mapping of personality could aid understanding personality contributors to psychopathology not only in personality disorders and could aid treatment by providing targets for psychotherapy.

Objectives: Our aim was to compare pathological personality traits according to DSM-5 AMPD in eating disorder patients, and matched healthy control subjects.

Methods: We are launching a large project focusing on personality disorders. For this analysis we used the adult form of PID-5 to assess pathological personality traits along 5 domains and 25 facets in eating disorder patients and psychiatrically healthy controls. Data were analyzed with the Mann-Whitney test using R.

Results: Preliminary results of a pilot analysis in 14 eating disorder patients and matched psychiatrically health controls are shown. Comparing the data of the two groups, a significant difference was observed in several personality facets, including Anxiousness, Deceitfulness, Grandiosity, Impulsivity, Manipulativeness, Perceptual dysregulation, Rigid perfectionism, Submissiveness, and Unusual beliefs. These differences in the above facets reflect differences in the two groups in all pathological personality domains including Anhedonia, Negative affect, Antagonism, Disinhibition, and Psychoticism.

Conclusions: Our results show complex differences between eating disorder patients and healthy control subjects in several facets, pointing to a unique pattern and the affectedness of all pathological personality domains. Such results could possibly add to identifying personality trait targets for psychotherapy in eating disorders besides increasing our understanding on the etiopsychopathology of this serious psychiatric illness. Our study is ongoing, but more complex analyses involving further measures and variables in larger samples bring the hope for increasing effectiveness of treatment for anorexia.

Validity and reliability of the Eating Disorder Examination-Questionnaire-7 Portuguese version in the perinatal period

A. T. Pereira¹, R. Lima², D. Pereira¹, J. M. Pinto¹, B. Barbosa², A. I. Araújo¹, C. Marques¹, A. Macedo¹ and C. Pinto Gouveia^{1*}

¹Institute of Psychological Medicine and ²Faculty of Medicine, University of Coimbra, Coimbra, Portugal

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.263

Introduction: The EDE-Q-7 Portuguese version presented good reliability and validity in Portuguese women from the general population (Pereira et al. 2022).

Objectives: The aim of our study was to analyse the psychometric properties of the EDE-Q-7 in a sample of Portuguese women during the perinatal period.

Methods: Participants were 346 women with a mean age of 31.68 of years old (± 4.061 ; range: 18-42). 160 were pregnant (second or third trimester) and 186 were in the post-partum (mean baby's age=4.37 months (± 2.87 ; range: 1-12). They answered an online survey including the Portuguese version of the EDE-Q-7 and of the Screen for Disordered Eating/SDE.

Results: Confirmatory factor analysis (CFA) presented adequate fit, in pregnancy (χ^2/df =; RMSEA=, $p<.001$; CFI=; TLI=; GFI=), postpartum (χ^2/df =; RMSEA=, $p<.001$; CFI=; TLI=; GFI=) and considering both – perinatal period (χ^2/df =2.7998; RMSEA=.0722, $p<.001$; CFI=.9709; TLI=.9444; GFI=.9761). The Cronbach's alpha coefficients were >0.90 for the total and approximately .70 for the three factors - Dietary restraint, Shape/weight overvaluation and Body dissatisfaction. All the items contributed to the internal consistency and presented high internal consistency. Pearson correlations between factors and total scores were significant, positive and high, as well as between the EDE-Q-7 measures and SDE ($>.60$ with the total; $>.40$ with the factors), in pregnancy, postpartum and considering both periods.

Conclusions: Presented sound psychometric properties across the perinatal period, the EDE-Q-7 and can be very useful to evaluate the presence and severity of eating disorders symptoms in women in pregnancy and post-partum.

Stigma towards mental health disorders - Has anything changed?

M. Subramaniam^{1*}, S. Shahwan¹, E. Abdin¹, Y. B. Tan¹, S. Gunasekaran¹, B. Lim¹, B. Tan¹, S. Shafie¹, G. Schomerus² and S. A. Chong¹

¹Research, Institute of Mental Health, Singapore, Singapore and

²University of Leipzig Medical Center, Leipzig, Germany

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.264

Introduction: Stigma towards mental disorders has been shown to be a major obstacle to recovery and quality of life among people with psychiatric disorders. Despite significant advances in the treatment of mental disorders, stigma remains concerning to patients, caregivers, and healthcare professionals. Singapore is a city state in South-East Asia with a multi-ethnic population. A nation-wide campaign launched in 2018, Beyond the Label, focusing on addressing stigma and promoting social inclusion for persons with mental health conditions.

Objectives: The aims of the current study were to (i) establish the dimensions of stigma and examine its correlates in the general population of Singapore using a vignette approach, and (ii) examine whether there was any change in stigma levels from 2016 to 2023.

Methods: Data for the current study comes from an ongoing nation-wide, cross-sectional study of mental health literacy conducted in Singapore since September 2022. The study population comprises Singapore Residents aged 18–65 years who are currently living in Singapore. Respondents were randomly assigned and presented a vignette describing one of seven specific disorders: alcohol abuse, dementia, depression, depression with suicidality, gambling disorder, obsessive-compulsive disorder, and schizophrenia. Stigma was assessed using Personal and Perceived scales of the Depression Stigma Scale (DSS) (Griffiths et al. Br J Psychiatry; 2004 185 342–349), and the Social Distance scale (SDS) (Link et al. Am J Public Health 1999; 89 1328–1333).

Results: 2500 respondents who completed the survey were included in the current analysis. The mean age of the respondents was 42.8 years. A three-factor model comprising 'weak-not-sick', 'dangerous/undesirable', and 'social distance' provided acceptable fit. Multivariable linear regression analyses revealed that younger age, female gender, students, and dementia vignette were significantly associated with lower weak-not-sick scores while Malay and Indian ethnicity, lower education, and alcohol abuse and gambling disorder vignette were significantly associated with higher weak-not-sick scores. Those of Malay and Indian ethnicities and those with a family member or close friend who had problems similar to the person in the vignette were significantly associated with lower social distance scores.

A significant decrease ($p < 0.001$) in all three factor scores was observed from 2016 to 2023 (Table 1).

Table 1. Mean stigma scores over time

	2016	2023
Factors	Mean (SD)	Mean (SD)
Weak-not-sick	10.2 (2.1)	9.5 (2.3)
Dangerous/undesirable	11.6 (2.8)	11.2 (2.7)
Social distance	12.0 (3.1)	11.6 (3.0)

Conclusions: Our study found a significant decrease in stigma from 2016 to 2023 in the Singapore population which indicates the positive impact of anti-stigma initiatives in Singapore. Interventions must be co-developed with males, older adults, and those with a lower education to further reduce stigma in this multi-ethnic population.

Epidemiology of a psychiatric day hospital service in rome: descriptive analysis of a two-year period of hospitalizations

A. Moschillo^{1*}, C. Zocchi¹, M. Pompili² and G. Manfredi²

¹Departments of Neurosciences, Mental Health and Sensory organs, Faculty of Medicine and Psychology, Suicide Prevention Centre, Sant'Andrea Hospital, Sapienza University of Rome and ²Faculty of Medicine and Psychology, Suicide Prevention Centre, Sant'Andrea Hospital, Sapienza University of Rome, Psychiatry Unit, Psychiatry Residency Training Program, Rome, Italy

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.265

Introduction: Psychiatric Day Hospital (DH) constitutes an area of semiresidential care for short- and medium-term diagnostic and therapeutic-rehabilitative services. Through a descriptive analysis, we analyzed the clinical rationale and expected goals leading to an admission to the psychiatric day hospital service at St. Andrew's Hospital in Rome, over a two-year period (2021-2022).

Objectives: We aim, through the evaluation of the epidemiological data of patients, particularly the causes of admission and sending institutions, to be able to have at our disposal important comparison data to understand the characteristics of the patient population received in psychiatric day hospital services.

Methods: Medical records of 218 patients admitted from 01.01.2021 to 31.12.2022 at the Psychiatry Day Hospital of Sant'Andrea Hospital in Rome were analyzed. The main sociodemographic and clinical characteristics and finally the type of psychiatric service from which the admission came were collected and analyzed, in addition to the reason for referral and therapeutic goal. Statistical analyses were conducted using Excel spreadsheets.

Results: 64% of admissions aimed to modify or start new medication regimens with monitoring (e.g., Clozapine, Carbolithium, Esketamine). 19% were for medical evaluations, mainly neurological, cardiological, endocrinological, or internal medicine. 9%

were for diagnostics. 2% were for infusion therapy, and an additional 2% for Esketamine treatment. The main findings highlight that Day Hospital use primarily focused on comprehensive patient assessments and therapy adjustments, often involving closely monitored drugs. Notably, 19% were for medical evaluations, with 28% of them being neurological assessments. This suggests challenges in conducting detailed medical assessments outside a context with prioritized access to such services.

Conclusions: Limited data in the literature make it challenging to conduct comparative analyses regarding patients in psychiatric day hospital services. However, our data can spark a discussion about admissions with objectives that could potentially be addressed through alternative services. We should also explore why this isn't happening. It could be interesting to conduct a descriptive analysis comparing epidemiological data from the two years before and after the period under investigation. Conducting retrospective statistical analysis on the collected data can yield more comprehensive results.

Trends of the mental health of the Hungarian adult population between 2010-2023

K. Kósa^{1*} and É. Bíró²

¹Department of Behavioural Sciences and ²Department of Public Health and Epidemiology, University of Debrecen, Debrecen, Hungary

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.266

Introduction: Several data have been published in the past decade on the mental health of the Hungarian population by different research teams but less information is available about the trends of mental status of the population based on comparable research methods.

Objectives: Our aim is to provide data on the time trends of mental status in Hungary using comparable methodology.

Methods: Four cross-sectional mental health surveys of the adult Hungarian population were designed by the authors; data collection was carried out by an opinion polling company between 2010 and 2023. Representative samples were selected by multistage stratified cluster sampling and weighted for analysis. Self-filling questionnaires were used to collect information on demographic data and socioeconomic status; validated scales were used to assess pathological distress (GHQ) and sense of coherence (SOC).

Results: Distribution of the respondents by permanent residence, age and sex in all surveys reflected that of the adult population of the country. The proportion of adults struggling with severe psychological distress approximately halved from 14.53% in 2010 to 6.78% in 2019 showing a significantly improving trend ($p < 0.001$) with higher proportions of women being severely stressed compared to men. Sense of coherence, a measure of psychological resilience increased by 3.43 points from 2010 to 2019 ($p < 0.001$), also reflecting a significantly improving trend without gender difference. However, the last survey of 2023 showed significant worsening with 18.85% of adults struggling with pathological distress, and a dramatic decrease in sense of coherence (-13.64 points).

Educational level and social support were found to be consistent and significant determinants of mental health.

Conclusions: Mental health status improved among Hungarian adults in the past decade up until 2019 but the trend turned into the opposite by 2023. Further research is warranted to uncover the underlying causes of the latest changes.

Regional Inequalities in Diagnosis and Therapies in Greece regarding Autism Spectrum Disorders

R. Kouznetsov¹, P. Angelopoulos², S. Moulinos³, A. Andrianopoulou^{4*}, I. Dimakos⁵, P. Gourzis⁶ and E. Jelastopulu¹

¹Department of Public Health, School of Medicine, University of Patras, Patras; ²National and Kapodistrian University of Athens, Athens; ³Department of Digital Media and Communication, Ionian University, Corfu; ⁴School of Medicine; ⁵Educational Sciences and Social Work and ⁶Department of Psychiatry, School of Medicine, University of Patras, Patras, Greece

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.267

Introduction: Autism spectrum disorders (ASD) represent a major public health concern on a global scale. The increasing prevalence of ASD worldwide, coupled with the arising demand for treatments, underscores its important role in the public mental health discourse. Ensuring the equitable integration of children with ASD and their families into all aspects of society becomes an imperative task, in order to eradicate the stigma associated with the broad spectrum of autism, encompassing both visible and concealed dimensions.

Objectives: The primary objective of this study was to determine the crude prevalence of ASD in Greece nationwide, while also examining regional disparities in both prevalence and therapies. The study spanned a three-year period from February 2019 to February 2022 and relied on retrospective data sourced from the Greek National Organization for Healthcare Services Provision (EOPYY).

Methods: EOPYY provided de-identified data, including information such as sex, age, diagnosis, and treatment for each child, facilitated by hashed social security numbers. Statistical analysis of the dataset was performed using the open-source statistical program R.

Results: A total of 18,245 children aged 2 -17 years were diagnosed with ASD in Greece, representing a nationwide crude prevalence rate of 1.16%. Regional disparities were evident, with prevalence rates ranging from 0.49% in the North Aegean to 1.57% in Crete. Over the three-year study period, a total of 15,328,327 non-medical therapies were prescribed, corresponding to an annual average of 264 therapies per child. Statistically significant differences between the thirteen regions in Greece were observed, ranging from 230 to 323 annual therapies per child.

Conclusions: Our findings align Greece's ASD prevalence with the global estimate of 1 in 100 children, as per the World Health Organization. Disparities between rural and urban areas in Greece may be attributed to differences in diagnostic procedures and the availability and accessibility of specialized services for autistic individuals. Thus, the establishment of a national surveillance system for ASD is recommended to enhance our understanding

of the autism spectrum, monitor changes in prevalence, and identify potential contributing factors to autism conditions. Furthermore, these evidence-based results offer invaluable insights for crafting policies concerning healthcare, education, and employment for individuals with ASD in order to ensure the development of people with autism, their wellbeing, and a good quality of life.

Exploring Causal Relationships in Mental Health Literacy Through Twitter Content: A Machine Learning Approach

Y.-J. Lien^{1*}, H.-P. Feng¹, C.-H. Chen¹, Y.-H. Tseng² and W.-H. Tseng²

¹Department of Health Promotion and Health Education and ²Graduate Institute of Library & Information Studies, National Taiwan Normal University, Taipei, Taiwan, Province of China

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.268

Introduction: The concept of Mental Health Literacy (MHL) is inherently multidimensional. However, the interrelationships among its various dimensions remain insufficiently elucidated. In recent years, the textual analysis of social media posts has emerged as a promising methodological approach for longitudinal research in this domain.

Objectives: This study aimed to investigate whether temporal causal associations exist between recognition of mental illness (R), mental illness stigma (S), help-seeking efficacy (HE), maintenance of positive mental health (M), and help-seeking attitude (HA).

Methods: Tweets were collected at three distinct time points: T1, T2, and T3, spanning the period from November 1, 2021, to December 31, 2022. We employed a machine-learning approach to categorize the posts into five MHL facets. Using these facets, we trained a machine learning model, specifically Bidirectional Encoder Representations from Transformers (BERT), to determine the MHL scores. To be eligible, an account must have an R facet score at T1, and M, S, HE facet scores at T2, as well as an HA facet score at T3. In total, we retrieved 4,471,951 MHL-related tweets from 941 users. We further employed structural equation modeling to validate the causal relationships within the MHL framework.

Results: In the evaluation, BERT achieved average accuracy scores exceeding 89% across the five MHL facets in the validation set, along with F1-scores ranging between 0.75 and 0.89. Among the five MHL facets—maintenance of positive mental health, recognition of mental illness, help-seeking efficacy, and help-seeking attitudes—each demonstrated a statistically significant positive correlation with the others. Conversely, mental illness stigma exhibited a statistically significant negative correlation with the remaining four facets. In the analysis using single-mediation models, each of the individual mediator variables—namely, mental illness stigma, help-seeking efficacy, and maintenance of positive mental health—exhibited significant indirect effects. In the multiple-mediation model, two mediator variables—help-seeking efficacy and maintenance of positive mental health—demonstrated significant indirect effects. These findings suggested that the

recognition of mental illness exerted an influence on help-seeking attitudes through one or more of these mediators.

Conclusions: By leveraging machine learning techniques for the textual analysis of social media and employing a longitudinal research design with panel data, this study elucidates the potential mechanisms through which the MHL framework influences attitudes toward seeking mental health services. These insights hold significant implications for the design of future interventions and the development of targeted policies aimed at promoting help-seeking behaviors.

Designing youth mental health services to improve access: A qualitative study and framework analysis of youths' perspectives in Singapore

J. A. Vaingankar^{1*}, M. Subramaniam^{1,2}, E. Samari¹, S. Chang¹, C. Tang³, Y. P. Lee³, S. A. Chong¹ and S. Verma^{4,5}

¹Research Division, Institute of Mental Health; ²Saw Swee Hock School of Public Health, NUS; ³Department of Psychosis, Institute of Mental Health; ⁴Institute of Mental Health and ⁵Duke-NUS Medical School, Singapore, Singapore

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.269

Introduction: Although there is an increasing interest in making mental health services (MHS) accessible to youths, there is limited ground-up involvement of youths while designing MHS in Asian settings.

Objectives: This qualitative study sought to understand what youths considered as important elements of youth centric MHS and how these could be designed to improve access by youths in Singapore.

Methods: We conducted seven focus group discussions, and four semi-structured interviews with 50 multiracial youths aged 15-35 years in Singapore - a high-income Southeast Asian country. Purposive sampling allowed adequate representation of age, gender, and race (mainly Chinese, Malay, and Indian) groups. Participants reflected on the features of an ideal MHS for youths and how these could improve youths' attitude and access to services. Participants also shared their preferences and additional opinions for culturally tailored and age appropriate MHS. Framework analysis using the 'Conceptual Framework of Access to Healthcare' (Levesque et al. *Int J Equity Health* 2013, 12:18) was used to code transcripts and identify the key themes (Ritchie & Spencer. *In Analyzing qualitative data*, 1994).

Results: The average age of the participants was 24 years. About one third of the participants had accessed MHS in the past. Three key themes were identified - making facilities 'approachable', 'available and appropriate' and 'affordable'. (i) Making facilities approachable related to having non-stigmatizing, non-threatening and welcoming aesthetics, organizational culture, and personnel. The participants also recommended a range of professional services, digital tools, and online features to enhance the approachability of MHS designed for youths. (ii) Flexible operating hours, easy appointment

management, accessible location, and easy availability to youths with unique needs (e.g., employed youths) or socio-cultural backgrounds were necessary for making facilities available and accessible to youths. (iii) While sharing challenges of family involvement in the help-seeking process, most of the participants, particularly those in the lower ages, talked about tailoring MHS to the ability of youths to pay for the services. Preferences such as having cheaper services for teenagers and initial contacts, offering more non-medical but trained professionals, and considering shorter in-person counselling sessions, followed by free online options were brought up by the participants.

Conclusions: The study provided insights into multiple aspects of MHS and how these could be designed to cater to the needs of youths in Singapore from their perspective. MHS that incorporate non-stigmatizing, flexible, non-threatening and affordable design approaches could improve help-seeking and early interventions in youths.

Recovery among people with mental health challenges and alcohol and drug use issues in the Northern Territory, Australia

N. Tari-Keresztes^{1*}, N. Armstrong², H. Gupta¹, J. A. Smith¹, S.-A. Endemann², S. Goding² and J. Downes²

¹Rural and Remote Health, Flinders University and ²Northern Territory Lived Experience Network, Darwin, Australia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.270

Introduction: The Northern Territory (NT) has Australia's highest mental health burden. It has a diverse and transient population, including Aboriginal and Torres Strait Islander people and various multicultural communities. While peer support has been widely used nationwide, in the NT, peer support is poorly implemented in psychosocial support activities.

Objectives: The NT Lived Experience Network (NTLEN), in allyship with a team of researchers from Flinders University, has secured multiple fundings aimed to develop, implement, and evaluate a peer education and recovery program called Recovery Together (RT) for individuals with mental health and alcohol and drug use issues and related challenges.

Methods: The suitable evaluation approach was co-designed with live experience representatives from NTLEN and other local key stakeholders. It applied a mixed-method approach, including pre and post-program surveys (n=64) and individual interviews with program participants and the program delivery team (n=32). The evaluation findings were also informed by data collected by NTLEN via feedback forms (n=38). We also used a co-design approach to develop survey instruments to ensure they were strengths-based and recovery-oriented.

Results: Participants reported poor and fair self-perceived health, high stress levels, dissatisfaction with their relationships and relatively low recovery scores, which showed improvements at post-program completion. They discussed their journeys in the interviews and shared their experiences with local mental health services and the Recovery Together program. Many expressed that mental

health professionals are not necessarily the care providers they feel comfortable engaging with. However, they described their experience with the peer program as highly positive, empowering, safe, non-judgmental, and beneficial, satisfying their support needs. The program gave them hope and tools to manage their mental health challenges and opportunities to gain insight into non-clinical aspects of recovery. Participants conceptualised personal recovery in their own words and described the facilitators and barriers to their recovery. They emphasised that recovery is being empowered, strong within themselves and the leader of their journey, living their best possible life, understanding themselves, having the necessary knowledge about mental health, and looking forward in a hopeful way.

Conclusions: Our findings highlighted the demand and need for ongoing delivery of the RT program in the NT, which was highly effective in supporting personal recovery, addressing the service delivery gap and complementing the available clinical and mental health practices. They also showed the importance of providing recovery-oriented and trauma-informed education for medical and mental health professionals.

EPP0034

The impact of clinical context on the recognition of facial expressions

C. De Sousa¹, S. Morgado², J. Ferreira^{3*}, S. Tukaiev⁴ and R. Fonseca²

¹Higher School of Health Atlântica, Barcarena; ²ISEIT, Almada;

³Faculty of Medicine, Coimbra University, Coimbra, Portugal and

⁴Università della Svizzera italiana, Lugano, Switzerland

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.271

Introduction: Several authors have demonstrated the relevance of the therapist sensitivity to the affective expression of his client (Merten & Schwab, 2005; 150-158), as well as to his own emotional experience (Haynal-Raymond et al., 2005; 142-148) in order to build a more effective therapeutic relationship, and results. An important source of information to decode the emotional expression hints is the face, and its expression (Ekman & Friesen, 1975; Russel & Fernández-Dolls, 1997; 275-294). Despite common sense saying that context is relevant to understand the meaning of the emotional facial expression, the literature review shows inconsistent results.

Objectives: The main goal of this study was to evaluate the impact of clinical context over the perception of the emotional facial expression.

Methods: This study followed a within-subjects design, and its sample consisted of 60 clinical psychologists. 21 combinations of prototypical expression images with mixed emotional signals, and clinical information texts were presented to the participants. Then their judgement on the type of emotion displayed was requested. The presentation of the text-image pairs was randomized between three conditions: consistent, and non-consistent, and neutral.

Results: The results suggest that emotions are more easily recognized in the presence of a concordant context than a non-concordant or neutral one, and that the greater the similarity

between the facial expression of the image presented and the face prototypically associated with the context, the greater the influence of the context.

However, In the recognition of mixed emotional signs, there was greater recognition of signs of anger in the facial expression, as a non-dominant emotion, when in the presence of the neutral story than of the story that agreed with the dominant emotion (sadness). There was also greater recognition of sadness, as a non-dominant emotion, in the presence of a story in agreement with fear than in the presence of a neutral story. There was also a statistically significant increase in the attribution of anger to images in which it is not present and whose dominant emotion is fear, when associated with a context of aggression vs. a neutral context.

It was also found that there was a significant decrease in the attribution of fear to the sadness-anger image (25%-75%) in the presence of the aggression context compared to the neutral and panic contexts. There was also a statistically significant decrease in the attribution of sadness to an image of fear in the neutral context compared to the other contexts (panic and aggression).

Conclusions: In conclusion, our study have shown an impact of context over overvaluation or the undervaluation of the emotional facial expression as well as either with prototypical expressions or the mixed emotional signals when referring to sadness, fear, and anger. Thus, mental health clinicians should consider the influence of these contexts.

Guidelines of inclusive architecture design for autism spectrum disorder: What is new?

E. Abdelmoula^{1*}, N. Bouayed Abdelmoula² and B. Abdelmoula²

¹LR AMC, Ecole Doctorale Sciences et Ingénierie Architecturales (ED-SIA), Tunis and ²Genomics of Signalopathies at the service of Precision Medicine - LR23ES07, Medical University of Sfax, Sfax, Tunisia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.272

Introduction: Autism spectrum disorder (ASD) is a complex neuro-developmental condition. According to the Diagnostic and Statistical Manual of Mental Disorders (DSM-5), restricted interests and repetitive behaviors and difficulties with social communication and interaction characterize ASD. Different ways of learning, moving, or paying attention are related to the degree of impairments. By reducing environmental and social obstacles in school, work, and other areas of life, architecture could play a pivotal role in helping people on the spectrum become more independent and acquire more abilities.

Objectives: The aim of this study was to outline the recommendations and guidelines of the inclusive architecture design for ASD.

Methods: We conducted a comprehensive review of the scientific literature using the following keywords: inclusive design, architecture, autism or ADS.

Results: Our research found that the Autism ASPECTSS design index reported in 2013 by Magda Mostafa from Canada, which was based on the sensory design theory, is the world's first set of evidence-based design guidelines for managing built environments to serve ADS individuals interaction, particularly in schools and

workspaces. ASPECTSS conceptual framework delineate seven design concepts: acoustics, spatial sequencing, escape space, compartmentalization, transition spaces, sensory zoning, and safety. In 2023, the same author published an autism friendly design guide for the world's first autism-friendly university. This guide is characterized by a better understanding of human-centered design and advocates beyond the mere inclusion, aspiring to a state where the boundaries between 'normal' and 'special' are blurred in order to treat all users as human beings with equal rights, thus calling for equal opportunities beyond the ADS spectrum.

Conclusions: With such well-established conceptual framework, it is nowadays imperative to expand our buildings in cities, schools, workplaces, hospitals, and public areas using the guidelines of autism-friendly environments. These buildings will enhance our individual and social well-being.

Investigating Sex Differences in Opioid Use Disorder Risk Factors: Insights from Cross-Section Lebanese Study Population

K. Chamoun^{1,2,3}, P. Salameh^{4,5,6,7}, H. Sacre⁴, J. Mouawad², L. Rabbaa^{1,2}, B. Megarbane³ and A. Hajj^{1,4,8,9*}

¹Laboratoire de Pharmacologie, Pharmacie Clinique et Contrôle de Qualité des Médicaments; ²Faculty of Pharmacy, Saint Joseph University, Beirut, Lebanon; ³Inserm, UMR-S1144, Université Paris Cité, Paris, France; ⁴INSPECT-LB (Institut National de Santé Publique, d'Épidémiologie Clinique et de Toxicologie-Liban), Beirut; ⁵School of Medicine, Lebanese American University, Byblos, Lebanon; ⁶Department of Primary Care and Population Health, University of Nicosia Medical School, Nicosia, Cyprus; ⁷Faculty of Pharmacy, Lebanese University, Hadat, Lebanon; ⁸Faculty of Pharmacy, Université Laval and ⁹Oncology Division, CHU de Québec-Université Laval Research Center, Quebec, Canada

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.273

Introduction: Opioid use disorder (OUD) is a significant public health concern, and understanding the risk factors associated with OUD is crucial for effective prevention and management strategies. However, limited information is available regarding the role of sex differences in OUD risk factors. Women have often been excluded from clinical studies to create more homogeneous samples and simplify the analysis of treatment effects. The underrepresentation of women in clinical trials and the lack of sex stratification, typically limited to binary comparisons without considering gender dynamics, raise concerns about potential sex disparities. Given the emerging evidence suggesting the possibility of sex differences in the likelihood of developing OUD, further research is needed to investigate and understand these potential disparities to optimize the individualized management of OUD.

Objectives: The primary objective of this study was to examine and identify any sex-related variations in OUD risk variables within the Lebanese community. By pinpointing sociodemographic, psychiatric, and other factors related to sleep and chronotype, we aim to

elucidate their impact on the onset and progression of OUD in both males and females.

Methods: A cross-sectional study was conducted among 581 Lebanese adults using an online questionnaire that included sociodemographic questions, validated scales for substance use disorders and sleep disorders, and assessments for depression and anxiety. Multivariate analyses were performed to identify associations between risk factors and OUD scores in both male and female populations.

Results: Common risk factors for OUD were identified, including family and personal history of substance use disorder, co-occurrence of sedative and alcohol misuse, and psychiatric illnesses. Sex-specific risk factors were also observed. Among women, the ASSIST-opioids subscore was significantly associated with the Pittsburgh Sleep Quality Index (B=0.143) and Insomnia Severity Index (B=0.286) scores. Men demonstrated a correlation between ORT-OUD and younger age (B=0.882). Waterpipe consumption was negatively correlated with the ORT-OUD score in men (B=-0.018).

Conclusions: Our study emphasizes the importance of examining sex differences in risk factors for OUD, particularly within the Lebanese population. By acknowledging these gender-specific risk factors, interventions can be customized to address the distinct vulnerabilities of each sex. This approach could potentially improve prevention efforts, facilitate early identification, and implement treatment strategies tailored to the specific needs of individuals with OUD. Further research is needed to delve into the underlying mechanisms and develop targeted interventions for enhanced management of OUD.

Bipolar Disorder in Pregnancy: A Challenging Case Managed with Maintenance Electroconvulsive Therapy

B. Arribas-Simon^{1*}, M. J. Mateos-Sexmero¹, O. Martin-Santiago¹, P. Andres-Olivera², B. Rodriguez-Rodriguez², P. Martinez-Gimeno¹, N. Navarro-Barriga³, T. Jimenez-Aparicio¹, P. Fernandez-Pando¹ and M. Andreu-Vidal³

¹Psychiatry, Hospital Clinico Universitario, Valladolid; ²Psychiatry, Complejo Asistencial Universitario, Salamanca and ³Hospital Clinico Universitario, Valladolid, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.274

Introduction: Pregnancy is a high-risk period for major affective disorders and can lead to a destabilizing period for our patients. Standard pharmacological strategies must be carefully evaluated due to potential teratogenic or side effects. We present a case of bipolar disorder type I with challenging-to-control maniac episodes during pregnancy, which has required Electroconvulsive Therapy for its management.

Objectives: Presenting maintenance electroconvulsive therapy (ECT) as a safe and effective therapeutic strategy during pregnancy, with the presentation of a case in which it has been administered every 3 weeks from the second trimester until the baby's birth at 37 weeks

Methods: This concerns a 28-year-old immigrant woman, married, with a 10-year-old child. She was diagnosed with bipolar disorder

type I at the age of 16 when she experienced her first manic episode in her country of origin. Subsequently, during her first pregnancy, she required hospitalization for electroconvulsive therapy (ECT) treatment, with a positive response after a single session. She remained stable for several years without maintenance pharmacological treatment or follow-up until the ninth week of her second pregnancy when she experienced a manic episode requiring hospitalization.

Results: She was initially treated with Olanzapine and Lorazepam with a positive response, but three weeks later, she was readmitted with a similar episode. These decompensations occurred almost monthly, leading to the consideration of introducing mood stabilizers after the first trimester. However, due to the patient's severe hyperemesis gravidarum, this stabilizing treatment was ruled out due to the difficulty in controlling its blood levels and the associated risk of intoxication. During the fifth admission at the 20th week of gestation, the decision was made to initiate ECT treatment, which yielded an excellent response and subsequent maintenance.

Conclusions: The indications for electroconvulsive therapy (ECT) during pregnancy are the same as in the rest of adult patients. In individuals with a psychiatric history, it is possible for a relapse of mental illness to occur during pregnancy, although the risk is considerably higher during the postpartum period. ECT is considered an effective and safe treatment option in all three trimesters of pregnancy and the postpartum period. During the informed consent process, patients should be informed about the potential impact of ECT as well as alternative treatment options.

¹Department of Child and Adolescent Psychiatry; ²Endocrinology and Metabolism Laboratory, Faculty of Medicine; ³Translational Psychiatry Laboratory (Psiquislab), University Psychiatric Clinic, Universidad de Chile and ⁴Endocrinology Unit, Department of Medicine, Clínica Alemana de Santiago, Faculty of Medicine, Universidad del Desarrollo, Santiago, Chile

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.275

Introduction: Polycystic Ovarian Syndrome (PCOS) is the most prevalent endocrine disorder in adolescents. It affects brain maturation, specially in highly neuronal plasticity periods. However, there is a lack of information about the impact of this exposure during brain plasticity windows.

Objectives: Characterize the consequences of hyperandrogenism in emotional status and social cognition (SC) on adolescents daughters of women with PCOS (dPCOS).

Methods: Analytical cross sectional study. dPCOS and controls between ages of 12 to 25 years old were recruited. Participants underwent a complete clinical evaluation, plasmatic hormones determinations (including total testosterone, SHBG, androstenedione and 17-OH-progesterone) and ovarian ultrasound

characterization. SC was estimated by: measurements of affects (PANAS), strength and difficulties (SDQ), self-reported empathy (EQ/SQ and AQ), and gaze patterns for autonomic response measurement via Eye-Tracking.

Results: 33 participants were recruited, 15 cases and 18 controls. Median age was 17 and 18 years, respectively. The dPCOS presented a larger anogenital distance (cm) (9.7 vs 7.8; $p=0.014$), Ferryman-Gallwey score mean (13.0 vs 2.0; $p<0.001$) and free androgen index value (7.5 vs 4.1; $p=0.004$), suggesting hyperandrogenism exposure during intrauterine and adolescence periods. Regarding SC, dPCOS exhibited a predominantly negative affective status (PANAS 8.0 vs 2.0, $p=0.049$) and a higher score in socio-emotional problems (SDQ 2.5 vs 1.5; $p=0.047$). The eye-tracking registration showed that dPCOS presents longer time to first fixation in areas of interest (s) (0.35 vs 0.28; $p=0.037$), which was associated with a worse endpoint in emotional recognition ($aR^2=-0.920$; $f=19.48$; $Pr >|t|<0.049$). Furthermore, the 2D:4D ratio (intrauterine marker of androgen exposure) was correlated with a predominance of negative affect ($\rho=0.51$; $p=0.019$) and less prosocial behaviors ($\text{coef}=-2.39$; $P>|t|=0.049$).

Conclusions: Clinical and hormonal markers suggest that dPCOS are exposed to hyperandrogenism during the most critical neuroplasticity periods. This exposure is associated with negative affects, more social-emotional difficulties and less score on emotional recognition and prosocial behavior. Due to a high psychiatric comorbidity in PCOS patients, these findings are relevant and emphasize the importance of early mental health treatment in these patients.

Diversity and gender at the largest European university hospital: The effects of discrimination on mental health

I. Enarovic^{1,*}, V. M. Straßburger^{1,2}, M. Berger¹, J. Smith¹, G. Stadler^{1,3} and P. J. Buspavanich^{1,4}

¹Charité-Universitätsmedizin, Berlin; ²Medical School, Hamburg, Germany; ³University of Aberdeen, Aberdeen, United Kingdom and ⁴Brandenburg Medical School Theodor Fontane, Neuruppin, Germany

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.276

Introduction: Discrimination is known to have different effects on health. In particular the mental health of affected people diminishes. Although it is known that marginalized groups are discriminated against more, at present only research on gender and ethnicity has been done. Further diversity domains like socioeconomic status, care responsibilities, sexual orientation, disability, mental and physical health, and their intersections have been scarcely looked at.

Objectives: The aim of the study was to determine the effects of discrimination on the mental health for employees and students of a university hospital taking diversity domains into account.

Methods: A web-based survey between June 22 to October 23 was conducted using the PHQ-4 and WHO-5 as well as innovative Diversity Minimal Item set to measure different diversity domains.

Results: Preliminary data shows that discrimination among employees and students is common, widespread and most frequent

based on gender, ethnicity and health. The mental health of those who feel discriminated against tends to be poorer, especially looking at the intersectionality of diversity domains.

Conclusions: The results of this study suggest that both more measures to prevent discrimination in a university hospital have to be implemented and individuals from marginalized groups need special psychosocial support to ensure a safer working environment. In addition, greater attention to diversity and inclusion in medical research is needed to develop appropriate responses and interventions, including diversity policies.

Piled-up Risk Factors: a Case Report of Diogenes Syndrome

J. L. Freixo*, S. G. Rodrigues, T. Novo and D. Brandão

Psychiatry, Unidade Local de Saúde do Alto Minho, Viana do Castelo, Portugal

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.277

Introduction: Diogenes Syndrome (DS) is an uncommon neuro-behavioral syndrome characterized by social isolation, extreme neglect of personal care and a tendency to excessively accumulate useless objects in the home, usually leading to unsanitary living conditions. It is further characterized by a lack of insight into the condition, leading to a refusal to seek assistance.

Objectives: To outline the clinical features of primary DS, unassociated with other psychiatric conditions, emphasizing key risk factors contributing to its development.

Methods: Descriptive report of a case of DS, based on an interview with the patient, review of his clinical file, and a non-systematic literature review using the PubMed database.

Results: We report a case of a 62-year-old man, widowed since the age of 33, without children, living alone in a rural area in the north of Portugal. Currently retired, he worked as a Philosophy Professor. He had no known psychiatric history until 2015, when he attended two psychiatric appointments, due to anxiety and changes in sleep pattern. He has since lost psychiatric follow-up and in May 2022 he was brought to the emergency department by his neighbor, due to changes in his behavior. He was seen several times rummaging through trash and he didn't leave the house for a few weeks, resulting in a cluttered and unsanitary living space. He looked malnourished, unkempt and dirty. Despite not recognizing his behavior as problematic, he accepted hospitalization. No obsessive-compulsive, depressive or psychotic symptoms were detected, nor were dysfunctional personality traits. Reversible causes of dementia were excluded, a cranioencephalic CT scan revealed no abnormal findings and a neuropsychological assessment showed no changes in cognitive functions. Post-discharge, local health services provided home support, with meal delivery and house cleaning. However, he did not buy the medication and canceled the home support service several times, ending up being hospitalized again. After this second hospitalization in August 2023, he went to live with his brother in another city and has

remained stable, medicated with an SSRI and low dose Aripiprazole.

Conclusions: Primary Diogenes Syndrome is rare and its etiopathogenesis remains poorly understood. It is known that there is no distinction between genders, profession or socioeconomic status, and that it is more common in the elderly, single people, widowers and people with poor or non-existent social links with their local community. Familiarity with DS characteristics enables earlier recognition of such individuals, thereby facilitating prompt provision of social and clinical support in order to reduce morbidity, mortality, and enhance public health.

Community psychiatric care for people with mental disorder and homelessness, with the involvement of peer support. Cooperation of the Awakenings Foundation and BMSZKI

T. Bulyáki^{1*}, J. Harangozó², Z. Harangozó³ and P. Kéri^{4,5}

¹Department of Social Work, ELTE TÁTK; ²Community Psychiatric Center-Awakenings Foundation, Semmelweis University; ³BMSZKI; ⁴GAMIAN-Europe and ⁵Awakenings Foundation, Budapest, Hungary

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.278

Introduction: A person diagnosed with a psychiatric illness, must face labels and discrimination most of the time. Fear of these undermines the motivation of people in need to seek help. A special example of this phenomenon is the case of people experiencing homelessness and mental disorder, avoiding the additional stigma of homelessness and therefore do not seek any help for their mental ill-health. Availability of the specific services complicates their problem.

Fear of stigma, trauma, and previous bad experiences of using services also keep people experiencing homelessness away from services.

In Hungary, the February Third Working Group (F3) Report on the 2020 Homelessness Survey After the Penal Code - Before the Pandemic Homelessness - Services Perspectives by Péter Győri shows in his summary paper that only 29% had received psychiatric treatment.

Objectives: Methodology Center of Social and Its Institutions (BMSZKI), in collaboration with the Awakenings Foundation, developed a complex rehabilitation service for people experiencing homelessness and mental disorder. This presentation aims to present this good practice.

Methods: Complex rehabilitation based on the methodology of community psychiatric care with the involvement of peer support.

Results:

- provision of community psychiatric care for people experiencing homelessness and mental disorder,
- introduction of screening for effective care of undiagnosed persons with mental disorders,
- provision of outpatient and day hospital care
- focus of care in accommodation services on persons with mental disorders,
- the involvement of peer-support work in the service,

- building a network of contact points, organizing case conferences,
- developing and organizing training on recovery-based rehabilitation for people with mental disorders in cooperation between the two organizations,
- telemedicine, making digital mental health available
- presence of resources represented by self-help groups
- running a working group to promote improvements based on practical experience homelessness and mental disorder.

Conclusions: extra-institutional teamwork multiplies the resources for people experiencing homelessness and mental disorder.

Keywords: mental disorder, homelessness, community psychiatric care, peer support, collaboration

Relations between the Arabic BFI-2 and HEXACO-60 scales among Kuwaiti Undergraduates.

B. M. Alansari

Psychology, Kuwait University, College of Social Sciences, Shuwaikh, Kuwait

doi: 10.1192/j.eurpsy.2024.279

Introduction: Many researchers are likely to use the BFI-2 as a measure of the Big Five personality factors. The HEXACO-60 Honesty-Humility factor has no direct counterpart in the Big Five system; however, it should show modest positive correlations with Big Five Agreeableness.

Objectives: The study aimed to examine the BFI-2 in relation to a similar-length version of the HEXACO-60.

Methods: Participants were 1536 undergraduate students (960 women 576 men) at Kuwait university who completed the personality questionnaires. Participants aged 18–23-years-old mean age = 21.26 ± 1.20. The Arabic versions of HEXACO-60 and the BFI-2 instruments were administered in paper-and-pencil format in research laboratories.

Results: Cronbach's alphas ranged from 0.75 to 0.88 for the BFI-2 Domains and 0.70 to 0.75 for the HEXACO-60 Domains denoting good internal consistency. Regarding cross-inventory correlations, these were high for the two inventories variants of Openness (0.77), Conscientiousness (0.75), and Extraversion (0.71). BFI-2 Agreeableness correlated 0.56 with HEXACO-60 Agreeableness. The HEXACO-60 Honesty-Humility was weakly related to the BFI-2 scales, showing only modest correlation with Agreeableness (0.48). In addition, the BFI-2 Neuroticism correlated 0.53 with HEXACO-60 Emotionality, -0.33 with HEXACO-60 Extraversion, and -0.30 with HEXACO-60 Agreeableness.

Conclusions: The BFI-2 scales captured well the variance of the HEXACO-60 scales apart from Honesty-Humility. In particular, the BFI-2 accounted for about as much variance in the HEXACO Openness, Conscientiousness, Extraversion, and Agreeableness scales as the HEXACO-60 scales accounted for in the BFI-2 scales of the same names. The results confirm the BFI-2 and HEXACO-60 are heavily overlapping.

EPP0047

Pharmacotherapy and psychotherapy interventions in patients with borderline personality disorder in outpatient clinical practice

E. Chumakov*, D. Charnaia and N. Petrova

Department of Psychiatry and Addiction, Saint Petersburg State University, Saint Petersburg, Russian Federation

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.280

Introduction: Despite the high prevalence of borderline personality disorder (BPD) in the population, the evidence regarding approaches to therapy for BPD is inconsistent. No psychopharmacological medications are approved for the treatment of BPD, yet most patients with BPD are treated with pharmacotherapy. Meanwhile, psychotherapy is the method of choice for the treatment of BPD. Little is known about the clinical practice of BPD treatment in Russia, since most studies have been conducted in Western countries.

Objectives: The aim of the study: analysis of approaches to treatment of BPD in real outpatient clinical practice in Saint-Petersburg, Russia.

Methods: Fifty patients (72% female; n=36; mean age 22.4±4.3) who were treated in an outpatient community care were included in the study. Diagnosis was made according to the ICD-10 criteria (F60.31), as it does in clinical practice in Russia. Research methods included a clinical-catamnestic method.

Results: All examined patients received pharmacotherapy. Twenty-four patients (48.0%) received monotherapy with a selective serotonin reuptake inhibitor antidepressant. The remaining patients (52.0%) received two or more psychotropic medications simultaneously. The most frequent combination of psychopharmacotherapeutic agents was a combination of an antidepressant and a mood stabilizer. Analysis of therapy revealed that antipsychotics (always of the second generation) as well as mood stabilizers were prescribed to target emotional instability and impulsivity as symptoms of BPD, as well as increased self-harming behavior in order to reduce impulsivity. Despite the assumption that the simultaneous prescription of several medications to patients with BPD was due to the presence of a comorbid psychiatric diagnosis, this was not confirmed ($p>0.05$). Most of the patients (n=42; 84.0%) received individual and group psychotherapy (cognitive-behavioral with elements of dialectical-behavioral therapy). It was found that patients who received psychotherapy had a faster response to pharmacotherapy ($p<0.05$).

Conclusions: An analysis of approaches to the treatment of BPD in outpatient clinical practice in Saint-Petersburg, Russia, showed a predominance of medication-assisted psychopharmacotherapy (selective serotonin reuptake inhibitors, antipsychotics, mood stabilizers) over the frequency of prescription of psychotherapeutic care. In none of the cases was a first-line psychotherapy method (with proven efficacy for BPD) used. An assessment of the availability of psychotherapeutic care for patients with BPD is required. An earlier initiation of psychotherapeutic care after the BPD diagnosis is recommended, which may lead to an increase in the effectiveness of psychiatric care for patients with BPD in outpatient clinical practice.

Use of Long-Acting Injectables in Borderline Personality Disorder: What Do We Know?

E. D. S. Almeida, J. Abreu, R. P. Vaz, J. Martins, F. Cunha*,
I. Santos, N. Castro, R. P. Andrade and E. Monteiro

Centro Hospitalar Tondela-Viseu, Viseu, Portugal

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.281

Introduction: Psychotherapy serves as the foundation of care for individuals with borderline personality disorder (BPD), with pharmacotherapy being regarded as a supplementary measure to be considered when necessary. In clinical practice, however, most of BPD patients receive medication.

A major problem in the treatment of BPD is the lack of compliance derived from the pathological impulsivity of BPD patients. The use of long-acting antipsychotics (LAI) may be an option.

Objectives: This work aims to address the use of long-acting injectables in borderline personality disorder.

Methods: Non-systematic review of literature using the PubMed® database, based on terms “Borderline Personality Disorder” and “Long-acting antipsychotics”. Only six articles were found.

Results: Several studies have shown promising results in the treatment of Borderline Personality Disorder (BPD) with long-acting injectable (LAI) antipsychotics. A six-month study using IM risperidone demonstrated significant improvement, while LAI Aripiprazole also exhibited positive outcomes in individuals with BPD and Substance Abuse. Additionally, Palomares et al. (2015) found that palmitate paliperidone LAI reduced impulsive-disruptive behaviors and enhanced overall functioning in BPD patients. Carmona et al. (2021) compared oral and LAI antipsychotics and concluded that LAIs may have a role to play in the management of BPD.

Conclusions: Treatment with LAIs may play an important role in clinical and functional improvement in BPD patients.

Title: Misdiagnosis in young females – Autism versus Borderline Personality Disorders

H. Sholinghur

Psychiatry, Equilibrium Healthcare, Eleanor Hospital, Manchester, United Kingdom

doi: 10.1192/j.eurpsy.2024.282

Introduction: The diagnostic overlap between Autism Spectrum Disorder (ASD) and Emotionally Unstable Personality Disorder (EUPD), commonly referred to as Borderline Personality Disorder (BPD), presents a considerable challenge in psychiatric practice, particularly for young females. These complexities are amplified by gender biases in the healthcare system and can lead to misdiagnosis, affecting both treatment planning and long-term outcomes.

Objectives: There are differences and similarities between ASD and EUPD/BPD which encompass its own challenges in diagnosis and treatment

The presentation seeks to:

1. Offer an in-depth overview of the relationship between ASD and EUPD/BPD in young females.
2. Evaluate the diagnostic challenges associated with distinguishing between these two conditions.
3. Discuss the practical implications of misdiagnosis on treatment and quality of life.

Methods: Drawing from a rich corpus of evidence, including longitudinal studies (e.g., Kerns et al., 2015; Gunderson et al., 2018), meta-analyses, and patient case studies, the presentation adopts a multidisciplinary approach. It utilises clinical interviews, validated diagnostic tools such as the Autism Diagnostic Observation Schedule (ADOS) and the Structured Clinical Interview for DSM-5 (SCID-5), as well as direct observation to provide a nuanced understanding of ASD and EUPD/BPD characteristics.

Results:

Shared Characteristics: Both ASD and EUPD/BPD manifest challenges in social functioning and mood regulation, supported by studies indicating sensory sensitivities and affective dysregulation in both conditions (Zanarini et al., 2019; Happé et al., 2019).

Differentiating Factors: ASD individuals often struggle with verbal and non-verbal communication, whereas those with EUPD/BPD may excel in these areas but display emotional volatility and unstable relationships, substantiated by differing neurobiological markers (King-Casas et al., 2008; Minshew & Williams, 2007).

Misdiagnosis Risks: The failure to correctly diagnose these conditions may lead to ineffective or potentially harmful treatment plans (Zanarini et al., 2013; Solomon et al., 2012).

Necessity for Comprehensive Assessment: A multimodal and culturally sensitive diagnostic approach is essential for accurate clinical evaluation (Mandy et al., 2012; Betancur et al., 2009).

Conclusions: The complexities surrounding the accurate diagnosis of ASD and EUPD/BPD in young females necessitate a thorough and multifaceted approach. An incorrect diagnosis could have long-lasting implications, affecting not just the efficacy of therapeutic interventions but also the overall well-being and quality of life of the individual. This presentation underscores the critical importance of drawing from a robust body of evidence and utilising comprehensive diagnostic approaches to differentiate these conditions.

Examining the Association Between Psychopathy Clusters and Risk-Taking Behaviors

R. Gómez Leal*, P. Fernández-Berrocal and A. Megías-Robles

University of Málaga, Málaga, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.283

Introduction: Psychopathy encompasses the sub-dimensions of interpersonal manipulation, callous affect, erratic lifestyle, and criminal tendencies. Most studies investigating this trait have traditionally utilized a variable-centered approach. However, in the current study, we have adopted a person-centered approach.

Objectives: Our objective was to analyze distinct homogeneous subgroups of individuals characterized by specific psychopathy profiles and examine their relationship with risk-taking behavior.

Methods: Our sample consisted of 371 participants (26.4% men, aged 18 to 59 years), who completed the 34-item Self-Report Psychopathy Scale-III to assess psychopathy and Risk-taking behaviors were assessed using the Domain-Specific Risk-Taking Scale (DOSPERT-30).

Results: Through cluster analysis, we identified four distinct groups: Low psychopathy, Low criminal tendencies, High erratic lifestyle, and High psychopathy group. The primary findings revealed that the High psychopathy group, characterized by elevated scores in all sub-dimensions, exhibited higher levels of Risk-Taking Behaviors and a lower Perception of Risk compared to the other groups. Furthermore, the Low criminal tendencies group, marked by high scores in all dimensions and low scores in criminal tendencies, demonstrated greater risk-taking behavior compared to the Low psychopathy and High erratic lifestyle groups.

Conclusions: These results stimulate the debate about whether it is appropriate to incorporate the dimension of criminal tendencies within the concept of psychopathy. Certain clinical implications emerge from this study that are deserving of a comprehensive and thoughtful discussion.

Instagram addiction, life satisfaction and self esteem in young adults

G. Reis¹ and B. R. Maia^{2*}

¹Universidade Católica Portuguesa and ²Universidade Católica Portuguesa, Center for Philosophical and Humanistic Studies, Braga, Portugal

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.284

Introduction: Addiction to Instagram can have severe consequences at a psychological, physiological and social level. On the other hand, social networks can be useful tools for an individual's daily life. Studies show that the problematic use of some social networks, namely Instagram, can have an impact on users' self-esteem. This construct is considered a predictor of life satisfaction, which is why in the literature these two variables appear positively related.

Objectives: To explore the relationship between addiction to Instagram, life satisfaction and self-esteem in young adult university students and to carry out a comparison between groups with and without probable addiction to Instagram.

Methods: The sample was composed by 241 Portuguese university students with a mean age of 22.03, (SD = 2.29, range 18-29), and who have an Instagram account. Subjects fulfilled a sociodemographic questionnaire, and the Portuguese version of the Bergen Instagram Addiction Scale, the Life Satisfaction Scale and the Rosenberg Self-Esteem Scale.

Results: The average score on the Bergen Instagram Addiction Scale was of 13.37 (SD = 4.41), with 29.5% of the sample spending

one to two hours a day ($n = 71$) on the social network and 29.1% showing a probable Instagram addiction ($n = 70$). Mean scores of 27.17 (SD = 5.34) were found on the Rosenberg Self-Esteem Scale and 16.31 (SD = 3.97) on the Satisfaction with Life Scale. A strong relationship was found between life satisfaction and self-esteem, with males tending to have an higher self-esteem comparing to females. A low negative correlation was found between self-esteem and the total score on the Bergen Instagram Addiction Scale, which was not maintained when analyzing groups with and without a probable Instagram addiction.

Conclusions: This study demonstrates the probable presence of instagram addiction and the potential role of low self-esteem. It also emphasizes the strong relationship between life satisfaction and self-esteem. Instagram updates, as well as habits developed during the pandemic period, may have worsened the instagram use. The study shows how paradoxical the impacts of using this social network can be. Furthermore, the present study raises awareness to new national investigations that explore the use of Instagram and how they are related to the impacts on users' lives.

EPP0052

Anxious-depressive symptoms after a first episode of schizophrenia: Response to treatment and psychopathological considerations from a 2-year follow-up study in Italy

L. Pelizza¹, E. Leuci², E. Quattrone² and A. Di Lisi^{3*}

¹Università di Bologna, Bologna; ²AUSL di Parma, Parma and ³Alma Mater Studiorum University of Bologna, Bologna, Italy

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.285

Introduction: Depression is common in schizophrenia and is correlated with suicide risk and poor long-term outcomes. However, the presence of depressive symptoms is often underestimated in both research and treatment, particularly at the illness onset.

Objectives: The goals of this study were: (a) to longitudinally observe anxious-depressive symptom levels in patients with First Episode Schizophrenia (FES) during a 24 months of follow-up period, and (b) to examine their associations with other psychopathology and the intervention patients received in an "Early Intervention in Psychosis" (EIP) program during the follow-up period.

Methods: The Global Assessment of Functioning (GAF) and the Positive And Negative Syndrome Scale (PANSS) were completed by 159 FES patients both at baseline and across the follow-up. Data were analyzed by linear regression analysis and Spearman's coefficients.

Results: Anxious-depressive symptoms had significant longitudinal associations with GAF deterioration and PANSS "Positive Symptoms", "Negative Symptoms" and "Disorganization" subscores. During the follow-up period, FES participants significantly improved the level of anxious-depressive symptoms. This was significantly associated with the number of case management and individual psychotherapy meetings the patient engaged in, as well as with lower antipsychotic doses prescribed during the follow-up period.

Conclusions: In conclusion, anxious-depressive symptoms are prominent in FES and at the initial entry into EIP programs. Anxious-depressive symptom severity tends to diminish overtime, especially with the provision of specialized EIP treatments. However, since we did not have a control population studied in parallel, we cannot say whether these results are specific to the protocols of EIP programs or just to the intensity of engagement in care.

¹Doctoral School of Psychology, Eötvös Loránd University; ²Institute of Psychology, Faculty of Education and Psychology, Eötvös Loránd University, Budapest; ³Institute of Social and Media Studies, Department of Sociology, University of Pécs, Pécs; ⁴Department of Psychiatry and Psychotherapy, Semmelweis University; ⁵NAP3.0-SE Neuropsychopharmacology Research Group, Hungarian Brain Research Program, Semmelweis University; ⁶Community Psychiatry Centre, Semmelweis University – Awakenings Foundation; ⁷National Institute of Mental Health, Neurology, and Neurosurgery, Nyíró Gyula Hospital, Budapest, Hungary; ⁸Human Flourishing Program, Institute for Quantitative Social Science, Harvard University, Cambridge, United States; ⁹Department of Cognitive Science, Budapest University of Technology and Economics; ¹⁰Institute of Behavioural Sciences, Faculty of Medicine, Semmelweis University and ¹¹Person- and Family-Oriented Health Science Research Group, Institute of Psychology, Faculty of Humanities and Social Sciences, Károli Gáspár University of the Reformed Church in Hungary, Budapest, Hungary

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.286

Introduction: The Mental Health Test serves as the operationalized, comprehensive measurement of Maintainable Positive Mental Theory which defines mental health (for either the non-clinical or psychiatric population) as a high level of global well-being, psychological, social and spiritual functioning, resilience, effective creative and executive functioning, savoring capacities, coping and enjoyment, regardless of the presence or absence of symptoms of psychopathology.

Objectives: To assist psychiatrists and clinical psychologists to assess their patients' psychological immune competence-based capacities and resources, depending on the mental health disorder diagnosis and the severity of the symptoms, the present study examined the psychometric properties of the Mental Health Test in a psychiatric sample.

Methods: The research was carried out in four Hungarian health-care facilities using a cross-sectional design. A total of 331 patients (140 male, 188 female, and 3 who preferred not to disclose their gender) completed the Mental Health Test, six well-being and mental health measures, and the Symptom Checklist-90. Clinical psychologists reported the mental disorder status of each participant.

Results: Confirmatory factor analysis showed a good fit of the five-factor model to the data for the clinical version of the Mental Health Test (CFI = 0.972, RMSEA = 0.034). High internal consistency coefficients (α : 0.70–0.84; ω : 0.71–0.85) and excellent external and content validity were reported. The Mental Health Test was not sensitive to sociodemographic indicators but was sensitive to correlates of well-being and symptoms of mental disorders in a psychiatric sample. Regression analyses demonstrated that unipolar depression and number of mental disorders were related to a lower overall Mental Health Test score. Personality disorders, unipolar depression, and the greater severity and higher number of mental disorders were associated with a lower global well-being score. Unipolar depression was related to lower savouring capacity. Self-regulation showed a correlation with the self-reported number of mental disorders only. Anxiety and somatization disorders, unipolar depression, and a higher number of self-reported mental disorders were related to a lower psychological resilience score. The regression model for the creative and executive efficiency subscale did not fit our data. The interaction of all combinations of psychotherapy and pharmacotherapy was significantly related to the overall Mental Health Test score and to the subscales. These results can later serve as a basis for designing intervention studies.

Conclusions: Our preliminary findings suggest that the Mental Health Test is a suitable measure for assessing mental health capacities and resources in psychiatric samples.

Premenstrual dysphoric disorder—an undervalued diagnosis? Preliminary results of a prospective study on Hungarian women

B. Pataki^{1*}, B. L. Kiss², I. Juhász², S. Kálmán¹ and I. Kovács¹

¹Department of Psychiatry, Albert Szent-Györgyi Medical School, University of Szeged and ²Albert Szent-Györgyi Medical School, University of Szeged, Szeged, Hungary

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.287

Introduction: The premenstrual dysphoric disorder (PMDD) is a new distinct diagnostic entity in the Fifth Edition of the Diagnostic and Statistical Manual of Mental Disorders (DSM-5). However, the severe premenstrual (PM) symptoms associated with PMDD result in functional impairment, globally, it remains highly underdiagnosed, underscoring the need for enhanced clinical recognition.

Objectives: This ongoing study aims to assess the prevalence and symptom profile of PMDD in a sample of Hungarian women. It is part of a comprehensive research process aiming to validate a prospective PMDD diagnostic questionnaire (Daily Record of Severity of Problems, DRSP) in order to facilitate the diagnosis of the disorder.

Methods: The study was performed in three steps. Firstly, retrospective data were collected from 112 women. Probable PMDD was assessed using the DSM-5 Based Screening Tool, while anxious-depressive symptoms and well-being were evaluated using the Beck Depression Inventory, the state subscale of the State-Trait Anxiety Inventory, and the WHO Well-Being Scale. Subsequently, prospective data were obtained from 9 women who completed the

DRSP along with the aforementioned mood questionnaires during both their PM and follicular phases.

Results: In the first research phase, the sample was divided into women with probable PMDD diagnosis (PMDD group, $n=68$) and women without probable PMDD diagnosis (nonPMDD group, $n=45$) based on the DSM-5-Based Screening Tool. The PMDD group reported significantly more severe depressive ($F(1; 56.2) = 19.394, p \leq 0.001$) and anxiety ($F(1; 35.6) = 17.714, p \leq 0.001$) symptoms and lower well-being ($F(1; 44.3) = 4.288, p = 0.04$) compared to the non-PMDD group, irrespective of the menstrual phase they experienced.

In the second and third research phases based on the DRSP, the sample was divided into women with probable PMDD diagnosis (PMDD group, $n=3$) and those without probable PMDD diagnosis (nonPMDD group, $n=6$). A statistically significant association was observed between the classifications according to the DSM-5 Based Screening Tool and the DRSP ($p=0.048$; Cramer's $V=0.79$). The PMDD group showed a tendency of lower well-being and more severe anxio-depressive symptoms than the nonPMDD group (Well-being: between phases $p=0.93$, between groups $p=0.06$; BDI-II: between phases $p=0.79$, between groups $p=0.07$; STAI-S: between phases $p=0.87$, between groups $p=0.17$).

Conclusions: The prevalence of PMDD was high in our sample. Women with probable PMDD retrospectively reported substantial affective difficulties and a decline in subjective well-being, regardless of their menstrual cycle. Prospective preliminary findings suggest a trend toward differentiation associated with probable PMDD. These results highlight the need for prospective clinical studies addressing the psychological symptoms of women with PM issues and the importance of appropriate treatment of the clinical appearance of PMDD.

doi: 10.1192/j.eurpsy.2024.288

Introduction: Adverse childhood experiences (ACE) have a significant negative impact on health. ACEs lead to more pronounced trait anxiety, among others, which serves as a basis for various mental and somatic symptoms. Recent findings suggest that the fact that individuals with more ACEs also have more maladaptive metacognitive beliefs may contribute to the development of these symptoms.

Objectives: We aim to study the possible mediating role of maladaptive metacognitive beliefs, resulting from adverse childhood experiences, on trait anxiety.

Methods: Data was collected online, anonymously, in a non-clinical population of adults over 18 years of age. The sample consisted of 304 subjects (84.21 % women, 15.79 % men). The applied questionnaires included a demographic questionnaire, the

Adverse Childhood Experiences Questionnaire 10 item version, the Meta-Cognitions Questionnaire, and the Spielberger Trait Anxiety Questionnaire. The system of correlations between the examined variables was explored using structural equation modeling (SEM). The study was carried out with ethical approval and in accordance with the Declaration of Helsinki.

Results: Our results confirm that ACEs have a significant impact on all the measured dimensions of maladaptive metacognitive beliefs. The direct effect of ACEs on adult trait anxiety is also significant. The results of the study on indirect effects support the joint mediating role of the five metacognitive dimensions. The strongest significant mediating effect was found for the uncontrollability and dangerousness of negative beliefs about worry. Both the direct and indirect effects of cognitive self-consciousness on adult trait anxiety are negative, which means that the more the cognitive self-consciousness is characteristic of someone, the lower the degree of trait anxiety in adulthood is.

Conclusions: Our results confirm the mediating effect of metacognitive beliefs on trait anxiety in the context of adverse childhood experiences, which points to the importance of further research on metacognition among the population that suffered early adversities. One of the limitations of the study roots in online data collection: the examined sample is not representative. Moreover, to extend the results, it is recommended to repeat the study on a clinical population. This would enable us to compare our results with those of the clinical population, which could provide further important results in the field of metacognition and adverse childhood experiences.

doi: 10.1192/j.eurpsy.2024.289

Introduction: Disturbances in the hypothalamic-pituitary-thyroid (HPT) and hypothalamic-pituitary-adrenal (HPA) axes have been frequently reported in treatment resistant depressed patients (TRDs). So far, the effects of intermittent theta-burst stimulation (iTBS) treatment—a form of repetitive transcranial magnetic stimulation (rTMS) technique—on the activity of the HPT and HPA axes are poorly understood.

Objectives: The present study aimed to evaluate the effects of iTBS sessions, applied to the left dorsolateral prefrontal cortex, in TRDs with abnormal chronobiological HPT functioning at baseline (BL) possibly associated with hypercortisolemia.

Methods: The $\Delta\Delta\text{TSH}$ test (i.e., the difference between the thyrotropin response to protirelin tests [ΔTSH] performed at 8 AM and 11 PM on the same day) and the dexamethasone suppression test (DST) were performed in 12 TRDs and 14 healthy hospitalized

control subjects (HCs). To be enrolled in this study, patients had to show at BL reduced $\Delta\Delta$ TSH values (i.e., < 2.5 mU/L) and a score of 18 or greater on the 17-item Hamilton Rating Scale for Depression (HAMD-17). Post-DST cortisol maximum (COR_{max}) serum level in excess of 120 nmol/L defined DST non-suppression (i.e., hypercortisolemia)—6 TRDs were DST non-suppressors at BL. After 10 and 20 iTBS sessions the $\Delta\Delta$ TSH test and the DST were repeated in all inpatients. A positive clinical response was defined by a final HAMD-17 score ≤ 8 .

Results: Compared to HCs, $\Delta\Delta$ TSH values were lower in TRDs at BL ($p < 0.00001$), and remained reduced after 10 and 20 iTBS sessions ($p < 0.001$ and $p < 0.02$ respectively). Post-DST COR_{max} levels were higher in TRDs than in HCs at BL ($p < 0.01$), but were comparable to those of HCs after 10 and 20 iTBS sessions. Responders ($n = 5$) were characterized by 1) a normalization of their $\Delta\Delta$ TSH values after 20 iTBS sessions (whereas after 10 iTBS sessions $\Delta\Delta$ TSH values were still reduced compared to HCs [$p < 0.05$]), and 2) a normality of post-DST COR_{max} levels at BL—while after 10 and 20 iTBS sessions post-DST COR_{max} levels were decreased compared to HCs ($p < 0.006$ and $p < 0.03$ respectively). Non-responders ($n = 7$) showed 1) no significant change in their $\Delta\Delta$ TSH values which remained lower than those of HCs at each assessment (all $p < 0.001$), 2) while increased post-DST COR_{max} levels found at BL ($p < 0.0008$ vs. HCs) normalized from the 10th iTBS session.

Conclusions: The present pilot study suggests that successful iTBS treatment can restore the chronobiological activity of the HPT axis. Although iTBS may increase glucocorticoid receptor signaling, baseline hypercortisolemia could negatively impact subsequent response to iTBS treatment.

Brain atrophy but not white matter lesions associate with ECT-related confusion

A. A. Politis¹, N. Kokras^{1*}, G. Velonakis² and A. M. Politis¹

¹First Department of Psychiatry and ²Research Unit of Radiology and Medical Imaging - Second Department of Radiology, National and Kapodistrian University of Athens, Medical School, Athens, Greece

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.290

Introduction: Patients undergoing electroconvulsive treatment (ECT) may display an acute confusional state, often characterized by transient disorientation, inattention, memory and cognitive deficits.

Objectives: In this retrospective medical chart naturalistic study, we sought to determine whether white matter lesions and brain atrophy associate with the emergence of confusion during ECT treatment and preliminary results are presented herein

Methods: Medical charts of 24 consecutive inpatients with depression admitted to a psychogeriatric ward and subjected to bilateral frontotemporal ECT were examined retrospectively for patient and clinical characteristics. Mini-Mental State Examination (MMSE) and Geriatric Depression Scale (GDS) scores at admission and hospital discharge were retrospectively collected. Available brain

Magnetic Resonance Imaging (MRI) scans were graded for lesions (white matter hyperintensities, WMH), parietal, temporal and global brain atrophy

Results: In this pilot study of mostly elderly patients, 50% displayed signs of confusion. All patients improved substantially, as indicated by MMSE and GDS scores, irrespectively of whether they experienced transient confusion during ECT. Preliminary results indicate that WMH are unrelated to the emergence of confusion. Instead, brain atrophy, and in particular temporal lobe and mostly frontal lobe atrophy associated with confusion

Conclusions: In our sample of elderly inpatients with depression subjected to bilateral ECT, preliminary results of this pilot study indicate that brain atrophy, as evidenced by MRI scans, appears as a predictor of post-ECT confusion. Moreover, the Pasquier scale, and specifically the scale sub-scores regarding brain atrophy in the frontal and temporal sulci, could prove useful in helping the clinician estimate the probability of ECT-related confusion during ECT treatment

Changing Tactics? Optimizing ECT in difficult-to-treat depression (ChaT): study protocol

L. Van den Eynde^{1*}, K. Vansteelandt¹, K. Hebbrecht¹, J. Obbels¹, S. Verspecht¹, L. Gistelinck², P.-J. Geerts³, D. Schrijvers⁴ and P. Sienaert¹

¹Academic Center for ECT and Neuromodulation (AcCENT), UPC KU Leuven, Kortenberg; ²Psychiatry, AZ Sint Jan Bruges, Bruges; ³Psychiatry, AZ Groeninge, Kortrijk and ⁴Collaborative Antwerp Psychiatric Research Institute (CAPRI), UAntwerpen, Antwerp, Belgium

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.291

Introduction: Electroconvulsive therapy (ECT) is an evidence-based treatment for difficult-to-treat depression, in which an electrical stimulus is applied via right unilateral (RUL) (Fig 1) or bitemporal (BT) electrodes (Fig 2). Current guidelines recommend to start ECT with RUL placement, except for cases where rapid response is needed. BT ECT has the reputation of exerting a stronger and faster antidepressive effect, but is associated with more pronounced cognitive side effects, as compared to RUL ECT. Recent studies, however, suggest comparable outcomes. In patients responding to ECT, most of the improvement in depressive symptom severity is witnessed early in the treatment course. In case of non-response, it is common practice to switch from RUL to BT electrode placement, although scientific evidence is lacking. As an answer to this research gap, the ChaT-trial was designed: a randomized controlled trial (RCT) to address which treatment strategy (either continue RUL ECT or switch to BT ECT) speeds up recovery with the least impact on cognitive function, in case of early non-response after 4 ECT sessions.

Objectives:

- 1) To compare the antidepressant efficacy and cognitive effects of continuing RUL ECT vs switching to BT ECT.

- 2) To assess group and subject-specific trajectories of depressive symptom severity and neurocognitive performance during the acute ECT course and up to 3 months post-treatment.

Methods: This multi-center double-blind RCT includes adult patients with a uni- or bipolar depression. In case of non-response (<50% decrease of IDS-CR score (Inventory of Depressive Symptomatology-Clinician Rated)) after 4 sessions of brief-pulse high-dose RUL ECT, patients are randomized to either continue RUL ECT, or switch to brief-pulse moderate dose BT ECT until remission. Depressive symptoms are assessed by IDS-CR, Psychotic Depression Assessment Scale (PDAS) and CORE assessment of psychomotor change. An extensive neuropsychological test battery is used to assess different domains of cognitive functioning, e.g., autobiographical memory using the Colombia University- Autobiographical Memory Interview Short- Form (CU-AMI-SF)(Fig 3). **Results:** Our hypotheses are: (1) continuing RUL ECT is non-inferior to switching to BT ECT in terms of depressive symptom severity, and (2) continuing RUL ECT is superior to switching to BT ECT in terms of cognitive side effects.

Image:

Figure 1: Right unilateral electrode placement (RUL)

Figure 2: Bitemporal electrode placement (BT)

Image 2:

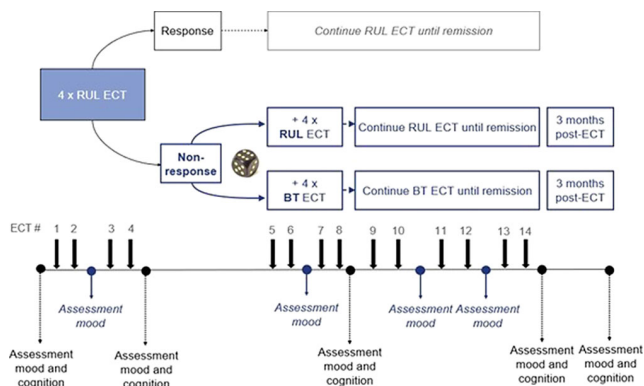

Figure 3: Study design

Conclusions: The ChaT-trial is the first RCT comparing anti-depressant efficacy and cognitive effects of continuing RUL ECT with switching to BT ECT in case of early non-response during an acute ECT-course. The results may optimize clinical decision making, speeding up recovery, while minimizing cognitive side effects.

Postictal recovery of orientation in person, place and time relates to restoration of cortical activity after electroconvulsive therapy

S. Stuiver^{1,2*}, J. Pottkämper^{2,3}, J. Verdijk^{1,2}, F. ten Doesschate¹, M. van Putten^{2,4}, J. Hofmeijer^{2,3} and J. van Waarde¹

¹Psychiatry, Rijnstate Hospital, Arnhem; ²University of Twente, Enschede; ³Neurology, Rijnstate Hospital, Arnhem and ⁴Clinical Neurophysiology, Medisch Spectrum Twente, Enschede, Netherlands

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.292

Introduction: Most patients show temporary impairments in clinical orientation (i.e., orientation in person, place, and time) after electroconvulsive therapy (ECT)-induced seizures. It is unclear whether postictal reorientation is related to electroencephalography (EEG) restoration. This tentative relationship may shed light on mechanistic aspects of reorientation after ECT.

Objectives: To study whether postictal EEG restoration after an ECT-induced seizure is related to recovery of clinical orientation in the cognitive domains person, place and time.

Methods: We performed a longitudinal study in ECT patients and collected continuous postictal EEGs. Postictal EEG restoration was estimated by the evolution of the normalized alpha/delta ratio (ADR). Recovery of orientation in the cognitive domains of person, place, and time was assessed using the Reorientation Time (ROT) questionnaire. In each cognitive domain, a linear mixed model was fitted to investigate the relationship between ROT and postictal EEG restoration. In these models, other (ECT-)parameters including seizure duration, use of benzodiazepines and electrode placement were included.

Results: In total, 272 ictal and postictal EEG recordings of 32 patients were included. In all domains, longer ROT was associated with slower postictal EEG recovery. Longer seizure duration and use of benzodiazepines were related to longer ROT in all domains. Increased total charge of the ECT-stimulus was associated with increased ROT in place and age was positively associated with ROT in time.

Image:

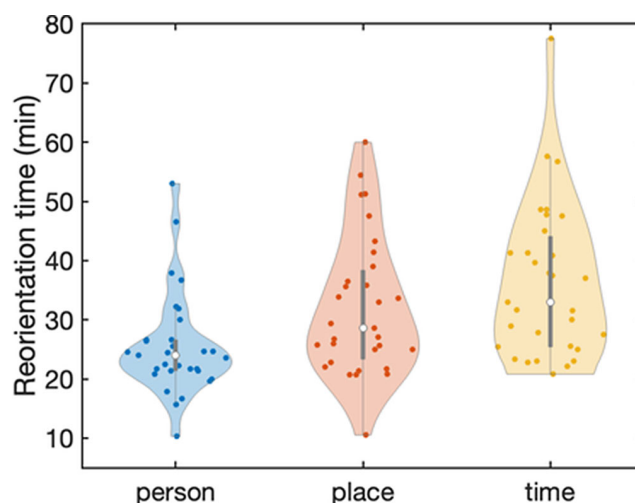

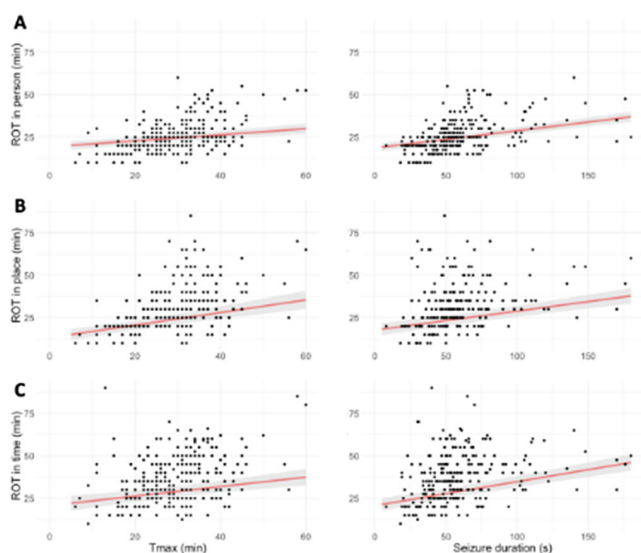

Image 2:

Conclusions: We show a relationship between restoration of the postictal EEG and clinical reorientation in person, place and time after ECT-induced seizures. This indicates that clinical reorientation probably depends on gradual cortical synaptic recovery. Increased seizure duration and the use of benzodiazepines were also related to increased ROT values. Longer seizures and use of benzodiazepines may induce longer postictal synaptic depression.

Relation between biomarkers and suicide attempts in patients with schizophrenia

A. Garcia Fernandez¹, C. Martínez-Cao¹, M. Couce-Sánchez^{1*}, L. González-Blanco¹, P. Sáiz¹ and P. García-Portilla¹

¹University of Oviedo, Oviedo, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.293

Introduction: An increased risk of suicide has been reported by psychiatric patients, including schizophrenia¹. Numerous evidence suggests alterations in the grade of pro-inflammatory impact on suicidal behavior², and this relation has been shown in patients with mood or anxious disorders^{3,4}. However, the grade of inflammation impact suicidal behavior in patients with schizophrenia has hardly been investigated.

Objectives: Identify peripheral blood biomarkers of suicidal behavior in patients with schizophrenia, including inflammatory and lipid profile parameters.

Methods: Secondary analysis of a cross-sectional study. Sample: 254 patients with schizophrenia, aged 18-72. Assessments: ad-hoc demographic and clinical questionnaire, PANSS, CDS, CAINS,

PSP. Inflammatory and lipid parameters: C-reactive protein (PCR), interleukin 6 (IL-6); high-density lipoprotein cholesterol (HDL-C), low density lipoprotein cholesterol (LDL-C), total cholesterol (TC), triglyceridaemia (TG). Statistical analysis: Correlations, T Student, U Mann-Withney and lineal regression.

Results: Mean age: 40.49 (13.10). Men: 64.2%.

No statistically significant differences were found between patients with suicide attempts and those without in any of the inflammatory or lipid parameters ($p > 0.05$). However, differences were found in terms of suicide attempts (yes/no) in the PANSS negative ($T = -2.217$; $p = 0.028$) and PANSS general psychopathy ($T = -4.224$; $p < 0.001$), in depressive symptoms ($T = -6.967$; $p < 0.001$), and the MAP subscale of the CAINS ($T = -3.741$; $p < 0.001$).

Among patients with suicide attempts ($n = 42$; 16.52% of the sample) (mean = 1.90; $sd = 1.73$; Range: 1-7), statistically significant correlations were found with PCR ($r = 0.309$; $p = 0.046$), but not with cytokines and lipid parameters. On the other hand, no correlations were found with age, sex, length of illness, and any of the clinical scales.

A multiple linear regression was performed considering the number of suicide attempts as the dependent variable and as independent variables, age, sex, and those that were significant in the bivariate analysis (PCR).

A predictive model was found that explains 9.60% of the variance of number of suicide attempts ($F = 4.224$; $p < 0.001$). The variable that entered the model was PCR ($\beta = 0.309$; $p = 0.046$).

Conclusions: The increase in inflammation (manifested by the elevation of PCR) is related to an increase in the number of suicides. On the contrary, no correlations were found with lipid parameters or interleukins.

EPP0062

Relevance of measurement of bêta-2-microglobulin in schizophrenia

A. Aissa^{1,2*}, A. B. C. Arij³, S. Jedda¹, F. Askri¹, R. Jomli¹ and H. Abaza⁴

¹Psychiatry A, Razi Hospital, Manouba; ²Psychiatry, Faculty of Medicine of Tunis; ³Human genetic lab, Salah Azaiez Institute, Tunis and ⁴Clinical biology, Razi Hospital, Manouba, Tunisia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.294

Introduction: There are several arguments supporting the inflammatory hypothesis in schizophrenia (SCZ). Among the inflammatory markers, beta-2- microglobulin ($\beta 2M$) is associated with abnormalities in neurogenesis and cognitive impairment described in (SCZ).

Objectives: The objectives of our study were to evaluate the level of $\beta 2M$ in a group of patients compared with a control group and to investigate the sociodemographic, clinical, and environmental factors associated with elevated $\beta 2M$ levels

Methods: We conducted a cross-sectional in outpatients with SCZ. We collected patients sociodemographic, environmental, and clinical data. We assessed psychopathology with the PANSS. We measured serum $\beta 2M$ concentration.

Results: We included 30 patients with SCZ compared with 20 controls. Patients mean age was 40.23 ± 10.66 . The mean level of $\beta 2M$

was $1,98 \pm 0.42$ mg/L for patients and 1.65 ± 0.56 mg/L for control group. The difference was significant between the patient group and the control group ($p < 10^{-3}$). No environmental or clinical factors have been associated with $\beta 2M$ levels other than smoking status ($p = 0.046$).

Conclusions: Further research with larger samples investigating the different stages of SCZ especially early psychosis would be needed to confirm the relevance of this biomarker in SCZ.

EPP0064

Aberrant Salience, Psychotic-Like Experiences, and Anxiety: a Case-Control Study

G. P. Merola¹, A. Patti¹, D. Benedetti^{2*}, B. Bozza¹, A. Ballerini¹ and V. Ricca¹

¹Psychiatry and ²University of Florence, Florence, Italy
*Corresponding author.
doi: 10.1192/j.eurpsy.2024.295

Introduction: In this research, we investigate how Aberrant Salience (AS), Psychotic-Like Experiences (PLEs), and anxiety are interlinked in both healthy individuals and subjects with psychotic disorders. AS is a trait contributing to a susceptibility to psychosis and anxiety, while PLEs are subclinical states often leading to psychosis. We hypothesize that AS impacts the occurrence and severity of PLEs, which in turn influences anxiety.

Objectives: The goal is to offer a more nuanced understanding of the risk factors leading to psychotic disorders and to shed light on anxiety psychopathogenesis in healthy and psychotic populations.

Methods: We used self-reported questionnaires like the Aberrant Salience Inventory (ASI), Community Assessment of Psychic Experiences (CAPE), and Symptom Check List-90-revised (SCL-90-R). Data analysis included descriptive statistics and mediation analysis, adjusting for age, gender, and education. Controls were sourced through convenience and snowball sampling, while out-patients diagnosed with Schizophrenia Spectrum Disorder, Bipolar Disorder with psychotic features, or Major Depression with psychotic features were recruited from Florence University Hospital.

Results: A total of 207 participants were included, with 163 controls and 44 patients. Descriptive statistics are shown in Table 1. Mediation analysis showed that PLEs frequency acted as a mediator between AS and anxiety only in the control group (Figure 1), not in patients (Figure 2).

Table 1. Descriptive statistics - Mean ± Std. Deviation.

	Control Group (N=163)	Psychotic Group (N=44)	p-value
ASI	11.690 ± 6.098	14.360 ± 7.163	0.014
CAPEposF	1.391 ± 0.340	1.617 ± 0.488	0.001
CAPEposD	1.792 ± 0.615	1.941 ± 0.694	0.167
SCL-90-R-ANX	0.678 ± 0.600	0.905 ± 0.643	0.030

Legend: ASI, Aberrant Salience Inventory; CAPEposF, Community Assessment of Psychic Experiences - positive dimension - Frequency; CAPEposD, Community Assessment of Psychic Experiences - positive dimension - Distress; SCL-90-R-ANX, Symptom Check List-90-revised, Anxiety.

Image:

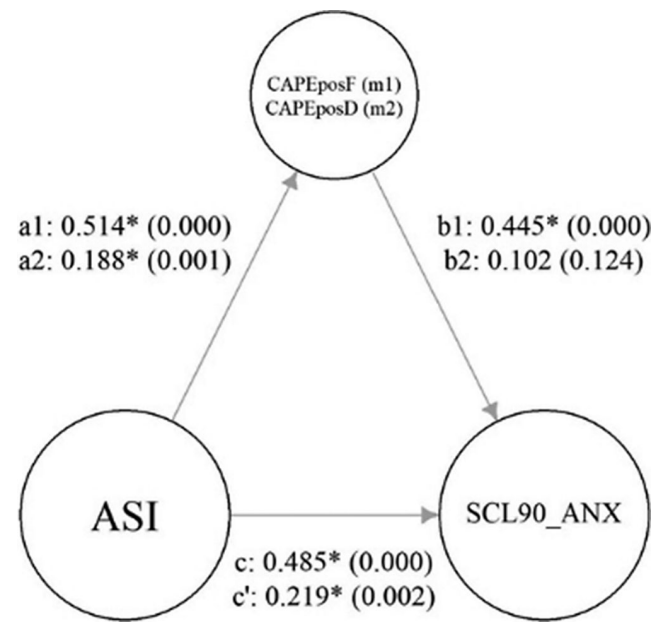

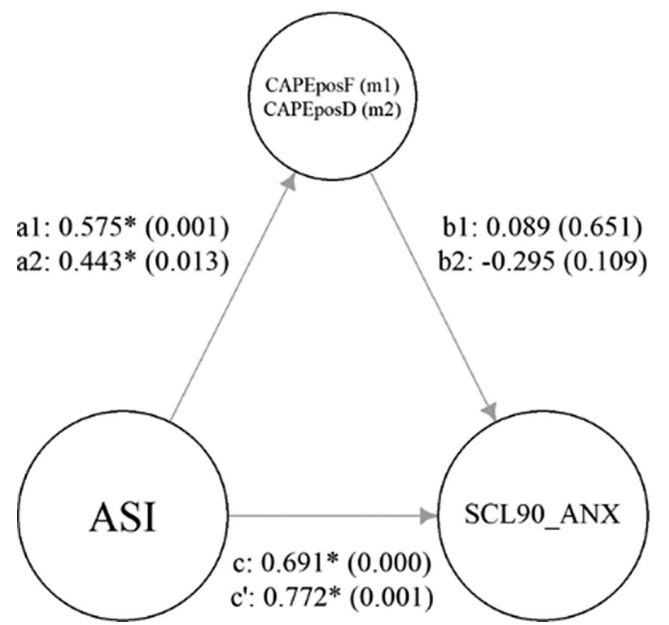

Image 2:

Conclusions: PLEs triggered by AS led to anxiety in the control group but not in psychotic patients. The discrepancy could be due to reduced novelty and awareness of experiences in the patient group. This may affect how bodily responses to PLEs are perceived and suggests the need for specialized treatment approaches for anxiety in these two groups.

Challenges in Managing Antipsychotic-Induced Hyperprolactinemia: A Case Study and Clinical Considerations for Aripiprazole Integration

J. Garde Gonzalez*, P. Herrero Ortega, A. Oliva Lozano, M. A. Morillas Romerosa and M. N. P. Soler

Psychiatry, La Paz University Hospital, Madrid, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.296

Introduction: Current guidelines for managing antipsychotic-induced hyperprolactinemia recommend the use of aripiprazole, either as a substitute or in combination with the primary antipsychotic. However, there have been reported cases of exacerbated psychotic symptoms when introducing aripiprazole after chronic treatment with another antipsychotic.

Objectives: We present a case of a patient with unspecified schizophrenia spectrum disorder receiving amisulpride, who developed worsened psychotic symptoms following the introduction of aripiprazole to treat hyperprolactinemia. We also review this phenomenon and its clinical management in the literature.

Methods: Clinical case report and brief literature review.

Results: Ms. G, a 54-year-old woman diagnosed with unspecified schizophrenia spectrum disorder, was on amisulpride 400mg/day and had remained asymptomatic for months. During a follow-up, she complained of mastalgia and had a prolactin level of 71.7 ng/mL. Following clinical guidelines, aripiprazole was added at 10mg/day. Within a month, anxiety and sleep disturbances escalated, followed by the reappearance of psychotic symptoms. Aripiprazole was discontinued, amisulpride reinstated, achieving stability. Subsequently, hyperprolactinemia was managed using metformin.

Antipsychotic-induced hyperprolactinemia is common, especially with first-generation antipsychotics, causing various symptoms in both genders. Long-term consequences may include weight gain, reduced bone density, and potentially increased breast cancer risk, among others.

Aripiprazole is an atypical antipsychotic with a partial agonist effect on dopamine D2 and D3 receptors. This means that aripiprazole will act as a functional D2-antagonist under hyperdopaminergic conditions, but a functional D2-agonist under hypodopaminergic conditions. This property of aripiprazole may contribute to counteract 'prolactin-raising' agents, acting as a D2 agonist, potentially reducing prolactin rise.

Chronic use of presynaptic D2/D3 antagonist (amisulpride) might create a hypodopaminergic environment and hypersensitivity to dopamine agonists, possibly explaining worsened symptoms with aripiprazole introduction.

To prevent adverse outcomes when adding or switching to aripiprazole, gradual reduction of the previous antipsychotic (amisulpride) and high-dose aripiprazole initiation (30-40 mg/day) can help.

Conclusions: Antipsychotic-induced hyperprolactinemia is a serious issue that deserves our attention. While aripiprazole is recommended by several guidelines to treat it, introducing it to patients on chronic antipsychotic treatment may lead to a worsening of psychotic symptoms. Caution is recommended when combining aripiprazole with potent D2 receptor blockers. To mitigate this effect, gradual dose reduction of the previous antipsychotic and high-dose aripiprazole initiation are crucial.

Prescription practices for antipsychotic medication in an acute inpatient ward: Risks / benefits discussions with patients and performance of baseline investigations as per NICE guidelines

M. Elesawy, G. J. Munday and N. Lekka*

Sheffield Health and Social Care Foundation Trust, Sheffield, United Kingdom

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.297

Introduction: Antipsychotic medications are essential for managing psychiatric disorders, offering symptom relief and improved functioning. However, their use carries potential risks. Vigilant monitoring and patient engagement are crucial when initiating antipsychotics.

Objectives: To explore whether comprehensive discussions with patients concerning the benefits and risks of antipsychotics are taking place, and whether baseline investigations are performed before initiation of antipsychotics as per NICE guidelines.

Methods: This retrospective study focused on admissions to a male acute ward between March 1 and May 31, 2023. Data from electronic patient records included demographics, Mental Health Act (MHA) status, psychiatric diagnoses, medical co-morbidities, documentation of medication benefits / side effects discussions with patients, medication information provision, as well as baseline investigations involving weight, height, waist/hip circumference, pulse, blood pressure, blood glucose, HbA1c, lipid profile, prolactin levels, movement disorder assessment, nutritional status, diet, physical activity, and ECG.

Results: Among 23 admitted patients, 15 were newly initiated or reintroduced to antipsychotics, with 14(93.3%) admitted under the MHA. Primary diagnoses included Paranoid Schizophrenia (33.33%), Unspecified Non-Organic Psychosis (20%), Bipolar Affective Disorder (20%), and others. Medical comorbidities were observed in 10(66.7%), notably type 2 diabetes (40%). Among initiates, 6(40%) were new to treatment, while in 9(60%) it was re-initiated.

Within the 15-patient group, discussions on treatment benefits engaged 11(73.3%), while 4(26.7%) lacked complete documentation. Only 6(40%) had discussions about side effects. Metabolic side effects were discussed with 3(20%), extrapyramidal effects with 2(13.33%), while 4(26.7%) had general side effect talks. Patient information leaflets were given to 5(33.3%) patients. Baseline measurements: 12(80%) had weight/height, 4(26.7%) waist/hip, and 14(93.3%) pulse/blood pressure assessed. Blood tests were declined by 4(26.7%). Baseline glucose, HbA1c, lipids, and prolactin were assessed in 8(53.3%), 10(66.7%), 9(60%), and 8(53.3%) patients respectively. Nutritional status was assessed in 13(86.7%), movement disorders in 1(6.7%), and physical activity in 1(6.7%). All 15(100%) patients were offered ECGs, although 5(33.3%) declined.

Conclusions: Adherence to NICE guidelines for baseline investigations and risk/benefit discussions prior to antipsychotic initiation was low, apart from ECGs, weight/height, pulse/blood pressure, assessment of nutritional status, and discussions about antipsychotics' benefits. Implementing effective monitoring and patient engagement to mitigate potential side effects, is crucial to facilitating the safe and efficient utilisation of antipsychotics.

Differences in adherence to treatment, relapses and healthcare costs between delusional disorder and paranoid personality disorder

R. Álvarez-García^{1*}, S. Abascal-Peiró², A. Gonzalo de Miguel², C. Blanco-Londono¹, A. Martínez-Pillado¹, L. Mata-Iturralde² and E. Baca-García²

¹Hospital Universitario Rey Juan Carlos and ²Hospital Universitario Fundacion Jimenez Diaz, Madrid, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.298

Introduction: Limited information is available regarding the clinical features, optimal treatment and prognosis of Paranoid Personality Disorder (PPD) and Delusional Disorder (DD). This is partly due to the low prevalence of cases and poor patient insight. The difference between DD and PPD has been questioned in the literature, as some studies have described them as a continuum, highlighting the role of specific personality traits in the transition to clinical delusions.

Nonadherence to pharmacological treatment is one of the most challenging aspects. This further leads to relapses, increased use of emergency psychiatric services, psychiatric admissions, longer periods of hospitalization, and an increased cost of illness to healthcare systems.

Objectives: The primary goal of this study is to compare the differences between DD and PPD in terms of medication adherence, relapses, lost to follow-up, and costs. Other aims of this study are to analyze the differences in these variables between patients who are adequately adherent and patients who are not

Methods: An observational, retrospective, and multicenter descriptive epidemiological study was conducted. Patients were selected from four public departments of psychiatry in Madrid, providing an area of roughly one million people. All patients were older than 18 years-old, diagnosed with DD or PPD from 2005 to 2022. Data were extracted from electronic medical records and from electronic prescribing program used in the public health system. The study was approved by the Hospital Fundación Jiménez Díaz Ethics Committee.

Results: 1227 individuals diagnosed with DD (974 patients, 79.3%) or PPD (253 patients, 20.61%). 23.81% (232 patients) of the DD-group did not take out the prescribed medication of the pharmacy, and 16.6% (42 patients) of the PPD-group were considered non-adherent.

Adherent patients had greater follow-up (4.02 vs 2.89 years) and shorter hospital stays (5.15 vs 8.6 days, $p < 0.05$) compared to non-adherent patients. DD patients doubled the average hospitalization stay compared to the PPD group (6.7 vs 2.96 days, $p < 0.01$).

Regarding costs: DD had higher hospitalization costs than PPD (1164 vs 488 euros per year) and higher total costs than PPD (2180 vs 1528 euros per year, $p < 0.05$). The costs were also higher in non-adherent than in adherent patients (2570 vs 1895 euros per year, $p < 0.05$).

Conclusions: Our sample of 1227 DD and PPD patients followed from 2005-2022 is, to our knowledge, one of the largest collected to date. We found sociodemographic and clinical differences between the DD and the PPD group. We also found differences between adherent and non-adherent patients, highlighting that non-adherence is associated with longer mean stay of hospitalization and more costs, both hospitalization and total direct healthcare

costs. We have also found association between non-adherence and risk of psychotic relapse.

doi: 10.1192/j.eurpsy.2024.299

Introduction: Psychotic patients often require pharmacological treatment, which may prove ineffective, leading to treatment-resistant psychosis necessitating the use of clozapine. However, the emergence of side effects can result in discontinuation, potentially triggering a relapse of psychotic symptoms. One significant side effect is antipsychotic-induced weight gain which, over time, can lead to adverse metabolic events. Recent translational research is evaluating the impact of prenatal factors on the metabolic outcomes of psychotic patients, using a surrogate marker of the intra-uterine milieu such as birth weight (BW).

Objectives: We aim to evaluate the changes in leptin, adiponectin, and insulin levels in patients with treatment-resistant psychosis who initiate clozapine treatment due to persistent psychotic symptoms.

Methods: Subjects older than 18 years with a diagnosis of a major mental disorder and initiating clozapine were enrolled in this 18-months longitudinal study. Neurohormones levels, including leptin, adiponectin, and insulin were measured at baseline, 8 and 18 months during follow-up. Statistical analysis were conducted by using a fixed-effects model.

Results: A total of 23 subjects initiating clozapine were evaluated during the initial mandatory 18-week period. Neurohormones, specifically leptin and adiponectin, were measured at three time points: baseline, 8 weeks, and 18 weeks. The changes in leptin levels were significantly associated with birth BW with sex differences, being inversely correlated only in females. Adiponectin was

significantly associated with BW, being inversely correlated in males. Conversely, there was no observed association between insulin levels and BW.

Conclusions: Our findings highlight the significance of prenatal factors in influencing the subsequent evolution of neurohormones in individuals initiating clozapine treatment. This suggests that subjects with lower BW tend to exhibit elevated neurohormone values, emphasizing the role of prenatal events in this context.

Fictional faces of female suicide: Qualitative analysis of selected Russian-language texts of the school reader

E. B. Lyubov* and N. D. Semenova

Moscow Research Institute of Psychiatry – a branch of the V. Serbsky National Medical Research Centre for Psychiatry and Narcology of the Ministry of Health of the Russian Federation, Moscow, Russian Federation

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.300

Introduction: Isaiah Berlin's (1948) exploration of the self-searching of Russian thinkers includes studies of the writers – Tolstoy and others (now – Russian-language texts of the school reader). These studies refute a widespread misconception about the relations between Russian writers and thinkers: namely, that in Russia literature and radical thought form two distinct traditions related only by mutual hostility. The works of Tolstoy, Dostoevsky, Karamzin, Leskov, Ostrovsky, and of minor novelists too, are penetrated with a sense of their own time, of this or that particular social and historical milieu and its ideological content, to an even higher degree than the 'social' novels of the west. The personal characteristics of suicide victims, heroines of Russian literature, along with the gender aspects, deserve attention in suicidal behavior (SP) focus.

Objectives: To study personal characteristics of suicide victims, heroines of fiction.

Methods: Qualitative analysis of selected Russian-language texts of the school reader.

Results: At the dawn of literature, we have seen fiery heroines and tremulous victims in the arms of death. As psychology approach was developed, and we get acquainted with the tragic backstory. Psychotypes of suicides are exaggerated and overlapped. «Hysterical»: manipulative, frigid nymphomaniac (e.g., Anna Karenina). «Freedom-loving rebel» (i.e., Katerina reincarnations from A. Ostrovsky) in conditions of excessive regulation. «She-Devil, or Rebel Without a Cause». The obsession with death turns into a criminal and a victim (e.g., «Lady Macbeth of the Mtsensk» by N. Leskov, Turgenev's Susanna or Klara Milich). The image of a vindictively furious («velvet and tiger claws») woman descends to the Victorian view of female self-will. «Mimosa» is a sensitive, dreamy person, unable to resist the hardships of life, dependent (dies with her beloved, objection). In suicide, the strength of weakness is the outcome of a humiliating life (e.g., Karamzin's

«Poor Liza», «A Gentle Creature» by F. Dostoevsky. The meaning of suicides is the following: a call (to compassion, salvation), a «cry for help», atonement for one's (imaginary) – someone else's (by proxy) guilt, and release from encumbrance.

Conclusions: Fiction and life are united by emotionally unstable characters and/or depression as markers of unsatisfactory resilience. The cultural diversity of gender patterns and interpretations of SP challenges the essentialist view that «femininity» and marriage are protective factors. SP patterns illustrate and complement the explanatory concepts of SP. The inner world of suicidal people is fascinating and contributes to the evidence-based optimism in the «patient-centric» crisis care model.

Decision-making competence in patients with depression and a history of suicide attempt: A systematic review

I. Pavlou¹, V. Efstathiou², A. Karvouni³, I. Theodoridou³, N. Smyrnis³, I. Michopoulos³, R. Gournellis³ and A. Papadopoulou^{3*}

¹MSc «Liaison Psychiatry: Integrative Care of Physical and Mental Health»; ²Psychology Department, National and Kapodistrian University of Athens and ³Second Department of Psychiatry, National and Kapodistrian University of Athens, «Attikon» University General Hospital, Athens, Greece

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.301

Introduction: Decision-making is a complex process, and little is known about the various elements that comprise it. Recent literature on neurocognitive deficits in patients with a history of suicidality has highlighted that impaired (non-adaptive) decision-making is one of the most consistent deficits in individuals with a history of suicidality.

Objectives: This study aims to systematically review the available evidence on decision-making capacity in depressed patients with a history of suicide attempts.

Methods: A systematic search was conducted in PubMed, Psycnet, Elsevier and Scopus with additional searching through bibliographic references. This search was performed until the 31st of August 2022 and provided information on decision-making capacity in relation to suicidality and depression.

Results: The literature review provided 377 references, the titles and abstracts of which were reviewed for relevance to this study and the entry criteria set. The review of the title and abstract of these studies resulted in 50 articles that were potentially relevant to the study topic and a further review was then conducted to re-examine the selected studies and articles, which resulted in the final selection of 20 studies. The outcome measure used by the majority of studies as a measure of decision-making ability was the IOWA Gambling Task (IGT), in which the performance of patients with a history of depression and self-harm in most studies was significantly worse than that of healthy controls. Some methodological characteristics of the studies included in this review complicated the interpretation of the results, such as the sample size and characteristics of each study.

Conclusions: Decision-making ability shows alterations in patients with a history of suicidality and depression, confirming the findings of previous studies. Furthermore, an impaired or dysfunctional decision-making ability may potentially be a predictor of suicidal behaviour in patients with depression, a possibility that could be a reason for further research in this field, both in the context of investigating predictors and in developing appropriate treatments for these patients.

The Global Burden of Suicidal Behavior Among People Experiencing Food Insecurity: A Systematic Review and Meta-analysis

M. M. M. Kaggwa

Department of Psychiatry and Behavioral Neurosciences, mcmaster University, Hamilton, Canada
doi: 10.1192/j.eurpsy.2024.302

Introduction: Food insecurity has become a growing burden within a global context where climate change, catastrophes, wars, and insurgencies are increasingly prevalent. Several studies have reported an association between suicidal behaviors (i.e., suicide ideation, plans, and attempts) and food insecurity. This meta-analytic review for the first time, synthesized the available literature to determine the pooled prevalence of suicidal behaviors among individuals experiencing food insecurity, and examined the strength of their association.

Objectives: To determine the pooled prevalence of suicidal behaviors among individuals experiencing food insecurity, and examine the strength of their association.

Methods: Databases (*Ovid, PubMed, Web of Science, and CINAHL*) were searched using the appropriate search term from inception to July 2022. Eligible studies reporting the number/prevalence of suicidal behaviors among individuals experiencing food insecurity or the association between food insecurity and suicidal behaviors were included. The pooled prevalence of suicidal behaviors was determined using the random-effects model. The review was registered with PROSPERO (CRD42022352858).

Results: A total of 47 studies comprising 75,346 individuals having experienced food insecurity were included. The pooled prevalence was 22.3% for suicide ideation (95% CI: 14.7-29.9; $I^2=99.6\%$, $p<0.001$, $k=18$), 18.1% for suicide plans (95% CI: 7.0-29.1; $I^2=99.6\%$, $p<0.001$, $k=4$), 17.2% for suicide attempts (95% CI: 9.6-24.8; $I^2=99.9\%$, $p<0.001$, $k=12$), and 4.6% for unspecified suicidal behavior (95% CI: 2.8-6.4; $I^2=85.5\%$, $p<0.001$, $k=5$). There was a positive relationship between experiencing food insecurity and (i) suicide ideation (aOR=1.049 [95% CI: 1.046-1.052; $I^2=99.6\%$, $p<0.001$, $k=31$]), (ii) suicide plans (aOR=1.480 [95% CI: 1.465-1.496; $I^2=99.1\%$, $p<0.001$, $k=5$]), and (iii) unspecified suicide behaviors (aOR=1.133 [95% CI: 1.052-1.219; $I^2=53.0\%$, $p=0.047$, $k=6$]). However, a negative relationship was observed between experiencing food insecurity and suicide attempts (aOR=0.622 [95% CI: 0.617-0.627; $I^2=98.8\%$, $p<0.001$, $k=15$]). The continent and the countries income status where the study was conducted were the common cause of heterogeneity of the differences in the odds of the relationships between experiencing

food insecurity and suicidal behaviors - with North America and high-income countries (HICs) having higher odds. For suicide attempts, all non HICs had a negative relationship with food insecurity.

Conclusions: There is a high prevalence of suicidal behaviors among individuals experiencing food insecurity. Initiatives to reduce food insecurity would likely be beneficial for mental well-being and to mitigate the risk of suicidal behaviors among population experiencing food insecurity.

The paradoxical finding of suicide attempts having a negative relationship with food insecurity warrants further research.

Examining the Effects of COVID-19 on Suicide Attempts in Budapest: A Focus on Violent and Non-Violent Attempts

M. Bérdi^{1*}, N. Hajduska-Dér¹, B. Sebők², N. Szeifert^{3,4}, L. Bálint^{5,6} and S. Szilágyi¹

¹Psychiatry and Crisis Intervention, Péterfy Sándor Utcai Hospital-Clinic and Trauma Centre; ²School of PhD Studies Workgroup for Science Management, Semmelweis University; ³National Institute of Sports Medicine; ⁴Clinical Psychology and Addictology, Eötvös Lóránd University; ⁵Demographic Research Institute of the Hungarian Central Statistical Office, Budapest and ⁶Department of Sociology, University of Pécs, Pécs, Hungary

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.303

Introduction: In Hungary, in contrast to most other countries, suicide deaths increased significantly during the first year of the COVID-19 epidemic (March to December 2020). Globally, the burden of emergency care in the healthcare system tended to decrease during the first period of the epidemic.

Objectives: Our research aimed to evaluate the changes in the number of intentional suicide attempts by violent and non-violent means during the first two years of the epidemic, compared to the trend before March 2020 in the Budapest metropolitan area and Pest County.

Methods: We analyzed psychiatric assessment reports of self-poisoning patients admitted to Péterfy Hospital's Emergency Department and Clinical Toxicology from Jan 2019 to Dec 2021 to estimate non-violent suicide attempt trends. We analyzed patient data for violent suicide attempts treated at Dr. Manninger Jenő Trauma Centre from 2016-2021, focusing on trends during the first two years of the pandemic. Negative binomial regression estimates were used for interrupted time series analysis with Prais-Winsten regression, controlling for time and seasonal and autoregressive effects. We used change-point detection to examine the leveling of trends. The Institutional Review Board approved the research in both institutions. Approval numbers: 08-2022 (Péterfy Hospital) and 19-2021 (Traumatology Center).

Results: The number of male non-violent suicide attempts decreased by 16.6% compared with the pre-epidemic period ($p<0.001$). A similar and significant decrease was observed in females and in the total population (Image 1). The female and total population trends, i.e., the decrease, were reversed by August 2020,

and the male trends were reversed by October 2020. The total number of patients treated for violent suicide attempts increased significantly ($p < 0.05$) during the first two years of the pandemic (Image 2). There was a slight increase in violent attempts in men and a small decrease in women, but these changes are not statistically significant.

Image:

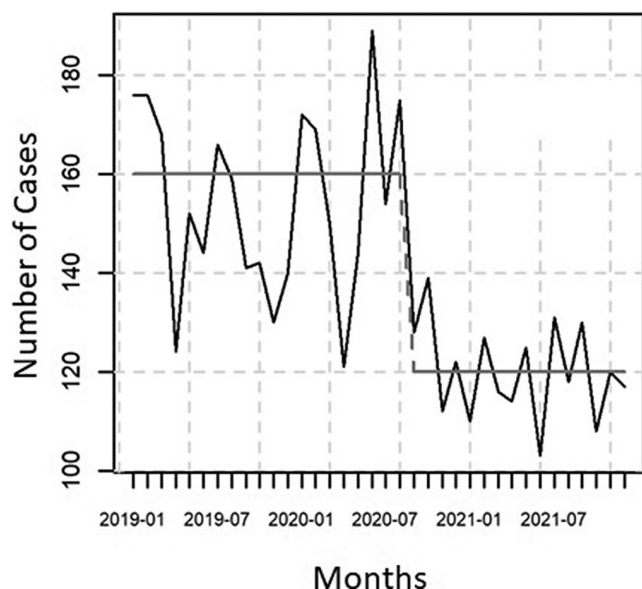

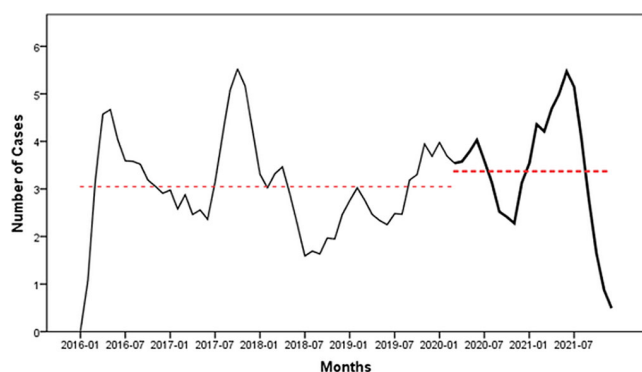

Image 2:

Conclusions: We hypothesize that those who tried to end their life through non-violent drug use were less inclined to seek assistance because they were concerned about being hospitalized during the COVID-19 outbreak. The surge in violent attempts is striking, as it correlates with the rise in suicide fatalities documented in Hungary during the initial year of the outbreak. Our data was obtained from two prominent public hospitals in Budapest, enabling us to conduct a more concentrated and thorough examination of the circumstances in the capital.

Suicidal thoughts and behaviors (STB) among psychiatric emergency patients at the emergency unit of a university hospital in Belgium (UZ Leuven). A twenty year perspective using cross-sectional data.

L. Van Eldere*, S. Claes, W. Voorspoels, M. Sabbe and R. Bruffaerts

KU Leuven, Leuven, Belgium

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.304

Introduction: Suicidal thoughts and behaviors (STB) are a serious public health problem. Suicide prevention programs have been established over the years, but many people who are suicidal do not seek treatment, and when they do, they end up in low-threshold sectors such as the Emergency Department in general hospitals. Previous studies about STB at the ED are mostly narrative, rather than a data-driven approach and limited in sample size.

Objectives: This study describes the prevalence and evolution over time of suicidal ideation (SI) and suicidal attempts (SA) in terms of sociodemographic, clinical and service use variables of the psychiatric patient referred to the Emergency Department of the University Hospital Gasthuisberg (Leuven, Belgium) over a 20 year period.

Methods: During a 20 year period (2002-2022), all patients with a psychiatric referral to the Psychiatric Emergency Department (PED) of the University Hospital Gasthuisberg (Leuven) were included ($N \sim 18,000$). We use descriptive statistics to summarize the data set, focusing on STB in terms of sociodemographic, clinical and service use variables.

Results: Around 1/10 patients presents with SA; another 1/5 with SI. Despite several reforms, SI and SA have remained relatively stable over the years. Notably, there is a higher prevalence of referrals for females in both SI and SA compared to males. However, there has been a notable increase in male SA cases over time. In the age group 36-49, both sexes exhibit the highest percentages of SI and SA cases, with exception for women in SI, where the age category 18-25 has the most referrals. Approximately one-third of male patients referred with STB have never accessed outpatient care, underscoring a critical gap in mental health services for this demographic.

Conclusions: Despite several reforms in mental health care, the PED remains a major entry point into mental healthcare for large proportions of STB patients.

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.305

Introduction: Alcohol and sedative substance use disorders are escalating global public health challenges. Lebanon has grappled with multiple crises, including economic, healthcare, and social issues.

Objectives: This study aimed to assess the correlates of the alcohol and sedative substance use risk scores with sociodemographic and clinical factors, including sleep disorders, chronotype, anxiety, and depression.

Methods: A cross-sectional study was conducted among the Lebanese population using several validated scales to assess the risk of alcohol and sedative substance use, including the Alcohol, Smoking, and Substance Involvement Screening Test (ASSIST). Other tools evaluated chronotype, sleep, and mood disturbances. Bivariate and multivariable analyses were then performed, taking the alcohol and sedative scores as dependent variables.

Results: A total of 646 participants were included. Multivariate analysis revealed positive and significant correlations between higher ASSIST-alcohol scores and personal history of alcohol abuse ($B=4.61$), family history of prescription substance abuse ($B=1.763$), psychiatric disorders ($B=2.898$), and worse Insomnia Severity Index scores ($Beta=0.14$). Conversely, ASSIST-alcohol scores negatively correlated with weight ($B=-0.39$) and morning chronotype ($B=-0.084$). Positive correlations were identified between higher ASSIST-alcohol scores and personal history of illicit substance abuse ($B=2.834$), prescription substance abuse ($B=2.252$), sleep quality ($B=0.130$), and sleep severity ($B=0.082$), while negatively correlating with cigarette smoking ($B=-0.038$).

Conclusions: This study elucidates the role of several predisposing factors to alcohol and sedative use disorders in Lebanon, including history of substance abuse, psychiatric disorders, sleep disorders, and chronotype. These findings advocate, in particular, for the integration of sleep disorder assessment and management into addiction rehabilitation programs.

EPP0077

Changing drinking patterns among Italians: 7 out of 10 students experience Binge Drinking

F. Marcolini*, D. De Ronchi and A. R. Atti

Department of Biomedical and Neuromotor Sciences, University of Bologna, Bologna, Italy

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.306

Introduction: The expression Binge Drinking (BD) refers to dysregulated alcohol consumption, characterized by the intake of large

quantities of alcohol, regardless of their nature, consecutively in a limited period of time. BD is a significant public health problem in many European countries, including Italy. According to data from the *Istituto Superiore di Sanità*, dated 2020, over 4 million Italians exhibit episodic excessive alcohol consumption (compared to 2019 data, there was an increase of approximately 5,3%).

Objectives: This study aims to examine alcohol consumption habits in the Italian population, evaluating psychopathological correlations that can explain its diffusion.

Methods: Between January and May 2023, an anonymous online questionnaire was randomly sent to the general population. Alongside with tests to evaluate psycho-social features, to estimate the presence of alcohol abuse or dependence the AUDIT scale (Saunders *et al.* Addict Abingdon Engl. 1993; 88:791–804) was used. It included two specific questions to frame the phenomenon of BD (Cranford *et al.* Alcohol Clin Exp Res. 2006; 30:1896–905). No other study conducted in Italy has so far used the aforementioned validated questions.

Results: The sample consists of 308 people (189 F, 119 M), with an average age of 32 years (sd 14). The AUDIT indicates a state of chronic alcohol consumption in 11,7% (95% confidence interval 8,5%-15,7%), of the recruited sample, positively correlating with the element of impulsivity ($p<0,005$) confirming what has already been reported in literature. BD prevalence reaches 56% (M 57%, F 55%) without any significant correlation with impulsivity, personality disorders, emotional dysregulation, or sensitivity to rejection. Among university students the prevalence of BD exceeds 70% (95% confidence interval 60%-76%), with a number of drinks reported for a single occasion reaching up to 25 units and a reported number of binge episodes, in a two-week span, ranging from 2 to 10.

Conclusions: Despite possible *biases*, this study raises the relevant issue of the extremely high prevalence of BD disorder, which is particularly alarming in light of the numerous issues related to the behavior itself. A direct correlation with reduced school performance, an increase in risky sexual behavior, and an increase in cases of drunk driving have been evaluated. Considering these consequences, it is of primary importance on a medical, but even more social level, to best characterize this phenomenon in such a way as to be able to implement awareness-raising and prevention interventions.

EPP0079

A preliminary analysis of clinical characteristics of patient with alcohol use disorder and suicidal ideation

R. F. Palma-Alvarez*, A. Rios-Landeo, G. Ortega-Hernandez, E. Ros-Cucurull, C. Daigre, M. Perea-Ortueta, M. Sorribes, L. Grau-López and J. A. Ramos-Quiroga

Hospital Universitari Vall d'Hebron, Barcelona, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.307

Introduction: Suicidal behaviors are frequently observed among patients with substance use disorder, including suicidal ideation (SI) (1). Alcohol use disorder (AUD) is one of the most prevalent addictions and may be related to suicidal behaviors (2,3). However,

the association between AUD and SI requires a deeper analysis which includes several clinical features observed among AUD patients.

Objectives: To analyze the clinical characteristics and features associated with lifetime SI among patients who had AUD.

Methods: This is a cross-sectional study performed in an outpatient center for addiction treatment in patients seeking for treatment who met the criteria for AUD between 01/01/2010 and 12/31/2021. Patients were evaluated with an ad-hoc questionnaire and the European Addiction Severity Index (EuropASI), SI was evaluated using the item for SI in EuropASI.

Results: From a potential sample of $n=3729$ patients, only $n=1082$ (73.8% males; mean age 42.82 ± 12.51) met inclusion criteria and had data for the current analysis. Lifetime SI was present in 50.9% of the AUD patients. Several clinical features were related to SI, including: sex differences, any type of lifetime abuse, polyconsumption, benzodiazepine use disorder, any psychiatric diagnosis aside from SUD, and higher addiction severity according to the EuropASI.

Conclusions: SI among AUD patients is related to several clinical features which indicate a higher addiction severity, more polyconsumption, and a higher prevalence of psychiatric comorbidities. These findings may contribute to the understanding of suicidal behaviors in AUD patients but it is required further investigations, including longitudinal studies.

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.308

Introduction: Alcohol and illicit drug use are highly prevalent among the homeless population. Religiosity and spirituality (RS) have been widely associated with lower substance use. However, evidence of this relationship among the homeless is still scarce.

Objectives: To assess the association between RS and the use of alcohol and illicit drugs among the homeless population of a large Brazilian urban center.

Methods: This cross-sectional study was conducted in São Paulo, Brazil. Aspects such as spirituality (FACIT-Sp12), religiosity (P-DUREL), religious-spiritual coping (Brief-RCOPE), and self-applied questions about current substance use (alcohol and illicit drugs) were evaluated. Adjusted Logistic Regression models were performed.

Results: A total of 456 homeless individuals were included, with an average age of 44.5 (SD=12.6) years. More than half of the participants used alcohol (55.7%) weekly and 34.2% used illicit drugs weekly. The adjusted Logistic Regression models identified that aspects of RS were associated with a lower propensity for alcohol and illicit drug use, whereas negative religious-spiritual coping strategies were associated with a higher propensity for the use of both.

Conclusions: The prevalence of alcohol and illicit drug use among participants was high. Positive RS and religious-spiritual coping were significant protective factors against the use of these substances. Conversely, negative religious-spiritual coping strategies were associated with risk factors.

Research of cognitive disorders and quality of life in patients, who are receiving methadone replacement maintenance therapy

N. Halytska-Pasichnyk^{1,2*} and V. Ogorenko¹

¹Psychiatric, narcologic and medical psychologic department, Dnipro State Medical University and ²Department of replacement maintenance therapy, "Dnipropetrovsk multiprofile clinical hospital for provision of psychiatric care" Dnipropetrovsk regional council", Dnipro, Ukraine

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.309

Introduction: Important goals of substitution therapy include: reducing the desire to use opioids - methadone enters the brain with a minimal euphoric effect, reduce the desire to use opioids, allowing to avoid the risk of overdose and control their addiction; prevention of withdrawal syndrome; improving the quality of life - can contribute to the restoration of patients, allowing them to return to a normal life, improve their social, professional and family situation; reducing the risk of transmission of infections HIV and hepatitis; reducing crime - control addiction can reduce related crime and to illicitly obtain opioids; psychosocial support helps patients develop coping strategies and increases their chances of long-term recovery.

The goal of substitution therapy is not to completely get rid of addiction, but it can help stabilize the patient's life and facilitate the recovery process.

Objectives: Many patients receiving MT also have mental disorders such as cognitive decline, depression, anxiety, PTSD, or even bipolar disorder. These conditions can greatly affect the course and results of treatment. They may also have problems with employment, housing, family conflicts, and legal issues.

Methods: In the course of the study, 134 patients aged 26 to 64 years (105 men and 29 women) with a diagnosis of opioid addiction and receiving methadone therapy were examined. Of them, 48 patients had a period of stay at MT of up to three years and 86 – more than three years. The Montreal Cognitive Scale (MoCA) was used to assess comorbid cognitive impairments. The WHOQOL-BREF questionnaire was used to assess the quality of life.

Results: The range of indicators of cognitive functions varied from 21 to 29 points (average - 25.3). 61 patients (46%) showed a result of 26 and above, indicating the absence of cognitive impairment, 51 patients (38%) received from 24 to 21, indicating moderate cognitive impairment. 22 patients (16%) had borderline indicators.

When assessing the level of quality of life, indicators of physical and psychological components varied from 12 to 31; self-perception in the range from 10 to 27 points; microsocial support from 3 to 14 points; social well-being from 11 to 36. In general, the level of satisfaction with the quality of life was in the range of 38-83%.

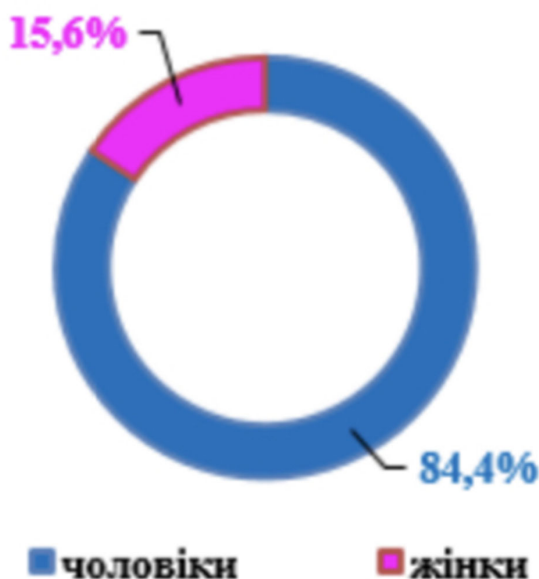

Image:

Частки пацієнтів ЗПТ за призначеними лікарськими засобами у 2021 році

Image 2:

Частки пацієнтів ЗПТ за статтю у 2021 році (%)

Conclusions: Opioid addiction therapy should consist of an assessment of physical and psychological status, comorbid disorders, quality of life, etc. We can see, MT does not significantly affect the cognitive functions. The differences in the assessment of the quality of life were noted in the components of microsocial support and social well-being, which indicates the vulnerability of patients in these areas. Duration of opioid dependence, availability of psychosocial support, presence of comorbid conditions affect the quality of life. It is important that treatment is tailored to individual needs of patients.

Clinical features and factors related to suicidal ideation in adult patients with benzodiazepine use disorder

P. Querol Clares^{1*}, G. Ortega Fernandez¹, R.-F. Palma Alvarez¹, C. Daigre², M. Alijotas Capdevila¹, J.-A. Ramos Quiroga¹ and L. Grau Lopez¹

¹psychiatry and ²Hospital Vall d'Hebron, Barcelona, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.310

Introduction: Benzodiazepine use disorder (BUD) has been associated with the presence of suicidal ideation (SI) in general population. It seems there is an overall increase in the risk of attempting suicide due to the increase of impulsivity, rebound and withdrawal of those who use benzodiazepines (1). However, this association has been scarcely studied.

Objectives: To explore the prevalence, clinical features and factors related to lifetime SI in adults with BUD.

Methods: A cross-sectional study was conducted in an outpatient center for addiction treatment between 01/01/2010 and 12/31/2021. Adult patients who met criteria for active BUD were included. Patients with language barriers, cognitive impairments and those who were participating in any clinical trial were excluded. All patients were evaluated with an ad-hoc questionnaire, Euro-ASI (European Addiction Severity Index), BDI (Beck Depression Inventory) and HRQoL SF-36 (Health-related quality of life according to SF-36). Univariate and bivariate analyses were performed comparing BUD patients with or without SI.

Results: 554 patients were included (65.2% males; M age 42.6 ±12.6 years). SI was reported in 57.2% of the patients. Regarding the sociodemographic variables, any type of lifetime abuse was correlated with SI (67.8%, 73.5% and 77.8% of the patients with emotional, physical and sexual abuse respectively). Considering the different psychiatric features studied, having any psychiatric diagnosis increased SI up to 64%. Depressive and cluster B personality disorders were the ones with a higher presence of SI (67.1% and 68.1% respectively). Anxiety and cluster A personality disorders had also higher proportions of SI (56.1% and 58.7% respectively). Regarding the different assessment instruments used, a higher punctuation on BDI score was seen in the group of patients with SI (23.73±12.86). The scores also showed a worse perception of the mental quality of life of those people with SI, measured by HRQoL (13.76 and 36.82±31.93 in patients with SI and no SI respectively). Considering the Euro-ASI, there was an increased proportion of SI in those patients with a worse familiar situation (0.44±0.30), a

higher alcohol consumption (0.26±0.28) and a worse psychological condition (0.48±0.24).

Conclusions: The prevalence of SI in patients with BUD is significant and is related to several clinical factors. Those factors should be taken into account in daily clinical practice, research, and any health policies on suicide. Further research should be developed.

Factors Associated with Voluntary Discharge in a Hospital Detoxification Unit: An Observational and Descriptive Analysis

P. Gamboa Lozada¹, G. Ortega Hernández^{2*}, R. F. Palma Álvarez², A. Ríos Landeo², J. A. Ramos Quiroga² and L. Grau López²

¹Department of Psychiatry, Hospital Universitari Vall d'Hebron and

²Department of Psychiatry, Hospital Vall d'Hebron, Barcelona, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.311

Introduction: Adherence to treatment for addictive disorders remains a clinical challenge. Despite detoxification admissions being scheduled and initiated voluntarily by the patient, several factors may contribute to treatment discontinuation.¹ Understanding these factors will enable the development of specific interventions for a more effective approach.²

Objectives: To identify and analyze the relationship between specific clinical factors and voluntary treatment discontinuation.

Methods: An observational and descriptive study was conducted using a retrospective database of 1146 patients admitted to the "Hospital Universitari Vall d'Hebron" Detoxification Unit between June 2008 and December 2019. Bivariate analysis was conducted to identify individual associations between clinical factors and voluntary discharge. Subsequently, a multivariate analysis was performed to assess the combined influence of these factors while controlling for potential confounding variables.

Results: A total of 135 patients (11.8%) requested voluntary discharge. Significant differences were found between the voluntary discharge and non-voluntary discharge groups in patients with dual diagnosis (91.1% vs 80.9%, $p<0.0001$), specifically the presence of psychotic disorder (18.7% vs 12%, $p<0.05$) and cluster B personality disorder (66.7% vs 31%, $p<0.0001$). Significant associations were also observed with prior detoxification admissions (64.5% vs 54.1%, $p<0.05$), heroin as the main admission substance (29.6% vs 13.3%, $p<0.0001$), lifetime use of more than three substances (65.3% vs 45.3%, $p<0.0001$), and pre-admission binge-pattern substance use (72.1% vs 51.4%, $p<0.0001$). A significant relationship was found with therapeutic discharge in the diagnosis of major depressive disorder (14.6% vs. 24.8%, $p<0.05$), admission for alcohol detoxification (25.9% vs. 42.8%, $p<0.0001$), and participation in group therapy during admission (27.4% vs. 49.9%, $p<0.0001$). In the multivariate analysis, it was found that cluster B personality disorder ($p<0.0001$), heroin as the primary substance of admission ($p<0.05$), and pre-admission binge-pattern substance use ($p<0.05$) were independently related to voluntary discharge.

Conclusions: Cluster B personality disorder, admission for heroin detoxification, and pre-admission binge-pattern substance use are factors associated with voluntary treatment discontinuation.

Associations between cerebellar development and autistic traits during adolescence: a population-based cohort study

C. Morimoto^{1*} and S. Koike²

¹Faculty of Allied Health Science, Niigata University of Rehabilitation, Niigata and ²Department of Neuropsychiatry, Graduate School of Medicine, University of Tokyo, Tokyo, Japan

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.312

Introduction: Brain maturation is associated with adolescent socio-cognitive development. The lateral posterior region of the cerebellum plays a critical role in higher cognitive processes, and deviations of this region are associated with autism-related behaviors. Hence, it is plausible that developmental changes in this region of the cerebellum during adolescence are different along a variation in autistic traits. Additionally, its difference may be moderated by parental age at birth and weight growth during infancy, which have effects on brain development.

Objectives: The aim of this study was two folds: (1) to test whether cerebellar development during adolescence is different along a variation in autistic traits (2) to test whether parental age at birth and weight growth during infancy moderate the results of (1).

Methods: Longitudinal study was conducted over a 6-year period with 256, 230 and 187 participants ranging from 10.5 to 17.6 years, observing adolescent development respectively at 2-year time periods. We undertook a detailed investigation into differences in the lateral posterior region of the cerebellum volume. The 50-item Autism-Spectrum Quotient (AQ) was rated by primary parents. Weight growth and parental age were evaluated using maternal and child health handbook records. A multiple regression analysis was performed to examine whether AQ subscales, sex, and their interactions affected cerebellar development. Moderation analysis assessed whether parental age and weight growth moderated associations between cerebellar development and autistic traits. All participants provided written informed consent, and the study was approved by the Ethics Committee (No.10069).

Results: Interactions between sex and attention switching and sex and attention to detail were significantly associated with cerebellar development in the bilateral gray matter (GM) and white matter (WM) of Crus I and Crus II (Fig1, 2). Simple slope analyses showed that the slopes of cerebellar development were significant for girls ($p_{FDR} < 0.001$). Although no significant interaction was found between them, the main effect of attention to detail was significantly associated with cerebellar development in WM of VIIB ($p_{FDR} = 0.006$). Further, moderation analysis found that the association between the cerebellar development and autistic traits were significantly moderated by maternal age; the magnitude of its effect was significant for high maternal age in boys ($p_{FDR} = 0.036$, Fig3).

Paternal age, early (0-9 months) and late weight growth (4-18 months) also moderated associations between them, however, no significance remained after FDR controlling.

Image:

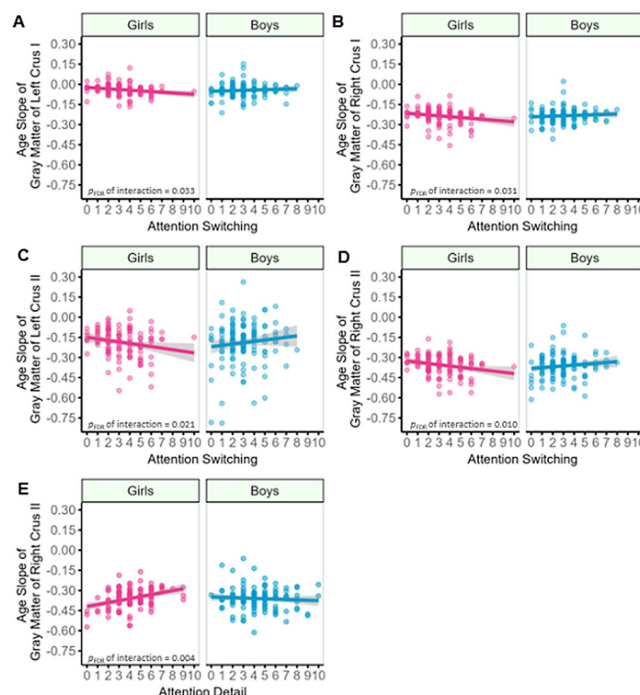

Figure.1

Image 2:

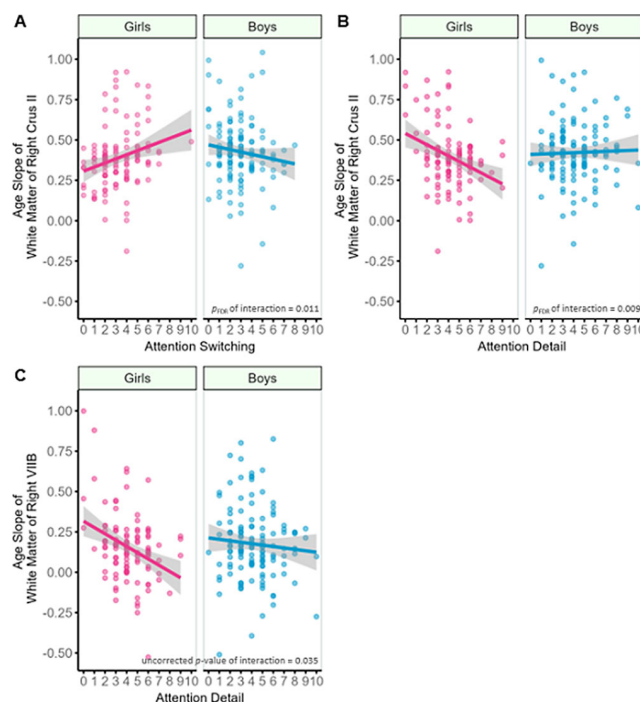

Figure.2

Image 3:

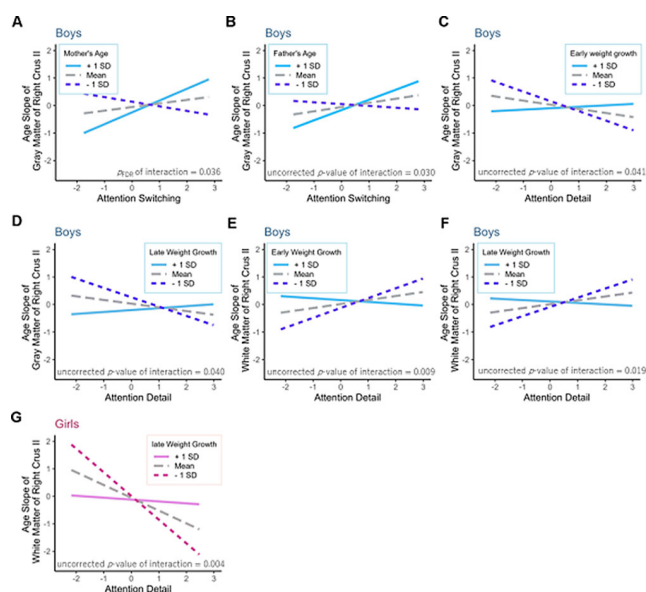

Figure.3

Conclusions: There are significant associations between cerebellar development during adolescence and autistic traits, and its pattern of association can be moderated by parental ages at birth and weight growth during infancy in a cerebellar region- and sex-specific manner.

Changes in Parental Reflective Functioning before and after a postpartum depression group therapy

L. Erkoreka^{1,2,3*}, Z. Alonso⁴ and L. Pérez Cabeza⁵

¹Galdakao-Usansolo University Hospital, Galdakao; ²University of the Basque Country UPV/EHU, Leioa; ³Biocruces Bizkaia Health Research Institute, Barakaldo; ⁴Bizkaia Mental Health Network, Getxo and ⁵Bizkaia Mental Health Network, Bilbao, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.313

Introduction: Parental Reflective Functioning (PRF) refers to parents' ability to view their children's and their own behavior by considering internal mental states, such as thoughts, desires, and intentions. Depression has been described as compromising reflective functioning in female samples, whereas other studies have not detected differences in RF between depressed and non-depressed mothers.

Objectives: We aim to study whether a group intervention focused on postpartum depression, which we have already observed to cause significant changes in the mother-child bond and the severity of depressive, also improves parental reflective functioning.

Methods: To that end, we analyzed pre-post data from two different groups (N=12), composed of mothers who had been clinically diagnosed with postpartum depression. They received the 6-week Mothers & Babies Program© and completed the Parental Bonding

Questionnaire (PBQ), the Edinburgh Postnatal Depression Scale (EPDS) and the Parental Reflective Functioning Questionnaire (PRFQ) before and after group therapy. Pre-post data from the PRFQ were analyzed using the repeated measures t-test. The correlation between changes in the three questionnaires was also analyzed using Pearson's correlation test.

Results: Significant changes were observed in the Pre-Mentalization Modes (pre= $2.37 \pm .457$, post= $2.03 \pm .520$, $t = 2.0206$, $p = 0.027$) and Certainty About Mental States (pre= 2.87 ± 1.141 , post= $3.68 \pm .908$, $t = -2.814$, $p = 0.010$) subscales of the PRFQ, with no significant changes in the Interest and Curiosity subscale ($t = -.516$, $p = 0.309$). A significant correlation was also observed between pre-post change in EPDS scores and pre-post change in the Certainty About Mental States subscale of the PRFQ ($r = -.640$, $p < .05$), while no significant correlations were observed with the rest of the PRFQ subscales, nor with the PBQ.

Conclusions: A brief cognitive-behavioral group therapy developed specifically to treat postpartum depression improves pre-post scores on the Pre-Mentalization (lower post- than pre- score) and Certainty About Mental States (higher post- than pre- score) subscales of the PRFQ. Although a control group is needed to determine the actual effect of the intervention, as time could also play a role in the observed changes, this is an encouraging result. Moreover, the improvement obtained in Certainty About Mental States is inversely correlated with the pre-post changes observed in the EPDS, meaning that the greater the improvement in depression, the greater the improvement in the aforementioned subscale of the PRFQ. A larger sample is needed to assess a hypothetical mediating effect of depression in the observed change.

The Effect of Depression on Smartphone Addiction: The Medicating Effects of Interpersonal Problem in Korean Adolescents

Y. Seo*, Y. Nam and J. Lee

Department of Psychiatry, Yonsei University Wonju College of Medicine, Wonju, Korea, Republic Of

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.314

Introduction: Problematic smartphone use is twice as common among teenagers as it is among adults. Smartphone addiction is associated with anxiety, depression, attention deficit disorder, impulsivity, and sleep problems, among other issues.

Objectives: To assess whether interpersonal relationship problems mediate the relationship between smartphone addiction and depression among adolescents (ages 12-17) currently enrolled in middle and high school.

Methods: A cross-sectional study was conducted among 653 middle and high school students living in Wonju, South Korea between September 1 and November 30, 2019. Depression was measured by Center for Epidemiologic Studies Depression Scale (CES-D). In order to evaluate smartphone addiction, the Smartphone Addiction Scale Short Form Version (SAS-SV) was used. To examine interpersonal problems, the Korea Inventory of Interpersonal Problems

Circumplex scale (KIIP-SC) was employed. We used the dplyr package to check for skew, kurtosis, and create density plots. Scatterplots and Pearson correlation analysis were used to examine the relationships between the main variables. For the mediation analysis, we used the 8 sub-scales of KIIP-SC (Domineering, Vindictive, Cold, Socially avoidant, Nonassertive, Exploitable, Overly Nurturant, Intrusive) as mediators and conducted a mediation analysis with 10,000 bootstrap samples using the lavaan package in R, version 4.2.2. Each analysis was evaluated based on a 95% confidence interval to determine significance.

Results: Depression, interpersonal problems, and smartphone addiction exhibited significant positive correlations with each other. The direct effect of smartphone addiction was found to be significant. The association between depression and smartphone addiction was mediated by the KIIP-HI (Nonassertive), the KIIP-JK (Exploitable) and the KIIP-NO (Intrusive).

Conclusions: Interpersonal problems mediate the relationship between depression and smartphone addiction. Identifying the high-risk group is essential for treatment strategy development.

Impact of the Covid pandemic on the mental health of children and young people with pre-existing mental health and neurodevelopmental conditions: a systematic review and meta-analysis

B. C. F. Ching*, V. Parlatini, S. Zhang, H. Abdul Cader, J. Penhallow, E. Voraite, T. Popnikolova, A. Wickersham, J. Downs and E. Simonoff

King's College London, London, United Kingdom

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.315

Introduction: Existing systematic reviews have suggested mixed effects of the Covid pandemic on the mental health of children and young people. Those with pre-existing mental health and neurodevelopmental conditions have been suggested to be disproportionately affected, but this has not been meta-analysed. Most reviews of studies in clinical populations to date only include cross-sectional studies during the first lockdown or longitudinal cohorts up to early 2021, which limits our understanding of causality and long-term effects. To our knowledge, this is the first systematic review and meta-analysis to examine the longitudinal impact of the pandemic on the mental health of children and young people with pre-existing mental health and neurodevelopmental conditions.

Objectives: To compare 1) mental health pre versus during Covid, and 2) mental health during Covid.

Methods: Medline, Embase, APA PsycInfo, and Global Health databases were searched up to August 2023. Longitudinal studies reporting mental health outcomes in children and young people (≤ 18 years old) with pre-Covid mental health and/or neurodevelopmental conditions were included. Cohorts were deemed eligible if children and young people were diagnosed using a diagnostic assessment, scored above clinical threshold on validated measures, or attended mental health services pre-Covid. Outcomes included internalising, externalising, and other symptoms. Studies were

narratively synthesised by symptom category and meta-analyses performed where number of studies reporting the same outcomes were sufficient (≥ 5).

Results: 6,083 records were identified and 21 studies (N=2,617) were included. These widely differed in country, setting, diagnosis, outcome, and timepoints under study. The narrative synthesis highlighted mixed findings in mental health changes during the pandemic for all three symptom categories showing increases, reductions, and no changes. Only studies reporting changes in internalising symptoms pre- versus during the pandemic were in sufficient number to be amenable to meta-analysis.

Conclusions: Our findings suggest the pandemic's impact on the mental health of children and young people with pre-existing mental health and neurodevelopmental conditions were complex and varied. We highlight an urgent need for longitudinal Covid research on long-term mental health outcomes in this vulnerable group. Understanding risk factors and longitudinal trajectories is warranted to guide clinical practice and policy.

EPP0090

Adherence to therapy of patients with adolescent depression

V. Kaleda* and M. Omelchenko

Mental Health Research Center, Moscow, Russian Federation

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.316

Introduction: Therapy of adolescent depression is accompanied by a number of difficulties associated with the influence of the age factor, which include the following aspects: social - with the possibility of forming a fear of stigmatization, biological - with low tolerance of psychopharmacological agents due to the immaturity of the functional systems of the body, psychological - with a combination of oppositional behavior of adolescents and their desire to "be like everyone else". All these factors may lead to a decrease in patients' compliance in the treatment of adolescent depression and premature refusal to continue treatment, which may provoke a relapse of the disorder.

Objectives: To assess the adherence of adolescent patients with a first depressive episode regarding the continuation of therapy after discharge from the hospital.

Methods: 124 patients (average age - 19.4) were examined after discharge from the hospital where they were treated for a depressive episode (according to ICD-10: F32.1, F32.2, F32.38, F32.8). The severity of depression during hospitalization and at discharge was assessed according to the HDRS scale. During hospitalization, 45.9% of patients (n=57) were diagnosed with severe depression (HDRS score of more than 24), 54.1% (n=67) were diagnosed with moderate depression (HDRS score of 17-23) (Zimmerman M. et al. JAD 2013; 150(2):384-8). At discharge, 35.5% of patients (n=44) had moderate depression, 38.7% of patients (n=48) had mild depression (HDRS score of more than 7-16) and only 25.8% of patients (n=32) had no depression (HDRS score of less than 7 points). This indicated the need to continue therapy after discharge. The degree of adherence to therapy and the main reasons

for its refusal were analyzed using the Medication Compliance Scale (Lutova N. NIPNI, 2007; 26).

Results: The average duration of treatment continuation in patients with adolescent depression was 7.4 ± 9.6 months. At the same time, 42 patients (33.9%) refused to continue therapy within 30 days after discharge from the hospital. 15 patients (12.1%) turned out to be fully compliant, following the doctor's prescriptions. The main reasons for refusing therapy were: negative attitude to the fact of receiving therapy and visiting a psychiatrist ($n=50$, 40.3%), the development of side effects of therapy ($n=46$, 37.1%), negative attitude of relatives to the continuation of therapy ($n=11$, 8.9%), and negative attitude to the attending psychiatrist ($n=2$, 1.6%). In general, formally, the average duration of continuation of therapy coincides with the recommended 6-12 months (Sim K. et al. IGN 2015;19(2) pyv076), however, it is noteworthy that some patients tend to self-cancel therapy without the approval of the attending physician.

Conclusions: The results indicate a low level of adherence to therapy in patients with adolescent depression and require additional measures to improve it.

The work was carried out with the financial support of the RSF grant 22-15-00437.

The association between maternal diabetes and the risk of attention deficit/hyperactivity disorder in offspring: Updated systematic review and meta-analysis.

Y. D. Sinishaw*, B. A. Dachew, G. Ayano, K. Betts and R. Alati
University, Curtin, Perth, Australia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.317

Introduction: The existing body of evidence on the association between maternal diabetes and attention deficit/hyperactivity disorder (ADHD) in offspring is inconsistent and inconclusive. Thus, we need to synthesise the available evidence to examine the association between maternal diabetes and risk of ADHD in offspring.

Objectives: The aim of this meta-analysis was to examine the association between maternal diabetes and the risk of ADHD in offspring.

Methods: We conducted a comprehensive search across PubMed, MEDLINE, EMBASE, Scopus, CINAHL and PsychINFO databases from their inception to September 8th, 2023. The methodological quality of the included studies was evaluated using Joanna Briggs Institute (JBI) and Newcastle-Ottawa Scale (NOS). Between-study heterogeneity was assessed using I² statistic and potential publication bias was checked using both funnel plot and Egger's test. Random effect model was used to calculate the pooled effect estimates and subgroup, sensitivity, and meta-regression were further performed to support our findings

Results: Twenty observational studies (two cross-sectional, five case-control and thirteen cohort studies) were included in this systematic review and meta-analysis. Our meta-analysis indicated that intra-uterine exposure to any type of maternal diabetes was associated with an increased risk ADHD in offspring [RR=1.33; 95 % CI: 1.23–1.43, I²=79.9%]. When we stratified the analysis by

maternal diabetes type, we found 17%, and 37% higher risk of ADHD in offspring exposed to maternal gestational [RR=1.17; 95 % CI: 1.07–1.29] and pre-existing diabetes [RR=1.37; 95 % CI: 1.27–1.48] compared to unexposed offspring respectively. Results of subgroup and sensitivity analysis further supported the robustness of our main finding.

Conclusions: Our review suggested that exposure to maternal diabetes increased the risk of ADHD in offspring. These findings underscore the need for early screening and prompt interventions for exposed offspring.

The Influence of Nonparental Care on Internalizing and Externalizing Behaviors Across Adolescence: An individual Participant Meta-Analysis

K. M. Barry^{1,2*}

¹Social Epidemiology, INSERM and ²Social Epidemiology, Sorbonne University, Paris, France

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.318

Introduction: In Europe, associations between different types of nonparental care and internalizing and externalizing behaviors in children have not been adequately explored (Gialamas, A et al. J Epidemiol Community Health. 2015). Internalizing and externalizing symptoms in childhood can have lifetime repercussions, thus understanding their risk factors and the potentially protective role of family policies is highly relevant.

Objectives: To explore the associations between different types of nonparental care prior to primary school and internalizing and externalizing behaviors across young adolescence.

Methods: Six parent-offspring prospective birth cohort studies across five European countries within the EU Child Cohort Network (EUCCN) were included in the study. A two-stage individual participant data (IPD) meta-analysis on complete cases was performed. Linear regression models (one for each age group: 5-6 years, 7-9 years, 10-13 years) were applied in each cohort separately and then cohort-specific coefficients and standard errors were combined using random-effects (restricted estimate maximum likelihood (REMD) meta-analysis to attain overall effect estimates. Data were then stratified by socioeconomic position and sex.

Results: There were 74 453 parent-offspring dyads to study children's internalizing difficulties and 72 462 parent-offspring dyads to study children's externalizing difficulties. Center-based care attendance was associated with lower levels of internalizing difficulties 5-6 years [-1.13 (95%CI:- 2.68, 0.42), $p=0.15$]; 7-9 years [-1.38 (95%CI:- 2.85, 0.10), $p=0.07$]; 10-13 years [-1.06 (95%CI:- 1.95, -0.17), $p=0.02$]. Children who attended other forms of nonparental care appeared to have higher levels of internalizing difficulties: 5-6 years [0.02 (95%CI:- 1.96, 2.01), $p=0.98$], 7-9 years [0.91 (95%CI:0.23, 1.58), $p=0.009$]; 10-13 years [0.52 (95%CI:- 0.23, 1.27), $p=0.17$]. Other forms of nonparental care (not including center-based care) had a positive association with externalizing symptoms : 5-6 years [2.45 (95%CI:0.35, 4.55), $p=0.02$]; 7-9 years [2.78 (95%CI: 0.60, 4.95), $p=0.01$]; 10-13 years [1.93 (95%CI:-0.45,

4.32), $p=0.11$]. We found some evidence of effect moderation by the child's sex and socioeconomic position (SEP).

Conclusions: The results suggest that center-based care may protect children from developing internalizing behaviors, but other forms of nonparental care may put children at more risk of developing more internalizing and externalizing behaviors. Also, factors such as sex and SEP may interact with nonparental care in influencing externalizing behaviors.

EPP0095

"Beenomials": exploring beekeeping as a rehabilitation tool in the field of mental health

A. Barbieri

Department of Mental Health, ASL CN1, Cuneo, Italy
doi: 10.1192/j.eurpsy.2024.319

Introduction: Beekeeping is a peculiar activity able to connect people both to nature and to other people. Extant research shows how it provides beekeepers with meaning, opportunities for learning, and a sense of connection to bees as well as to the surrounding ecosystem. The relationship of care and interdependence that is established supports well-being, encourages collaboration and positive social relations.

Objectives: "Beenomies" is a pilot project inspired by the union of opposites symbolically associated with bees: love and war, sweetness (honey) and bitterness (venom), the individual and multiplicity (society), regeneration and death. As CG Jung observed, honey expresses, psychologically, "the joy of life and the life urge which overcome [...] the dark and the inhibiting. Where spring-like joy and expectation reign, spirit can embrace nature and nature, spirit". Drawing on this psychological and philosophical basis, the project aimed to introduce beekeeping in a therapeutic community placed in the Alpine environment (Mondovì, Italy), to explore its rehabilitative potential and its ability to promote well-being in the field of mental health.

Methods: The project stems from the collaboration between mental health services, a local agriculture high school, and a farm involved in social agriculture. Initially, some beehives have been settled on the land surrounding the therapeutic community. Activities of beekeeping have been conducted and supervised by experienced beekeepers of the farm involved, who engaged a selected group of users hosted in the community ($n=15$), instructed them and worked side by side for several weeks, according to the bees' needs and the seasonal rhythms. Once the training was completed, teaching activities have been co-conducted by beekeepers and participants, to introduce and train a group of students from the local agriculture high school. A study encompassing observational data, surveys, and semi-structured interviews was conducted to monitor and evaluate the project as it unfolded.

Results: The performance of practical activities (i.e. beekeeping operations) proved successful in relaxing social norms around talking, lowering the emotional intensity of the encounter, allowing non-verbal communication and normalizing silence. These features supported participants with relational difficulties and

encouraged the gradual development of skills in the social area. In the second part of the project, the involvement of high school students that needed to be trained allowed participants to have an active role as teachers; this contributed to the development of positive feelings, increased self-esteem and self-efficacy, eventually supporting the recovery process.

Conclusions: Preliminary findings suggest further collaboration between different social actors and further research to develop inclusive, effective, and community-based interventions in the field of mental health and rehabilitation.

Classification of mental disorders

EPP0096

A nosological approach to brief psychotic disorders and acute and transient psychoses

C. M. Coelho

Psychiatry, Centro Hospitalar e Universitário de Coimbra, Coimbra, Portugal
doi: 10.1192/j.eurpsy.2024.320

Introduction: Acute and transient psychoses (International Classification of Diseases) and Brief Psychotic Disorders (Diagnostic and Statistical Manual of Mental Disorders) constitute heterogeneous nosological groups, which have undergone successive reformulations in the past decades, remaining doubts regarding their diagnostic validity and independence.

Objectives: This work aims to review the nosological evolution of these complex and neglected groups.

Methods: A review of the literature was conducted using PubMed and The Cochrane Library. The following terms were used: "acute and transient psychoses"; "brief psychotic disorders"; "cycloid psychosis"; "reactive psychosis".

Results: Since the early 20th century, a group of non-affective psychoses with acute onset and brief duration have been described in different countries and under various names, such as bouffée délirante, reactive psychosis or cycloid psychosis, denominations still present in ICD-9. In present-day classifications, as ICD-10 and DSM-IV, an effort was made to homogenise the various regional and national concepts creating the group of 'Brief Psychoses' (DSM) or 'Acute and Transient Psychotic Disorders' (ICD). The marked heterogeneity and low diagnostic stability of these groups, mainly based on temporal criteria, has posed significant obstacles to further research and conceptualization. Given these difficulties, the latest revision of the International Classification of Diseases (ICD-11) brought about a substantial change, restricting this diagnosis to polymorphic psychotic conditions of acute onset and rapid resolution, subgroup with greater diagnostic stability and characteristics distinct clinical features.

Conclusions: The relevance of a better clarification for this nosological group is evident in the successive changes over the last century. ICD 11, once again, substantially changed the diagnostic criteria and the scope of this nosological entity, leaving doubts about the independent nature of this group, its connection to schizophrenia, as an attenuated form (more common in women

and in developing countries), or even as a form of psychosis that is closer to affective disorders (due to its clinical evolution). Although little explored, this issue remains a source of doubt and interest, calling into question the Kraepelinian dichotomy for the so-called endogenous psychoses.

ICD-11 Burnout for the psychiatrist: Meaning of the concept and prevalence of the condition.

J. M. Pelayo-Terán^{1,2,3,4,*}, Z. Gutiérrez-Hervás¹, S. Vega-García¹, M. E. García-Llamas¹, C. López-Zapico⁵ and Y. Zapico-Merayo¹

¹Servicio de Psiquiatría y Salud Mental; ²Unidad de Calidad y Seguridad del Paciente, Hospital El Bierzo. Gerencia de Asistencia Sanitaria del Bierzo (GASBI). SACYL, Ponferrada; ³Área de Medicina Preventiva y Salud Pública. Departamento de Ciencias Biomédicas, Universidad de León, León; ⁴Grupo CB07/09/2001, Centro de Investigación Biomédica en Red de Salud Mental (CIBERSAM), Madrid and ⁵Facultad de Ciencias Jurídicas y Sociales, Universidad Juan Carlos I, Móstoles, Madrid, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.321

Introduction: Burnout was reclassified in 2019 as an occupational phenomenon in ICD-11. The new condition includes the classic tridimensional definition with symptoms in areas of fatigue/energy depletion, mental distance/cinism and sense of ineffectiveness/lack of accomplishment.

Objectives: To evaluate the knowledge and perceptions of psychiatrists regarding new ICD-11 burnout definition.

To analyse the frequency of burnout symptoms in the psychiatric consultations and among the psychiatrists as healthcare professionals.

Methods: An online survey (designed with Microsoft® Forms) was sent in June 2023 to psychiatrists from three regions of Spain, contacted from local scientific societies. Psychiatrists, currently working, had to consent and answer a brief survey (average time: 2 min 32 sec) of 9 questions regarding the definition of burnout, their experience in clinical practice, their own symptoms and symptoms observed in colleagues.

Results: 164 psychiatrists answered, 114 females (69.5%), mean age: 43.61 ± 11.28 years. 48.2% assured they had never used the term Burnout or the ICD codes Z73.0/QD85, whereas a 9.1% used them frequently in clinical practice. 58.5% considered burnout just a condition related to work and a 38.4% either a syndrome or a disorder.

Most psychiatrists referred that their patients exhibited symptoms of the three dimensions. Fatigue was the most common, attended frequently by 79.5% of the surveyed, followed by ineffectiveness (73.1%) and cinism (65.3%).

When reporting their own symptoms, only 16.5% psychiatrists referred not suffering any symptom. The most frequently involved was fatigue (66.5%), then ineffectiveness (56.1%) and cinism

(41.5%). 28,7% reported concomitant symptoms of the three dimensions.

70.7% recognized fatigue symptoms in their colleagues, 61% ineffectiveness, 72.6% cinism and 45,5% recognized symptoms from the three dimensions. Only a 7.3% did not identify any of them.

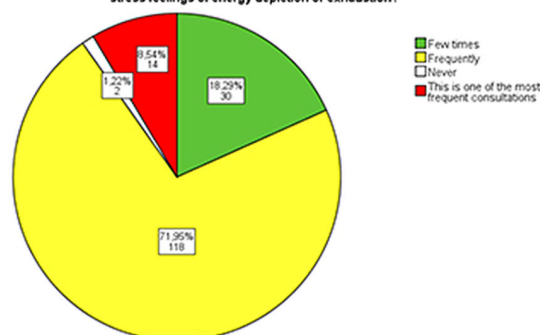

A younger age was related to higher probability of suffering cinism (T:2.546; p=0.012) and ineffectiveness (T:2.900; p=0.004) and to a higher probability of recognizing cinism (T=3,293; p=0,001) an ineffectiveness in others (T=2.355; p=0.020)

Females showed a higher frequency of ineffectiveness symptoms (61.4% vs 44%; $\chi^2:4.274$; p=0,029).

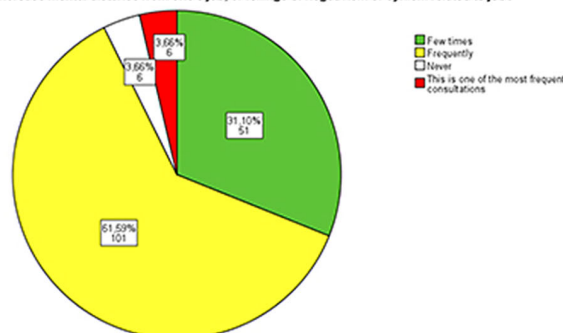

Image:

Image1. Frequency of Burnout dimension symptoms in psychiatric clinical practice

QUESTION 5. In your clinical practice, Do you attend patients that present, as a result of chronic workplace stress feelings of energy depletion or exhaustion?

QUESTION 6. In your clinical practice, Do you attend patients that have, as a result of chronic workplace stress increase mental distance from one's job, or feelings of negativism or cynism related to job?

QUESTION 7. In your clinical practice, Do you attend patients that have, as a result of chronic workplace stress a sense of ineffectiveness and lack of accomplishment?

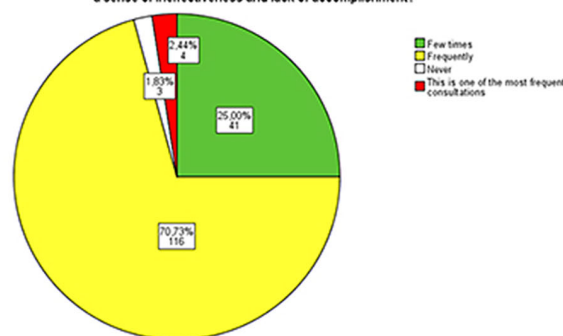

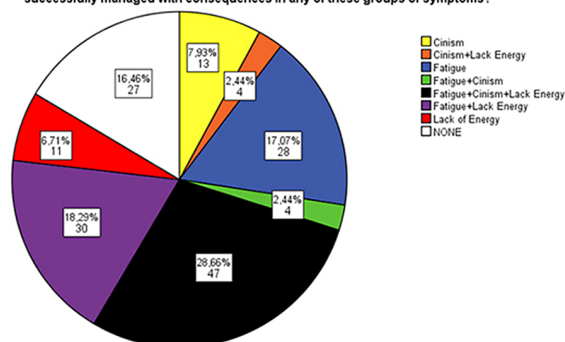

Image 2:

Image 2. Burnout dimension symptoms self reported by the surveyed psychiatrists and observed on their colleagues

QUESTION 8: Have yourself perceived that your work occasioned you chronic stress that you did not successfully managed with consequences in any of these groups of symptoms?

QUESTION 9: Have you observed in your colleagues that your work occasioned them chronic stress that they did not successfully managed with consequences in any of these groups of symptoms?

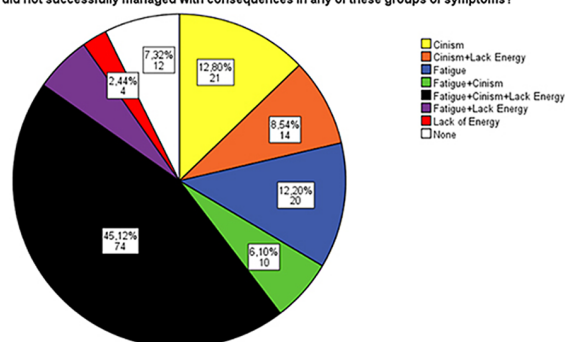

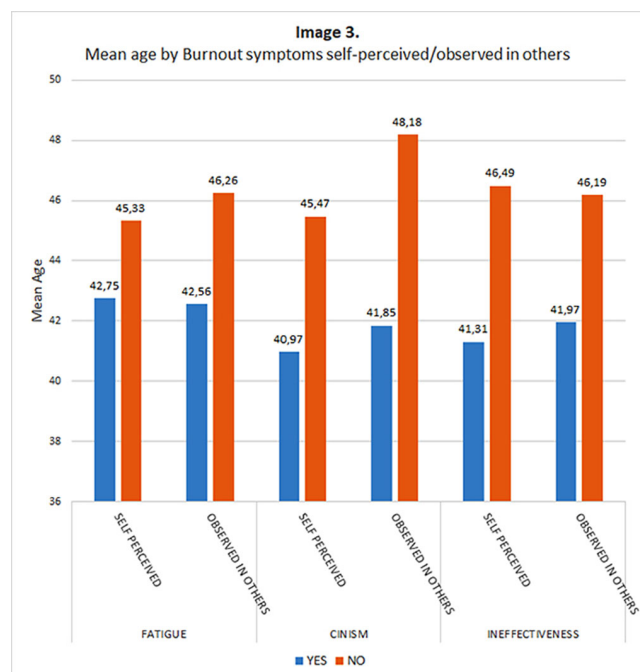

Image 3:

Conclusions: Psychiatrists' concept of burnout is diverse but the main construct is convergent with ICD definition, not a medical illness but a condition related to work.

The three classic dimensions of burnout are common in clinical conditions and also in the laboral environment of psychiatrists themselves. Psychiatrists tend to recognize more easily burnout in other colleagues, particularly cinism symptoms. Cinism and ineffectiveness appear to be related to younger age that can be associated to an imbalance between work demands and individual resources.

These results highlight the challenge of preventing, detecting and addressing burnout syndrome in psychiatric services.

Who benefits from multifamily psychoeducation groups ? Descriptive analysis of participants

O. Amiot*, C. Genis, L. Baziret, L. Champlon and S. Saïd

92100, GH Paul Guiraud, Boulogne Billancourt, France

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.322

Introduction: Guidelines for relapse prevention in schizophrenia recommend psychoeducation for patients and caregivers (Bighelli I, Leucht S et al. Lancet Psychiatry 2021). Considering that, in 2021, we implemented in our Psychiatric community center a multifamily therapy (MFT). The program is based on systemic approach and psychoeducation, focusing on schizophrenia.

Objectives: Describe participants of MFT groups focusing on schizophrenia.

* Patients' characteristics : age, gender, duration of psychiatric follow-up, history of hospitalization

* Caregivers' characteristics: status, age.

Methods: We carried out a descriptive study of the different profile of MFT groups participants in our community center from 2021 to today.

Results: Since 2021, 4 MFT groups took place including 50 participants: 18 patients suffering from schizophrenia and 32 relatives.

Image 1 illustrates the different participants of each group.

Each group was different. Some patients came with both their parents, even if divorced, some came only with their mother. Some came with a sibling. Nevertheless, the numbers of fathers and siblings did not always allow us to work in sub-groups.

Considering patients: 18 patients benefited from our program. 8 female and 10 male patients (55.6%) were admitted and distributed in each group as described in image 2. The mean age of patients was 31.9 years old [20.1 – 57.5]. Each group was made up of patients with psychiatric follow-up ranging from 1 year to more than 20 years, and having experienced between 1 to more than 5 psychiatric hospitalizations. It appears that Group 4 was noticeably younger than the other groups with a mean age of 22.4 years old [20.4 – 26.7] and a shorter history in psychiatry with less hospitalizations (image 3).

Considering relatives: 15 mothers, 9 fathers, 5 siblings, 1 spouse, 1 aunt and 1 uncle benefited from psychoeducation to caregivers. The relatives were from 47 to 81 years old for the parents, and from

17 to 50,7 for the siblings. Unlike parents, siblings generally attended a limited number of sessions.

Image:

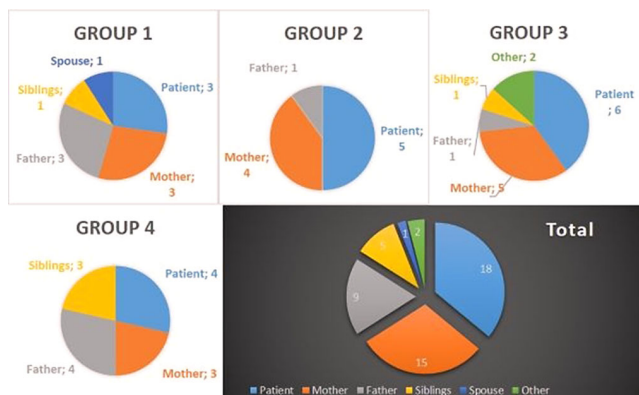

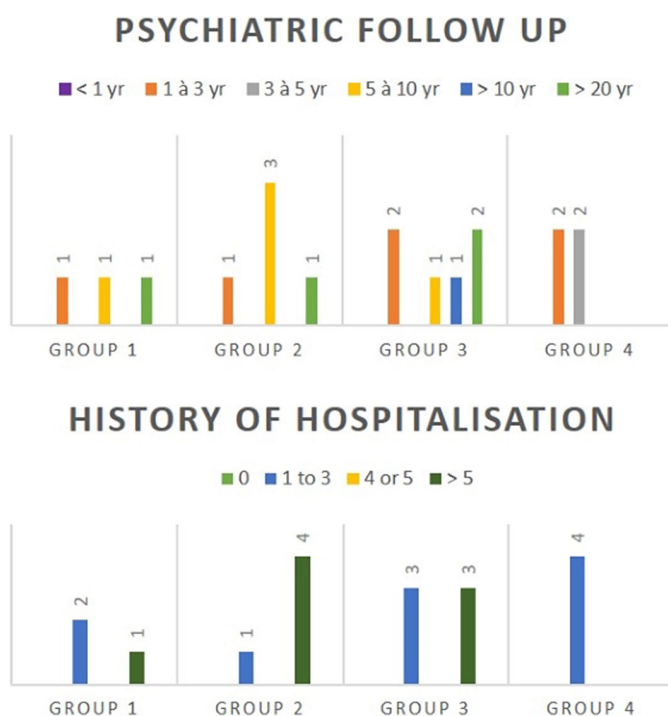

Image 2:

	PATIENTS				MOTHER		FATHER		SIBLINGS		SPOUSE	
	Patient	Age	sex	PRESENT	Age	PRESENT	Age	PRESENT	Age	Sex	Age	Sex

	17	21,5	M			Yes	54,3		24,3	SISTER		
	18	20,4	F	Yes	51,1	Yes	50,8		17,2	SISTER		

Image 3:

Conclusions: This descriptive study reflects the work carried out with 18 patients and their relatives in an MFT group providing psychoeducation to patients suffering from schizophrenia and their caregivers. 50 persons benefited from psychoeducation in 2 years. We learned from these results to improve the constitution of our groups and the benefits of our psychoeducation program. We were careful to include families with siblings as we know they are affected by the mental illness in the family and are often left aside of all care/support proposals. We questioned ourselves on the advantages of homogeneous or heterogeneous groups, considering age, history of follow up. How could it impact affiliation to the group or differentiation movements? How useful or harmful it is for sharing experiences between the families. A proper study would be necessary to answer these questions.

Traumatic Brain Injury and Conversion Disorder in a Veteran's Atypical Presentation

O. Inanc^{1*} and B. Garip²

¹Gulhane Training and Research Hospital, Ankara, Türkiye and

²Psychiatry, Gulhane Training and Research Hospital, Ankara, Türkiye

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.323

Introduction: Traumatic brain injury (TBI) induces cognitive and behavioral changes due to environmental impacts on brain tissue.

Objectives: Highlighting the atypical TBI presentation challenging conventional diagnostics and obscured by conversion disorders.

Methods: A 36-year-old male veteran, injured by a sniper rifle in 2011, presented with right ear tinnitus and monthly, unresponsive right hemispheric headaches. Seizures occurred every two weeks with no reported loss of consciousness or sensation. The gunshot wound to the neck in 2011 prompted emergency intervention, with entry and exit wounds located in the posterior lateral neck. Post-injury symptoms comprised hearing loss, tinnitus, restricted neck movement, and weakness in the right arm. Seizures persisted, accompanied by numbness and neck movement. Management included physical therapy, hyperbaric oxygen therapy (improving weakness but not tinnitus), and administration of piracetam (2400 mg/day), sertraline (100 mg/day), and ginkgo biloba (2400 mg/day). Psychiatric consultation suggested a diagnosis of "conversion disorder."

Results: Neuropsychological Evaluation: Raven Standard Progressive Matrices Test showed borderline impairment. Psychiatric Evaluation noted monotonous mimics, occasional depersonalization, reduced emotional involvement, and slowed psychomotor activity. Elevated trait anxiety was observed per the State-Trait Anxiety Inventory. Neurological Examination identified left arm weakness and impaired resting balance. Imaging Findings: F18-FDG PET/CT Scan at 1 year post-GSW showed hypermetabolism in the right frontal lobe, and at 3.5 years post-GSW demonstrated decreased glucose metabolism in the bilateral cerebellar cortex, temporal lobe, and bilateral parietal lobe.

Conclusions: A high-kinetic-energy bullet passed through the right lateral base of the neck without causing apparent brain damage.

Proposed is the generation of upward pressure waves in neck tissues through the transmission of kinetic energy, compressing and displacing soft tissues toward the skull. Gunshot injuries create cavities, forming high-pressure waves capable of damaging distant brain regions, leading to TBI such as crush injury, edema, and myelin and axonal damage (Courtney & Courtney, 2007). Microscopic brain damage, undetectable by current imaging, may only surface during autopsy (Yilmaz & Pekdemir, 2007). Rat studies after primary blast injuries reveal brain alterations, highlighting that high-pressure pulses can cause neuronal damage, potentially yielding related symptoms (Cernak et al., 2001). The patient's atypical symptoms, combined with the initial conversion disorder hypothesis, underscore the need for a diagnostic paradigm shift to differentiate traumatic brain injury from other potential misnomers.

Self-stigma and its reduction in patients with bipolar affective disorder

V. Mitikhin*, D. Oshevsky and L. Alieva

Mental Health Research Centre, Moscow, Russian Federation

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.324

Introduction: The phenomenon of self-stigma in patients with bipolar affective disorder (BD) has been studied much less than in other mental disorders (Favre, Richard-Lepourie, 2023). However, self-stigma has equally negative psychosocial consequences for them (Shargh et al, 2015). Therefore, identifying the clinical and psychological characteristics of self-stigma in BD patients, especially in the initial stages of the disease, and developing on this basis new directions for their psychosocial rehabilitation to reduce self-stigma is relevant.

Objectives: To identify clinical and psychological characteristics of self-stigma in BD patients, to identify targets for psychosocial rehabilitation.

Methods: «Questionnaire for assessing the phenomenon of self-stigmatization of mentally ill people» (Mikhailova et al., 2005), «Insight Scale for Psychosis» - ISP (Birchwood et al., 1994). We examined 17 patients (12 women and 5 men) with a diagnosis of bipolar affective disorder (F31.xxx according to ICD-10). The average age of the patients was 25.52±4.55 years. The duration of the disorder is 0.5-3 years.

Results: It was shown, that patients with BD had a high level of self-stigma. Indicator «General level of self-stigma» was 1.22±0.73 points, that higher its average values. The main component in the structure of self-stigmatization was an overestimation of possible limitations of one's own internal activity and self-realization (1.96 ± 0.87 and 1.62 ± 0.82 points, respectively) associated with the disease. Idealization of one's pre-illness qualities and achievements (1.62±0.82 points) and the formation of misconceptions about the loss of previous opportunities will able to lead to negative personal changes and limit the activity of patients. Correlation analysis revealed significant ($p \leq 0.01$) correlations between the «Patient's ability to recognize painful phenomena as symptoms of mental

illness» scale of the ISP scale and individual parameters of the questionnaire for assessing self-stigma: «Imagination of one's own failure due to illness» - $r = 0,52$; «Fear of becoming insolvent due to illness» - $r = 0,54$; «Idealization of the «healthy self», $r = 0,51$. Thus, in BD patients, self-stigma is associated with low awareness of the disease and misconceptions about it and about themselves.

Conclusions: Psychoeducation programs, aimed at formation an adequate perception of mental disorder, the ability to recognize its symptoms, and destigmatization trainings to increase the social activity are needed for BD patients. Such trainings were developed during the research and are currently being tested.

Participation limitations as a transdiagnostic feature in serious mental illness: confirmatory modeling

J. Bar Yosef^{1*} and L. Lipskaya-Velikovsky²

¹Occupational Therapy, Clalit, Afula and ²The school of occupational therapy, Hebrew University of Jerusalem, Jerusalem, Israel

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.325

Introduction: Participation in daily life occupations of personal and community meaning is an important component of health and recovery from mental illness. Limitations in participation were found to be a hallmark of serious mental illness (SMI). Still, previous research has mainly focused on objective dimensions of participation, largely neglecting the subjective aspects that hold particular relevance for health outcomes. Next, participation was addressed by specific diagnoses, approach which is divergent from the recovery model, a transdiagnostic approach and clinical practice. Hence, further research into participation is warranted to broaden our understanding.

Objectives: We investigated objective and subjective patterns of participation across a range of SMI diagnoses to delineate differences, and to identify personal and illness-related factors associated with participation dimensions.

Methods: A secondary analysis of cross-sectional studies (N=14). The analysis included data from 489 men (40.7%) and women (59.3%) diagnosed with one of 4 SMI conditions: psychotic, affective (AD), post-traumatic (PTSD) or personality (PD) disorders. The participants were aged 18 to 60 ($M = 34.41$; $SD = 10.9$) and were in contact with intensive mental health services. All participants completed the Adult Subjective Assessment of Participation (ASAP), which comprised participation intensity, diversity, satisfaction and enjoyment, and standard evaluations of cognitive functioning, symptom severity, and functional capacity. Z-scores were calculated for independent variables to enable comparison. Demographic and illness-related (IR) information was also collected.

Results: Frequency of participation was found to be significantly different between diagnostic groups, but not participation diversity, enjoyment and satisfaction. Participation diversity was altered by range of demographic variables ($5.26 < F < 10.6$, $p < .01$, $0.3 < \eta^2 < 0.4$) while participation frequency differs by employment status ($t(485) = -2.84$, $p < 0.05$, Cohen's $d = 0.25$). No differences were found

between groups in symptoms' severity. Regression analysis indicates that cognition, functional capacity and employment status explain in a significant way integrated index of objective participation ($\chi^2=47.52$, $p<0.001$). For the subjective dimension, the logistic regression was not found statistically significant ($\chi^2=20.99$, $p=0.51$).

Conclusions: Limitations in diversity, enjoyment and satisfaction with participation, were demonstrated to be a transdiagnostic feature in SMI. Objective participation dimensions can be explained with demographic, personal and illness related factors, while modeling of subjective dimensions should be further investigated.

Transcranial Magnetic Stimulation and Dual Pathology: An Integrative Protocol

A. Moleon*, P. Alvarez de Toledo, M. Martín-Bejarano and J. Narbona

Instituto Andaluz de Salud Cerebral, Sevilla, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.326

Introduction: Dual pathology, characterized by the simultaneous presence of substance use disorders and psychiatric disorders, is a topic of growing interest in the scientific community. In particular, obsessive-compulsive disorder (OCD) is a common comorbid psychiatric condition in patients with substance use disorders.

Objectives: To evaluate the efficacy of rTMS on comorbid disorder symptoms by applying specific protocols for OCD and substance use disorder in a clinical case of dual pathology.

Methods: Case Description: A 36-year-old male diagnosed with OCD and habitual cocaine use (an average of 6 times per month). Previous unsuccessful attempts to quit substance use. Undergoing psychotherapy and psychopharmacological treatment for OCD since the age of 22 with no significant clinical improvement.

Methodology: The severity of OCD was quantified before and after the intervention using the Yale-Brown Obsessive Compulsive Scale (YBOCS). To assess addictive behavior, the Maudsley Addiction Profile (MAP) was used. During the intervention period, the occurrence of substance use was recorded based on the patient's and family members' reports. The intervention involved the administration of an rTMS protocol tailored to the specific case, consisting of the simultaneous application, using a double-cone coil, of rTMS at 20Hz over the right dorsomedial prefrontal cortex (DMPFC) at an intensity of 100% of the resting motor threshold (RMT) to treat OCD symptoms, followed by intermittent theta burst stimulation (TBS) over the left DMPFC at an intensity of 120% of the RMT to address substance addiction. The patient received a total of 30 sessions at a rate of one session per day, five days a week, for six weeks.

Results: Results: The results showed an improvement in the total score on the YBOCS scale, decreasing from a value of 26 in the pre-intervention assessment to 16 in the post-intervention assessment, representing a reduction of more than 35% from pre- to post-intervention, meeting response criteria. Thus, there was a decrease in both obsessive and compulsive symptoms, with reduced

associated distress and increased control. Additionally, throughout the intervention, there was a gradual decrease in substance use, decreasing from an average of 6 monthly instances before treatment initiation to a total of 1 in the month the treatment ended.

Conclusions: Conclusions: This unique case study represents a therapeutic window for the treatment of patients with comorbid disorders, demonstrating promising preliminary benefits of the combined rTMS intervention for both conditions, especially in the field of addictions.

Keywords: rTMS, neuromodulation, obsessive-compulsive disorder, addictions

EPP0104

A Challenging Conundrum; Learning Disability, Schizophrenia and Autism - a Case Report

F. Rouhani, G. Aperis* and S. Digpal

General Internal Medicine, Queen Alexandra Hospital, Cosham, United Kingdom

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.327

Introduction: Psychiatric disorders are common in patients with learning disabilities. There are also patients with the triad of autism, schizophrenia and learning disability. Patients with this background can be admitted to general hospitals for psychiatric or non-psychiatric reasons.

We are presenting a case who had a very complicated clinical course and her discharge planning was challenging.

Objectives: The objective of this work was to show the challenges in the investigation, medical management, and discharge planning of the patients with concomitant learning disability, schizophrenia and autism.

Methods: We scrutinized the patient's casenotes, including blood results and all relevant imaging. We paid a particular attention to all the entries from the psychiatry team, general medical doctors, oncologists, learning disability team and discharge planners.

Results: The lady had a protracted 4-month inpatient admission throughout which she was physically and verbally aggressive to hospital staff. She was deemed to lack capacity for hospital admission and treated in her best interests under Mental Capacity Act (MCA), frequently requiring sedation with Haloperidol and Lorazepam. Following consultation with the local Psychiatrist her medications were altered to: Risperidone 2 mg BD, Diazepam 5 mg OM, 5 mg afternoon and 10 mg evening, Procyclidine 5 mg BD, Chlorpromazine 25 mg BD, Promethazine 25 mg OD PRN, and Midazolam 10 mg buccal PRN.

A change in her clinical condition was noted by the Psychiatry team; increased agitation, confusion and dysarthria. A repeat blood test was advised, due to patient refusal this took weeks to achieve despite the use of buccal Midazolam following Anaesthesiologist advice. Although blood tests were not significantly deranged, she was treated for presumed urinary tract infection with a course of antibiotics. A urine sample was unobtainable.

She reported right breast pain and underwent a mammogram. This showed a hypochoic lesion 8x7x9 mm. Following consultation with a Breast Surgeon and Oncologist, Letrozole was replaced with

Tamoxifen. The Psychiatric team concluded that the clinical deterioration with dysarthria was related to anxiety, associated with Autistic patients. The movement disorder was deemed secondary to antipsychotics exacerbated by stress and anxiety.

The patient's discharge planning was complex. She was declined by numerous care homes. At time of writing, she remains an inpatient.

Conclusions: The management of patients with a triad of Learning Disability, Schizophrenia and Autism is extremely difficult, particularly within an acute medical setting. Physical deterioration could be related to medication adverse effects or change in environment. Anxiety and stress are linked to these conditions. The challenging behaviour that these patients often have will make discharge planning very difficult as specialised care homes to accommodate these unique patients are very limited.

Clozapine-induced pyoderma gangrenosum. A case report

M. Peyioti^{1*}, P. Argitis¹ and O. Pikou²

¹Psychiatric and ²Dermatology, General Hospital of Corfu, Corfu, Greece

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.328

Introduction: Clozapine is an atypical antipsychotic medication which is mainly used in cases of treatment-resistant schizophrenia. Although it has several advantages over other typical and atypical antipsychotic medication, such as fewer relapses and lowering the risk of tardive dyskinesia and suicide it also has a range of adverse effects which makes compliance an issue for many patients.

Pyoderma gangrenosum (PG) is a rare neutrophilic dermatosis clinically characterized by painful pustules or nodules that rapidly evolve in ulcers with violaceous, undermined borders and raised periphery. The etiopathogenesis of the disease remains unclear, however PG is usually manifested in the setting of an underlying immune-mediated disease, more commonly inflammatory bowel disease, rheumatoid arthritis and haematological malignancies.

Objectives: Nevertheless, in the literature there are scarce reports of drug-induced PG.

Methods: We present the case of a 56-year-old woman with a diagnosis of refractory schizophrenia on clozapine treatment for 4 months, who was admitted to the emergency department for a skin eruption localized on the trunk, genital area and extremities. The clinical examination revealed numerous, discrete erythematous macules, papules and plaques with central necrosis, and multiple, sharply marginated ulcers with undermined, red to purple border. Further physical examination disclosed no systemic findings and laboratory analyses and skin biopsy were performed.

Results: On work-up, white blood cell count and C-reactive protein (CRP) were elevated, while blood and pustule cultures were negative. Histologic examination revealed dermal necrosis and inflammation, features consistent with the diagnosis of PG. The pathergy test was positive.

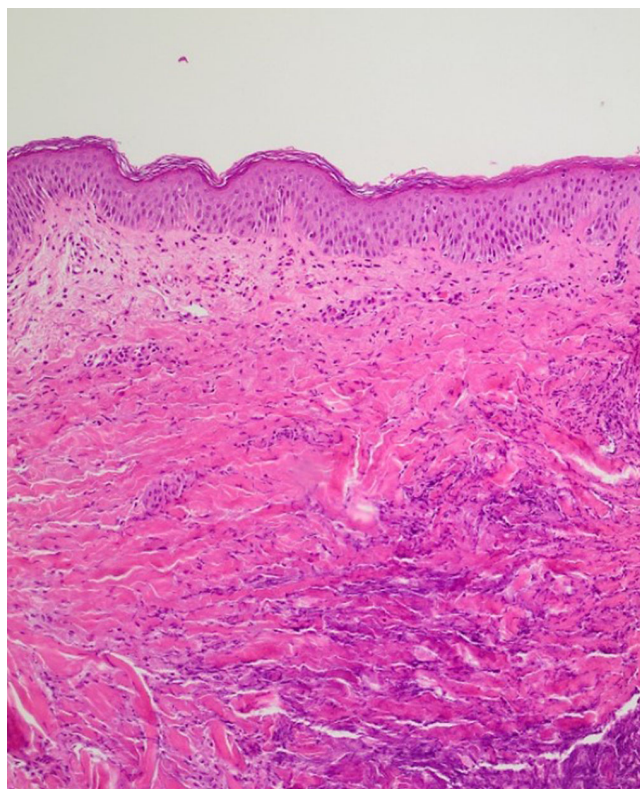

Image:

Image 2:

Image 3:

Conclusions: Pyoderma gangrenosum is a rare autoinflammatory skin disorder of unknown etiology. The pathogenesis of the disease is not well understood, but drug-induced PG is considered to result from neutrophil dysfunction and dysregulation of the inflammatory response. Cases of drug-induced PG are rare and attributed to certain drugs. Clozapine is an antipsychotic medication for the treatment of refractory schizophrenia. It is suggested that clozapine alters plasma TNF- α levels and thus can modulate the inflammatory response. To date, a variety of adverse skin reactions (Stevens-Johnson syndrome, DRESS syndrome etc) have been previously described in the literature. However, to the best of our knowledge, this is the first case which strongly indicates the likely association between clozapine and drug-induced PG.

New ways in delivering services for people with dual diagnosis

L. Lien¹ and N. Halvorsen^{2*}

¹Norwegian psychiatric association and ²Norwegian psychiatric association, Norway, Oslo, Norway

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.329

Introduction: People with severe mental health disorders and concurrent addiction problems are one of the most challenges

patients to treat within mental health and addiction. They often find themselves fallen between different chairs within mental health and addiction services and between specialist and primary care. There is a need for new ways of delivering services for this group.

Objectives: The objective of this presentation is to present how Flexible assertive outreach teams (FACT) are delivered in a densely populated country and the results on changes in use of specialist services and detention. We will also present the results of changes in quality of life before and after entering FACT and which factors that might be associated with life quality.

Methods: The establishing of FACT in Norway has been extensively evaluated both in the form of official reports to the health authorities and academic research papers. We will do a scoping review of the Norwegian research on the effect of FACT teams with a specific attention to the results obtained in densely populated areas. The review will cover the years from 2018 up to today.

Results: The results so far indicate that it is possible to deliver FACT services in densely populated areas and that there is an increase in quality of life before and after entering a FACT team. The use of hospitalization days are reduced with about 50 % and the same applies for days in detention.

Conclusions: FACT teams seem to be a viable way of delivering mental health care services to one of the most vulnerable groups in our society.

Options for the recovery of mental activity in children after acute brain damage

Y. Sidneva^{1,2*}, A. Zakrepina^{1,3}, S. Valiullina¹ and M. Bratkova^{1,4}

¹Rehabilitation, Clinical and Research Institute of Emergency Pediatric Surgery and Trauma; ²Neuropsychiatric research, N.N.Burdenko National Medical Research Center of Neurosurgery; ³Defectology, Federal state budgetary scientific institution "Institute of correctional pedagogy" and ⁴Moscow City University, Moscow, Russian Federation

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.330

Introduction: Children with acute brain damage make up a large group of patients who require multi-stage rehabilitation. Rehabilitation requires the creation of special conditions for psychiatric care and psychological and pedagogical correction of the consequences of severe damage to the nervous system. A differentiated approach to rehabilitation will help restore mental activity with greater efficiency, and subsequently adapt the child to the familiar environment.

Objectives: The aim of the study is to identify the options for mental activity during the restoration of the level of consciousness in children after acute severe brain damage.

Methods: 210 children under the age of 18 with severe brain damage (traumatic brain injury, hypoxia, hydrocephalus), admitted for treatment and rehabilitation. Clinical-psychopathological, pedagogical methods were used; additionally - diagnostic scales, questionnaires.

Results: Depending on the level of consciousness, mental activity, 4 groups were formed:

1st group - 37 (18%) patients had manifestations of mental activity with physical, cognitive and social capabilities in the minimal

consciousness “+” (a- / hyperkinetic mutism with emotional reactions, understanding of addressed speech);

2nd - 67 (32%) patients had manifestations of physical and cognitive abilities with minimal consciousness “-” (a- / hyperkinetic mutism without emotional manifestations and understanding of addressed speech);

3rd - 95 (40%) patients had only the manifestation of physical capabilities at the exit from the vegetative status.

4th - 11 (10%) patients had a low manifestation of mental activity in the form of physical capabilities with a vegetative status.

Conclusions: 4 variants of mental activity in children after acute severe brain damage have been identified: from minimal involuntary reactions or their absence in vegetative status to voluntary actions according to the instructions of an adult in minimal consciousness “+”. Taking into account the variability of mental activity helps to differentiate the methods of psychiatric and psychological-pedagogical assistance in the recovery of children already in the early stages of rehabilitation.

Schizophrenia and Polycythemia Vera: A Case Report

N. El Moussaoui*, S. Bahetta, I. Belabbes, F. Laboudi and A. Ouanass

Arrazi University Psychiatric Hospital, Salé, Morocco

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.331

Introduction: Schizophrenia is a severe mental disorder marked by abnormal interpretations of reality, often resulting in hallucinations, delusions, and disordered thinking that significantly impairs daily functioning and can be disabling. Lifelong treatment is necessary, and early intervention can help manage symptoms and improve long-term outcomes.

Polycythemia Vera (PV) is a chronic myeloproliferative neoplasm causing an excess of red blood cells in the peripheral blood (polyglobulia). While the disease typically presents with symptoms, it can also be asymptomatic and discovered incidentally during routine laboratory tests, leading to a diagnosis of polycythemia when no secondary cause is apparent.

While early 20th-century literature linked PV to intense neurological and psychiatric symptoms, contemporary studies rarely make such references.

Objectives: The aim of this study is to explore, through a clinical case of a patient undergoing treatment for treatment-resistant schizophrenia with clozapine, and concurrently diagnosed with Polycythemia Vera, the potential causes of this condition. We seek to discern whether it represents mere comorbidities or if Polycythemia Vera is an adverse effect of antipsychotic treatment, particularly with clozapine.

Methods: A 41-year-old patient, with a history of cranial trauma at the age of 5 and 19 years of treatment for schizophrenia, also has a tobacco use disorder. While hospitalized for the management of symptomatic reactivation of schizophrenia, despite being on clozapine, the patient underwent various therapeutic combinations with no observed clinical improvement. A few months later, follow-up blood tests indicated an elevation in all blood cell lines.

An internal medicine consultation was sought, resulting in the diagnosis of Polycythemia Vera.

Results: The evaluations conducted led us to the conclusion that there are two distinct nosological entities, with the treatment of the psychiatric condition revealing true polycythemia. Even after reducing the doses of clozapine and changing the atypical antipsychotic, all subsequent evaluations showed no effectiveness in managing the psychiatric disorder or improvement in the hematological condition.

Conclusions: In summary, schizophrenia is a severe and lifelong mental disorder requiring early intervention for symptom management. Polycythemia Vera (PV), a myeloproliferative disorder, typically presents with symptoms but can also be asymptomatic. While early literature linked PV to intense neurological and psychiatric symptoms, contemporary studies seldom reference such associations. The coexistence of schizophrenia and PV in a patient underscores the need for comprehensive and interdisciplinary care to address the complex interplay between mental and physical health. Further research is needed to deepen our understanding of concurrent psychiatric and hematological conditions.

The Impact of Internet Use on the Parameters of Attention in Adults

A. Mihai^{1*} and M. Rebeca-Isabela²

¹Psychiatry, University of Medicine, Pharmacy, Science and Technology and ²Mureş County Hospital, Targu-Mures, Romania

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.332

Introduction: Internet use in the adult population is growing at alarming rates. The latest statistical data show an average internet usage time of 6 hours and 58 minutes (2023), an increase of 1% compared to 2021. Research studies on the influence of the excess use of internet on attention is in its prime years, and clear steps need to be made in an attempt to clarify current hypotheses and to find effective methods for prevention. Nowadays, one of the most powerful influences on attention is the use of the internet, which, more often than not, crosses the line of addiction.

Objectives: The initial hypothesis is that in the event of exposure to a high number of stimuli, the ability to switch attention to a single task may only be possible at a superficial level. The aim of this study was to assess the impact that excess internet use has on the ability to maintain attention in the adult population. The present study aims to sketch a well-established structure and direction of research in the field of attention and its effects on human functioning.

Methods: Using the DSM 5-TR diagnostic criteria for pathological Internet gaming disorder we enrolled 60 people who expressed their consent to participate in the study. We check psychiatric comorbidities using SCID II. As a method for evaluating changes in the level of attention, we used of the Stroop test. The results were analysed with the SPSS program (version 23).

Results: The results showed a marked decrease in the ability to maintain attention, without increasing the number of stimuli. Although excessive Internet use leads to changes in attention parameters, research in this area is scarce and incomplete.

Currently, most of the published studies focus on a causal relationship between the pathological use of the Internet and the appearance of attention deficit/hyperkinetic disorder, especially in children and adolescents. Although the results are promising, we cannot neglect the multitude of additional consequences of excess Internet use, which these studies targeting a single pathology overlook. Moreover, using the Internet involves exposure to an ever-increasing number of stimuli, which is why switching attention and maintaining it is currently an insufficiently researched parameter. Regarding the impact of Internet use on individual functioning, there is a relatively modest number of studies in the literature that outline a correlation between excess Internet use and various psychiatric comorbidities.

Conclusions: The impact of the research on the general population could be an increased awareness of negative effects and the development of prevention programs.

Psychometric Properties of the Depression, Anxiety, Stress Scales-21 (DASS-21) in a Portuguese Sample during the early stage of the COVID-19 pandemic

C. Laranjeira^{1,2*}, M. A. Dixe^{1,2} and A. I. Querido^{1,2}

¹School of Health Sciences and ²ciTechCare, Polytechnic University of Leiria, Leiria, Portugal

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.333

Introduction: The COVID-19 global crisis has resulted in significant disruptions in the lives of students in higher education, leading to negative consequences for their academic achievements and general psychological well-being.

Objectives: In this study, we sought to examine the psychometric properties of the Depression Anxiety Stress Scale-21 (DASS-21) among students in Portuguese higher education institutions during the initial phase of the COVID-19 pandemic and its efficacy in capturing mental health symptoms due to a global health crisis.

Methods: In this cross-sectional study, a convenience sampling method was used to enlist a total of 1522 participants. The sample consisted of 75.1% women and 79.2% undergraduate students. Participants completed an electronic survey that was designed using the Depression Anxiety Stress Scale-21 (DASS-21) — a self-report instrument measuring anxiety, depression, and stress.

Results: The findings of the study indicated a significant occurrence of depressive symptoms [≥ 10] (N = 434, 28.5%), anxiety symptoms [≥ 7] (N = 551, 36.2%), and stress symptoms [≥ 11] (N = 544, 35.7%). Based on the collected data, a Confirmatory Factor Analysis (CFA) was conducted in order to examine the factor structure of the scale. The analysis revealed a three-factor solution that corresponded to the three subscales of the DASS-21. The Heterotrait-Monotrait (HTMT) correlation ratio was then used to assess the discriminant validity, with good results. Results showed that the DASS21 has satisfactory reliability indexes (Cronbach's $\alpha > 0.90$).

Conclusions: In light of the notable changes in living conditions brought by the COVID-19 pandemic, the present study has shown that the DASS-21 instrument has maintained its reliability and validity. Consequently, this finding supports the appropriateness of using the DASS-21 as a screening tool for assessing mental health among students in Portugal. Moreover, it is recommended that academics and healthcare practitioners use the DASS-21 as a tool for assessing the levels of psychological distress experienced by students. Additional validation studies of this scale are required, using bigger and more representative populations.

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.334

Introduction: At the beginning of the Covid-19 pandemic, respiratory expression of SARS-CoV-2 infection was the most worrying one. Later, other symptoms appeared to be more disturbing such as neurological and psychiatric manifestations, which may be due to direct or indirect effects of this virus on the central nervous system.

Objectives: To assess the prevalence of neuropsychological manifestations of covid-19 in healthcareworkers and to identify their risk factors.

Methods: This is a cross-sectional descriptive epidemiological study, carried out in the teaching hospitals of Farhat Hached and Sahloul of Sousse. All healthcareworkers, having tested positive for SARS-COV 2 during the period from 01/09/2020 to 28/02/2021 were enrolled. The collection of socio-professional and medical data was based on a pre-established synoptic form completed during an interview with the participants.

Results: A total of 953 COVID-19 patients were enrolled in this study. The mean age was 40.1 ± 10.5 years, with a sex ratio of 0.32. In our sample, 37.9% of patients had comorbidities such as psychiatric history (4.9%) and neurological history (2.4%). The prevalence of neuropsychological manifestations of covid-19 was 72.6%. The main neuropsychological manifestations were headache (50.3%), anosmia (40.7%), dysgeusia (29.9%), sleep disturbances (0.5%), dizziness (1, 2%) and paresthesia (0.3%). Neuropsychological symptoms of long covid were dominated by memory impairment (10.7%), anosmia (8.5%), headache (7.3%), dizziness (3.4%) and sleep disturbances (3.1%).

The occurrence of neuropsychological manifestations was significantly associated with age (OR=1.6; $p < 10^{-3}$), male gender (OR=0.57; $p=0.03$), smoking (OR=1.7; $p=0.033$), history of hypertension (OR=1.6; $p=0.038$), history of diabetes (OR=2.4; $p < 10^{-3}$) and hospitalization (OR=4.03 ; $p < 10^{-3}$).

Conclusions: The high prevalence of neuropsychological manifestations underlines the importance of studying their pathogenesis in order to better adapt their therapeutic protocols.

Emergency Department Presentations to the Mental Health Services at Sligo University Hospital during the COVID pandemic

S. M. Gunawardena^{1*}, A. Godavarthi¹ and E. Gethins¹

¹Department of Liaison Psychiatry, Sligo University Hospital, Sligo, Ireland

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.335

Introduction: In March 2020, the WHO declared the outbreak of SARS-CoV-2 a pandemic and Ireland went into its first lockdown. The Mental Health Liaison team at Sligo University Hospital operate 8 am to 8 pm, 7 days a week, with out of hours covered by the on-call Psychiatry junior doctors. The service has seen an increase in referrals, many of whom are known to community mental health teams.

Objectives: We reviewed the numbers and trends of mental health presentations to the Emergency Department at Sligo University Hospital throughout the pandemic, including the patterns of presentations around the implementation of lockdowns.

Methods: The Liaison Mental Health Service at Sligo University Hospital gathers data relating to numbers and types of presentation to the service. Data was taken from a pre-existing database of psychiatric presentations to the emergency department at Sligo University Hospital including patient demographics, nature of presenting complaint, time period in which they presented and whether they were previously linked in with a community mental health team in the preceding six months. We also looked at the pattern of ED mental health presentations from March 2019 to August 2021. In order to compare psychiatric presentations pre and during covid, data was broken down into two groups: the twelve months preceding March 2020 and the twelve months from March 2020. Categorical data were analysed using the Chi squared test for homogeneity in SPSS.

Results: Overall, there was a 14% increase in mental health presentations during the pandemic. There was a significantly greater proportion of presentations of psychosis during the pandemic period ($p < .014$) and for medication review ($p = .03$) and significantly less presenting with addiction ($p < .001$). Of those patients seen in the Emergency Department in 2021, 54.3% were known to the CMHT in the previous 6 months. In 2019, mental health presentations made up 1.36% of total ED attendances. This increased to 1.47% in 2020. From January to August 2021, 2.62% of ED attendances were mental health presentations.

Image:

	Pre Covid 19	During Covid 19	P value
Gender (Male/female)	280/282	297/343	.19
SI/DSH	336 (61%)	357(56%)	.13
Depression/Anxiety	69 (12.5%)	100 (16%)	.10
Addictions	70 (13%)	36 (6%)	.00
Psychosis	22 (4%)	46 (7.3%)	.01
aggression/agitation	8 (1.5%)	14 (2%)	.33
Medication rv/Advice	6 (1%)	18 (3%)	.03
Mania	2 (0.5%)	6 (1%)	.23
Others	39 (7%)	54 ((8.5%)	.34
Total	562	640	

Conclusions: The Covid-19 pandemic led to increased mental health presentations to Sligo University Hospital emergency department, with a significantly greater proportion presenting with psychosis and for medication review. These findings have implications around patient care and service provision. These results show that the prevalence of mental health has increased during the pandemic, particularly severe and enduring mental illnesses. New strategies must be implemented to accommodate to this increase in presentations.

The Role of Pet Companionship in Older Adults' Mental Health: A Qualitative Study during the Covid-19 Pandemic

S. von Humboldt^{1*}, S. Silva² and I. Leal¹

¹William James Center for Research, ISPA – Instituto Universitário and ²ISPA – Instituto Universitário, Lisbon, Portugal

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.336

Introduction: Human functioning in the physical, emotional, psychological, and social arenas is improved by contact with animals.

Objectives: This study aimed to explore the affective relationship of older adults with their pets during the COVID-19 pandemic; and to assess how the affective relationship with pets contributed to older adults' mental health.

Methods: This qualitative study included 176 participants aged 65-88 years from Portugal, the United Kingdom, and Spain. All interviews went through content analysis.

Results: Findings indicated five themes: (1) Meaningful Emotional Relations (86%); (2) Intimacy with Partners (68%); (3) New Emotional Connections (61%); (4) Sensory Stimulation (55%); and; (5) Physical Enjoyment (23%). As for the second objective, three main themes emerged from the content analysis: (1) Decreasing Depressive and Anxiety Symptoms (73%); (2) Easing Feelings of Loneliness (68%); and (3) Reducing Mood Swings (43%).

Conclusions: The affective relationship between older adults and their pets was relevant during the COVID-19 pandemic, since it allowed for solidifying affection relationships with their partner and creating new ones. Additionally, it contributed for deepening the affective relationship with themselves, in terms of sensory stimulus, physical touch and physical pleasure. Owning a pet, was important for improvement in mental health symptoms, associated to depression, anxiety, and mood swings.

Keywords: Affective relationship; animal companionship; COVID-19 pandemic; mental health; older adults; pets.

SARS-CoV-2 infection and psychological distress : a prospective sero-survey in southern Switzerland

B. Bano^{1*}, C. Sculco², G. Piumatti³, R. Amati¹, M. Purgato⁴ and E. Albanese¹

¹Institute of Public Health, Università della Svizzera italiana; ²Institute of Public Health, Università della Svizzera italiana, Lugano, Switzerland; ³Fondazione Agnelli, Turin and ⁴Department of Neurosciences, Biomedicine, Movement Sciences, University of Verona, Verona, Italy

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.337

Introduction: The COVID-19 pandemic has had an impact on the mental health of the population that, to some extent, may be due to the neurotropism of SARS-CoV-2. However, evidence is extremely sparse on the prospective association between serological evidence of COVID-19 infection and psychological distress.

Objectives: We aimed to explore the prospective association between seropositivity and psychological distress – assessed by symptoms of depression, anxiety and stress – in the general adult population in southern Switzerland. Further, we investigated whether this association varied over time and between pandemic waves.

Methods: We used data from 305 adults who participated in the Corona Immunitas Ticino (CIT) prospective sero-survey cohort study. We tested the association between serologically confirmed SARS-CoV-2 infection at baseline (June–December 2020) and depression, anxiety and stress scores as measured by the DASS-21 scale at three time points between December 2020 and March 2021, also taking into account for sociodemographic characteristics (age, gender, education level, presence of chronic diseases, smoking, obesity).

Results: In our sample, 84.3% (mean age of 51.30, SD= ± .93) were never infected. Seropositive participants were significantly younger on average (M=46.90, SD= ±2.00, P= .04). At the first follow-up (see Table 1), seropositive participants had higher rates of mild

conditions for depression (OR= .64; P= .014) and anxiety (OR= .50; P= .030), than seronegatives. Overall, after the 6-month follow-up, seropositive participants had significantly lower rates of mild conditions for DASS-21 subscales. In addition, prevalence of mild conditions for depression, anxiety and stress decreased more rapidly over time among infected vs. never infected (see Figure 1). Older age and the presence of chronic diseases were associated with mild anxiety (OR= .97; P= .013; OR=3.47; P= .001) and stress (OR= .96; P= .003; OR= 2.56; P= .010).

Table 1. Associations (Odds Ratios) between seropositive immunological status and mental health between December 2020 and March 2021 in Ticino, southern Switzerland (N=305)

DASS-21 defined mild condition	OR	P value	CI (95%)
Depression	0.641	0.014	0.449 – 0.914
Anxiety	0.502	0.030	0.270 – 0.936
Stress	0.712	0.113	0.468 – 1.083

Note. Generalized estimating equation models results. Co-variables include time, age, gender, chronic diseases, obesity, smoking and education level.

Conclusions: Our results provide new evidence on the association between COVID-19 seropositivity and poor mental health and underline the public health implications of the pandemic because the number of infected individuals largely exceed the 770 million of recorded COVID-19 (symptomatic) cases.

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.338

Introduction: Digital interventions have been found to be successful in preventing occupational mental health concerns, however, they seem to be affected by attrition bias through high attrition rates and differential attrition. Differential attrition arises when the rates

of participant dropouts differ across different treatment conditions and is considered a significant challenge to internal validity.

Objectives: We aimed at systematically review and meta-analyse differential attrition of digital mental health interventions in the workplace setting.

Methods: On January 2, 2022, we performed a search in the following electronic databases: PubMed, Scopus, and Web of Science Core. We utilized a combination of terms from five distinct areas, namely mental health, intervention, workplace, implementation, and study design. The study encompassed adult employees who took part in a randomized control trial aimed at preventing mental health issues in the workplace through an online intervention. A team of six reviewers collaborated on the study selection process, while two independent researchers conducted the data extraction for the selected studies. We performed a meta-analysis of the log-transformed relative attrition rates of the included studies using a random-effects model with limited maximum-likelihood (REML) estimation to account for the degree of heterogeneity.

Results: A total of 19 studies were included in the meta-analysis. For baseline to post-intervention, the average total attrition was 26.27% (SD = 21.16%, range = 0 – 66.3%) and the random effects model revealed a higher attrition rate in the intervention group compared to the control group, with a pooled risk ratio of 1.05 (95% CI: 1.01 – 1.10, $p = .014$). For baseline to follow-up measurement the average total attrition was 27.71% (SD = 20.80%, range = 0 – 67.78%), however, in this case the random effects model did not indicate a higher attrition in the intervention group when compared to the control group (pooled risk ratio = 1.05, 95% CI: 0.98 – 1.12, $p = .183$).

Conclusions: There is an indication of higher attrition in the intervention group as compared to the control group in occupational e-mental health interventions from baseline to post-intervention, however this does not seem to be the case for baseline to follow-up attrition. These results should be taken into account in the design process of studies and statistical analyses should be adapted to counteract the bias that could result from differential attrition.

University students' perspectives towards digital mental health: a qualitative analysis of interviews from the cross-country 'CAMPUS study'

I. Riboldi¹, A. Calabrese¹, S. Piacenti¹, C. A. Capogrosso¹, S. Lucini Paioni^{1*}, F. Bartoli¹, G. Carrà^{1,2}, J. Armes³, C. Taylor³ and C. Crocamo¹

¹Department of Medicine and Surgery, University of Milano-Bicocca, Monza, Italy; ²Division of Psychiatry, University College London, London and ³Faculty of Health and Medical Sciences, School of Health and Sciences, University of Surrey, Guildford, United Kingdom
*Corresponding author.

doi: 10.1192/j.eurpsy.2024.339

Introduction: Poor mental health of university students is a growing concern for public health. Indeed, academic settings may exacerbate students' vulnerability to mental health issues. Nonetheless, university students are often unable to seek mental health

support due to barriers, at both individual and organisational level. Digital technologies are proved to be effective in collecting health-related information and in managing psychological distress, representing useful instruments to tackle mental health needs, especially considering their accessibility and cost-effectiveness.

Objectives: Although digital tools are recognised to be useful for mental health support, university students' opinions and experiences related to such interventions are still to be explored. In this qualitative research, we aimed to address this gap in the scientific literature.

Methods: Data were drawn from "the CAMPUS study", which longitudinally assesses students' mental health at the University of Milano-Bicocca (Italy) and the University of Surrey (United Kingdom). We performed detailed interviews and analysed the main themes of the transcripts. We also performed a cross-cultural comparison between Italy and the United Kingdom.

Results: Across 33 interviews, five themes were identified, and an explanatory model was developed. From the students' perspective, social media, podcasts, and apps could be sources of significant mental health content. On the one hand, students recognised wide availability and anonymity as advantages that make digital technologies suitable for primary to tertiary prevention, to reduce mental health stigma, and as an extension of face-to-face interventions. On the other hand, perceived disadvantages were lower efficacy compared to in-person approaches, lack of personalisation, and difficulties in engagement. Students' opinions and perspectives could be widely influenced by cultural and individual background.

Conclusions: Digital tools may be an effective option to address mental health needs of university students. Since face-to-face contact remains essential, digital interventions should be integrated with in-person ones, in order to offer a multi-modal approach to mental well-being.

Introduction: Psychiatric care faces a significant challenge in the regular monitoring of patient states, predicting relapses, and ensuring treatment adherence. To address this, we aim to develop a mobile application tailored to individual patient needs. This application will revolutionize mental health care by offering real-time monitoring, education, evidence-based interventions, and enhanced communication between patients and clinicians.

Objectives: This ongoing study seeks to develop and evaluate a mobile application for individuals with schizophrenia spectrum

disorders, aiming to transform personalized mental health care by addressing critical challenges in psychiatric care.

Methods: The study follows a multi-phase approach, incorporating prototype development, a proof-of-concept trial, and a Randomized Controlled Efficacy Study (RCT). Each phase is informed by iterative stakeholder feedback, ensuring responsiveness to real-world needs and experiences. The research was approved by the Semmelweis University Regional and Institutional Committee of Science and Research Ethics (SE RKEB: 85/2023).

Results: In the pilot phase, we have effectively tracked the daily well-being of participating patients through interactive activities and structured questionnaires. Our experiences in this phase promise to offer valuable insights for the psychiatric community, shedding light on the potential of personalized mental health care interventions.

Conclusions: This ongoing study represents a pivotal step towards redefining interventions for individuals with schizophrenia spectrum disorders. Early results signal a transformative potential in enhancing symptom management. As the study advances, deeper insights will emerge, emphasizing the profound impact of leveraging mobile technology in personalized mental health care.

Emotion Regulation and Physiological Reactivity in the Parent-Child Relationship: A Preliminary Study of an Online Attachment-Based Program for Parents of Preadolescents with Behavioral Disorders

M. Tironi^{1*}, S. Charpentier Mora¹ and F. Bizzi¹

¹University of Genoa, Genoa, Italy

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.341

Introduction: Behavioral disorders have been defined as a “health crisis” of modern times that has a significant impact on the parent-child relationship. In this scenario, the emotional regulation (ER) of each partner plays a central role and serves a protective factor, configuring as an area to intervene. The Connect Parent Group, an attachment-based intervention for parents, has shown evidence of effectiveness. However, its online version (e-Connect) has not yet garnered specific evidence related to emotional and physiological regulation in parents and preadolescents.

Objectives: This study aimed to explore changes in the short and medium term regarding ER abilities - both self-reported and measured through physiological indices - in parents and preadolescents with behavioral disorders, building upon initial findings from an online parenting intervention.

Methods: 28 parents (82.1% mothers, 17.9% fathers, $M_{age} = 47.48$, $SD = 4.73$) and their 28 preadolescents with behavioral disorders ($M_{age} = 11.22$ years, $SD = 2.69$, 35.7% girls) were recruited from child neuropsychiatry services in Northern Italy and subsequently took part in the pilot study. They were assessed at three time points: before intervention (T1), one month after the intervention (T2) and at 6-months follow-up (T3). ER were assessed with a multimethod approach: parents and children

completed a self-report questionnaire (i.e., Difficulties in Emotion Regulation Scale and How I Feel, respectively) and then they interact during a stress-task in which physiological parameters (i.e., Galvanic Skin Response, GSR; Heart Rate/Beat per Minute, BPM) have been measured.

Results: Regarding self-reported ER, mixed-effects regression models showed an improvement in parent emotion dysregulation between T1 and T3 ($p=0.004$), a decrease in preadolescents' negative emotions ($p=.012$) between T1 and T2 and a lower emotion intensity in preadolescents between the three-time points ($p=.003$). Regarding physiological ER, the two overall models of GSR and BPM were not significant for both parents and children. Yet GSR correlations within three-time points were positive and significant for children (T1-T2: $r=.58$; T1-T3: $r=.68$) but not for parents, while BPM correlations between T1 and T2 were significant for parents ($r=.49$) but not for children.

Conclusions: The online attachment-based parenting program appears to have contributed to a reduction in emotional dysregulation in parents and preadolescents, which seems to persist to some extent in the medium term. The non-significant results at the physiological level may suggest that changes reported by parents and children through self-report questionnaires do not align with changes in the physiological response to interpersonal stress experienced after an online intervention. Clinical and research implications will be discussed.

Aggression management of criminal offenders in prison setting

G. Nikolić^{1*}, N. M. Stojanović², J. Branković³, S. Tošić Golubović⁴, O. Žikić¹ and J. Kostić¹

¹Department of psychiatry; ²Department of Physiology, Faculty of Medicine; ³Daily hospital, Center for mental health protection and ⁴Clinic for Psychiatry, Faculty of Medicine, Niš, Serbia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.342

Introduction: A new approach of social therapy for criminal offenders was applied in Penalty Facility in Niš, Serbia. It is based on three month peer-training focusing on recognizing of triggers for anger, understanding emotional manifestation and learning socially acceptable ways of anger expression.

Objectives: To estimate how the impact of peer-based training influences the level of aggression of criminal offenders in prison settings.

Methods: One hundred and six prisoners were randomly assigned to program. The six previously educated inmates trained the participants through 12 work-shops. An independent professional evaluated change in aggression levels after training using Buss&Perry Aggression Scale. We compared subgroups with shorter versus longer sentences pre and post training using Student's t test. And univariate logistic regression analysis for impacts of sociodemographic variables on aggression scores.

Results: We found a significant higher scores of anger (6.6 ± 4.7 & 11.8 ± 4.2 , $p=0,043$) hostility (15.5 ± 8 & 20.1 ± 6.5 , $p=0,029$) and total aggression (32 ± 14 & 48 ± 21 , $p=0,023$ in subgroup with longer sentences at baseline. After training anger (12.4 ± 4.8 & 15.5 ± 5.6 , $p= 0,0167$), physical aggression (14.6 ± 5.1 & 17.2 ± 5.6 , $p=0,024$) and total aggression score (55.5 ± 14.1 & 68.2 ± 18 , $p=0,0152$) remained higher in the group with sentences more than five years. Lower education level is associated with undesirable outcome-higher level of aggression after training.

Conclusions: Three months training was not sufficient for adopting skills for better control of aggressive behavior in criminal offenders never the less the length of the sentences.

EPP0127

How psychopathy is associated with the level and change of impulsivity in correctional treatment

A. Voulgaris*, P. Briken and E. Stück
Institute for Sex Research, Sexual Medicine and Forensic Psychiatry, Medical University Hamburg, Hamburg, Germany
*Corresponding author.
doi: 10.1192/j.eurpsy.2024.343

Introduction: Research indicates that psychopathy can hinder treatment success and can lead to dropout. Impulsivity is a complex construct that overlaps with psychopathic personality traits and is often targeted in forensic psychotherapy due to its relation to the risk of reoffending.

Objectives: Our aim was to investigate the overlap between psychopathy and impulsivity and the influence of psychopathic traits on change in impulsivity.

Methods: We conducted a pre-post-study for measures of psychopathy and impulsivity in men imprisoned for sexual and non-sexual violent offenses. All participants took part in standardized pre- and post-treatment ratings shortly after admission as well as after an average of 19 months ($n=370$ for pre-rating, $n=168$ for post-rating). Psychopathy was measured via the PCL-R, impulsivity with the BIS-15.

We calculated two-tailed Pearson correlations for BIS-15 Pre-, Post-, and Change Scores and the PCL-R. In a second step, the BIS-15 pre-post-differences were compared using independent t-Tests, effect sizes were calculated using Cohen’s d (small, medium, and large effect sizes are $d = .20$, $.50$, and $.80$). Further, unpaired t-tests were carried out to compare between participants with lower and higher PCL-R sum scores (median split, $mdn= 15.8$, $M=15.5$, $SD=7.9$).

Results: In the total population a significant reduction of self assessed impulsivity can be demonstrated for total impulsivity ($p<.001$, cohens $d= .34$) nonplanned ($p<.001$, cohens $d= .39$) and motor impulsivity ($p=.004$, cohens $d= .23$). In both groups, with higher and lower psychopathic traits, a significant reduction in total and nonplanned impulsivity can be seen.

While the reduction in total impulsivity was 0.9 points higher in the group with higher psychopathy, the difference was not significant, $t(147.8)= -1.1$, $p = .285$. Also, the nonplanned impulsivity was showed a stronger reduction in the high PCL group, though the effect was not significant, $t, t(166)= -1.2$, $p = .243$.

Table 1. Correlationen between BIS-15 post-ratings and PCL-R

		PCL-R				
		PCL-R Sum	Interpersonal	affective	lifestyle	antisocial
BIS-15 prä (n=370)	Total Impulsivity	.20 **	-.14 **	.02	.34 **	.28 **
BIS-15 post (n=168)	Total Impulsivity	.33**	.04	.20**	.35**	.36**
BIS-15 Change (n=168)	Total Impulsivity	-.03	-.15	-.09	.07	.01

Note: * correlation significant für $p \leq .05$; ** correlation significant für $p \leq .001$.

Conclusions: We demonstrate a significant correlation between psychopathy and impulsivity, especially regarding facets 3 and 4, but also for the sum score. Neither the PCL-R sum core, nor the facets correlate with the change in impulsivity during treatment progress in the STU. In both groups, with higher and lower psychopathy, impulsivity was reduced during therapy but there was no significant difference in the change scores. Our results underline that treatment progress can be achieved also in patients with higher psychopathic traits.

Insight into Illness Among Inpatients in a National Forensic Mental Health Service: A Dundrum Forensic Redeployment Evaluation Study (D-FOREST)

M. U. Waqar^{1,2}, S. Murray¹, A. O’Reilly¹, H. G. Kennedy² and M. Davoren^{1,2*}
¹Central Mental Hospital, National Forensic Mental Health Service, Portrane and ²Dundrum Centre for Forensic Excellence, Trinity College Dublin, Dublin, Ireland
*Corresponding author.
doi: 10.1192/j.eurpsy.2024.344

Introduction: Forensic psychiatric services serve a dual purpose: treatment of mental disorders and prevention of associated violent reoffending. Progression along the secure care pathway is often impeded by impaired insight, mainly as a result of treatment-resistant psychoses.

Objectives: We assessed levels of insight among patients in Ireland’s National Forensic Mental Health Service before and after its relocation from the historic 1850 campus in Dundrum to a modern facility in Portrane, Dublin.

Methods: The VAGUS insight scale was used in this repeated measures study before and after the relocation at two time points 42 months apart. All inpatients were invited to participate in completing the self-report (VAGUS-SR) and clinician-rated (VAGUS-CR) versions on both occasions. Total scores of both versions were averaged to obtain a combined VAGUS insight score. Corresponding Positive and Negative Syndrome Scale (PANSS) scores were used to ascertain correlations between the insight and symptomatology scales. This study is part of the Dundrum Forensic Redeployment Evaluation Study (D-FOREST)

Results: 40 pairs of observations were available for legal capacity to consent to medication, combined VAGUS-CR and VAGUS-SR assessments of insight (Cronbach’s $\alpha=0.927$), and PANSS.

VAGUS-CR insight and PANSS scores were progressively better from admission and high dependency wards through medium-term medium secure wards to rehabilitation and pre-discharge wards. Mean scores did not change significantly over this time interval. Those legally certified fit to give or withhold consent by their treating consultant psychiatrists scored significantly better on the VAGUS combined insight scale: 8.3 (SD 1.7) v 5.3 (2.2) at baseline, paired $t=25.9$, $p<0.001$; and also 42 months later: 8.2 (1.4) v 5.7 (3.9), paired $t=5.2$, $p=0.022$. PANSS subscales were all significantly better for those assessed as being capacitous. Change in combined VAGUS score correlated with change in all PANSS subscales. Binary logistic regression with legal capacity as the dependent variable yielded a model in which combined VAGUS score and PANSS positive symptom score were independent determinants of assessed capacity status. Receiver operating characteristic area under the curve was 0.873, 95% CI 0.760-0.986, at baseline and 0.856, 95% CI 0.720-0.991, at 42 months. A score of 7.3 yielded a sensitivity of 0.8 and a specificity of 0.8.

Conclusions: The combined VAGUS score is a reliable and valid measure of insight relevant to functional mental capacity to consent to treatment with sensitivity and specificity sufficient to guide but not bind clinical decision-making. It measures a quality that varies with symptom severity but is also partly independent of symptom severity; the constructive inclusion of self-reported insight is notable.

EPP0130

A bibliometric analysis of research in the field of forensic psychiatry

M. M. M. Kaggwa

Department of Psychiatry and Behavioral Neurosciences, mcmaster University, Hamilton, Canada
doi: 10.1192/j.eurpsy.2024.345

Introduction: Forensic psychiatry is a subspeciality that encompasses applying scientific and clinical expertise in legal contexts. As a field of psychiatry, forensic psychiatry has continued to evolve in various jurisdictions. Several journal publications continue to highlight the contributions and works of various psychiatry researchers in this area on scientific development and trends in practice. However, a quantitative assessment of these publications using a bibliometric analysis has yet to be done. Thus, the present study.

Objectives: Provide a qualitative assessment of the bibliometrics of peer-reviewed research in forensic psychiatry.

Methods: In this bibliometric analysis, we used Web of Science (the most frequently used database) to identify research articles in forensic psychiatry from inception to December 2023. Analysis was done using citespace and VOSviewer software.

Results: Five thousand six hundred ninety articles were identified with 115 countries, 4144 institutions and universities, and 1660 authors. The articles were published in 1022 journals (most are specific to the field), and 4707 unique keywords were used to identify relevant articles. Risk assessments, violence, recidivism, psychopathy, and schizophrenia are the main areas researched.

Sixteen funding agencies have funded ten or more articles in the field. The studies were mainly from high-income countries and a relatively scant number from low-income countries, especially African countries. Publications with themes on risk assessment tools – such as the HCR-20- appeared predominant across the analyzed publications.

Conclusions: Research in forensic psychiatry has continued to grow over time. While many jurisdictions across the globe have embraced the field, more effort is needed to promote forensic psychiatry and research in low- and middle-income countries (LMICs). The themes or keywords that emerged from the publications included in this analysis suggest that forensic psychiatry mainly deals with offenders with schizophrenia or psychopathy.

Service system and care pathway of forensic psychiatry patients-international research project 2023-2026

R. Askola^{1*}, O. Louheranta², A. Seppänen² and T. Lantta¹

¹Department of Nursing Science, University of Turku, Turku and

²Niuvanniemi Hospital, Kuopio, Finland

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.346

Introduction: The Finnish forensic psychiatric service system lacks the standards and criteria guiding the quality and contents of patient care. Ensuring best recovery-oriented practices in forensic psychiatric services need to be developed at several levels.

Objectives: The purpose of this research project is to develop safe, high-quality psychiatric care. The outcome of this project is the production of quality criteria for the forensic psychiatric care and service system.

Methods: The study will be executed at the Department of Nursing Science of the University of Turku during 2023-2026. The research methods include a literature review, a survey based on validated measurement questionnaires (Downes Survey, QPC-FIP, QPC-FIPS), individual and group interviews as well as the Delphi method. The research will cover the multidisciplinary employees at adult psychiatric wards in Finland's larger hospital districts, employees of forensic psychiatric hospitals, and patients of forensic psychiatric hospitals. International specialists and specialists within Finland from various fields (nursing, medicine, psychology) will be invited to partake in the expert panel.

Results: The research results will allow the development of the service system for forensic psychiatric patients in such a way that the identification of so-called risk patients can be improved already at the early stages of treatment, at the general psychiatric level. Moreover, the substance of care and participation during care can be created and the care following inpatient care and the patient's transfer out of forensic psychiatric care can be developed. The research may promote the effectiveness of treatment by highlighting areas in the care chains that, when reinforced, will allow patients to receive the right kind of treatment at the right time. A proposal of standardized operating methods and quality criteria will be created for the Finnish forensic psychiatric treatment system. The research

project will also reveal previously unresearched information that can be utilized in national health policy.

Conclusions: The project will promote equal prospects for well-being and a participatory society for citizens by exploring the views of forensic psychiatric patients and thus developing forensic psychiatric services. The project will promote sustainable employment by exploring the views of psychiatric personnel and increasing the quality and safety of psychiatric services.

The forensic assessment of human trafficking victims in Catalonia (Spain): characteristics and mental health status

A. Bertomeu¹, E. Cano^{1*}, A. Mateu¹, A. Xifró^{1,2} and E. Barbería^{1,3}

¹Institut de Medicina Legal i Ciències Forenses de Catalunya; ²Universitat de Barcelona, Barcelona and ³Universitat Rovira i Virgili, Reus, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.347

Introduction: Systematic reviews show a high prevalence of mental distress among victims of human trafficking. In criminal proceedings in Spain, a forensic expert assessment of survivors may be ordered by the courts. Its aims are mainly, albeit not exclusively, to determine the consequences of trafficking on the physical, mental, and social health of the victims. The Institute of Legal Medicine and Forensic Sciences is the public institution providing psychiatric expert assessments in the autonomous region of Catalonia (Spain). Recently, a unit devoted to the forensic assessment of human trafficking victims has been created at the central headquarters of the Institute in Barcelona.

Objectives: To describe the characteristics and the mental health status of trafficked people identified as victims in criminal proceedings.

Methods: Retrospective study of case records of victims of human trafficking at the Institute of Legal Medicine and Forensic Sciences of Catalonia (2016-2023).

Results: Case records of 50 survivors were identified. 38 (76%) were female; mean age was 30,5 years (SD 10,42; range 17 to 69 years). All of them were foreigners, mainly from Latin America (24; 48%). Most of them were trafficked for sexual exploitation (32; 64%). 11 (22%) were assessed immediately after their rescue (emerging cases). Some of the victims had previous mental health problems, including intellectual disability (3; 6%). Among the non-emerging cases, the most frequently recorded mental disorders at the moment of the psychiatric expert assessment were post-traumatic stress disorder (PTSD; 21; 53,8%) and anxiety (12; 30,8%). Complex PTSD was observed in 1 case.

Conclusions: The majority of human trafficking survivors in the forensic setting suffer from persistent mental health problems as a consequence of their victimisation. A trauma-informed forensic psychiatric assessment is recommended.

EPP0133

Sexual Experiences and Sexuality of Forensic Mental Health Patients - A Theoretical Framework

V. Šendula Jengi^{1*} and P. Cargonja²

¹Forensic Psychiatry and ²County hospital Insula, Rab, Croatia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.348

Introduction: Sexuality and sexual experiences in forensic mental health patients are intricate issues at the crossroads of mental health, legal contexts, and societal perceptions. Forensic mental health patients, situated within the criminal justice system, require psychiatric treatment due to offenses committed. Understanding their sexual behaviors, experiences, and attitudes towards sexuality is pivotal for effective therapeutic interventions and rehabilitation. Various factors influence the sexuality of forensic mental health patients. Mental health disorders impact an individual's sexual expression, and medications used to treat these conditions may affect libido, sexual functioning, and arousal patterns, posing challenges in their sexual experiences.

Objectives: Addressing the sexual needs and experiences of these individuals requires a comprehensive approach. Mental health professionals must create safe and non-judgmental spaces for patients to openly discuss their sexual concerns. Therapeutic interventions should focus on facilitating healthy sexual expression and providing education on consent, healthy relationships, and understanding boundaries. Forensic mental health professionals often receive specialized training to address the complex intersection of sexuality and mental health within legal contexts. Navigating ethical and legal boundaries while providing support to these individuals is crucial, ensuring that interventions align with legal regulations and ethical standards. Rehabilitation programs in forensic mental health facilities should integrate sex education and relationship-building skills to help patients develop a healthy understanding of sexuality. These programs aim to reduce reoffending and support the reintegration of individuals into society by promoting responsible and respectful sexual behaviors.

Methods: This study conducts a systematic literature review to comprehend the intricate nature of sexuality and sexual experiences among forensic mental health patients.

Results: Research in this area faces limitations and ethical challenges due to the sensitivity of the topic. Ethical considerations, such as confidentiality and consent, must be meticulously addressed in studies and while providing care to this population.

Conclusions: Understanding the sexuality and sexual experiences of forensic mental health patients is integral to their treatment and rehabilitation. It requires a multifaceted approach that acknowledges the complexities these individuals face due to mental health conditions, personal histories, and the nature of their care environment. Tailored and comprehensive support can promote healthier sexual behaviors, relationships, and overall well-being among this population.

EPP0134

Mental Health in Medicine: A novel stepped care model in medical psychiatry and the implementation of measurement-based care

D. Wiercigroch^{1,2*}, S. Wright¹, N. Bangloy¹, S. Bush^{1,2}, A. Wai^{1,2}, D. Koshy^{1,2}, L. Thomson^{1,2}, N. Abdel Gawad^{1,2}, S. Abbey^{1,2}, M. Kaye¹, M. Kelsey¹, A. Tan^{1,2}, J. Delwo^{1,2} and K. Sheehan^{1,2}

¹University Health Network and ²Psychiatry, University of Toronto, Toronto, Canada

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.349

Introduction: Individuals with co-occurring mental and physical health issues have worse health outcomes in both domains. Integration improves outcomes and aligns with patient preference, but health services tend to be siloed. The Mental Health in Medicine Clinic (MHIM) supports patients receiving inpatient or outpatient medical or surgical care at a tertiary academic hospital in Toronto, Canada. The predominantly virtual clinic has an interdisciplinary team offering services via stepped care, matching patient need with service intensity. Measurement-based care (MBC), the systematic evaluation of patient reported outcomes, was not initially used routinely in the clinic, but its implementation may improve treatment decision-making and may be useful in allocating patients within a stepped care model.

Objectives: 1) To describe the stepped care model, referral patterns, diagnoses, and level of care provided since implementation of stepped care. 2) To conduct a quality improvement initiative to implement MBC in the clinic, with a goal of 50% of patients completing at the time of first assessment and prior to discharge from the clinic.

Methods: We reviewed the electronic medical record for referral source, diagnoses, and level of stepped care within the clinic. We conducted semi-structured interviews with stakeholders (clinicians, administrative staff, patients) to explore barriers to implementation of MBC. Interviews were analyzed for themes around barriers and facilitators to MBC. Plan, Do, Study, Act cycles were carried out around change concepts informed by stakeholder interviews and relevant literature.

Results: The MHIM clinic began operations in August 2020. The clinic operated on a physician-only model until March 2022 and then shifted to a stepped care model with an interdisciplinary team. The most frequent referral sources were internal medicine, COVID19 clinics, consultation-liaison psychiatry, red blood cell disorders clinic and cardiology. Since the implementation of stepped care, 250 referrals were assessed. 58% of new referrals were assessed by the psychiatrist, 42% were managed by the NP, and 25% consulted with the social worker. Referrals consisted of trauma and stress-related disorders (32%), depression (21%) or anxiety disorders (20%). Personality, substance use, and psychotic disorders accounted for less than 10% of referrals combined. Some patients did not have any diagnosis (6%). Results from the quality improvement initiative to implement MBC will also be presented.

Conclusions: The MHIM clinic provides an integrated care pathway addressing comorbid mental and physical health conditions. We describe a novel stepped care model and the implementation of MBC. Future directions include ongoing quality improvement of MBC and its integration within the clinic to assess and re-assess service intensity.

Impact of a daily supportive text message program (text4hope) on the stress, anxiety, and depression levels of elderly (60 years and above) subscribers during the COVID-19 pandemic in Alberta.

E. Owusu^{1*}, R. Shalaby¹, B. Agyapong¹, W. Vuong², A. Gusnowski², S. Surood², A. J. Greenshaw¹ and V. I. Agyapong^{1,3}

¹Psychiatry, University of Alberta; ²Psychiatry, Alberta Health Services, Edmonton and ³Psychiatry, Dalhousie University, Halifax, Canada

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.350

Introduction: One of the biggest global crises in our generation is the COVID-19 pandemic. It has had a severe and far-reaching negative impact on our health systems, economies, and societies. Older adults were particularly at higher risk of severe illness, isolation from social distancing measures, and concerns about their health.

Objectives: The objective of this study is to evaluate the impact of the daily supportive text message program (Text4Hope) on the levels of stress, anxiety, and depression experienced by elderly subscribers during the COVID-19 pandemic in Alberta six weeks after enrollment.

Methods: An online survey link was used to gather demographic and clinical information on several self-report scales, such as the Perceived Stress Scale (PSS) ≥ 14 and Generalized Anxiety Disorder 7-item (GAD-7). Scale ≥ 10 , and Patient Health Questionnaire-9 (PHQ-9) ≥ 10 . Descriptive and inferential statistics were run using SPSS version 25.

Results: 172 subscribers out of 1136 completed baseline and six weeks using an online questionnaire, giving a response rate of 15.1%. There were significant reductions in mean scores on the PSS-10 and GAD-7 scales at six weeks compared to baseline ($P > .05$), but not on the PHQ-9 scale. There were also significant reductions in the prevalence of moderate or high stress (68.6% vs 60.5%, $p = 0.036$) and likely GAD (14.9% vs 22.7%, $p = 0.029$) from baseline to six weeks, with the highest reduction in stress (8.1%). A change (27.6% to 25.2%) in the prevalence of likely MDD from baseline to six weeks was insignificant. ($P > .05$)

Conclusions: This study's findings show a decrease in the prevalence rates and the mean scores for stress and anxiety on standardized scales, indicating an improvement from baseline to six weeks. This outcome has potential implications for planning an intervention to meet the mental health needs of the elderly in similar situations like the pandemic

Psychological struggles in tunisian Infertile couples: A gender Perspective

K. Mahfoudh*, F. Askri, S. Hamzaoui, A. Ouertani, U. Ouali, A. Aissa and R. Jomli

Psychiatry "A", Razi Hospital, Manouba, Tunisia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.351

Introduction: Defined by the World Health Organization (WHO) as the inability to conceive after a year of unprotected sexual intercourse, infertility remains a current and compelling topic of interest for both scientists and the general public.

Over the past few decades, the prevalence of infertility, regardless of its cause, has significantly increased. Furthermore, it affects approximately 15% of Tunisian couples. However, previous studies have primarily assessed the psychological impact on women, leaving a gap in understanding gender differences.

Objectives: Our study aims to compare the psychological impact of infertility between genders in a Tunisian sample.

Methods: We conducted a cross-sectional study in a public hospital specializing in Assisted Reproductive Technology (ART) from August 30th to December 1st, 2022, involving sexually active infertile couples who had been under observation for at least one year. The participants provided information related to socio-demographic data. Additionally, we used the Hospital Anxiety Depression Scale (HADS) to assess anxiety and depression, and the Fertility Quality of Life (FertiQoL) questionnaire to evaluate the quality of life. These questionnaires were administered in the Tunisian dialect.

Results: A sample of 60 infertile couples were recruited to this study. Primary infertility was present in 97% of cases and male infertility was the most common cause, accounting for 35%. Our findings revealed that women experienced higher rates of depression (35%) and anxiety (52%) compared to men (15% and 28%), with a statistically significant difference ($p \leq 0.001$).

Furthermore, women reported a significantly compromised overall quality of life, particularly in the context of treatment-related aspects ($p=0.03$).

Notably, anxiety was identified as a significant risk factor for reduced quality of life among women ($B = -5.27$). In contrast, lower socioeconomic status was associated with diminished overall quality of life in men ($B = -7.09$).

Conclusions: It is important to consider gender differences in the management of infertility in order to guide and target psychological interventions and to improve the quality of life of infertile couples.

Food for the Mind: A systematic review of mindful and intuitive eating approaches for mental health & wellbeing

M. Eaton^{1*}, T. Foster¹, J. Messoré², L. Robinson² and Y. Probst¹

¹School of Medical, Indigenous and Health Sciences and ²School of Psychology, University of Wollongong, Wollongong, Australia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.352

Introduction: A growing body of literature has investigated diet and mental health, however, it is often viewed through a “weight-centric” lens, where weight loss is considered a primary outcome and motivator. This review aims to shed new insights into the connections between mental health and wellbeing, and eating behaviours that focus on internal cues and regulators and do not centralise around weight. Such “weight-neutral approaches” have been associated with improved psychological health and wellbeing, however, consolidated evidence is lacking.

Objectives: To explore eating styles that do not centralise around weight, and their relationship with mental health and wellbeing and other health outcomes.

Methods: A systematic search was performed including observational studies of adult populations, with ≥ 1 mental health and wellbeing or physical health outcome, and ≥ 1 validated measure of eating behaviour reflective of a weight-neutral approach. Outcomes were characterised into four domains (mental health and wellbeing, physical health, health promoting behaviours and other eating behaviours). Risk of bias was assessed using the Newcastle-Ottawa Scale.

Results: In total 8281 records were identified with 86 studies including 75 unique datasets and 78 unique exposures included. Eating behaviours included intuitive eating ($n=48$), mindful eating ($n=19$), and eating competence ($n=11$). All eating behaviours incorporated biological, physiological, and social factors, with 297 outcomes categorised for mental health and wellbeing ($n=122$), physical health ($n=116$), health promoting behaviours ($n=51$) and other eating behaviour ($n=8$). Greater intuitive and mindful eating were significantly related to lower levels of disordered eating, and depressive symptoms, as well as greater body image, self-compassion, and mindfulness. Greater intuitive eating, mindful eating and eating competence were significantly related to a lower BMI, and greater diet quality and physical activity. Eating competence and intuitive eating were significantly related to higher fruit and vegetable intake, and eating competence alone was significantly related to higher fibre intake, and greater sleep quality.

Conclusions: This review provides evidence that intuitive eating, mindful eating and eating competence are positively related to a range of mental and physical health outcomes. Considered within the biopsychosocial model, these findings enhance understanding around the impact of approaches to healthy eating patterns that are not focused on weight loss, and contributes a case towards promoting health-centric eating behaviour in mental health care. Future research should focus on experimental studies and broader population groups.

Stigmatizing attitude of psychiatrists in the Netherlands

S. Kakar^{1,2*}, T. Birkenhäger¹, L. Baars² and D. Öri^{3,4}

¹Department of Psychiatry, Erasmus University Medical Center, Rotterdam; ²Department of Mentalization Based Treatment in Adults, Viersprong Institute for Studies on Personality Disorder, Bergen op Zoom, Netherlands; ³Institute of Behavioural Sciences, Semmelweis University and ⁴Department of Mental Health, Heim Pal National Pediatric Institute, Budapest, Hungary

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.353

Introduction: Even in the current times people with mental health disorders face negative treatment due to negative stereotyping. This occurs not only within their private environment and in the public community, but also by healthcare professionals. Mental health related stigma results in various disadvantages, such as: worse treatment in healthcare and discrimination in job interviews, in work environment, in education and in housing.

Objectives: Our aim with this cross-sectional study, was to investigate the attitudes of adult and child psychiatrists in the Netherlands towards people with mental health problems.

Methods: We used the Opening Minds Stigma Scale for Health Care Providers (OMS-HC) to measure the stigmatizing attitudes. Participants filled in this internet-based survey anonymously. The OMS-HC total scores as well as the subscales were used to determine the stigma.

Results: Altogether, N=170 practitioners (n=45 males, n=124 females) completed the survey. The bifactor ESEM model showed the best model fit (RMSEA=0.057, CFI=0.968, TLI=0.935); however, exploratory factor analysis results indicated the weakness of items 13 and 15. Participants who provide psychotherapy to their patients prefer less social distance towards them (9(7-10) vs 10(7.5-11), $p=0.051$). Also those who have ever been treated medically for their own mental health problems, prefer less social distance (7,5(6-10) vs 9(8-11), $p=0.009$). Rural working psychiatrists are more willing to disclose and seek help for their mental health problems than those working in urban areas (9 (8-10) vs 8 (6.5-9.5), $p=0.024$). Those who are open to (29(26-32.5) vs 32.5(31.25-35), $p=0.009$) or having an opportunity to regularly participate in case discussion groups (29(25.25-32) vs 32(28-35.25), $p=0.012$) have an overall favourable attitude towards people with mental health problems.

Conclusions: This is the first study on the stigmatizing attitude of practicing psychiatrists in the Netherlands from their own perspectives. It will contribute to the gaps of knowledge of the stigmatizing attitude of psychiatrists towards people with mental health problems. Moreover this study will provide new interventions towards less stigmatizing attitude of psychiatrists.

Impact of mother's childhood trauma on development of psychopathological dimensions in patients with peripartum mental disorders

A. Bassi de Toni^{1*}, G. Culicchia¹, A. Del Casale², M. Tinè¹, A. V. Vallergera¹, L. Cutillo¹, S. Bernardi¹, I. Bilotta¹, A. Fattorini¹, R. D'Alessio¹, D. De Felici¹, M. Pompili² and G. Angeletti²

¹Psychiatry Residency Training Program, Faculty of Medicine and Psychology and ²Department of Neurosciences, Mental Health and Sensory Organs, Faculty of Medicine and Psychology, Sant'Andrea Hospital, Sapienza University of Rome, Rome, Italy

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.354

Introduction: Peripartum mental disorders (PPMD) are characterized by heterogeneous psychopathological symptoms related to specific personality traits, which are only taken into account by a few preventive and therapeutic strategies. Traumatic experiences during childhood could predispose to develop those disorders during adulthood, especially in more stressful conditions, such as pregnancy and postpartum.

Objectives: Our study aims to evaluate the correlation between mother's childhood trauma and the development of certain psychopathological dimensions during peripartum and which of these dimensions could be indicative of mother's childhood trauma.

Methods: The sample included 74 women, recruited from Sant'Andrea Hospital in Rome between 2011 and 2022, diagnosed with a psychiatric disorder during peripartum, according to criteria of DSM-5. All recruited women were administered the Childhood Trauma Questionnaire – Short Form (CTQ-SF) and the Minnesota Multiphasic Personality Inventory-2 (MMPI-2). We performed a linear regression using the total CTQ score as a dependent variable and the MMPI-2 scale's scores as independent variables.

Results: The linear regression used showed two significant models, of which the most inclusive explained 60% of the variance ($R^2 = 0.597$), resulting significant ($F = 31.141$; $p < 0.001$). This model showed that a greater expression of childhood traumatic aspects was associated with greater expression of Pa (paranoia) ($t = 4.04$; $p < 0.001$) and Ma (hypomania) ($t = 3.873$; $p < 0.001$) in the clinical scales of the MMPI-2, which were indicative of childhood trauma.

Conclusions: Our study shows that paranoid and hypomanic symptoms in PPMD, assumed by the MMPI-2 scale, are indicative of previous traumatic dimension. Thus, in the presence of a positive history of trauma, clinicians should pay attention especially to these aspects, in order to optimally set both pharmacological and psychotherapeutic treatment.

Scale for Body Image Concerns During the Perinatal Period – Adaptation and validation

A. T. Pereira¹, B. Barbosa², R. Lima², A. I. Araújo¹, C. Marques¹, D. Pereira¹, A. Macedo¹ and C. Pinto Gouveia^{1*}

¹Institute of Psychological Medicine and ²Faculty of Medicine, University of Coimbra, Coimbra, Portugal

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.355

Introduction: The perinatal period may intensify weight and body image concerns. Due to its specifics, the traditional body image scales are inaccurate in the perinatal period (Fuller-Tyszkiewicz et al. 2013). The Body Image Concerns During Pregnancy (Uçar et al. 2018) was developed to measure this cognitive-emotional variable in pregnancy.

Objectives: To analyze the psychometric properties of the Portuguese adapted (both for pregnancy and postpartum) version of the Body Image Concerns during the Perinatal Period (BICPP), namely its construct validity and the internal consistency.

Methods: A sample of 346 women recruited through social media and Family Health Units, assessed in the second trimester of pregnancy (mean gestational age=28.11±7.67 weeks) and after delivery (baby's age 4.37±2.87 months), completed a survey including the Portuguese BICPP.

The total sample was randomly divided into two sub-samples: sample A (n=173) was used to perform an exploratory factor analysis/EFA; sample B (n=173) to perform a confirmatory factor analysis/CFA.

Results: EFA resulted in four components. CFA revealed that the second-order model with four factors presented good fit indexes (X²/df=2.4141; CFI=.9195; GFI=.948; TLI=.9028; GFI=.8181; RMSEA=.0807). BICPP Cronbach alphas was $\alpha=.936$; for F1 Concern about future weight and image, F2 Concern with the new body image, F3 Social avoidance and concern and F4 Concern with appearance were .922, .930, .809, .807, respectively.

Conclusions: This psychometric study provides evidence for the validity and reliability of the Portuguese version of BIC-Perinatal Period, which will be used in an ongoing research project on the relationship between eating, depressive and anxiety disorders in the perinatal period.

Screen for Cognitive Impairment in Psychiatry (SCIP): Adaptation and validation for Portuguese Version

B. Couto^{1*}, R. Ortiga¹, A. S. Gonçalves¹, F. Monteleone¹, S. Oliveira¹, J. B. Fonseca¹ and R. Rodrigues¹

¹Psychiatry, Hospital Senhora da Oliveira Guimarães, Guimarães, Portugal

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.356

Introduction: Cognitive dysfunction has been reported in acute psychiatric patients for a long time and has profound implications for the management of severe mental disorders. The Screen for Cognitive Impairment in Psychiatry (SCIP) is a scale developed for screening cognitive deficits. This tool is simple and easy to administer.

Objectives: To translate and to validate to Portuguese the SCIP.

Methods: The accepted back-translation method is employed for translating from English into Portuguese. One-hundred individuals in good health were characterized using demographic questionnaires and a neuropsychological battery. Subsequently, the new version of the scale was administered on two distinct occasions with a minimum one-week gap between them.

Results: High internal consistencies as well as strong correlations with comparable neuropsychological tests were obtained.

Conclusions: The results obtained from the Portuguese version of SCIP are in line with those from the English version. Effectively, SCIP serves as a key instrument for the initial assessment of cognitive function. Its characteristics, particularly its conciseness and independence from a technological platform, allow it to be integrated into clinical practice. Our aim is to use this version and apply it to different pathologies, comparing patients with controls. This will allow us to study different patients and apply it to our population.

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.357

Introduction: Neurofilmology is a young and evolving research field, at the intersection between neuroscience and movie experiences, that explores how the brain processes and responds to visual storytelling. It involves examining the cognitive and emotional effects of movies on viewers, including social cognition and perspective-taking aspects. However, up to date, these studies have focused only on the neurotypical population, hence constituting a considerable gap in the literature with respect to individuals with neuroatypical functioning.

Objectives: Aim of this study was to investigate the experience of film viewing and its correlates in individuals with a diagnosis of Autism Spectrum Disorders (ASD).

Methods: 30 neurotypical individuals and 30 individuals with ASD without intellectual disabilities were asked to observe 12 short video clips of 3 seconds length, showing an agent grasping an object from a table, and filmed with three different camera techniques: Still, Steadycam, Zoom; for each clip, they were asked to respond to six question on a Visual Analogue Scale (0-100) designed to investigate participants' potential feeling of involvement with the observed scene, their comfort with the different filming conditions, and their estimation of the ecological plausibility of the different types of camera movements.

Results: Participants felt more involved watching videos filmed with a Steadycam, with respect to the Zoom and Still condition. Within the neurotypical group participants felt more comfortable when the camera was in motion (both Steadycam and Zoom condition) compared to the Still condition; no differences were found between conditions in the ASD group, as if they felt equally comfortable in every condition administered, regardless the filming technique.

Conclusions: First, our results reinforce prior findings regarding the influence of different camera techniques on neurotypical individuals. Second, they add to the existing literature suggesting that individuals with ASD may exhibit differences in their subjective experiences related to empathizing with characters and immersing themselves as actors when the camera replicates naturalistic movements, resulting in a diminished overall fulfillment in the movie-watching process.

A Study on the Disclosure of People with Mental Illness

M. Seo^{1*}, M. H. Lee² and Y. R. Kim²¹Gyeongsang National University, Jinju and ²Mokpo National University, Mokpo, Korea, Republic Of

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.358

Introduction: People with mental illness often experience a concealable stigmatized identity that may be invisible to others. As a result, they are often faced with the dilemmas of whether to disclose or conceal their diagnosis and their experience. However, in order to overcome the social stigma and self-stigma that hinder their recovery, they must establish a network and social support through identity disclosure.

Objectives: This study investigates the effect of clinical characteristics (symptom and social function level), self-stigma and social support on the disclosure of people with mental illness.

Methods: The research was conducted with 236 respondents who are currently using community mental health services. (Male: 51.9%, Female: 48.1%; Mean age = 47.97±13.24; SPR: 66.8%, other diagnosis: 33.2%).

Results: Most respondents disclosed their mental illness to health service providers and family, but they are least open about their identity toward neighbors and co-workers. A regression analysis of predictors of disclosure revealed that only social functioning level and social support had significant predictive power. It was discovered that individuals with better level of social function and social support disclosure more about their mental illness.

Conclusions: A program that increases social functions and support network can be recommended to improve disclosure efficacy.

healthcare provider based in Southeast England where we designed a project to enhance support to new consultants, based on Startwell principles.

Objectives: The aims of this project were to:

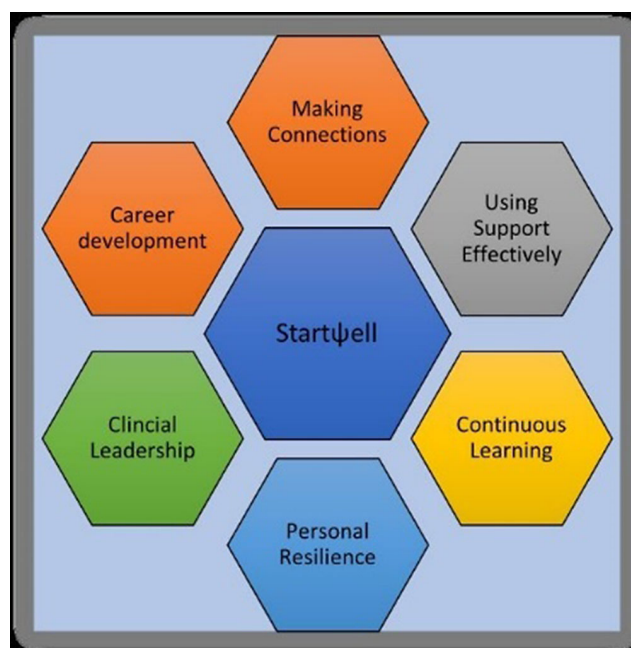

- Improve the experience of early career psychiatrists taking on their first consultant role in BHFT.
- Ensure that the new consultants are provided with relevant information and resources to fulfil their roles safely.
- Set up a system for ongoing support for new consultants till they complete five years in their post.

Methods: Having discussed the feasibility of setting up a local Startwell initiative in BHFT, plans were presented to the medical director and medical staff committee including new consultants, for their input. Under the guidance from senior consultants, monthly meetings were arranged which offered professional development talks and peer support. As several themes emerged at these meetings, we stratified and aligned these local to the RCPsych Startwell framework (**Image 2: Themes**). An induction folder was also collated with all the relevant information in paper and digital format. In addition, a yearly bespoke induction event for new consultant psychiatrists was delivered from 2019-2022 except in 2021, during the pandemic.

Results: We used Likert scales to gather quantitative feedback (**Table 1**) with free box for comments to capture qualitative feedback (**Image 3**). Feedback response rate for the three cohorts were 75%, 70% and 80% respectively.

	2019	2020	2022
Overall Satisfaction	100%	75%	100%
How relevant was the content of the programme to your new role?	70%	100%	100%
How far did the programme meet your expectations?	100%	75%	100%

Mental health impact of the Russian-Ukraine war on Canadian residents with or without Ukrainian descent

A. Belinda^{1*}, R. Shalaby¹, Y. Wei¹ and V. I. O. Agyapong^{1,2}

¹Department of psychiatry, University of Alberta, Edmonton and

²Department of psychiatry, Dalhousie University, Halifax, Canada

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.360

Introduction: War tends to produce fear. The devastating and traumatic occurrences of war can have both short- and long-term effects on the mental well-being of populations. Russia's invasion of Ukraine indirectly affects all populations, especially individuals of Ukrainian descent.

Objectives: To assess the mental health impact of the Russian invasion of Ukraine on Canadian residents who subscribed to 'Text4Hope Ukraine' program and to ascertain if there are differences in mental health impacts between those with and without Ukrainian descent.

Methods: Canadians were invited to self-subscribe to the text messaging program. An online survey was used to collect socio-demographic, war-related, and clinical information; stress, resilience, likely anxiety disorder and likely depressive disorder from subscribers. Outcome measures included baseline scores using validated scales. Data were analyzed using SPSS Version 25. To examine the association of psychological problems with the socio-demographic and war-related factors, univariate analysis using the Chi-square/Fishers Exact test was performed with two-tailed significance ($p \leq .05$). An independent sample t-test with two-tailed significance ($p\text{-value} \leq 0.05$) was employed to assess the differences in the respective mean scores of the psychological problems across the two groups. The first group represents the participants who did not have citizenship or ancestors from Ukraine (NUK), while the second group represents the respondents are Ukrainian who either have previously held citizenship or have ancestors/family from Ukraine (Ukr). No imputation of missing data and reported data represents the complete responses

Results: Study findings reflected prevalence of low resilience (59.7%), moderate to high stress (87.5%), likely Generalized Anxiety Disorder (45.8%) and likely Major Depressive Disorder (38.9%). Respondents who identified as female had a higher likelihood of presenting with low resilience ($\chi^2(1) = 5.68$, $p = .02$) and likely Generalized Anxiety Disorder ($\chi^2(1) = 4.85$, $p = .03$) compared to male respondents. There was no statistically significant difference in the mean scores of the four psychological problems based on any of the variables that suggest Ukrainian descent or not ($p > .05$).

Conclusions: War can have negative impacts on all populations irrespective of their location, or association of individuals with the impacted country. This study provides valuable insights into the mental health impact of the Russian invasion of Ukraine on a specific sample of Canadian residents who subscribed to the 'Text4Hope Ukraine' text messaging program. This information is relevant when planning mental health intervention for this population. Governments should target and provide adequate mental health and psychosocial support or interventions for global populations at risk during war.

Thyroid psychosis: when your hormones take over your mind: a case report

K. Razki^{1*}, C. Najjar^{1,1}, U. Ouali², S. Ben Aissa¹ and R. Jomli²

¹Razi Hospital, LaManouba, Tunisia and ²Psychiatry A, Razi Hospital, LaManouba, Tunisia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.361

Introduction: Hyperthyroidism, characterized by excessive production of thyroid hormones, is a common endocrine disorder that affects various body systems. While most commonly recognized for its classic symptoms such as weight loss, tremors, and palpitations,

it is important to acknowledge that hyperthyroidism can also lead to a rare but significant complication: psychosis. Psychosis in the context of hyperthyroidism refers to the presence of delusions, hallucinations, and disordered thinking, which can significantly impact an individual's mental health and overall well-being.

Objectives: This case report aims to describe a rare case of hyperthyroidism-related psychosis in a patient including the clinical presentation, diagnosis, and management. Additionally, we aim to increase awareness of and promote further research into this condition.

Methods: We present a comprehensive case report detailing the clinical course of a 29-year-old male patient with no previous medical or psychiatric history, who sought urgent psychiatric evaluation at the Razi Hospital La Manouba's emergency department due to escalating symptoms of agitation and paranoia persisting for three days. The patient, identified as Mr. S.O., a Tunisian male, presented with severe agitation and paranoia necessitating the use of restraints upon admission to the psychiatric emergency department. The initial physical examination revealed no notable abnormalities, except for the presence of tachycardia, which was subsequently confirmed on an electrocardiogram, arousing suspicion of a primary psychiatric illness.

Results: While the standard blood workup yielded unremarkable findings, the endocrine workup revealed decreased levels of thyroid-stimulating hormone (TSH) and elevated free thyroxine (FT4). Further laboratory investigations demonstrated elevated anti-thyroid-stimulating hormone receptor antibodies, leading to the diagnosis of Graves' disease. Collaborative consultation with an endocrinologist resulted in the initiation of a treatment regimen consisting of methimazole, propranolol, and risperidone. Notably, within three days of the initiated therapy, the patient exhibited significant improvement in terms of reduced agitation, coherent speech, and the development of self-reflection regarding the episode, ultimately leading to his discharge on the seventh day of hospitalization. This case report serves to highlight the complexity of psychiatric presentations associated with underlying endocrine disorders and underscores the importance of interdisciplinary collaboration in achieving optimal patient outcomes.

Conclusions: While mental health factors play a significant role in the development of psychosis, it is essential to recognize that underlying medical conditions may also contribute to its onset or exacerbation.

Sociodemographic and Clinical Profile of Perpetrators of conjugal Homicides

W. Haouari*, S. Omri, A. Labyadh, R. Feki, I. Gassara, L. Zouari, J. Ben Thabet, N. Charfi, M. B. Maalej, N. Smaoui and M. Maalej
Psychiatrie C, Hedi Chaker university Hospital, Sfax, Tunisia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.362

Introduction: Conjugal homicide refers to the act of killing a current or former intimate life partner, regardless of their marital status. This type of behavior is still inadequately addressed by prevention programs, as it is often regarded as exceptional compared to other forms of domestic violence.

Objectives: To describe the sociodemographic, clinical, and criminological data of individuals who commit spousal homicide.

Methods: This is a retrospective descriptive study of 21 psychiatric expertise files conducted between January 2002 and September 2023 in the psychiatric department of Hedi Chaker Hospital in Sfax. Sociodemographic, clinical, and criminological data were collected from criminal psychiatric expertise files and supplemented with information from medical records.

Results: The perpetrators of spousal homicide were predominantly male (85.7%), had an educational level above secondary school (57.1%), were married (85.7%), and had an average age at the time of the act of 40.3 years. Most of them had no psychiatric history (81%) or legal history (85%), and only 19% were using psychoactive substances.

Among the perpetrators, 66.7% had a history of violence against their partners, with threats of homicide in 19% of cases. The majority of homicides occurred during the day (42.9%), in a public place (28.6%), were perpetrated in isolation (95.2%), happened impulsively (47.6%), and employed a single method (81%), with knives being the primary weapon (42.9%). In 76.2% of cases, the perpetrators of spousal homicides were found criminally responsible, while 19% were hospitalized in a psychiatric setting as part of a judicial non-prosecution decision.

Conclusions: The study of specific characteristics of spousal homicides holds crucial importance for the early detection of domestic violence situations that carry a lethal risk. By highlighting these particularities, it enables the development of more targeted prevention strategies.

Impact of social media on Working Memory and Academic Performance of Undergraduate Students- A Cross-sectional Study

N. E. Mgbeto¹, M. E. Musa^{1*}, P. Chhikara², R. Chaturvedi², N. Vyas³ and N. Zavrashvili¹

¹Medicine, University of Georgia; ²Medicine, Batumi State University and ³Medicine, Eastern European University, Tbilisi, Georgia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.363

Introduction: Over the course of the last decade social media has become a very important part of the human experience; it has become the main source of communication and entertainment for a lot of people young and old.

Objectives: This study aimed to examine the influence of social media on undergraduates working memory and academic performance. We assessed the association between the harmful use of social media on gender differences, physical activities, academic performance, and working memory.

Methods: This cross-sectional study was designed to examine the effect of social media on the working memory of undergraduate students from three different Universities in Georgia involving 722 participants. The collection survey form was distributed among Undergraduate students from the University of Georgia (UG), Eastern European University (EEU), and Batumi State University (BSU) through google forms from 14th June to 2nd July 2023. The

questionnaire consisted of sociodemographic characteristics (e.g., age, gender, and institution), social media disorder scale (SMD), academic performance scale (APS), and working memory (WM). **Results:** 58.7% were female students, the mean age was 21.94 (SD \pm 2.8), and most of the participants were international students. More students from Tbilisi had persistence (59.8%), escape (69%) complaints, and students from Batumi had more preoccupation (43%), persistence (62.5%) and escape (65.7%) complaints. 64.1% of female students are at increased risk of using social media as an 'escape' from negative feelings (OR 0.50; χ^2 (18.206), p = 0.000, 95% CI[0.368-0.692]). 51.6% of male students and 48.4% of female students had the risk of 'conflict' with families and friends because of social media (OR 1.65; χ^2 (6.507), p = 0.011, 95% CI[1.122-2.452]). 80.3% of students that had good academic performance are at risk of neglecting activities such as hobbies, sports, and class assignments because of social media (OR 0.63; χ^2 (5.133), p = 0.023, 95% CI[0.425-0.942]). 94% of students with good working memory had the risk of withdrawal complaints (OR 0.34; χ^2 (6.865a), p = 0.009, 95% CI[0.154-0.793]). As 93.4% of having conflicts with parents, siblings, and partners because of social media.

Conclusions: Our studies presented the prevalence of social media addiction and its effect on academic performance and working memory among undergraduate students. The influence of social media on students has been significant. Students should establish boundaries, use digital moderation, and seek treatment for emotional difficulties as further studies are recommended.

Suicidal ideation, suicidal plans and suicide attempts in patients with chronic pain: a prospective qualitative research Study 1: 2011 – 2015 Study 2: 2015 - 2019

E. Z. Guertzenstein^{1*} and M. J. Teixeira²

¹DIVISÃO DE NEUROCIRURGIA DO DEPARTAMENTO DE NEUROLOGIA DA FACULDADE DE MEDICINA DA UNIVERSIDADE DE SÃO PAULO and ²Departamento de Neurocirurgia, Divisão de Neurocirurgia da Faculdade de Medicina da Universidade de São Paulo, São Paulo, Brazil

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.364

Introduction: The association among suicidal ideation, plans, attempts and pain has not attracted as much attention as the association between suicidal ideation and attempts and psychiatric disorder. **Objectives:** The aim of this prospective study was to establish if patients with chronic pain associated or not to psychiatric disorders with ideation and planning for a suicide attempt will always end in a suicide act.

Methods: The patients were initially examined through structured interview, scan-schedules for clinical assessment in neuropsychiatric – version 2.0 used only to diagnose. (HDRS – 17) - Hamilton Depression Rating Scale, 17 itens version, (HAMS) Hamilton Anxiety Rating Scale, (CGI) - Clinical Global Impression: (CGI – S) Severity of illness and (CGI – I) Clinical Global Improvement. Pain intensity through numerical rating scale. Those were repeated throughout the research.

Patients

Study 1 - 325 patients (244W, 81M aged 19 – 58) with chronic pain, suicidal ideation or plan associated or not to psychiatric disorders. 124 had chronic pain without psychiatric disorder. 54 suicidal ideation and 70 had suicidal plan.

201 had chronic pain associated with psychiatric disorders. 7 with opioid dependence after pain and suicidal plans. 4 with adjustment disorders before pain and suicidal ideation.

3 with somatoform disorder before pain and suicidal plan. 125 had chronic pain associated with: general anxiety disorder, mixed anxiety and depression, severe panic pain before or after pain with suicidal plans or ideation. 62 patients presented chronic pain associated with depressive disorder: recurrent severe depression without psychotic symptoms; moderate recurrent depression without psychotic symptoms. Before or after the occur of pain with suicidal ideation or suicidal plans.

Study 2 - 132 patients remained in treatment. (79W and 53M aged 20 to 59)

54 had chronic pain without psychiatric disorder with plans or ideation suicidal. 78 Patients had chronic pain and a psychiatric disorder. 16 became dependent on opioids after pain and suicidal plans. 36 with chronic pain associated with anxiety disorder: general anxiety disorder before or after pain with suicidal plans. 26 had chronic pain associated with depressive disorder: recurrent severe depressive disorder with or without psychotic symptoms with suicidal ideation.

Results: Study 1 - No patient attempted suicide. 54 patients with pain without psychiatric disorders considered suicidal thoughts absurd and intrusive.

Study 2 - No patient died. 51 attempted suicide 47 remained with suicidal ideation

33 did not have suicidal ideation or suicidal plans. They adapted their lives to chronic pain regardless of presenting a psychiatric illness.

Conclusions: The authors concluded that a suicidal act is not always necessarily an expression of chronic pain associated/not with psychiatric disorder.

EPP0160

Study of mental health perceptions among Central African refugee populations and host communities in the East Cameroon region

E. Dozio^{1*} and A. Jaccard²

¹Action contre la Faim, Paris, France and ²Action contre la Faim, Yaoundé, Cameroon

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.365

Introduction: Cameroon's eastern region faces numerous security challenges linked to successive crises in the Central African Republic, particularly with the massive influx of refugees especially since 2013. Official UNHCR figures speak of 349,409 Central African refugees present on Cameroonian soil. These are both refugees already well established in their host communities, and new arrivals. Since the post-electoral crisis in CAR at the end of 2020,

the situation has gradually stabilized in the Kadey department, but remains volatile due to daily insecurity in the northern regions of the Central African Republic.

Objectives: With a view to meeting the mental health and psychosocial support needs of the region's population and better integrating refugees into their host communities, it was necessary to obtain a more exhaustive picture of the population's perception of mental health, to understand the mechanisms of psychosocial support at community level and any differences between refugees and the indigenous population.

Methods: A mixed methodology with quantitative and qualitative data was chosen for a more detailed analysis. The survey was carried out in two communes in the Kadey department: Kentzou and Kette. The sample was disaggregated to take account of the socio-demographic characteristics and to enable to make comparisons between the situations of host communities, living in refugee sites and outside sites. For quantitative data, 205 the individuals responded to a questionnaire. 12 individual interviews and 12 Focus Group Discussions (involving 60 participants) guided by semi-structured questions were used to collect qualitative data from key members of the community.

Results: Analysis of quantitative and qualitative data has confirmed the successful integration of Central African refugees into the host community. Nevertheless, there is a difference between these two groups in terms of their perception and understanding of the definition of mental health, mental health disorders and treatment options. Thus, there was a clear difference in training and awareness needs between the host and refugee communities.

Conclusions: Based on the qualitative and quantitative results of our assessment, a number of recommendations have been drawn up. It would be interesting to find a balance in the definition, attribution of causes and treatment of mental disorders between the traditional, mystical and cultural vision and the psychological and psychiatric one. It would be important to encourage refugee communities to return to some of their traditional practices, and to allow several visions of the human being to coexist between a traditional and a more medical vision.

To address the lack of resources for mental health care in the Kadey area, more training in mental health and psychosocial support is needed for health and social workers in the area.

Ethnic differences in pathways to obtain care, maintain care and engage to Early Intervention Service in Spain

V. Sanchez-Gistau*, M. J. Algora, A. Cabezas, M. Sole, P. Miro and C. Saez

early intervention service, University Hospital Institut pere Mata, reus, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.366

Introduction: Ethnicity and migration have an impact on illness models and consequently how, when and where people seek and obtain care. Early Intervention Psychosis (EIP) teams attend high rates of migrant and ethnic diverse populations but the study of ethnic differences in pathways to obtain and maintain care is still scarce. The most consistent findings are that minorities are less

involved with primary services, have a higher risk of being treated in a coercive way and are at higher risk of early disengagement. Despite the increasing migration rates there has been very little investigation in Spain.

Objectives: To investigate ethno-racial differences in pathways to obtain care, adherence and engagement during their first year of follow-up of subjects who start treatment at EIP of Reus, Catalonia, Spain

Methods: Participants

This is an observational 12 months follow-up retrospective study including all consecutively subjects with First Episode of Psychosis (FEP) referred to the EIP from January 2015 to January 2019. Visible ethno-racial status was self-reported being grouped as belonging to minority ethno-racial group if they were coded "any other than White regardless of country of origin". 'White' was the majority group

Study variables:

At program entry:

Source of referral

At 12- months:

Adherence to the service:

Admissions to in-patient unit

Disengagement

Results: 184 FEP subjects (mean age 22.8 years and 66.1% of males) were included. Nearly 31% belonged to a minority ethno-racial group being the Maghrebi (60.4%) followed by the Latin-American (20.1%) the most frequent minority groups. The 81.2% of the minority group were first-generation migrants and 7.5% second generation migrants. The 52.2 % were referred from community services, 18.5% from emergency unit and 29.3% from inpatient unit. At follow up 64.5%, were highly adherent to EIP (> 75% of attended appointments), 16.7% required hospitalization and 11% disengaged. Multi-variate analysis showed that the minority group was 2.19 times more likely to be low adherent [(95% CI 0.78-3.17; p=0.03], 2.89 times more likely to be hospitalised [(95% CI 1.20-6.98); p=0.01], and 4 times more likely to disengage from the EIP [(95% CI 1.35-11.90); p= 0.01] during follow-up than the majority group. No group differences were found in pathways to obtain care or in causes of disengagement.

Conclusions: In agreement with previous studies from other countries we found high rates of ethno-racial diversity in the EIP of Reus. In addition, we also found inequalities in the use of services, being minorities more likely to disengage, to be low adherent to the program and at greater risk of hospitalization. On contrary to other studies we did not find significant differences between groups in the source of referral to EIP

Pain

EPP0163

Impact of an Internet-Delivered Sound Healing Intervention on Chronic Non-Malignant Pain and Sleep Disturbances in Community Settings

N. Sharma¹, D. Walker^{2*}, B. S. Prasad¹ and M. Patel¹

¹Aarogyam UK CIC, Leicester and ²Suara Sound Academy, Callington, United Kingdom

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.367

Introduction: Chronic pain patients often contend with insomnia symptoms, creating a reciprocal relationship that adds complexity to their condition. Evaluating interventions targeting insomnia in this population becomes paramount, given the intertwined nature of pain and sleep disturbances.

Objectives: This retrospective pretest design aimed to assess the efficacy of an Internet-delivered sound healing intervention in reducing insomnia severity and addressing sleep- and pain-related parameters among individuals with chronic pain.

Methods: Conducted as a community-based project, Tuning for Health provided support to individuals grappling with long-term illnesses. The intervention involved the virtual delivery of a specially crafted sound track using tuning forks over a 6-week period, supervised by an experienced therapist and administered weekly for an hour. Participants were instructed to play the track daily at a time convenient for them. A total of 68 participants (mean age 59.3 years) completed the intervention. Outcome measures, including the Insomnia Severity Index (ISI), a sleep diary, and assessments for anxiety, depression, and pain-related parameters, were collected at the end of the 6-week intervention and repeated after a 6-month follow-up. Negative effects were monitored and reported.

Results: Significant immediate interaction effects (time by treatment) were observed for the pain severity, ISI and various sleep parameters, such as sleep efficiency, sleep onset latency, early morning awakenings, and wake time after sleep onset. A time effect for anxiety and depression was noted at the 6-month follow-up. The group exhibited highly significant improvements in pain-related parameters. At the 6-month follow-up, sustained enhancements in sleep parameters and mental health were reported, with no reported side effects.

Conclusions: These unique results suggest the potential efficacy of sound healing in alleviating chronic pain and associated insomnia. Further research with a larger sample size is warranted to validate these findings. Combining sound healing with other treatments may offer enhanced outcomes for individuals dealing with both chronic pain and comorbid insomnia. This study lays the groundwork for future investigations into the promising intersection of sound healing, chronic pain management, and sleep improvement.

Migration and Mental health of Immigrants

EPP0164

Social Determinants and Mental Health in Newly Arrived Young Migrants in Spain

M. Franch-Roca^{1*}, A. Gabarrell-Pascuet^{1,2}, E. Salomon-Mallat¹, M. Group¹, J. M. Haro^{1,2} and P. Cristóbal-Narváez^{1,2}

¹Research and Development Unit, Institut de Recerca Sant Joan de Déu, Barcelona and ²Centre for Biomedical Research on Mental Health (CIBERSAM), Madrid, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.368

Introduction: Research has shown that factors related with the migratory process (such as travelling alone, living away from family, and discrimination after arrival) considerably increase the risk of mental health problems in young migrants. Moreover, they are among the most vulnerable migration groups with a high risk of social exclusion.

Objectives: To identify coping strategies and behavioural changes used to deal with perceived discrimination and its impact on the emotional well-being and mental health of newly arrived young migrants in Spain.

Methods: A subsample of 15 audio-recorded in-depth qualitative interviews were analysed from the national action-research Migra-salud project (II IN 190517 EN 162 FA 01). The interviews were transcribed, translated from Arabic to Spanish, and analysed through content analysis.

Results: Most participants were males (93.3%; n=14), ranging from 18 to 20 years, and from Morocco (93.3%; n=14). All participants were from foster care placements in Barcelona and arrived to Spain as minors. Newly arrived young migrants reported that they perceived themselves as being healthy before the migratory process. Adverse experiences during the journey and discrimination after arrival impacted their well-being and mental health. Specifically, they reported perceived discrimination in their daily life due to culture, language, or origin. This negatively impacted their well-being and mental health, increasing their emotional distress response and 'undervalued or inferior' and 'vulnerable' feelings about themselves. Concerning coping with discrimination, they reported using internalised coping strategies such as 'ignoring' or 'not responding' for fear of having their legal documents revoked or not obtaining them. Their behavioural changes often occurred when they perceived unfair treatment or prejudice towards their migrant status or their socioeconomics, culture or religion. These changes were motivated by being more accepted by the local community by 'westernisation or cultural assimilation' and by 'creating a good image' of oneself and its culture.

Conclusions: Findings establish that the cumulative experience of post-migration stressors (such as discrimination) negatively impacts their mental health and well-being in the long term. This suggests the need for specific policies and services to address this population's effects of post-migration risk factors. Further research is needed to explore the causes and effects of perceived discrimination on mental health more closely and to develop more targeted and effective interventions.

EPP0165

Mental disorders in internally displaced persons: clinical features, therapy, prevention

N. O. Maruta*, T. V. Panko, V. Y. Fedchenko, I. O. Yavdak and O. E. Semikina

Borderline psychiatry, "Institute of Neurology, Psychiatry and Narcology of the NAMS of Ukraine" SI, Kharkiv, Ukraine

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.369

Introduction: Military aggression significantly worsens the mental health of the population due to losses: human, economic-financial, social-psychological, ecological. One of the negative consequences of military aggression is migration, the movement of the population within the country and outside its borders, which disrupts adaptation and leads to the formation of a wide range of psychological and mental disorders.

Objectives: To study the state of mental health of internally displaced persons (IDPs) and to develop, on this basis, a system of therapy and prevention of mental disorders.

Methods: A combination of clinical-psychopathological and psychodiagnostics methods of studying were used to identify peculiarities of the mental state and various forms of mental pathology.

Results: 270 IDPs were examined. It was established that the group of IDPs is heterogeneous and includes 3 categories: 1 group of IDPs who do not have signs of mental disorders (conditionally healthy) (34.81%), 2 group of IDPs who have separate symptoms of mental disorders (risk group) (25.19 %) and the 3 group of IDPs with established mental disorders (40.00 %). The assessment of the general condition of the IDPs of the 1 group shows that they have various somato-neurological disorders and the absence of mental disorders. The assessment of the emotional state of the IDPs of the 2 group indicates the presence of various emotional disorders that include asthenic syndrome (41.18 ± 5.97 %), agripnic syndrome (45.59 ± 6.04 %), somato-vegetative syndrome (30.88 ± 5.60 %), anxiety-depressive syndrome (20.59 ± 4.90 %). That separate syndromes do not meet the criteria of ICD-10 and were subthreshold. The general features of mental disorders in group 3 IDPs are characterized by the predominance of disorders of the anxiety-depressive spectrum and includes adjustment disorders (F43.2) in 35.18%; post-traumatic stress disorder (F43.1) in 17.59%; a moderate depressive episode (F32.1) in 16, 67%; organic affective (depressive) disorder (F06.3) in 14.81%; organic anxiety disorder (F06.4) in 9.28%; recurrent depressive disorder (33.1) in 6.48%.

Conclusions: A system of treatment of mental disorders in IDPs has been developed, which includes pharmacotherapy (the usage of antidepressants, anxiolytics and, if necessary, antipsychotics), cognitive-behavioral and family psychotherapy. For prevention mental disorders among IDPs of groups 1 and 2, a psychoeducational program was created, aimed at forming awareness of clinical manifestations of mental disorders, opportunities to prevent their formation, and necessary actions in conditions of exacerbation of the mental state. Evaluation of the effectiveness of the developed system of therapy and psychoeducation has testified to their effectiveness.

EPP0166

Polish psychiatrists' experiences consulting displaced patients from Ukraine in 2022

K. Krysta*, K. Kamińska, Z. Mielczarek and M. Ciolek

Department of Rehabilitation Psychiatry, Medical University of Silesia, Katowice, Poland

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.370

Introduction: The ongoing conflict in Ukraine has resulted in a significant influx of refugees seeking asylum in other countries, including Poland. Among these refugees are individuals who are struggling with mental health issues. Polish psychiatrists have stepped up to provide care for these patients, despite facing a number of challenges in the process.

Objectives: This presentation aims to shed light on the experiences of Polish psychiatrists treating refugees during the war in Ukraine,

highlighting the difficulties they have encountered and the strategies they have employed to provide the best possible care to their patients. The presentation also examines the impact of war on mental health, and the long-term effects on the well-being of refugees.

Methods: A questionnaire study was done among Polish Psychiatrists about the forms of support they provided for Ukrainian psychiatric patients they consulted after 24 February 2022. The responses to questionnaires were collected during psychiatric Congresses.

Results: The most commonly reported symptoms were anxiety (44.1%), followed by depression (35.3%), and panic attacks (23.5%). Other symptoms like irritability and sleep disorders were reported by 11.8% and 8.8% of the respondents, respectively. Disturbingly, thoughts of resignation and suicidal ideation were also reported, albeit at lower frequencies (8.8% and 2.9%, respectively). A small percentage (2.9%) reported no new symptoms.

The high prevalence of anxiety and depression suggests that the war has had a profound impact on the mental health of the affected population. The emergence of severe symptoms like psychotic thoughts and suicidal ideation, although less frequent, is alarming and calls for immediate intervention. It is also noteworthy that a small but significant portion of the population reported no new symptoms, which may indicate resilience or other coping mechanisms at play.

Conclusions: The war in Ukraine has led to a range of new psychological symptoms among the affected populations, with anxiety, depression, and panic attacks being the most prevalent. Immediate and long-term psychological interventions are urgently needed to address these emerging mental health issues. Further research is also required to understand the resilience factors among those who reported no new symptoms.

Personality and Personality Disorders

EPP0167

Cognitive functioning of patients with borderline personality disorder

E. Chumakov*, D. Charnaia and N. Petrova

Department of Psychiatry and Addiction, Saint Petersburg State University, Saint Petersburg, Russian Federation

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.371

Introduction: The neurocognitive deficit model as a characteristic of patients with borderline personality disorder (BPD) has been the focus of research for the past 20 years. However, no such studies have been performed in Russia.

Objectives: The aim of the present study was to investigate the neurocognitive profile of patients with BPD.

Methods: Fifty patients with BPD (according to DSM-V criteria) in stable mental state (72% women; mean age 22.44 ± 4.32) were examined. BPD symptom severity was assessed using the Borderline Personality Disorder Questionnaire (PBQ-BPD), which was validated in the Russian population (34 points or more indicated a higher probability of BPD diagnosis). The Brief Assessment of Cognition in Schizophrenia (BACS) was used to assess cognitive function (in order to use these data for differential diagnosis with

schizophrenia spectrum disorders). The study was approved by the ethical committee of Saint Petersburg State University.

Results: On the PBQ-BPD results, 38% of patients (n=19) scored over 34 points, despite being stable. BACS subscales T-scores (presented as median [Q1; Q3]) were within normal limits (Verbal memory - 49.81 [46.56; 53.06]; Working memory - 43.73 [38.0; 47.50]; Motor function - 44.08 [41.0; 47.25]; Coding - 45.56 [42.50; 48.63]; Verbal fluency - 48.14 [46.0; 52.0]; Tower of London test - 52.33 [47.0; 57.0]). A number of patients had low scores on the BACS subscales (T-score < 40), particularly working memory (33.3%), coding (20.8%), and verbal memory (18.8%). The BACS Composite T Score (46.02 [43.65; 48.39]) correlated with the PBQ-BPD score (32.00 [27.00; 36.00]; $r=-0.316$; $p=0.028$). To better characterize the cognitive functioning of patients with BPD, patients were divided into two groups: those who scored less than 34 on the PBQ-BPD (group 1) and those who scored more than 34 on the PBQ-BPD (group 2). Group 2 patients had a lower BACS Composite T-score (42.32 [38.06; 46.58]; 48.45 [45.87; 51.03]; $p=0.009$) and nominally lower mean scores on all BACS subscales, compared with Group 1 patients. We found significant differences in T-scores values on the Working Memory subscale (Group 1 - 45.0 [41.0; 49.0]; Group 2 - 38.0 [33.0; 43.5], $p=0.003$), Verbal Fluency (49.0 [47.25; 53.75]; 48.0 [44.0; 49.0]; $p=0.047$), Tower of London Test (57.0 [52.0; 57.0]; 48.0 [42.0; 57.0]; $p=0.036$).

Conclusions: Neurocognitive impairment was detected in 33.3% of patients with BPD. The dominant cognitive impairments in the patients were decreased working and verbal memory and information processing speed. The severity of BPD symptoms has been confirmed to correlate with the neurocognitive functioning of these patients.

Disclosure of Interest: None Declared

A pilot Randomized Controlled Trial (RCT) study protocol for assessing physical activity in individuals diagnosed with Borderline Personality Disorder (PABORD)

A. Martinelli^{1*}, M. D'Addazio¹, S. Leone¹, R. Rossi¹, S. Pogliaghi², G. Marchitelli³, M. Zamparini¹, G. Moncalieri¹, E. Toffol¹ and G. de Girolamo¹

¹IRCCS Istituto Centro San Giovanni di Dio Fatebenefratelli, Brescia;

²University of Verona, Verona and ³ASST Pavia, Pavia, Italy

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.372

Introduction: Most treatments for severe mental disorders involve either pharmacotherapy or psychological interventions, which show mild to moderate effectiveness and may not lead to complete remission. Physical activity (PA), effective in enhancing physical health among the general population, emerges as a potential adjunctive treatment option that can address the existing gaps.

Borderline Personality Disorder (BPD) is a severe condition associated with profound psychosocial impairment, a heightened risk of suicide, and considerable burden on informal caregivers and mental health service providers. While there is a lack of approved medications for individuals with BPD, psychosocial interventions

demonstrated good efficacy. However, the implementation of these treatments is limited by the demanded extensive training for staff. No studies have investigated the effectiveness of structured PA as an adjunctive treatment for individuals with BPD.

Objectives: The primary objective of this study is to assess whether the intervention group outperforms the control group in terms of improvement on a standardized assessment scale evaluating BPD psychopathology, the *Zanarini Rating Scale for Borderline Disorder*. Secondary objective is to assess whether the intervention group can increase and sustain higher levels of PA. We hypothesise that a structured PA program will demonstrate superior results compared to the psychoeducation control group concerning PA levels upon completion of the intervention. Additionally, we hypothesise that the intervention group will exhibit enhanced outcomes in psychopathology, functioning, and sleep.

Methods: The PABORD Randomized Controlled Trial is designed for female outpatient individuals diagnosed with BPD aged 18-40 years. This trial will involve two distinct groups: (i) an intervention group (25 participants) that will engage in a 12-week structured PA program under the supervision of a sports medicine physician; (ii) a control group (25 individuals) that will undergo a 12-week psychoeducation program focused on PA and diet.

Patients are assessed at three different time points. Standardized assessments include psychopathology, psychosocial functioning, sleep, menstrual cycle and nutrition data. Measurements are taken on the amount and intensity of PA and sleep patterns using a biosensor device (Actigraph GT9X), dynamometric measures and BMI. Biomarkers and hormonal cycles are examined through the collection of plasma and saliva samples.

The trial is financially supported through donations (5x1000 fund), and has been submitted to the local Ethics Committee for approval. The trial registration process is also currently in progress.

Results: Not yet available.

Conclusions: The study will provide new knowledge which may enhance our treatment options with patients suffering from BPD.

Disclosure of Interest: None Declared

Temperamental differences in the Subtypes of Attention Deficit Hyperactivity Disorder

G. Longo*, M. Servasi, L. Orsolini and U. Volpe

Dipartimento di Neuroscienze Cliniche/DIMSC, Università Politecnica delle Marche, Ancona, Italy

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.373

Introduction: Attention-Deficit/Hyperactivity Disorder (ADHD) is a neurodevelopmental condition marked by difficulties in attention, hyperactivity, and impulsivity. Its subtypes—predominantly inattentive, predominantly hyperactive-impulsive, and combined—vary in symptom presentation and impact on daily functioning. Understanding these subtypes is crucial for tailored interventions and support.

Objectives: Our aim is to clinically characterize the psychopathological aspects of the subtypes of ADHD.

Methods: Our study is conducted on patients (>18 years) referred to the adult ADHD outpatient service of the Psychiatric Clinic of Ancona (Università Politecnica delle Marche, Italy). The

Diagnostic Interview for ADHD in adults (DIVA 5.0) was used for diagnosing ADHD. The following rating scale were administered: Temperament Evaluation in Memphis, Pisa and San Diego (TEMPS-M), and Temperament and Character Inventory-Revised (TCI-R).

Results: 76% (n=170) of all screened patients were diagnosed with ADHD in adulthood. 57.6% (n=98) were diagnosed with ADHD combined subtype, 35.3% (n=60) with ADHD inattentive subtype, and 7.1% (n=12) with ADHD hyperactive subtype. Only 12.9% (n=22) were diagnosed with ADHD in childhood. Based on the results obtained at TEMPS-M, 43.8% (n=32) of patients were found to have cyclothymic temperament. Subjects with ADHD combined subtype scored significantly higher mean on the irritable temperament subscale of the TEMPS-M than those with ADHD inattentive subtype ($p=0.016$), while patients with ADHD inattentive subtype had a significantly higher mean score on the disorderliness subscale of the TCI-R than those with ADHD hyperactive and combined subtype ($p=0.010$). Given the logistic regression analyses using the TCI-R, developing an inattentive type of ADHD is negatively predicted by the disorderliness subscale of the TCI-R ($\exp(B)=0.788$, $IC95\%=0.669-0.929$, $p=0.005$) and positively predicted by the extravagance subscale of the TCI-R ($\exp(B)=1.104$, $IC95\%=1.009-1.208$, $p=0.031$), the hyperactive subtype of ADHD is negatively predicted by the fatigability subscale of the TCI-R ($\exp(B)=0.775$, $IC95\%=0.597-1.005$, $p=0.055$) and the combined subtype that is positively predicted by the disorderliness subscale of the TCI-R ($\exp(B)=1.140$, $IC95\%=1.011-1.287$, $p=0.033$). Regarding temperament, through a logistic regression analysis, the inattentive subtype of ADHD is negatively predicted by the irritable temperament subscale of the TEMPS-M ($\exp(B)=0.904$, $IC95\%=0.839-0.974$, $p=0.008$), while for the combined subtype of ADHD it is positively predicted by the irritable temperament subscale of the TEMPS-M ($\exp(B)=1.088$, $IC95\%=1.014-1.167$, $p=0.019$).

Conclusions: The results show that irritable temperament is a predictor for the inattentive and combined subtype, but with different polarities. In addition, how different patterns of personality are specific to the various subtypes of ADHD are highlighted.

Sexuality in patients treated for borderline personality disorder at the Arrazi psychiatric hospital in Salé

N. Ait Bensaid*, Y. Bensalah, M. Sabir and F. El Omari

psychiatric hospital arrazi, salé, Morocco

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.374

Introduction: Borderline personality disorder is a severe mental disorder characterized by generalized instability of emotional regulation of interpersonal relationships and self-image, and marked impulsivity. Several features of this disorder are likely to be associated with problematic sexual health, such as impulsivity (impulsive sexual behavior), identity disorders (unstable sexual identity) and unstable and intense interpersonal relationships. In addition, childhood sexual abuse and violence are common in people's histories.

Objectives: Assessing sexuality in patients followed for borderline personality disorder at Arrazi Salé psychiatric hospital.

Methods: This is a descriptive cross-sectional study using a questionnaire including socio-demographic criteria with a questionnaire on sexual behavior in female patients followed for borderline personality disorder at the Arrazi Salé psychiatric hospital. Inclusion criteria: women over 18 years of age diagnosed with borderline personality disorder. Exclusion criteria: psychosis, intellectual disability.

Results: We collected 45 patients with borderline personality disorder. The average age was 22, 80% were single, 58% unemployed, 46% had dropped out of high school. The majority of participants were using psychoactive substances. 25% had attempted suicide. 83% were victims of childhood sexual abuse. The majority were significantly more likely to engage in sexual activity at a younger age than their peers. Over 60% had never used contraception 10% had their first pregnancy at a younger age, with termination. 15% have had genital infections. 53% were attracted to both sexes, and over 66% had more than one sexual partner. Over 73% did not experience sexual satisfaction (sexual satisfaction scale less than 10).

Conclusions: The results indicate that sexuality in patients with borderline personality disorder is present early in the course of the disorder, often at a young age, with significant physical, mental and social consequences. Primary care mental health, sexual health and sexual assault services need to be attentive to the clinical diagnosis of this personality disorder, as the nature of the disorder represents both a risk factor and a health threat.

EPP0171

A HORMONAL INFLUENCE? Polycystic ovary syndrome and borderline personality disorder

S. Jesus Magueta*, M. Almeida, E. Osório² and C. Guerra²

Departamento de Psiquiatria e Saúde Mental, Centro Hospitalar do Baixo Vouga, Aveiro and ²Serviço de Psiquiatria, Hospital de São João, Porto, Portugal

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.375

Introduction: Borderline Personality Disorder (BPD) is a chronic personality disorder characterized by emotional and interpersonal instability, difficulty in mentalization, impulsivity with functional impairment and increased rates of comorbid mental disorders. Polycystic ovary syndrome (PCOS) is the most prevalent endocrine disorder in premenopausal women, with important impact on quality of life and mental health. Studies have begun to explore the eventual relationship between these two pathologies.

Objectives: The authors aim to describe the existing evidence exploring the relationship between BPD and PCOS as well as explore eventual common causal pathways and the forms which one might influence the other.

Methods: The authors describe a clinical case of a 31 year old female patient with history of borderline personality disorder and polycystic ovary syndrome presenting with hyperandrogenism and hirsutism as well as menstrual irregularities. As a compliment to the case, the authors conducted a brief non-structured literature review using articles published in the Medline/Pubmed, ScienceDirect and Google

Scholar databases. The keywords used during the research, alone or in combination, included: Polycystic ovary syndrome and Borderline Personality Disorder. The studies consulted in this work included: cross-sectional studies, cohort studies, literature reviews and clinical case reports. Of these, those that were written in the English language and deemed most pertinent to the explored theme were chosen for review in this work.

Results: The results demonstrate a paucity in the literature with only 10 articles having been published between 2009 and 2023 having dedicated studies and research to the relationship between the pathologies. One study reports that those with PCOS show relevant psychiatric disorders in comparison to controls, including personality disorders, such as is demonstrated in the described clinical case. Of the few case studies available, these found that BPD was associated with PCOS with the latter having most frequently been diagnosed previously to the personality disorder. Altered androgen metabolism has been described in both these pathologies, thus further strengthening the relationship between these.

Conclusions: Hormonal fluctuation has been classically associated with psychopathological symptoms, including unstable mood and impulsivity. The alterations demonstrated in PCOS might serve as an exacerbating factor in the genesis of the emotional instability and other symptoms present in BPD. The literature on this topic is still in an embryonic phase with a clear lacuna existing which merits attention and further study so as to fully comprehend the potential of these comorbid states. Clinicians should remain attentive to this comorbidity and the influence that PCOS might have on the psychopathology of BPD so as to better quality of life and global functioning which is impacted in both.

Swipe & Slice: Decoding Digital Struggles with NSSI in Young Italians

S. Reina*, G. Longo, L. Orsolini and U. Volpe

University Psychiatric Clinic, Department of Clinical Neuroscience/ DIMSC, Università Politecnica delle Marche, Ancona, Italy

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.376

Introduction: Non-suicidal self-injury (NSSI) is defined as any deliberate destruction of one's body tissue, engaged in for reasons that are non-suicidal. Online platforms, notably social media, witness a surge in NSSI-related content, amplified by the COVID-19 pandemic. Young individuals increase video and post uploads, prompting scholarly inquiry into the impact on vulnerable demographics in the online environment. Despite potential benefits, concerns surface regarding content reinforcing self-injurious behavior. The Blue Whale phenomenon exemplifies serious consequences in this digital landscape.

Objectives: The present study aims at screening the prevalence of NSSIs on SNS among Italian young people.

Methods: An observational cross-sectional study was conducted by recruiting 373 Italian young people (aged 18-25). Bergen Social Media Addiction Scale (BSMAS), Fear Of Missing Out Scale (FOMO), Inventory of Statements About Self-Injury (ISAS) were

administered to investigate the relationship between NSSIs, social media use and frequency and underpinned motivations.

Results: Overall, 99.7 % (n=372) of participants declared to have used at least one social network. Around 92.5 % (n=345) declared to know Blue Whale Challenge and more than half of the sample (51.5%) referred to have looked for NSSI contents on SNS, mostly (28.7 % (n=107)) have sought for curiosity, 17.7 % (n=66) have sought for help/support. 53.4 % (n=199) of the sample was found to have problematic social media use (PSMU) according to BSMAS. 85 % (n=317) have committed self-injurious gestures in the past, 66.2 % (n=247) practice NSSI currently, most subjects practice them to vent 51.7% (n=193), calm themselves 41.6% (n=155), and punish themselves 30% (n=112). The mean age of transgender and nonbinary subjects (30 % n=112)) who sought/saw content pertaining to NSSIs appears to be lower (p=0.033) than cisgender subjects. Those who searched for content inherent to NSSIs scored higher mean scores on the FOMO (p=0.022) and BSMAS (p=0.013) scales. Those who follow social pages inherent to NSSIs scored higher on the FOMO scale (p=0.035). Subjects who practice NSSIs at their present state, on average, have higher scores on the FOMO and BSMAS scales (p=<.001). Linear regression analysis was conducted showing an association between BSMAS and FOMO (R²=0.199, B=0.260; F(1.371)=92.334; p=<.001). Logistic regression analyses were conducted to define the effects of FOMO, PMSU, sex, and NSSI search on the development of self-injurious conduct. The logistic regression model was statistically significant, $\chi^2(1)=3.909$; p=0.048.

Conclusions: The study examines NSSI behaviors among young Italian college students on digital platforms, particularly social networks. It stresses the critical need for targeted interventions, addressing concerns like social media addiction, to provide essential mental health support and foster a safer online environment for this population.

EPP0173

The feasibility of a combined approach including neuromodulation by tDCS and cognitive remediation for people with borderline personality disorder (BPD)

L. Cailhol

Psychiatry, Institut Universitaire de Santé Mentale de Montréal, Montreal, Canada

doi: 10.1192/j.eurpsy.2024.377

Introduction: BPD is a common and severe mental health condition. Longitudinal studies related to BPD show a reduction of symptoms related to the disorder but very little improvement in functionality. The betterment of executive functions of people with BPD after psychotherapy is very limited. The efficacy of those treatments on functionality appears to be mild with a small effect size. Based on previous studies, transcranial direct current stimulation (tDCS) can be used to improve impulsivity and emotional instability in patients with BPD. Moreover, cognitive remediation focuses on reducing neuropsychological alterations by re-educating patients and apply specific strategies to aid them long term on certain daily functions like developing healthy habits, executive

functions, problem solving, attention, working memory and cognition.

Objectives: Our objective is to assess the feasibility and efficacy of the tDCS and cognitive remediation on BPD symptoms and functioning.

Methods: The open study includes 10 daily sessions of tDCS for 2 weeks and 8 weekly group meetings for the cognitive remediation. Based on studies conducted on people with BPD, the settings for the tDCS are as follows; 20 minutes of continuous current at the intensity of 2mA and the electrodes are placed on specific stimulation sites related to impulsivity. To verify the effectiveness of the combination on the symptoms and evaluate the cognition and functionality of the patients, questionnaires at neuropsychological texts are conducted at the beginning of the study, after the tDCS, after the cognitive remediation and 3 months after the end of the study. The expected results of this study are that the combination of the two treatments will reduce the symptoms of BPD and improve executive functions compared to the treatment as usual or tDCS alone. This study would allow the implementation of an efficient and low-cost first-line treatment and a better functional progression of BPD patients.

Results: The expected results of this study are that the combination of the two treatments will reduce the symptoms of BPD and improve executive functions compared to the treatment as usual or tDCS alone. This study would allow the implementation of an efficient and low-cost first-line treatment and a better functional progression of BPD patients.

Conclusions: This study would allow the implementation of an efficient and low-cost first-line treatment and a better functional progression of BPD patients.

Sex and pathological personality traits: measurement invariance and comparisons

F. D. L. Osório^{1*} and A. M. Barchi-Ferreira¹

¹São Paulo University, Ribeirão Preto, Brazil

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.378

Introduction: The Personality Inventory for DSM-5 (PID-5) is an instrument that aims to assess pathological personality traits according to the alternative model proposed by the DSM-5. To validate the comparison of an instrument's scores between different groups, it is necessary that the measure's invariance be attested, in order to guarantee that the same underlying constructions are being evaluated between the groups. Differences between sex in relation to the predominance of adaptive personality traits were portrayed in previous studies, a fact that seems to be related to culture.

Objectives: This study aims to assess whether the PID-5 presents structural equivalence between sex (sex measurement invariance) and whether there are differences between pathological personality traits in Brazilian men and women.

Methods: A community sample of 1110 subjects was assessed (71.2% women, mean age 34.6 (± 15.8) years, 68.8% higher education). They were recruited through advertisements in different media and by the "snowball" method. Participants responded to

the PID-5 in person. The cross-culturally adapted version into Brazilian Portuguese was used

Results: The PID-5 showed that its structure was invariant for sex at the configural level (CFI= 1.000; TLI=1.007; RMSEA<0.001), metric ($\Delta CFI=0.01$; $\Delta TLI= 0.02$; $\Delta RMSEA=0.02$) and scalar ($\Delta CFI=0.006$; $\Delta TLI= 0.006$; $\Delta RMSEA=0.004$), allowing comparisons. Regarding the domains evaluated by the PID-5, men showed more traits of Distancing, Antagonism, Disinhibition and Psychoticism ($p<0.002$), while for Negative Affectivity there were no differences between genders ($p=0.06$). In terms of facets, women showed higher indicators of lability, anxiety and impulsivity ($p<0.01$), while men showed perseverance, withdrawal, restricted affectivity, manipulation, dishonesty, grandiosity, attention seeking, insensitivity, irresponsibility, exposure to risks, unusual beliefs and eccentricity ($p<0.04$).

Conclusions: The findings reinforce the validity evidence of the DSM-5 trait model, which, through the PID-5, similarly evaluates such aspects between sex. Differences between genders were observed in relation to pathological personality traits, which bear similarities with differences observed in terms of adaptive personality traits. Specificities are observed at the cultural level, when, for example, the findings are compared with a Japanese university sample, reinforcing the role of culture at this level

Predominant negative symptoms: views of patients vs. doctors in a 1-year observational study

J. Dragasek^{1*}, Z. B. Dombi², K. Acsai^{2,3}, V. Dzurilla⁴ and Á. Barabásky²

¹University of P. J. Safarik, Kosice, Slovakia; ²Gedeon Richter Plc.;

³Ceva Animal Health, Budapest, Hungary and ⁴Gedeon Richter Slovakia, Bratislava, Slovakia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.379

Introduction: Negative symptoms are a key aspect of schizophrenia, significantly impacting a patient's functioning and quality of life. These symptoms are deemed predominant when they dominate the clinical picture and positive symptoms are only minimally present. As articulated in the most recent guidance by the European Psychiatric Association, including self-report measures is encouraged in negative symptom studies as they can further complement the observer-rated scales when assessing negative symptoms of schizophrenia.

Objectives: The objective of the poster is to compare the views of patients vs. doctors regarding predominant negative symptoms during a 1-year observational study.

Methods: This was a 1-year-long, prospective, multicentric cohort study with three visits after baseline at 3, 6 and 12 months. Adult outpatients with a schizophrenia diagnosis according to the International Classification of Diseases 10th edition who exhibited predominant negative symptoms according to clinical judgement were included. Patients received pharmacological and some non-pharmacological treatment as usual.

The primary outcome measure was the modified Short Assessment of Negative Domains (m-SAND), an anamnesis-based scale that is

composed of 7 items: two positive items (delusions and hallucinations) which make the m-SAND Positive sub-scale (m-SAND-P) and five negative items (anhedonia, alogia, avolition, asociality and affective flattening) which make the m-SAND Negative sub-scale (m-SAND-N). Each item is rated from 0 to 5 (not observed; mild; moderate; moderately severe; severe; and extreme). Other measurements included the Self-evaluation of Negative Symptoms (SNS), a validated scale that provides meaningful information regarding the patients' own perception of their negative symptoms. Least squares (LS) means were calculated for the change from baseline to final visit using a mixed model for repeated measures (MMRM).

Results: 188 patients were included in the study. The mean age was 39.8 years and 65% of patients were men. The mean duration of illness was 12 years. At baseline, patients rated alogia and apathy (mean SNS score: 5.7) to be the most severe and then asociality (5.5). In contrast, doctors found affective blunting (mean m-SAND total score: 4.3), apathy (4.2) and anhedonia (4.0) to be the most severe.

After the end of the observational period all negative symptom sub-domains improved significantly according to both the patients' and doctors' views. The latter group reported -1.9 LS mean change from baseline in apathy, -1.8 in anhedonia, and -1.7 in asociality (all p-value <0.0001). Patients felt most change in alogia and asociality (-2.7), and apathy and anhedonia (-2.4).

Conclusions: In summary, both patients and doctors reported significant improvement in predominant negative symptoms. Nonetheless, there were some differences how they perceived severity and change in the specific domains.

Dandy-Walker malformation and psychotic disorder. Review in accordance with a clinical case

A. Calle González*, D. Batet Sánchez, Á. Martínez Hernanz and I. Roque González

Psychiatry, Hospital Universitario de Getafe, Getafe, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.380

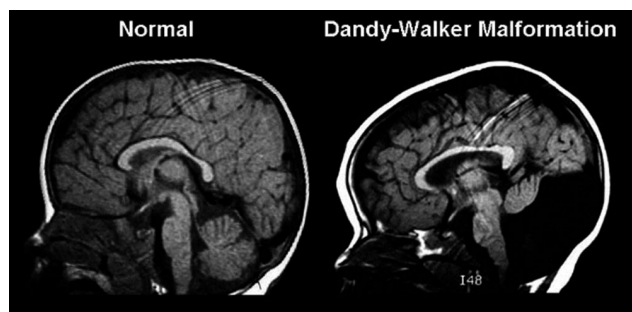

Introduction: A clinical case is presented of an 18-year-old woman diagnosed with Dandy-Walker malformation, who is admitted to an Acute Inpatient Psychiatry Unit due to atypical psychotic symptoms, pseudology and aggressive behaviour. After several medication trials, there is a partial response observed with low doses of clozapine, consolidating the improvement afterwards, being referred to an open-door community mental health center because of poor family and social network.

Objectives: Review clinical information about Dandy-Walker malformation and the development of psychiatric disorders, specifically psychotic symptoms, pointing out the peculiarities regarding clinical presentation and treatment management.

Methods: Search in the medical database PUBMED, MEDSCAPE and UPTODATE. Keywords: "Dandy-Walker Syndrome", "Psychotic Disorders".

Results: The Dandy-Walker syndrome consists on a cystic dilatation of the fourth ventricle, an abnormally high tentorium and the agenesis of the cerebellar vermis. Cerebellar structures are involved in cognitive, emotional and behavioural processes. This syndrome is related to the development of psychotic and affective disorders, as well as obsessive-compulsive disorder. The clinical presentation is usually atypical, being characterised by an early onset, a family history of psychosis and a high prevalence of cognitive deficit and borderline intelligence. There are no specific drugs recommended for the treatment of these patients, which present a high rate of refractoriness to antipsychotic treatments, together with a greater sensitivity to its side effects. Depending on the clinical presentation it is advisable to focus on the most relevant symptoms to be treated and potential side effects in order to reduce polypharmacy.

Image:

Conclusions:

- The Dandy-Walker syndrome is related to a higher risk of psychiatric disorders
- Clinical presentation is usually atypical and in early stages
- There is a high rate of refractoriness and greater sensitivity to treatments
- A specific pharmacological treatment is not recommended and it is recommended to avoid polypharmacy

EPP0177

Are direct costs in schizophrenia influenced by duration of illness? results from a retrospective follow-up study

I. Calzavara-Pinton¹, G. Nibbio¹, B. Cabassi^{1*}, E. Invernizzi¹, D. Di Carlo¹, N. Necchini¹, L. Bertoni¹, J. Lisoni², G. Deste^{1,2}, S. Barlati^{1,2} and A. Vita^{1,2}

¹DEPARTMENT OF CLINICAL AND EXPERIMENTAL SCIENCES, UNIVERSITY OF BRESCIA and ²Department of Mental Health and Addictions, ASST Spedali Civili di Brescia, BRESCIA, Italy

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.381

Introduction: In Italy, it was recently estimated that the total economic burden for schizophrenia is € 2.7 billions, of which around 50% is derived from direct costs and 81% of these are due to hospitalization, residential facilities and semi-residential facilities, whereas only 10% of direct costs is derived from

pharmacotherapy (Marcellusi *et al.* BMJ Open 2018; 8, e018359). Considered the high economic burden that schizophrenia has on healthcare systems (estimated to be between 1.4 % and 3 % of the total), a better characterization of the clinical variables that mostly influence the costs represent a topic of great clinical interest (Altamura *et al.* 2014 Official Journal of the Italian Society of Psychopathology 2014; 20, 223–243).

Objectives: The aim of this study was to analyze whether duration of illness has an impact on the costs derived from the use of services (which account for the majority of the direct costs) in a cohort of subjects living with schizophrenia spectrum disorders (SSD).

Methods: A total of 496 subjects receiving treatment from the Community Mental Health Centers (CMHC) of Brescia (Italy) were included in the study: for each patient demographic data, data regarding the duration of illness (in months), and data related to the use of service between January 1st, 2022 and December 31st, 2022 were derived from the regional database of mental health ("SIPRL"). Data on the use of service were then converted to costs using the regional rate tables for outpatient services, residential and semi-residential facilities, and the Diagnosis-Related Groups (DRG)-driven rate tables for hospitalization data. Partial correlations analyses were performed between duration of illness, corrected for age, and cost-related variables. All analyses were performed through SPSS v28 and p values <0.05 were considered significant.

Results: A higher duration of illness was correlated with higher costs for outpatient non-pharmacological interventions ($p=0.010$), for residential facilities ($p=0.025$) and total costs, both including and excluding hospital admissions ($p=0.005$ and $p=0.007$, respectively), but not with hospitalization costs ($p=0.773$).

Conclusions: The total expenditure for people living with SSD is higher for people with a longer duration of illness. These findings raise an important issue, which is that the mental health system in Italy invests more in subjects with a longer history of disease: this is in contrast with the international guidelines which prompt to intervene early in the course of the disease in patients living with SSD with outpatient rehabilitation interventions.

Evaluation of Relationship of Neutrophil/Lymphocyte, Platelet/Lymphocyte, Monocyte/Lymphocyte Monocyte/HDL Ratios and Systemic Immune Inflammatory Index Value with Antipsychotic Treatments in Schizophrenic Patients

H. Söylemez*, S. N. İspir, H. R. Demirel, E. Yıldız and M. Aydın
Department of Psychiatry, Selçuk University, Faculty of Medicine, Konya, Türkiye

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.382

Introduction: There are studies showing that the systemic inflammation response in patients diagnosed with schizophrenia is different from healthy controls. Neutrophil-lymphocyte ratio (NLR), platelet-lymphocyte ratio (TLR), monocyte-lymphocyte ratio (MLR),

monocyte-HDL ratio (MHO) and systemic immune inflammation index (SII) have recently been used as inflammation indicators.

Objectives: NLR, TLR, MLR, MHO and SII have been evaluated in many studies in schizophrenia patients. The aim of our study is to evaluate the relationship between NLR, TLR, MLR, MHO, SII values and antipsychotic treatments of patients diagnosed with schizophrenia.

Methods: 203 individuals diagnosed with schizophrenia who were followed up in the psychotic disorders outpatient clinic of Selçuk University Faculty of Medicine were included in the study. Neutrophil, lymphocyte, platelet and monocyte counts and HDL values were obtained retrospectively from blood tests. NLR, TLR, MLO, MHO and SII were calculated. The study approved by the ethics committee of Selçuk University Faculty of Medicine.

Results: 45.3% of the patients were female ($n = 92$); the mean age was 45.8 ± 14.0 . The average number of hospitalizations was 3.0 ± 2.7 years; the mean disease duration was 17.0 ± 9.6 years. 56.7% ($n=115$) use long-acting antipsychotic treatment, 21% ($n=43$) use monthly paliperidone long-acting (PP1M) treatment, and 14.8% ($n=30$) use 3-month paliperidone long-acting (PP3M) treatment. No significant difference was observed in NLR, TLR, MLR, MHO and SII values between individuals using and not using long-acting antipsychotics. However, a significant difference in NLR value was observed between PP1M and PP3M treatment ($p = 0.039$). Oral antipsychotic use was 71% ($n=137$), 19% ($n=38$) used clozapine monotherapy, and 25% ($n=51$) used non-clozapine oral monotherapy. No significant difference was detected in inflammatory markers between clozapine monotherapy and other oral monotherapies.

Conclusions: According to our findings, NLR levels in patients diagnosed with schizophrenia were found to be significantly higher in those using PP1M treatment compared to those using PP3M. This finding can be interpreted in favor of the fact that PP3M contributes to the reduction of inflammation due to its longer duration of action compared to PP1M. It is thought that schizophrenia progresses through inflammatory processes and antipsychotic treatments play a role in anti-inflammation. It is envisaged that future studies may be helpful in evaluating the onset, exacerbation and remission periods of the disease, including treatment doses and durations, and revealing the relationship between inflammatory markers and schizophrenia disease and the effects of antipsychotic treatments on inflammatory markers such as NLR, TLR, MLR, MHO and SII.

Machine Learning Analysis of Artistic Characteristics for Schizophrenia Classification

K. Vasilchenko^{1*}, A. Leonova², E. Kuznetsova³, P. Zdanovich³ and H. Keren¹

¹Human Artificial Control Keren Lab, Bar-Ilan University, Safed, Israel; ²Tyumen State Medical University, Tyumen and ³Omsk State Medical University, Omsk, Russian Federation

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.383

Introduction: Schizophrenia is affecting multiple functions such as cognition, perception, emotion, and social behaviors, and it has also

been shown to influence artistic works created by patients. Among the deviations observed in the art works are distinct characteristics like delusional themes, disordered shorter lines, and unique creativity. Such features, along with altered pictorial perceptions and possibly altered motoric function, suggest that it might be possible to differentiate art made by schizophrenic patients from that of healthy individuals. Given the shortcomings of existing diagnostic methods being very long and with a 25% error rate, we proposed a novel neural network model that leverages these artistic markers for classification to support diagnosis.

Objectives: To develop and train a neural network model leveraging unique artistic markers for the classification and support of diagnosing schizophrenia.

Methods: Our study involved 764 participants, 45% diagnosed with schizophrenia, while the others were either healthy or diagnosed with other mental disorders. The average age of the participants was 38.25 years (SD=13.43), and 43.88% of the participants were females. All participants were instructed to draw eight drawings of human faces. These drawings were digitized and categorized based on participants' schizophrenia status to form the initial training dataset for our model. This data was processed using Python and converted into a NumPy array, which served as input for our model developed using the Keras library. The structure of the model is presented (Image 1).

Results: We used area under curve (AUC), specificity, and sensitivity as key evaluation metrics for our model. The model achieved an AUC of 0.90 on a test dataset that was new to the model and was not used in the preceding training phase. It exhibited a sensitivity of 0.84 and a specificity of 0.85, indicating its capacity to identify schizophrenic and non-schizophrenic individuals, respectively (Image 2).

Image:

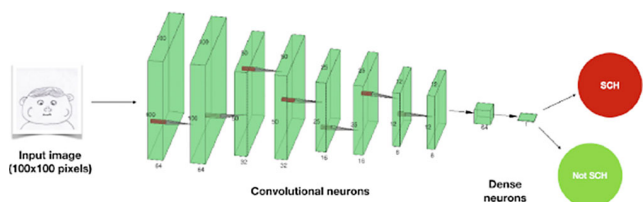

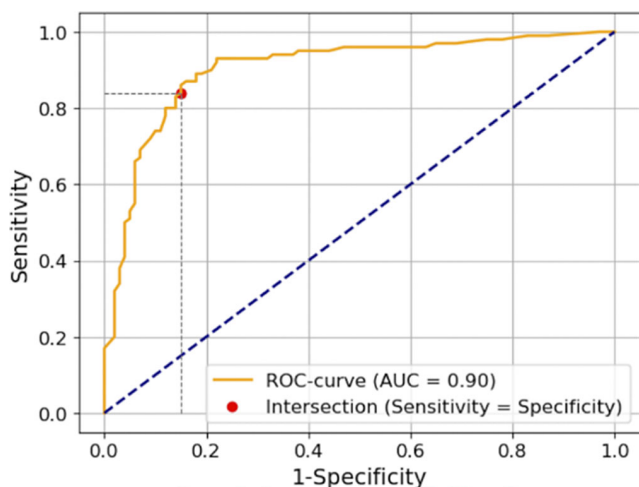

Image 2:

Conclusions: The application of machine learning and AI tools to analyze art created by schizophrenia patients, can offer a promising methodology for exploring the differences between schizophrenic and healthy individuals, as well as a possible support for current diagnostic methods. This approach has the potential to provide an additional fast and more accurate diagnosis, enhancing individualized patient care. Future research will focus on refining and validating the model across diverse populations and various art forms.

Athens Multifamily Group Therapy Project (A- MFGT) after FEP: Preliminary clinical results

M. Selakovic^{1*}, A. Zartaloudi², D. Galanis³ and P. Valeria⁴

¹Department of Psychiatry, "Sismanoglio" General Hospital;

²Department of Nursing, University of Western Attica; ³Department of Social Work, EPAPSY and ⁴First Department of Psychiatry, National & Kapodistrian University of Athens, Athens, Greece

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.384

Introduction: The Athens Multifamily Group Therapy Project (A-MFGT) aims to provide systemic multifamily therapy to youths who experienced a first psychotic episode and their families.

Objectives: Family interventions have been shown to reduce the likelihood of relapse for individuals across the spectrum of psychosis and are recommended in practice guidelines for psychosis internationally (Mc Farlane, 2016).

Methods: A group of 22 young adults who presented a first psychotic episode participated with their families to multi-family group systemic therapy, after discharged from in-patient treatment. Sessions were conducted by three therapists twice a month, for nine months and supervision meetings were provided once a month. Six groups of families have been conducted since 2017. Clinical outcome was assessed through PANSS at baseline, one month later after patient's discharge from in-patient treatment, and one year after, at the end of the multifamily group treatment. Time intervals till relapse were also assessed. Participants' clinical findings were compared with findings from a matched group of 42 patients who did not attend the multifamily therapy program and were treated as usual.

Results: Two-way mixed ANOVA was conducted to assess PANSS scores change over time (t1: at base line, t2: at one month and t3: one year), while differences were investigated between the two groups of patients and interactions were checked. Regarding PANSS-positive scale and PANSS-general scale, no differences were found between the two groups in neither of the three time points. Regarding PANSS-negative scale, patients attending MFGT presented statistically significantly lower scores in t3 than patients treated as usual, but not in t1 and in t2 (i.e., prior to therapy). Moreover, both patients' group showed improvement from t1 to t2, but only patients attending MFGT further improved from t2 to t3. Among patients attending MFGT, two (9.1%) had a relapse compared to nine (22.5%) of the patients treated as usual, however this comparison did not reach statistical significance ($p = 0.300$).

Conclusions: In term to provide early intervention in psychosis, A-MFGT seems to be a viable way to support the patient as well as the whole system facing psychosis, with the aim of preventing relapse and improved quality of life for all the participants.

EPP0181

Association of oral health related subjective quality of life and severity of negative symptoms of treatment-resistant schizophrenia: a cross-sectional study in Croatia

N. Mimica^{1*}, I. Pupi², K. Bosak³, P. Folnegović Grošić⁴, Ž. Bajić⁵, I. Filipčić³, V. Grošić³ and Z. Zoričić⁶

¹Women's Psychiatric Ward, Institute for Biological Psychiatry and Social Rehabilitation, Psychiatric Clinic Sveti Ivan; ²Children's Hospital Zagreb; ³Psychiatric Clinic Sveti Ivan; ⁴Department of Psychiatry, University Hospital Centre Zagreb; ⁵Research Unit "Dr. Mirko Grmek", Psychiatric Clinic Sveti Ivan and ⁶University Department of Psychiatry, University Hospital Sestre Milosrdnice, Zagreb, Croatia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.385

Introduction: Patients diagnosed with schizophrenia, particularly those with severe negative symptoms (NS) and treatment resistant schizophrenia (TRS), have poorer oral health than the general population, which can have serious consequences beyond oral and dental problems, but remains poorly addressed in psychiatric clinical practice and mental health research.

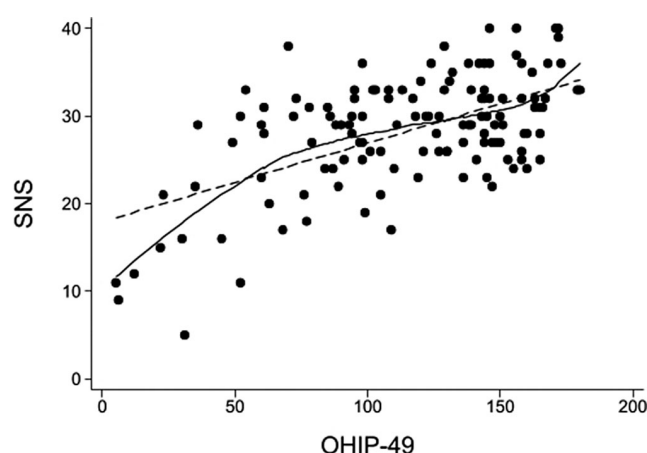

Objectives: To investigate the association between oral health-related subjective quality of life (OHR-sQoL) and severity of NS in TRS.

Methods: We conducted a cross-sectional study in a tertiary psychiatric clinic in Croatia during 2022-2023. The target population were patients diagnosed with TRS with more pronounced NS. The outcome was the Self-Evaluation of Negative Symptoms (SNS) scale and its five dimensions. Exposure was OHR-sQoL measured by the Oral Health Impact Profile questionnaire (OHR-sQoL). We tested the hypothesis using multivariable linear hierarchical regression analysis.

Results: We enrolled 130 participants with a median (interquartile range) age of 43 (36-51) years, with an equal number of women and men. Total SNS and OHR-sQoL scores were found to be significantly associated in both bivariate and multivariable analysis adjusted for a large number of covariates (R^2 increase over the effect of covariates = 0.22; $p < 0.001$; false discovery rate < 5%). Total SNS score was significantly associated with the functional limitation dimension of the OHIP-49, as well as diminished emotional range with psychological discomfort, physical and psychological disability, and anhedonia with functional limitation.

Figure 1. Scatter plot of the correlation between the total score of the Self-evaluation of Negative Symptoms (SNS) and the Oral Health Impact Profile (OHIP-49); the solid line represents the 80% smoothed local polynomial regression curve; the dashed line represents the linear regression line ($n = 130$)

Image:

Conclusions: NS of TRS are relatively strongly associated with OHR-sQoL, especially with functional limitations. The robustness of this association was confirmed by controlling for a large number of covariates. If the relationship between NS and OHR-sQoL is bidirectional, which should be verified by future studies, perhaps for further progress in solving the serious problems of NS and TRS it will be necessary to include the comorbidity with oral diseases and oral functional disorders and OHR-sQoL.

Hormones and Psychosis: The Role of Estrogen in Schizophrenia

S. Jesus Magueta*, A. L. Costa, G. Simões, A. I. Gomes, C. Madaíl Grego and P. Garrido

Departamento de Psiquiatria e Saúde Mental, Centro Hospitalar do Baixo Vouga, Aveiro, Portugal

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.386

Introduction: Schizophrenia is a complex psychiatric disorder in which biological sex differences, have been extensively documented and researched. What is less well described, is what motivates these differences. Of the various proposed and explored reasons, estrogen appears to be one that has maintained some interest and promise. An increase in symptoms of schizophrenia has been observed to correspond with decreasing levels of estrogen in menopausal women, this, allied to the later symptom onset, culminated in the interest in this hormone and its role in psychotic illness.

Objectives: The authors aim to briefly explore the current evidence on the association between estrogen and schizophrenia. Its relevance in symptom onset, protective status and eventual therapeutic applications will also be discussed.

Methods: The authors conducted a brief non-structured narrative literature review using articles published in the Medline/Pubmed, ScienceDirect and Google Scholar databases. The keywords used

during the research, alone or in combination, included: sex hormones, estrogen, schizophrenia and psychiatry. The studies consulted in this work included: cross-sectional studies, cohort studies, literature reviews and clinical case reports.

Results: The literature exploring the relationship between the sex hormone, estrogen, and schizophrenia is extensive. Various studies confirm that during periods of estrogen withdrawal, women appear more susceptible to psychotic episodes. Results also demonstrated that those with low estrogen, respond poorly to anti-psychotic drugs, whereas estrogen increased the efficiency of antipsychotics. In regards to symptoms, estrogen has been demonstrated to reduce the positive and cognitive symptoms of schizophrenia in the short term, thus being proposed as an eventual complementary treatment in those suffering from the disorder. It is known that estrogen regulates important pathophysiological pathways in schizophrenia, including dopamine activity, mitochondrial function, and the stress system. One of the explanations for this beneficial effect has been proposed to be action on cerebral blood flow and glucose metabolism, as well as sensitizing postsynaptic dopamine receptors, thus serving as a protective agent against schizophrenia.

Conclusions: The research appears to be pointing in the direction that estrogen appears to have an effect on psychosis in women, serving as a protective factor in these conditions as well as playing a significant part of the pathophysiology in schizophrenia. This influence on the pathophysiology, promises clinical pertinence, not only in a possible application so to attenuate positive and cognitive symptoms but also as a method to influence antipsychotic efficacy. Continued study in regards to the effects of sex hormones on the psychotic disorders is merited so as to further expand the tools in the mental health professional's repertoire in the treatment of these serious mental illnesses.

Impact of interpersonal relationships on academic burnout among trainee teachers: A comprehensive study

A. Bouhaba^{1*}, Z. Boumaaize¹, Y. El Madhi², A. Soulaymani¹, A. Mokhtari¹ and H. Hami¹

¹Laboratory of Biology and Health, Faculty of Sciences, Ibn Tofail University, Kenitra and ²Regional Center for Education and Training Professions, Rabat, Morocco

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.387

Introduction: Recent research has identified varying levels of burnout among teachers, particularly those in training. This condition is believed to be influenced by a combination of internal factors, such as psychological characteristics, and external factors, such as work-related pressures and the social environment.

Objectives: We examined the prevalence of burnout syndrome and assessed the potential risk factors associated with this condition. This study investigates the complicated correlation between academic burnout and interpersonal connections among trainee teachers in Morocco.

Methods: We used a comprehensive database generated from the Maslach Burnout Inventory-Student Survey (MBI-SS), a questionnaire designed specifically for this study, and validated for this context. We examined various dimensions of academic burnout to unravel the complexity of this connection. Our study analyzed individual, professional, and social factors within a cohort of 732 prospective teachers in Morocco during the 2021/2022 academic year.

Results: The findings revealed an intricate network of interrelated factors that contributed to the occurrence of academic burnout among trainee teachers. Significantly, the study highlighted the impact of interpersonal relationships on academic burnout. Trainee teachers who received support and positive interactions from colleagues and superiors showed significantly lower levels of academic burnout. Interpersonal relationships within the educational community also played a pivotal role in preventing burnout. Moreover, our multivariate analysis showed that certain sociodemographic factors, including age, gender, and prior educational experience, moderated the influence of interpersonal relationships on academic burnout.

Conclusions: This study significantly contributes to the comprehension of academic burnout in trainee teachers by emphasizing the vital role of interpersonal relationships in this context. The findings emphasize the necessity of interventions that enhance interactions within educational institutions to prevent academic burnout and promote a healthy learning environment for trainee teachers.

Psychiatry Pitstop: Enhancing Communication Skills of Medical Students in Mental Health Settings

D. Magalhaes^{1*}, F. Martinho¹, F. Viegas¹, M. Cativo¹, V. Ferreira¹, C. Manuel¹, S. Martins¹, J. Bastos¹, V. Barata¹, A. Pimentel¹, S. Carvalho¹, M. Santos¹, D. Almeida² and L. Fernandes¹

¹Mental Health Department, Hospital Prof. Doutor Fernando Fonseca and ²Hospital Beatriz Ângelo, Lisbon, Portugal

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.388

Introduction: *Psychiatry Pitstop* is a role-play-based program for medical students aimed to improve communication skills in the framework of mental health. The workshop involved amateur actors who simulated different clinical scenarios and psychiatry residents, who facilitated the sessions and provided constructive feedback following the Pendleton method. *Psychiatry Pitstop* was originally developed in the United Kingdom and it was expanded to Lisbon, Portugal, in 2019. The authors adapted the course to the Portuguese context, adjusting the number of sessions and altering the scenarios to match common clinical situations faced by junior doctors in Portugal. By now, we conducted four courses.

Objectives: Our study aims to describe the Portuguese adaptation of the program and to learn insights from the students feedback.

Methods: The course was assessed using satisfaction questionnaires, completed by the students after each session. These included a Likert scale ranging from 1 to 5, with items pertaining to Future Importance, Overall Quality, Theoretical Quality, and Practical

Quality. Quantitative data was analyzed using Excel and standard descriptive statistics to summarize the results. The open questions invited students to articulate the main positive aspects, suggestions for improvement and future topics. A Natural Language Processing (NLP) software was used to evaluate open-ended responses and extract the main concepts.

Results: We obtained a total of 39 single-answers from 4 different courses. Evaluation results yielded a mean score of 4.7 for Future Importance, 4.9 for Overall Quality, 4.3 for Theoretical Teaching, and 4.9 for Practical Teaching. Notable positive aspects included students' appreciation of the immersive interview environment, the dedication exhibited by actors and doctors, well-prepared case scenarios, and engaging interactions with participants. Suggestions for improvement encompass enhanced theoretical introductions, comprehensive topic coverage, universal participation in simulations, and expanded workshop days. Future prospects for the program include practicing interviews with other psychiatric diagnosis, addressing difficult patients, delivering bad news and covering topics related to sexuality, grief and moral dilemmas.

Conclusions: Our study shows that *Psychiatry Pitstop* adaptation to the Portuguese context was successful. Overall, the feedback from medical students has been consistently positive. Subsequent editions will draw upon the findings of this study to enhance overall program quality.

João (CHUS); ²CINTESIS; ³Neurosciences and Mental Health Department, Faculdade de Medicina da Universidade do Porto (FMUP), Porto, Portugal; ⁴Department of Medicine and Surgery, University of Milano-Bicocca, Monza, Italy; ⁵Psychiatry, Psychiatric Services Grisons, Chur, Switzerland; ⁶University Psychiatric Hospital Vrapče, Zagreb, Croatia; ⁷-, -, Russian Federation; ⁸Psychiatry Division, Imperial College London, London, United Kingdom; ⁹Kirov Military Medical Academy, -, Russian Federation; ¹⁰UMC Utrecht Brain Centre, UMC Utrecht, Utrecht, Netherlands; ¹¹Oxford Health NHS Foundation Trust; ¹²NIHR Oxford Health Biomedical Research Centre; ¹³Department of Psychiatry, University of Oxford, Oxford; ¹⁴University of Edinburgh, Edinburgh; ¹⁵Institute of Psychiatry, Psychology & Neuroscience, King's College London and ¹⁶South London and Maudsley NHS Foundation Trust, London, United Kingdom

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.389

Introduction: The *European Journal of Psychiatric Trainees* was founded in 2022 as the official journal of the European Federation of Psychiatric Trainees (EFPT) to offer a peer-reviewed open-access scientific journal with minimal article processing charges. The journal is edited by trainees and early career psychiatrists and published its first issue in July 2023. The journal aims to facilitate

publishing experience and opportunities for trainees. To reflect the global identity and inclusivity of psychiatric research, the journal changed its name in 2023 to become the *International Journal of Psychiatric Trainees*.

Objectives: To present the *International Journal of Psychiatric Trainees*, the successor of the *European Journal of Psychiatric Trainees*, and other practical aspects related to the article submission.

Methods: We will reflect on the *International Journal of Psychiatric Trainees*, focusing on what this name change will imply for the journal's scope, mission and readership.

Results: Due to training programmes' requirements or out of interest, psychiatric trainees are encouraged to conduct scientific research. However, several known barriers to scientific publishing exist, ranging from a lack of mentorship and supervision to limited scientific support. Like the *European Journal of Psychiatric Trainees*, the *International Journal of Psychiatric Trainees* continues to be an open-access, double-blind peer-reviewed journal with minimal/no publication fees that publishes original and innovative research as well as clinical, theory, perspective, and policy articles and reviews in the field of psychiatric training, psychiatry, and mental health.

Since the difficulties and needs in creating research output are not exclusive to European trainees, the journal will become more attractive to readers and authors from other countries while increasing the diversity of articles.

The first *International Journal of Psychiatric Trainees* issue will be dedicated to the 31st EFPT Forum with the theme "Trainee Mental Health", containing articles reporting on the projects from National Psychiatric Trainee Associations looking into trainee mental health. Submissions for the regular edition remain open, and articles should be submitted through the manuscript submission platform (<https://ijpt.scholasticahq.com>)

Conclusions: The *International Journal of Psychiatric Trainees* aims to be an educative scientific journal for psychiatric trainees and other psychiatry and mental health researchers. The name change and its increased openness will help the authors reach a wider readership while the journal can feature a more comprehensive record of psychiatric research through its global scope.

Positive outcomes of implementing applied theatrical improvisation in communication trainings/ workshops for healthcare students in two European countries: a comparative study

J. D. Fekete^{1*}, M. Jouin², K. Eklicsné Lepenye¹, Z. Póto³ and M. Hainselin²

¹Department of Languages for Biomedical Purposes and Communication, University of Pécs Medical School, Pécs, Hungary; ²Bureau E319bis - Campus Sud Psychologie Santé, Université de Picardie Jules Verne, Amiens, France and ³Institute of Pysiotherapy and sports sciences, University of Pécs Medical School Faculty of Health Sciences, Pécs, Hungary

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.390

Introduction: Effective communication has been shown to improve patients' health outcomes. This study utilizes medical improvisation techniques to teach communication skills to different groups of health students (nurses, midwives, medical doctors, speech therapists).

Objectives: Our objective was to design and compare an interprofessional workshop that incorporates applied improvisation to train different groups of healthcare students in communication skills, resilience, dealing with failure and empathy. Medical improvisation is an innovative concept to prepare healthcare students to be more effective communicators.

Methods: Required medical improv workshops (using applied improvisational theater techniques) were held for first to third-year students in France and in Hungary. Workshop evaluations were obtained before and following the last session and at 3 months post-workshop for one cohort. The courses incorporated role plays, listening, storytelling and verbal/ nonverbal exercises to help students communicate with empathy and clarity. The two countries used the same questionnaires for assessment (Interpersonal Communication Questionnaire and Intolerance Uncertainty Scale)

Results: 24 medical students participated in the Hungarian improvisation workshops, and 26 speech therapists students in the French improvisation workshops. In the finished Hungarian research over 90% of students rated the workshops as above average or excellent. Students reported a gain in insights regarding their role as a clinician ($\geq 90\%$), an improvement in their ability to demonstrate effective communication (80–87%), and a positive impact on teamwork (91–93%). At 3 months post-workshop, students reported they had used at least 1 improvisation skill on their clinical wards. Both countries can claim promising results so far in their separate studies, our results comparing the French and Hungarian data using synchronized scales and questionnaires is currently in progress, and will be processed by the end of this year.

Conclusions: This study demonstrates that medical improvisation exercises can be scaled to different fields of healthcare students in various years of their studies and that using improv in healthcare education is universal in its short and long-term effects. Further, we found that students felt that it improved their communication. This study also provides new insights regarding specific improvisation exercises that are most useful for the clinical environment.

Advancing Psychiatric Education: Leveraging Simulated Patients and Actors at the University of Pécs "Shame dies when stories are told in safe places"

J. D. Fekete^{1*}, M. Simon², V. Voros², T. Tényi², A. Hambuch¹ and A. Nagy²

¹Department of Languages for Biomedical Purposes and Communication and ²Department of Psychiatry and Psychotherapy, University of Pécs, Medical School, Pécs, Hungary

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.391

Introduction: The integration of simulated patients and actors (SPs) into psychiatric education has long been recognized as a transformative pedagogical approach, yielding substantial benefits to healthcare students and professionals.

Objectives: The aim of this investigation was to evaluate the SP methodology and to refine it for future implementation in psychiatric education at the University of Pécs, Hungary.

Methods: To investigate the feasibility and utility of incorporating SPs into psychiatric education, we conducted a preliminary study involving participants from the German Program in the University of Pécs, Hungary. This group consisted of 16 medical students in their 5th year of study. The study design involved participants forming groups of three, engaging in psychiatric interview with SPs. After the interview, SPs provided feedback from patient's perspective, articulating their emotional responses. These sessions lasted 60 to 90 minutes.

Results: Study participants expressed a range of apprehensive feelings, including inadequacy, the desire for correct performance, and acknowledgment of the emotional challenges involved. Another recurring issue was the students' initial confidence contrasting with their later realization of subpar performance. A subset of students voiced concerns related to performance anxiety, particularly in light of being observed. Nevertheless, by the culmination of the course, students spontaneously recognized and valued the enriching nature of the experience. Pre-existing skills have been confirmed authentically by the feedback of the SP.

Conclusions: Psychiatry, given its intricate and sensitive nature, necessitates a secure and controlled learning environment. SPs precisely provide this environment, facilitating the exploration of a broad spectrum of psychiatric disorders, emotional states, and patient interactions, all while upholding patient safety and confidentiality. Additionally, this methodology promotes the development of essential skills, including empathetic communication, the cultivation of therapeutic relationships. Moreover, the adaptability of SPs enables the creation of diverse scenarios reflecting real-world practice. Our preliminary findings and student feedback have provided a promising foundation for the design of a forthcoming pilot program in the next academic year. The integration of SPs into psychiatric education presents a dynamic, immersive, and highly effective approach, capable of markedly enhancing the quality of training.

Psychiatryai.com: Real-Time AI Scoping Review (RAISR 4D) in Psychiatry and Mental Health with Live Real-World Evidence and CPD/CME for Psychiatrists

P. Naik^{1,2*} and D. O'Leary³

¹Evidence-Based Healthcare MSc Student, University of Oxford, Oxford; ²Child and Adolescent Psychiatry, Central and North West London NHS Foundation Trust, London and ³Medical Sciences Division, University of Oxford, Oxford, United Kingdom

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.392

Introduction: Psychiatryai.com was launched in 2021 and initial findings were published at EPA 2023. The portal is an advanced

computing science project in Applied Data Science and Evidence-Based Healthcare for my MSc studies at the University of Oxford (Kellogg College). Artificial Intelligence (AI) and Data Science (DS) technology are utilised to analyse live Real-World Evidence (RWE) in Psychiatry and Mental Health from PubMed to provide CPD/CME online. A two-year review of the site and its performance will be presented to EPA 2024.

Objectives: To develop and study an experimental real-time AI and DS platform in Global Mental Health and Psychiatry, to provide the latest RWE from PubMed for online education and training, and to report findings to EPA 2024 for peer review in Budapest. AI and misinformation are newly identified risks in healthcare (AI Safety Summit 2023). The site also aims to raise awareness about “Aiatrogenesis” to address this problem, with RWE and CPD/CME utilising AI and DS technology for the categorisation and meta-analysis of evidence, rather than the production of possibly misleading or false Generative AI evidence (Monteith *et al.* BJP 2023; 1-3).

Methods: As reported to EPA 2023 in Paris, a free open-code WordPress site was launched on the 22nd of November 2021 (Psychiatryai.com). The portal has been further developed and now features over 90k pages comprising 7GB of data with Cloudflare security and speed. Live evidence is collected into an open database and research articles are categorised into evidence nodes with AI. The results are presented in a real-time Evidence Matrix and Blueprint, creating 15-minute CPD/CME reflection modules. Data analytics from Psychiatryai.com with Google Analytics (G4A) along with platform insights from two years of development and research will be presented to EPA 2024. The site is conceptualised and designed to be viewed in an interactive VR headset.

Results:

Live Citations	380000+
PubMed Articles Analysed with AI	92142
CPD/CME	23002 hours
Algorithms/Topics in Psychiatry	291
Open Data	7 GB

Image:

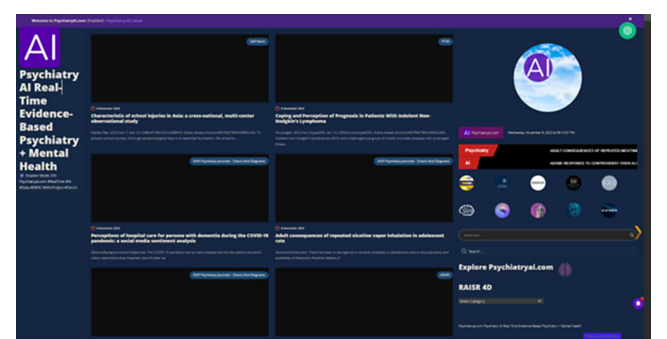

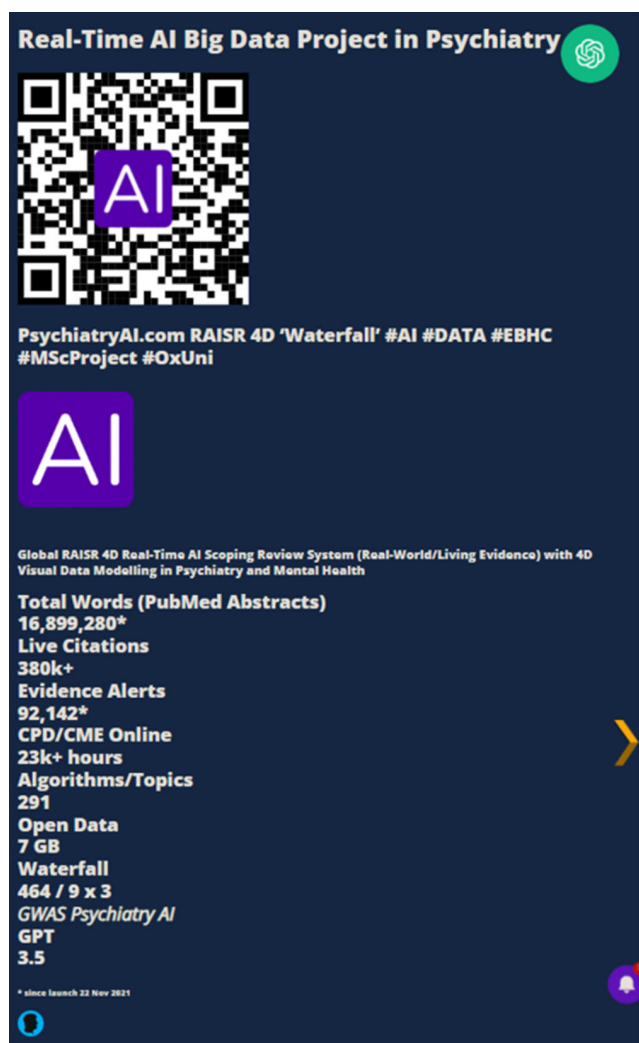

Image 2:

Image 3:

Conclusions: Psychiatryai.com has successfully developed a novel AI and DS platform that incorporates the latest research in mental health and psychiatry, providing real-world evidence (RWE) for psychiatrists and healthcare professionals worldwide, along with CPD/CME online. This enhances hypothesis testing in research by presenting a related Evidence Matrix and Blueprint (from the last 365 days) for each evidence node on the site (RAISR 4D). These matrices provide a real-time visual table (8 x 8 / 64) of global research related to the evidence node in the preceding year. The site is VR-ready and has a special focus on AI and Psychiatry, Disaster and Traumatology Sciences, and Youth Mental Health. This project is dedicated to the memory of Dr Denis O'Leary and Dr Navin Venkatraman.

Community Mental Health in Postgraduate Education of Psychiatrists and Public Health Professionals- A Proposal for a New Subspecialty

I. Polat¹, O. Karadag², A. Tiryakioglu Engin³, M. Altiner Yas⁴, B. O. Karazag^{5*}, B. Coskun⁶ and S. Karabey⁷

¹Psychiatry, İstanbul University Medical Faculty; ²Public Health, Bahçeşehir University School of Medicine; ³Public Health, İstanbul University Institute of Health Sciences; ⁴Public Health Nursing, İstanbul University - Cerrahpaşa Florence Nightingale Faculty of Nursing; ⁵Bahçeşehir University School of Medicine, İstanbul; ⁶Psychiatry, Kocaeli University Medical Faculty, Kocaeli and ⁷Public Health, İstanbul University Medical Faculty, İstanbul, Türkiye

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.393

Introduction: "Community Mental Health (CMH)" is defined as policies and practices aimed at improving mental health of communities and promoting healthy societies. Community mental health issues require a multidisciplinary approach because of their complex pattern, in which social determinants play a direct role in both their causes and solutions. However, training of healthcare professionals on CMH issues is still inadequate in many countries. **Objectives:** The purpose of this study was to assess mental health and public health professionals' awareness on CMH, as well as their opinion on the quality of their postgraduate education on CMH in Türkiye. The findings of this study are expected to provide guidance for the improvement of postgraduate education programs of psychiatry and public health.

Methods: The descriptive quantitative study was conducted with psychiatrists, public health physicians, and nurses with a postgraduate degree in Public Health or Psychiatric Nursing, who voluntarily participated by completing an online questionnaire. Data from a total of 131 physicians (43.5%) and nurses (56.5%) were analyzed by using the SPSS statistical package, where descriptive statistics, chi-square, t-test, and ANOVA were used.

Results: The majority (65.6%) of participating physicians and nurses were employed in tertiary healthcare institutions, with the remainder working in other healthcare settings. While half of the healthcare professionals had CMH topics embedded in their postgraduate education curriculum, only 40% had practical training in Community Mental Health Centers. Only one third (37.4%) expressed confidence in their knowledge of CMH, while only one participant reported feeling adequately informed about CMH services at the central and provincial level in Türkiye. One-third of the participants suggested CMH to become a subspecialty for health professionals, emphasizing the need for dedicated theoretical and practical courses in postgraduate curricula of public health and psychiatry education. The study also highlighted a significant difference between nurses and physicians regarding their postgraduate curriculum and perceived knowledge on CMH.

Conclusions: The study revealed that postgraduate education on CMH is still limited in Türkiye, with more emphasis of CMH in psychiatric nursing education. The findings indicate that education programs need to be revised to include more practical training,

including practicum in Community Mental Health Centers and that CMH can potentially become a subspecialty for public health professionals and psychiatrists. Conducting more comprehensive quantitative and qualitative studies on this subject, and enriching existing postgraduate education programs in terms of Community Mental Health, are of great importance for protecting and promoting community mental health.

Motivation to Motivate: Pilot of motivational interview training in a tertiary university hospital

K. Corrigan^{1*}, G. Crudden^{1,2}, A. M. Clarke³ and A. Doherty⁴

¹St. Vincent's University Hospital; ²Holles Street, The National Maternity Hospital, Dublin; ³Naas General Hospital, Kildare and ⁴The Mater Misericordiae Hospital, Dublin, Ireland

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.394

Introduction: Motivational interviewing (MI) is an evidence-based communication style that is effective in facilitating behaviour change and patient engagement. Originally developed in the field of addiction, MI can be applied to address a range of health behaviours including smoking cessation, medication adherence and diabetes and weight management. Given its demonstrated efficacy, training clinicians in medical and psychiatry specialties in MI has potential to enhance patient outcomes.

Objectives: 1. Enhance awareness and understanding of the basic concepts and methods of MI among NCHDs (Non-Consultant Hospital Doctors) and hospital staff.

1. Assess the perceived effectiveness of the training and help foster a culture of teaching and learning within the hospital.

Methods: MI training was organised by the psychiatry department and delivered by a certified external trainer. The training was structured into 2 sessions, each lasting three hours, with a six-week gap between sessions. The training was integrated into the regular academic teaching for psychiatry trainees and a circular email invite was sent to the medical NCHD cohort and psychology department. Pre and post-training questionnaires were collected from participants with five-point Likert scales used to gather responses

Results: There were 40 attendees across the two sessions. In total, 25 questionnaire responses were collected for the pre training (62.5%) and 30 responses were collected post-training (75%).

Prior to training 48% (12/25) indicated they were familiar with MI, 48% felt confident in using MI and 88% (22/25) felt it was applicable to their practice. Post-training, 73% (22/30) felt confident in using MI, 90% (27/40) felt MI was applicable to their practice and 100% indicated they would use MI in their practice. The perception of applicability ($p=0.011$) and likely utilisation of MI skills ($p<0.001$) significantly increased over the course of the training as measured by paired t-test ($n=23$). Ninety-seven percent of responders stated they would recommend the training and 57% (17/30) indicated that they would use MI on a weekly basis in the future.

Conclusions: NCHDs and other staff welcomed this training and indicated the training was relevant to their practice. MI demonstrated a positive effect on staff perceptions of applicability and future utilisation of MI skills. Increasing clinician self-perceived

efficacy through training events may help contribute to a culture of learning and teaching in hospital settings.

Transcranial Magnetic Stimulation and its Efficacy in Alleviating Depressive Symptoms in Patients with Suicidal Ideation

A. Moleon^{1*}, M. Martín-Bejarano¹, P. Alvarez de Toledo¹, I. Perez², J. Narbona¹, M. García-Ferriol², R. Perea¹, J. M. Oropesa¹ and J. Torres²

¹Instituto Andaluz de Salud Cerebral (IASC), Sevilla and ²Instituto Andaluz de Salud Cerebral (IASC), Huelva, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.395

Introduction: Suicide is a global public health issue. According to the latest available data from the National Institute of Statistics, 4,003 people died by suicide in 2021, reaching a new historical high. Approximately 90% of suicide victims suffer from one or more severe psychiatric disorders, and there is a documented 20-fold higher risk of suicide in individuals with affective disorders compared to healthy subjects (Abdelnaim et al., 2020). Repetitive transcranial magnetic stimulation (rTMS) has been established as an effective alternative or complementary treatment option for patients with depressive disorders, but little is known about its effects on suicide risk.

Objectives: To assess the efficacy of rTMS in reducing depressive symptoms in patients with suicidal ideation and behaviors.

Methods: Population and Methods: A retrospective analysis was conducted on a sample of 28 psychiatric patients (23 females; mean age 49.36 ± 16.23) with suicidal ideation identified by item 3 (suicidality) of the Hamilton Depression Rating Scale (HDRS), who were treated with rTMS. All patients received a minimum of 30 sessions, consisting of the application of a high-frequency ($>10\text{Hz}$) or intermittent theta burst stimulation (TBS) over the left dorsolateral prefrontal cortex (DLPFC) at an intensity of 120% of the resting motor threshold (RMT), and repeated low-frequency pulses (1Hz) or continuous TBS over the right DLPFC with an intensity of 110% of the RMT.

Results: Results: The results show a statistically significant improvement in depressive symptoms following rTMS intervention ($p < 0.001$). Furthermore, remission was observed in 46% of the sample ($\text{HDRS} < 8$).

Conclusions: Discussion: In line with recent studies (Abdelnaim et al., 2020; Hines et al., 2022) and systematic reviews (Cui et al., 2022; Bozday et al., 2020) on suicidal ideation in the context of psychiatric disorders, the findings of this study demonstrated that rTMS achieved satisfactory results in reducing depressive symptoms and suicidal ideation.

Conclusions: This clinical study indicates preliminary promise for the prevention of suicidal acts and underscores the need for more detailed and specific research on rTMS in the field of suicide.

Keywords: rTMS, neuromodulation, depression, suicide.

Suicidality during treatment with serotonin and norepinephrine reuptake inhibitorsI. Da Fonseca Pinto^{1*}, A. Elias de Sousa¹ and M. A. Vieira-Coelho^{1,2}¹Department of Psychiatry and Mental Health, University Hospital Center of São João and ²Department of Biomedicine - Pharmacology and Therapeutics Unit, Faculty of Medicine of Porto University, Porto, Portugal

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.396

Introduction: Treatment choice when prescribing antidepressants for major depressive disorder (MDD) is often influenced by safety and tolerability profiles. A transient increase in suicidality following antidepressant treatment initiation is a key concern. Although rare, its unpredictability and consequences make them a significant worry. In 2004, the U.S. Food and Drug Administration (FDA) issued a “black-box” warning regarding a potential increase in suicidality in adolescents receiving antidepressant treatment for depression that was later expanded to include both young adults and a broader range of antidepressants.

Objectives: The aim of this study is to evaluate the risk of increased suicidality during the treatment with serotonin and norepinephrine reuptake inhibitors (SNRIs) in young adults with MDD.

Methods: We conducted a non-systematic literature search on PubMed using the combination of MeSH terms ([Serotonin and Noradrenaline Reuptake Inhibitors] OR [Levomilnacipran] OR [Desvenlafaxine Succinate] OR [Venlafaxine Hydrochloride] OR [Duloxetine Hydrochloride]) AND [Suicide] AND [Young Adult], and the keywords [(“Serotonin and Noradrenaline Reuptake Inhibitors” OR “Levomilnacipran” OR “Desvenlafaxine” OR “Venlafaxine” OR “Duloxetine”) AND (“Suicide” OR “treatment-emergent suicidal ideation”) AND (“Young” OR “Youth”)].

Results: A total of 31 manuscripts were retrieved and 6 were selected, 3 original research and 3 non-systematic reviews of randomized clinical trials. Only studies written in English that provided information about suicidality with SNRIs in young adults with MDD. Globally, studies show that not only antidepressants decrease the risk of suicide attempt in depressed patients, but also there is no evidence of an increased suicidality in young adults treated with SNRIs.

Interestingly, one study showed that increasing suicidality could be related to side effects of the treatment, such as anxiety, agitation and irritability. The authors found that poor antidepressant response and greater severity of depression during follow-up were associated with treatment increasing suicidal ideation, as it was suggested in another study.

Another study reinforced that there may be an emotional component to the activating effects produced by some antidepressants that could explain their controversial association with rare cases of suicidal ideation and behaviour.

Conclusions: In conclusion, growing evidence shows that antidepressants overall decrease the risk of suicide attempt in depressed patients. Therefore, reducing antidepressant use over the FDA concerns about increased suicidal tendencies in young patients may actually increase suicide risks due to inadequate treatment of depression. Additional studies are essential to further confirm the importance of early treatment for depression.

EPP0194

Awareness of psychiatrists regarding physician suicide and prevention in developed and less developed countriesK. Kostyál^{1*}, J. H. Terje¹ and P. Z. Álmos¹¹Department of Psychiatry, Albert Szent-Györgyi Medical School, University of Szeged, Szeged, Hungary

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.397

Introduction: The World Health Organization estimates that more than 700,000 people worldwide die by suicide every year. Suicide is a complex issue, and occupation can be considered one of the risk factors. Data from the USA indicates that the suicide rate among doctors is higher compared to the general population. Among different specialties, general practitioners face the highest risk, followed by internal medicine, and then psychiatry. Apart from Anglo-Saxon countries, available data regarding physician suicide is limited; in some countries, the topic is considered taboo.

Objectives: The goal of this pilot study was to explore whether psychiatrists in different countries have access to suicide databases that include occupational information and to determine what prevention strategies and interventions are currently in use.

Methods: We distributed a short questionnaire to a group of psychiatrists (n=25) to assess the existing methods in their respective countries for collecting suicide data and implementing suicide prevention measures. The survey included both developed and less developed countries. Out of the 20 participating countries, 12 returned our questionnaire by the deadline. The final participating countries were Croatia, Czech Republic, Ethiopia, France, Germany, Hungary, Kazakhstan, Mexico, Qatar, Serbia, Sweden, and the UK.

Results: Based on our colleagues' reports, none of the responding countries have publicly available data on the number of physicians who committed suicide in the last three years. The risk of suicide and substance abuse among doctors is not systematically assessed or published in any of the participating countries. Kazakhstan is the only country where burnout, anxiety, and depression among doctors are regularly assessed. Ethiopia is the only participating country without a hotline for individuals in a suicide crisis. Mexico, Qatar, and Kazakhstan are the only countries with dedicated hotlines for health workers. Regarding preventive strategies, colleagues from Hungary, Serbia, Sweden, and Ethiopia did not report any strategies specifically aimed at preventing physician suicides. Germany and the UK were the two countries with more than one prevention strategy, both providing a free toolkit to identify and support at-risk populations. There are significant differences in the amount of mental health support that doctors receive in each country.

Conclusions: Psychiatrists are not aware of physician suicide data and the utilization of preventive strategies vary widely among the participating countries. There is no standard practice for screening doctors for suicide risk, burnout, anxiety, depression, substance abuse, or adequate data collection on suicide. Based on these findings, it would be necessary to include more countries in the sample and conduct a more detailed examination of the issue in the future.

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.398

Introduction: Suicide attempts (SA) leading to highly lethal consequences have been associated with heightened suicide planning (Barker et al., 2022), along with deficits in social cognition (Levi-Belz et al., 2022). Hypomentalizing, characterized by excessive uncertainty regarding mental states, may contribute to heightened social withdrawal and an increased risk of SA (Nestor & Sutherland, 2022). Although certain studies have identified a connection between hypomentalizing profiles and self-harm (Badoud et al., 2015), research into the lethality of SA remains limited.

Objectives: This study aimed to explore the association between hypomentalizing and SA lethality.

Methods: Our study encompassed a cohort of 1,371 patients who committed a SA. We conducted assessments of mentalizing using the RFQ-8 instrument, and evaluations of suicidal ideation and behavior employing the CSRSS questionnaire. Demographic and clinical characteristics were compared using the T-student and Chi-square tests. To investigate the relationship between hypomentalizing and the SA lethality, we employed logistic regression models.

Results: Descriptive data are presented in Table 1. Our results show that hypomentalizing do not predict a higher SA lethality. Additionally, hypomentalizing increased the risk of SA planning ($p \leq 0.001$, $B = -0.182$), and SA planning predicted a higher SA lethality (see Table 2).

Table 1. Means Comparison for low and high lethality (N=1371)

	Low lethality N=539	High lethality N=832	p value	Effect size
Age, mean (SD)	38.65 (15.65)	41.91 (15.37)	≤ 0.001	-0.209 ^a
Female sex, N (%)	392 (72.7)	571 (68.6)	0.116	0.044 ^b
Educational years, mean (SD)	12.45 (2.99)	12.43 (3.41)	0.890	0.0076 ^a
Employed, N (%)	220 (41.2)	332 (40)	0.692	0.012 ^b
Suicide Ideation, N (%)	475 (88.1)	742 (89.2)	0.541	0.016 ^b
Suicide Planning, N (%)	159 (39.2)	400 (58.1)	≤ 0.001	0.183 ^b
Number of attempts, mean (SD)	3.28 (5.48)	3.63 (5.74)	0.269	-0.169 ^a
RFQ, mean (SD)	4.68 (1.27)	4.56 (1.32)	0.087	0.095 ^a

Table 2. Logistic regression analyses for high SA lethality (N=1371).

	Univariate analysis		Multivariate analysis	
	OR	p value	OR	p value
Age	1.014 (1.007-1.021)	≤ 0.001	1.014 (1.005-1.022)	0.001
Female sex	0.820 (0.646-1.042)	0.105		
Educational years	0.998 (0.965-1.031)	0.890		
Employed	0.952 (0.763-1.187)	0.660		
Suicide ideation	1.111 (0.790-1.562)	0.545		
Suicide planning	2.150 (1.674-2.761)	≤ 0.001	2.183 (1.697-2.808)	≤ 0.001
Number SA	1.012 (0.990-1.034)	0.277		
RFQ	0.929 (0.854-1.011)	0.088		

Conclusions: While the association between hypomentalizing and high SA lethality was not significant, a discernible trend toward such relationship can be noted. Further studies examining the moderating effects of planning in the association between hypomentalizing and SA lethality are required.

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.399

Introduction: Childhood trauma is an important public health problem but there are limitations in our ability to measure childhood trauma. Early Trauma Inventory is a self-report instrument for the assessment of childhood trauma that is valid but simple to administer.

Objectives: We aimed to assess the frequency of childhood trauma in patients of a large sample of the Crisis Intervention and Psychiatric Ward in Budapest, Hungary.

Methods: Data from 279 patients referred to Péterfy Alexander Hospital, Crisis Intervention and Psychiatric Ward, Budapest, Hungary, were analyzed. Most participants were female ($n = 202$, 72.4%) between the ages of 17 and 86 ($M = 38.37$ yrs). Half of the participants were diagnosed with major depressive disorder ($n = 138$, 49.5%) or anxiety disorder ($n = 149$, 53.4%), while 47 of the participants suffered from bipolar disorder (16.8%). One hundred thirty-eight participants had at least one suicide attempt in

their life (49.5%). Childhood traumas were assessed by the Early Trauma Inventory– Self Report (ETI-SR), an instrument for the assessment of physical, emotional, and sexual abuse, as well as general traumas, which measures frequency, onset, emotional impact, and other variables. We assessed the most frequent traumas in the physical, emotional, and sexual abuse, as well as general trauma domains.

Results: Family mental illness ($n = 136$, 58.1%), witnessing violence ($n = 129$, 54.7%), divorce/separation of parents ($n = 114$, 48.3%), and observing death/serious injury of others ($n = 112$, 47.5%), were the most frequently experienced general traumas. Out of physical traumas, most of the participants experienced being slapped in the face ($n = 169$, 73.2%), being spanked with a hand ($n = 152$, 65.5%), being hit or spanked with an object ($n = 93$, 40.3%), and being pushed or shoved ($n = 81$, 33.4%). Among emotional traumas, being often put down or ridiculed ($n = 170$, 74.2%), the needs being failed to be understood by parents ($n = 164$, 72.7%), often shouted at or yelled at ($n = 154$, 67.5%), and being often ignored or made feel like they do not count ($n = 109$, 46.2%) were the most frequent. From the sexual abuse domain, being exposed to flashing ($n = 72$, 32.9%), being touched in intimate parts in an uncomfortable way ($n = 63$, 29.2%), being exposed to inappropriate comments about sex ($n = 61$, 28.5%), and being rubbed by someone's genitals ($n = 44$, 20.3%) were the most common. Further results will be presented at the conference.

Conclusions: It is already recognized and our study also confirms that childhood maltreatment, especially sexual abuse can lead to suicidal behaviour. The precise role of particular types of childhood maltreatment and the mediators of the relationship between childhood maltreatment and suicide is yet to be investigated in more details.

Comparison of Smartphone and internet addiction and Optical Coherence Tomography findings among University students

Y. S. Atan¹ and P. Güzel Özdemir^{2*}

¹Psychiatry and ²Yüzüncü Yıl University, Van, Türkiye

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.400

Introduction: Internet and smartphone use that reaches the level of addiction often leads to deterioration in the quality of life and functionality of individuals.

Objectives: In our study, we aimed to investigate possible differences in retinal nerve fiber layer (RNFL) thickness and central macular thickness obtained by optical coherence tomography in internet and smartphone addiction.

Methods: A total of 212 volunteer university students participated in our study. All participants were administered the Sociodemographic Information Form, Chen Internet Addiction Scale, Smartphone Addiction Scale-Short Form. Participants who completed the scales underwent routine eye examinations by experienced physicians in the ophthalmology outpatient clinic. Retinal nerve

fiber layer (RNFL) thickness and central macular thickness were measured by optical coherence tomography (OCT).

Results: In our study, internet addiction rate was 17% and smartphone addiction rate was 38.2%. RNFL thickness was found to be statistically significantly increased in the temporal superior and temporal inferior quadrants in those with internet addiction compared to healthy subjects ($p < 0.05$). In smartphone addiction, RNFL thickness was found to be statistically significantly increased in the temporal inferior quadrant compared to healthy subjects ($p < 0.05$). In the analyses comparing OCT measurements according to sex, it was found that nasal inferior ($p < 0.01$) and global ($p < 0.05$) quadrants in women and central macular thickness ($p < 0.01$) in men were statistically significantly increased.

The correlation analyses in our study revealed statistically significant positive correlations between internet addiction scale scores ($p < 0.01$) and smartphone addiction scale scores ($p < 0.01$), RNFL temporal superior quadrant thickness ($p < 0.01$); smartphone addiction scale scores and RNFL temporal superior quadrant thickness ($p < 0.05$).

Conclusions: Internet and smartphone addiction are seen considerable rates among university students. In OCT measurements, RNFL thickness was found to be increased in various quadrants in patients with addiction. In addition, RNFL thickness was found to be increased in all quadrants in female gender and central macular thickness was found to be increased in male gender. Correlation analysis revealed that internet addiction scale scores, smartphone addiction scale scores, and RNFL temporal superior quadrant thickness were positively correlated. In addition, there was a positive correlation between smartphone addiction scale scores, and RNFL temporal superior quadrant thickness

Alcoholism is the mental health issue that best predicts the mortality of individuals experiencing homelessness.

F. Calvo^{1*}, C. Giralt², X. Solench-Arco³, X. Carbonell⁴ and S. Font-Mayolas⁵

¹Departament de Pedagogia, Institut de Recerca sobre Qualitat de Vida;

²Institut Català de la Salut, Centre d'Atenció Primària Blanes 2;

³Universitat de Girona, Girona; ⁴FPCEE Blanquerna, Barcelona and

⁵Departament de Psicologia, Institut de Recerca sobre Qualitat de Vida, Girona, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.401

Introduction: The mortality rate among individuals experiencing homelessness tends to be premature and is linked to mental disorders and chronic diseases. In Spain, there is a significant gap in the study of mortality among individuals in situations of residential exclusion with real clinical data.

Objectives: This study aims to analyze mortality among individuals experiencing homelessness and its relationship with mental disorders and chronic diseases.

Methods: An observational and prospective longitudinal study was conducted on a cohort of 855 homeless individuals in the province of Girona over a 15-year period. Sociodemographic variables, mental health conditions, chronic diseases, and infections were analyzed, employing descriptive and inferential analyses. A binary

logistic regression model was created to establish explanatory relationships between mortality and associated variables.

Results: Among the participants, 87.7% were males with an average age of 53.03 years. A majority of 62.8% were foreign-born, mainly from Africa and Europe. It was identified that 40.8% had mental disorders, with substance dependencies (41.3%) and other disorders (36.4%) being the most prevalent. A total of 30.6% presented chronic diseases, notably hypertension (12.8%) and type 2 diabetes (10.9%). Furthermore, 22.3% had infections, with hepatitis C virus (8.7%) and HIV (4.7%) being the most common. During the follow-up period, 81 individuals (16.4%) passed away, with causes such as cancer (25%), suicide (21.7%), and heart conditions (11.7%).

The regression analysis demonstrated that age (OR = 0.915; 95% CI 0.884-0.947), alcohol addiction (OR = 2.354; 95% CI 1.486-3.731), and being born in Spain (OR = 2.906; 95% CI 1.594-5.299) were significantly associated with mortality in the homeless population.

Conclusions: This study highlights the high prevalence of mental disorders, chronic diseases, and infections among individuals experiencing homelessness. Mortality was associated with factors such as age, alcohol addiction, and place of birth. These findings underscore the importance of developing interventions aimed at enhancing the health and care of individuals experiencing homelessness, particularly within the immigrant population.

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.402

Introduction: Suicidal behaviors are frequently observed among patients with substance use disorder, including suicidal ideation (SI) (1). Alcohol use disorder (AUD) is one of the most prevalent addictions and may be related to suicidal behaviors (2,3). However, the association between AUD and SI requires a deeper analysis which includes several clinical features observed among AUD patients.

Objectives: To analyze the clinical characteristics and features associated with lifetime SI among patients who had AUD.

Methods: This is a cross-sectional study performed in an outpatient center for addiction treatment in patients seeking treatment who met the criteria for AUD between 01/01/2010 and 12/31/2021. Patients were evaluated with an ad-hoc questionnaire and the European addiction severity index (EuropASI). SI was evaluated by using the item for SI in EuropASI.

Results: From a potential sample of n=3729 patients, only n=1082 (73.8% males; mean age 42.82±12.51) met inclusion criteria and had data for the current analysis. Lifetime SI was present in 50.9% of the AUD patients. Several clinical features were related to SI,

including: sex differences, any type of lifetime abuse, polyconsumption, benzodiazepine use disorder, any psychiatric diagnosis aside of SUD, and higher addiction severity according to the EuropASI (See table)

Familiar	Yes	0.362±0.238	0.274±0.208	0.447±0.235	12.737	<0.001
	No					

Conclusions: SI among AUD patients is related to several clinical features which indicate a higher addiction severity, more polyconsumption, and a higher prevalence of psychiatric comorbidities. These findings may contribute to the understanding of suicidal behaviors in AUD patients but it is required further investigations, including longitudinal studies.

The Role of Personalization in Virtual Reality Exposure Therapy During the Treatment of Alcohol Use Disorder

V. J. A. Buwalda^{1,2*}, B. Jansen³, M. van Gisbergen³ and S. R. Rashnoodi³

¹Psychiatry, GGD, Amsterdam; ²Psychiatry, Novadic Kentron, Vught and ³Academy of AI, Games, and Media, BUas, Breda, Netherlands

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.403

Introduction: In Cue-Exposure-Therapy (CET), clients are exposed to triggers through objects, people and environments that arouse craving (Sinha et al. Neuropsychopharmacol. 2009;34 1198–1208). Virtual Reality Exposure therapy (VRET) is used to experience these triggers in a realistic, safe, and personalized way. VR has been used successfully in the treatment of psychiatric disorders. It has not yet been developed and sufficiently tested as an adjuvant in the clinical post-detoxification phase of treatment of alcohol use disorders (AUD) (e.g. Bordnick et al. Addict.Behav 2008;33 743-756; Hone-Blanchet et al. Front.Hum.Neurosci. 2014; 8(844) 1-15). Additionally, these treatment methods have been tested for effect, but not for effectiveness around different VR technologies (Ghita & Gutierrez-Maldonado. Addict.Behav 2018; 81 1-11;). This study focuses on VRET-Recovery to examine to what extent VR worlds could be personalized in an effective manner to help treat AUD as well as clarifying on the ways in which the VR worlds could be optimized to achieve its goal.

Objectives: The primary objectives of this study are to assess the necessity of personalization in VR environments for AUD treatment, identify the critical elements for personalization, and examine their impact on craving in AUD patients.

Methods: The study included 10 AUD patients diagnosed according to DSM-V criteria, aged between 18 and 65, who were in the final week of clinical detoxification at a large addiction clinic in The Netherlands. A controlled experiment was conducted using the Recovery 1.0 VR system on Samsung Gear VR and Samsung Galaxy S9. The experiment involved exposure to various VR scenes (CG and 360o), including a neutral setting, a bar scene, and a home situation, with the duration and sequence controlled by a therapist. Data collection consisted of pre- and post-exposure questionnaires, heart rate and blood pressure measurements, and interviews.

Results: Craving was remarkably low in the VR bar scene, primarily due to its unsociable context, limited alcohol visibility, and absence of peer pressure. Technical limitations, such as suboptimal resolution, also affected the feeling of presence. Positive results were

shown that craving was predominantly stimulated in the apartment scene, driven by the presence of alcohol-related visual cues and social elements, resembling relaxed drinking with others.

Conclusions: This study underscores that some degree of personalization is needed on all craving dimensions with clear preference was given to CG or 360°. The environments were dependent on the personal history and associations they represent to different levels of alcohol visibility (messy or clean), and types of drink (based on past drinking behavior), and different emotional contexts are needed (positive and negative).

The prevalence of self-injury in adolescence: a systematic review and meta-analysis

B. F. Farkas^{1*}, Z. K. Takács^{2,3}, N. Kollárovics¹ and J. Balázs^{4,5}

¹Doctoral School, Semmelweis University; ²Institute of Education, Eötvös Loránd University, Faculty of Education and Psychology, Budapest, Hungary; ³School of Health in Social Sciences, University of Edinburgh, Edinburgh, United Kingdom; ⁴Institute of Psychology, Department of Developmental and Clinical Child Psychology, Eötvös Loránd University, Faculty of Education and Psychology, Budapest, Hungary and ⁵Oslo New University College, Oslo, Norway

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.404

Introduction: Self-injurious behavior (SIB) among adolescents has become a hot topic in psychiatry. Despite the consensus that the prevalence of SIB is high, 26-22% among adolescence, there are conflicting results about whether it has increased in the 21st century and about the global distribution of the prevalence.

Objectives: The aim of the current study was to make a systematic search and meta-analysis of publications from the last 5 years on the prevalence of SIB in adolescents and to examine definitions and assessments of SIB, gender, continental, and year differences. The hypotheses were the following: 1) the prevalence of SIB did not change over time between the examined period for both girls and boys; 2) girls reported a higher prevalence of a history of SIB than boys.

Methods: The systematic search was made in June 2020. Six databases were used. The main search terms were “self-injurious behavior”, “prevalence” and “adolescence”. First the titles and abstracts of the relevant articles were checked, then the full texts were read and collected those papers that met the inclusion criteria. The inclusion criteria were the following: published between 01/01/2015, and 06/18/2020, focused on community sample, and written in English. Comprehensive Meta-Analysis software was used to conduct the analyses.

Results: In sum, a total of 97 articles were included in the meta-analysis with data from 439 818 participants. The overall average SIB prevalence was 16.0% in these studies. The first hypothesis was only partially confirmed. When all data that were published between 2015 and 2018 were considered, a significant increase was found in the prevalence of SIB between 1998 and 2018. However, when the analysis was restricted to the time frame between 2013 and 2018, no change in prevalence was found. The second

hypothesis was fulfilled, girls reported a significant higher prevalence than boys (19.4% and 12.9%, respectively). A significantly higher prevalence was found when suicidal intent was excluded (18.3%), than when it was not excluded (11.3%) from the definition of SIB. The largest prevalence was found when measurement instruments were used that had been validated for SIB (18.9%). A significantly higher SEB prevalence was found among Asian articles than those from other continents (19.5% and 14.7% respectively).

Conclusions: The current systematic review and meta-analysis draw attention to the high prevalence of SIB among adolescents, especially among girls and those living in Asia. It is important to address this behavior, in terms of prevention and intervention as well.

Experiences of commissioning mental health services for children and young people in England: qualitative study of commissioners' perspectives

S. P. Trethewey*, K. A. Allen, F. Matthews, A. Price and T. Newlove-Delgado

Children and Young People's Mental Health (ChYMe) research collaboration, University of Exeter, Exeter, United Kingdom

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.405

Introduction: Commissioners play a central role in coordinating and planning CAMHS. However, there is little research on their experiences and approaches to understanding the needs of their populations. An improved understanding is likely to benefit the translation of research into practice, by ensuring research outputs meet the needs of key stakeholders and in optimising the sharing and use of data to improve services.

Objectives: To better understand commissioners' experiences of commissioning child and adolescent mental health services (CAMHS) and the challenges they face.

Methods: Between May to June 2023, we conducted twelve individual, semi-structured interviews with Integrated Care Board commissioners of CAMHS across England. We analysed data using framework analysis; a qualitative analysis method which involves systematically charting and organising data using a framework to generate themes.

Results: We generated five core themes from the data: 1) 'Reflections on role' – how commissioners' roles are informed by their background and 'positioning' within the system in which they work, 2) 'Priorities and Tensions' – the wider context in which commissioners work and how this may present challenges, 3) 'Insights and evidence' – how commissioners develop an understanding of child mental health need and the different roles of quantitative and qualitative data, 4) 'Children's mental health in the limelight' – commissioners' perceptions of changes in child mental health in their populations, 5) 'Responding to need' – how commissioners are addressing the needs of their populations and the challenges they perceive.

Conclusions: CAMHS commissioners are negotiating a complex and changing political, social and economic environment with differing priorities and pressures. Commissioners draw heavily on insights from providers and their role is shifting towards managing relationships and bringing the system together. A key challenge is balancing investment in prevention/early intervention

versus specialist services needed by children with more severe and complex problems.

The effect of catastrophising on health-related quality of life in two chronic somatic illness groups among Hungarian adolescents

M. Klein^{1,2*}, S. Török³, Z. Papp³ and G. Kökönyei^{2,4,5}

¹Doctoral School of Psychology; ²Institute of Psychology, ELTE Eötvös Loránd University; ³Institute of Mental Health; ⁴NAP3.0-SE Neuropsychopharmacology Research Group, National Brain Research Program and ⁵Department of Pharmacodynamics, Faculty of Pharmacy, Semmelweis University, Budapest, Hungary

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.406

Introduction: Psychological factors, such as emotional regulation strategies, play a crucial role in the management and care of chronic somatic health conditions among adolescents. In the existing literature, catastrophising has been associated negatively with health-related quality of life in the context of chronic health conditions in general. However, there is limited knowledge about its role in specific illness types.

Objectives: We aimed to evaluate the impact of catastrophising on the health-related quality of life in two distinct illness groups: diabetes and oncology, within a Hungarian sample.

Methods: A cross-sectional study using self-report measures was carried out, involving a total of 273 adolescents (mean age: 14.72 years, SD: 1.82 years; 50.2% females) in the two paediatric samples. The diabetes group consisted of 171 participants, while the oncology group was comprised of 102 individuals. No significant differences were found between the two chronic condition groups in terms of gender ($\chi^2 = 116.51$; $p = 0.50$), or mean age ($F(-0.82; 0.77) = 1.66$; $p = 0.19$). The short-version of the Cognitive Emotion Regulation Questionnaire (CERQ-short) was used to assess the cognitive emotional regulation strategies of the children, specifically focusing on the catastrophising subscale. Health-related quality of life was measured using the 4.0 version of the PedsQL, which included subscales for Physical, Emotional, Social, and School Functioning.

Results: A Hayes-moderation analysis with an interaction effect was conducted, controlling for gender, age, and the duration of the illness. A significant interaction effect was observed between catastrophising and the illness groups, impacting School Functioning ($F(1, 243) = 4.17$; $p = 0.04$), Physical Functioning ($F(1, 245) = 4.67$; $p = 0.03$), Social Functioning ($F(1, 245) = 4.23$; $p = 0.04$), and Emotional Functioning ($F(1, 245) = 4.20$; $p = 0.04$). The association between catastrophising and health-related quality of life remained stronger in the oncology group.

Conclusions: Catastrophising appears to be a risk factor that affects the quality of life of children facing oncology illnesses. Therefore, addressing catastrophising in interventions tailored to this paediatric illness group may be beneficial.

Keywords: catastrophising, health-related quality of life, adolescents, chronic somatic

doi: 10.1192/j.eurpsy.2024.407

Introduction: One of the forms of early comprehensive care for children after severe brain injuries is inpatient habilitation/ rehabilitation. Children receive help from a team of medical, psychological and pedagogical specialists. The process of special education consists mainly in the development of cognitive interest, because it is the basis of socialization.

Objectives: To study cognitive activity in children who have suffered severe brain damage.

Methods: observation, pedagogical examination, psychiatric supervision.

Materials: 36 children aged 1.2-1.8 years during hospital treatment.

Results: According to the results of the pedagogical survey, three groups of children were identified.

Group 1 (11%): fixed gaze; emotional response to sound (smile); short-term eye tracking of an object; ability to touch an object and hold it for a short time; walking skill is formed.

Group 2 (33%): short-term gaze fixation; reaction to sound by involuntary hand movements; lack of eye tracking of an adult's face; lack of ability to touch or hold an object; walking skill is formed.

Group 3 (56%): lack of fixed gaze; reaction to sound by shouting and increased motor activity; lack of ability to touch or hold an object; lack of walking skills.

Conclusions: Indicative responses to an adult's voice and face, eye tracking of an object, sensorimotor activity, and so on. these are indicators that show whether a child has cognitive activity. The rehabilitation team can rely on these indicators when choosing treatment and the content of the special educational process.

Key words: early intervention, toddlers, organic damage of central nervous system, rehabilitation/ habilitation

Adaptation of the brief psychoeducational intervention programme (BREF) for carers of patients with eating disorders

E. Scanferla^{1*}, J. de Salle¹ and P. GORWOOD¹

¹GHU Paris psychiatrie et neurosciences, Paris, France

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.408

Introduction: Even though international guidelines suggest that psychoeducation for carers should be provided systematically, it

remains insufficiently available in psychiatry (1), including for eating disorders (EDs). The complicated interplay of factors contributing to the maintenance of EDs, including family/carer influences, highlights the importance of carer interventions within ED treatment (2). Carer interventions demonstrate positive outcomes for carers themselves, though are also hypothesised to benefit the patient indirectly. The BREF programme is a short, early and systematic single-family psycho-educational programme. The BREF programme is already proven to be effective for other mental disorders (3)

Objectives: The aim of this study is to adapt the BREF programme to the specific needs of carers of patients eating disorders (ED). The main objective was to identify the issues in the experience of the disorder that are most important to carers and which should be the focus of the BREF programme for carers of patients with eating disorders.

Methods: Twenty-eight topics relating to difficulties commonly encountered by carers of patients with eating disorders were identified by a group including mental health professionals with expertise in these disorders, patients and their relatives. The topics tested are illustrated by 2 decks of cards presented to the participants; the first concerns the problems frequently encountered by users living with ED and the other the problems frequently encountered by their carers. The 2 decks were tested by the participants to the first 15 sessions of the BREF ED programme run from January to July 2023 as part of the pilot conducted in a university-hospital department specialised in eating disorders.

Results: 30 participants participated in the study.

The 10 most frequently selected topics relating to patient problems were, in descending order: relative's fear and anxiety; relative's false-self functioning; ambivalence towards care; dysmorphophobia; food restrictions; relative's hyperactivity; eating disorders; denial of symptoms; perfectionism; malnutrition. The 10 most frequently selected topics concerning the issues of carers were: social withdrawal; difficulty navigating care; fatigue/helplessness; disruption to family life as a result of the illness; guilt; right attitude to have with the ill relative; fear for your loved one's future; fragility of the relative; not knowing/understanding the care their relative is receiving; cost of care and food expenses.

Conclusions: The priority topics highlighted in this study helped to identify relevant content for the BREF programme adapted to the context of eating disorders. This programme appears to be a promising way of responding to the concerns and information needs of carers of patients with ED. In this regard, it addresses a major shortcoming in the organisation of mental health services.

EPP0212

Evaluation of the effectiveness of psychosocial rehabilitation: an innovative approach based on the analytic hierarchy process

V. Mitikhin^{1*} and T. Solokhina¹

¹Mental Health Research Centre, Moscow, Russian Federation

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.409

Introduction: In psychosocial rehabilitation (PSR), rank scales are widely used to assess the severity of functional disorders in patients. The main problem of evaluating the effectiveness of PSR is related

to the methods of processing data obtained using psychometric scales used to evaluate the effectiveness of interventions within PSR. The proof of the non-numerical nature of ranks was obtained by J. Pfanagl (1968). Incorrect processing of rank information obtained in the framework of psychosocial research leads to contradictions in the assessment of the patient's condition. Consequently, rank processing does not allow classical mathematical operations (summation, average), which makes it impossible to correctly estimate the effectiveness of PSR numerically.

Objectives: Development of algorithms for numerical evaluation of PSR efficiency based on rank information processing using the analytic hierarchy process (AHP) [1].

Methods: Clinical, psychometric, AHP algorithms

Results: The analysis of the problems of assessing the patient's conditions on the basis of categorical and psychometric (rank) scales and subscales shows that these problems can be presented in the form of appropriate hierarchies, the structure of which must be taken into account when processing the initial information.

According to the results of the analysis of the data of preliminary studies, the main areas of impaired functioning of patients affecting the evaluation of the effectiveness of PSR have been identified. Rank estimates of changes in the relevant areas of the patient's dysfunction after the PSR program compared to the initial level are the basis for the conclusion about the effectiveness of the PSR components. Algorithms of the AHP normative approach were used to translate rank information into numerical information [2]. The weight of the areas of the patient's functioning disorders was used in the formation of integral estimates of the effectiveness of PSR.

The fundamental difference between AHP-based assessments and rank assessments is due to the fact that numerical estimates of the weight of the criteria and the corresponding changes in the patient's condition are obtained, which depend on the qualifications of specialists, the characteristics of the scales used to measure violations in the relevant areas and the procedures of the PSR.

Conclusions: Obtaining the results of processing rank information in a numerical scale allows to obtain the correct integration of the patient's personal characteristics when considering PSR procedures and to obtain correct prognostic models of the patient's condition. 1. HERV-E λ 4-1 activation in peripheral blood mononuclear cells of the recurrent depression patients under the influence of human recombinant IL-1 β

E. Markova^{1*}, I. Goldina¹ and B. Goldin²

¹Neuroimmunology Lab, State Research Institute of Fundamental and Clinical Immunology and ²Novosibirsk State Medical University, Novosibirsk, Russian Federation

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.411

Introduction: Mental disorders represent complex phenotypes and are the leading causes of global disease burden. Human endogenous

retroviruses (HERVs) are ancient retroviral DNA sequences established into germline. Their tight regulation is mainly achieved by epigenetic mechanisms, which can be altered by environmental factors - viral infections, inflammation, leading to HERV activation. The aberrant expression of HERVs associates with neurological diseases and mood disorders. We showed earlier that HERV-E λ 4-1 activation is associated with the recurrent depression stage of exacerbation and are accompanied by a pronounced increase in the proinflammatory activity of the peripheral blood mononuclear cells (PBMC).

Objectives: The purpose of the study was to evaluate the activity of HERV-E λ 4-1 on PBMCs of patients with recurrent depression in remission, including under the influence of recombinant human IL-1 β .

Methods: The study included 30 patients with an established diagnosis of recurrent depression (F 33.0) aged 26–45 years. PBMC were isolated using the Ficoll density gradient method and further cultured in the presence or absence of 1 mkg/ml of recombinant human IL-1 β for 24 hours. HERV-E λ 4 – 1 env gene expression was determined by the PCR. Cells proliferative activity was determined by H³-thymidine incorporation. Cytokines content in culture supernatants was assessed by ELISA.

Results: It was shown that in all samples of PBMC cultured without IL-1 β the HERV-E λ 4 – 1 env expression was not determined. After the PBMC cocultivation with recombinant human IL-1 β , HERV-E λ 4 – 1 env gene expression was determined in 86,7% of cases. The HERV-E λ 4-1 activation in PBMC after IL-1 β influence was accompanied by increased cells proliferative activity and production of IL-1 β , IL-6.

Conclusions: Our data indicate that the HERV-E λ 4 – 1 env expression in PBMC of recurrent depression patients in the stage of remission induced by the influence of proinflammatory cytokines, such as IL-1 β . This mechanism may be one of the possible regulators of HERV-E λ 4 – 1 activation in recurrent depression.

Depression and Medierranean diet: analysis of the PREDIDEP randomised trial

B. M. Cabrera Suárez^{1*}, A. Sánchez Villegas², J. L. Hernández Fleta¹, P. Molero Santos² and J. T. R. Sosa¹

¹Hopsital Universitario de Gran Canaria Dr. Negrín, Las Palmas de Gran Canaria and ²Universidad Pública de Navarra, Navarra, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2024.412

Introduction: Unipolar depression is a growing global Public Health challenge. During last years, life factors such as diet, have been identified as a target for the development of adjunctive treatment that could reduce the rates of depression. The Mediterranean Diet (MD) is one of the most studied dietary factors that has been inversely associated with depression (Rahe et al. Eur J Nutr. 2014;53:997–1013). The PREDIDEP study is an ongoing secondary prevention trial aimed at assessing the effect of a MD enriched with extra virgin olive oil (EVOO) on depression recurrence (Sánchez-Villegas et al. BMC Psychiatry. 2019 Feb 11;19(1):63).

Objectives: This study aims to assess the effectiveness of a remote Mediterranean diet–based nutritional intervention in the context of a trial of depression.

Methods: The PREDIDEP study is a 2-year multicenter, randomized, single-blinded trial designed to analyse the effect of the MD enriched with extra virgin olive oil (EVOO) on the prevention of depression recurrence. The inervention group received phone contacts with dietist and had access to web-based information, and the control group had usual care for depressed patients. The 14-item MD Adherence Screener (MEDAS) questionnaire and a semiquantitative food frequency questionnaire (FFQ) were collected by dietitians at baseline and at 1-year and 2-year of follow-up. We used mixed effects linear models to assess changes in nutritional variables according to the group of intervention. The trial was registered at ClinicalTrials.gov NCT03081065.

Results: We observed that participants in the MD group increased their adherence to MD (between-group difference: 2.50; 95% CI 1.88-3.12; p<0.001) after one and two years (between-group difference: 2.57; 95% CI 1.93-3.22; p<0.001) of intervention compared with control group.

MEDAS questionnaire	Control, mean (95% CI)	Intervention, mean (95% CI)	Between group difference, mean (95% CI)	P value
Baseline	6.96 (6.54-7.39)	7 (6.63-7.39)	N/A	N/A
1 year	7.2 (6.82-7.58)	9.74 (9.3-10.18)	N/A	N/A
1-year change	0.23 (-0.19-0.65)	2.74 (2.28-3.19)	2.50 (1.88-3.12)	<0.001
2 years	7.06 (6.66-7.46)	9.68 (9.28-10.07)	N/A	N/A
2-years change	0.10 (-0.38-0.58)	2.67 (2.24-3.1)	2.57 (1.93-3.22)	<0.001

Calculated using mixed-effect models with center as random factor.
P value between group intervention difference.
N/A: not applicable.
MEDAS: Mediterranean Diet Adherence Screener

Conclusions: We found that this multifaceted remote nutritional intervention is a useful tool kit to maintain the quality of the diet according to the goals of the MD among patients at risk of depression.

doi: 10.1192/j.eurpsy.2024.413

Introduction: Adolescence is a period marked by highest vulnerability to the onset of depression, with profound implications for adult health. Neuroimaging studies have revealed considerable atrophy in brain structure in these patients with depression. Of particular importance are regions responsible for cognitive control, reward, and self-referential processing. However, the causal structural networks underpinning brain region atrophies in adolescents with depression remain unclear.

Objectives: This study aimed to investigate the temporal course and causal relationships of gray matter atrophy within the brains of adolescents with depression.

Methods: We analyzed T1-weighted structural images using voxel-based morphometry in first-episode adolescent patients with depression ($n=80$, 22 males; age = 15.57 ± 1.78) and age, gender matched healthy controls ($n=82$, 25 males; age = 16.11 ± 2.76) to identify the disease stage-specific gray matter abnormalities. Then, with granger causality analysis, we arranged the patients' illness duration chronologically to construct the causal structural covariance networks that investigated the causal relationships of those atypical structures.

Results: Compared to controls, smaller volumes in ventral medial prefrontal cortex (vmPFC), dorsal anterior cingulate cortex (dACC), middle cingulate cortex (MCC) and insula areas were identified in patients with less than 1 year illness duration, and further progressed to the subgenual ACC, regions of default, frontoparietal networks in longer duration. Causal network results revealed that dACC, vmPFC, MCC and insula were prominent nodes projecting exerted positive causal effects to regions of the default mode and frontoparietal networks. The dACC, vmPFC and insula also had positive projections to the reward network, which included mainly the thalamus, caudate and putamen, while MCC also exerted a positive causal effect on the insula and thalamus.

Conclusions: These findings revealed the progression of structural atrophy in adolescent patients with depression and demonstrated the causal relationships between regions involving cognitive control, reward and self-referential processes.

Prevalence And Risk Factors Of Eating Disorders In The Tunisian General Population

M. Turki, A. Hadj Ali*, G. Chakchouk, S. Ellouze, N. Halouani and J. Aloulou

Psychiatric department B, Hedi Chaker University Hospital, Sfax, Tunisia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.414

Introduction: Eating disorders (ED) negatively affect physical, mental, and social well-being. The exact psychopathology of ED is still unknown, with research suggesting the interplay of a combination of factors.

Objectives: The aim of our study was to estimate the prevalence of ED in the Tunisian general population, and to identify associated risk factors.

Methods: We conducted a cross-sectional, descriptive and analytical study among Facebook group members, using an online

questionnaire, over the period from February 17, 2023 to May 26, 2023. All respondents over the age of 18 were included in the study. All participants filled a socio-demographic questionnaire. The Eating Attitudes Test (EAT-26) was used to screen for those at risk of eating disorders.

Results: A total of 528 responses were included in the study. The mean age of the sample was 33.3 ± 11.95 years. The subjects were unmarried in 63.4% of cases, of low socio-economic level in 19.5%, with a university education in 75.2% and with a regular occupation in 56.1% of cases.

The mean EAT-26 score was 12.36 ± 10.34 . according to this scale, 12.3% of our population were at high risk of developing an ED.

In a multivariate analysis, the female gender ($p = 0.006$), the low economic status ($p = 0.012$), a psychiatric comorbidity ($p < 0.001$), and physical activity ($p = 0.037$) were strongly associated with ED.

Conclusions: This study highlighted the magnitude of the risk of disordered eating attitudes in the Tunisian population and the need for programs to prevent and control these disorders.

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.415

Introduction: In recent decades, there has been extensive research on the association between Autism Spectrum Disorders (ASD) and Eating Disorders (ED), as well as the existence of sensory sensitivity alterations in both diagnostic groups.

Objectives: The present study aimed to examine the presence of autistic traits in a sample of adult women diagnosed with different ED, and the concurrent role of autistic traits and sensory sensitivity in both their eating disorder symptomatology and their autism-related eating behaviours.

Methods: Seventy-five women with different ED completed the Eating Attitude Test (EAT-26), the Autism Quotient (AQ), the Ritvo Autism Asperger Diagnostic Scale-Revised (RAADS-R), the Sensory Perception Quotient - Short Form 35 item (SPQ-SF35) and the Swedish Eating Assessment for Autism Spectrum Disorders (SWEAA), which investigates specific eating behaviour related to autism.

Results: 12% of the sample scored above the cut-off at both the AQ and the RAADS-R, while 68% scored above the cut-off at the RAADS-R only. We found an association between: i) hypersensitivity in the taste domain and ED severity and autistic-like eating behaviours; ii) hypersensitivity in the vision domain and

autistic-like eating behaviours; iii) higher autistic traits and ED severity and autistic-like eating behaviours.

Conclusions: This study confirms the presence of autistic traits in patients with ED and underscores the significance of conducting additional systematical investigations on this topic across all diagnostic categories of ED. It is becoming progressively evident that identifying and measuring the levels of autistic traits in patients with ASD is crucial not only for a better understanding of the causes of these disorders, but also because it would help to tailor specific therapeutic interventions, especially considering the cognitive flexibility issues presented by these patients and the socio-emotional challenges they face. Additionally, this study has laid the foundation for further insights into the relationship between sensory sensitivity and dysfunctional eating behaviours typical of ED and ASD.

Features of attachment in women with eating disorders

M. N. Samoilova¹ and N. D. Semenova^{2*}

¹Institute of Clinical Psychology and Social Work, Pirogov Russian National Research Medical University and ²Moscow Research Institute of Psychiatry – a branch of the V. Serbsky National Medical Research Centre for Psychiatry and Narcology of the Ministry of Health of the Russian Federation, Moscow, Russian Federation

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.416

Introduction: Eating disorders (ED), especially anorexia nervosa, are known to be the most associated with high mortality rates among psychiatric conditions. In many cases, they are resistant to treatment because patients tend to show low compliance, concealing symptoms from doctors. Body image concerns may affect communication and hinder building connections with people, making patients feel alienated.

Objectives: The study aimed to examine the specific characteristics of attachment styles and evaluate their interrelationships with psychological features in women with eating disorders.

Methods: A total of 52 women with a clinical diagnosis of eating disorder (namely, 26 with anorexia nervosa (AN) and 26 with bulimia nervosa (BN)) and 43 healthy controls were included in the study. All participants completed the following psychometric scales: Relationship Questionnaire (RQ), Experience in Close Relationships (ECR), Relationship Profile Test (RPT), and Multidimensional Perfectionism Scale (MPS). The Kolmogorov-Smirnov normality test was applied, confirming a non-normal distribution of the sample; therefore, the non-parametric Mann-Whitney test and Spearman statistics were administered.

Results: The results show a marked difference between the two groups. In the ED patients' group, only 15% of respondents classified their attachment style as secure, compared to 37% of the participants in the control group. 85% of women in the ED group identified themselves as having one of the insecure attachment styles (anxious, avoidant, or disorganized). The level of relationship anxiety and the rate of relationship avoidance in the respondents of

the ED group is 27% and 19% higher, respectively, compared to the control group. Likewise, the level of destructive interpersonal overdependence is 20% higher in the ED patients' group respondents, whereas healthy dependence is 18% lower compared to the controls. The respondents with ED showed 18% higher self-oriented perfectionism and 39% higher socially prescribed perfectionism. A direct correlation between avoidant attachment style and destructive interpersonal overdependence was found in women with diagnoses belonging to the ED group. When comparing AN and BN patients, no statistically significant differences in the distribution and peculiarities of attachment styles in the anorexia and bulimia groups were found.

Conclusions: The study has proved the hypothesis that insecure attachment is more common among women with eating disorders than those without the diagnosis. We suggest a more profound scientific elaboration of the attachment in ED patients to increase the level of compliance of this group of patients, to improve the effectiveness and reduce the duration of treatment, and develop new therapeutic approaches to cure this disease.

doi: 10.1192/j.eurpsy.2024.417

Introduction: Orthorexia nervosa is defined as an unhealthy obsession with eating healthy food. Recent studies currently demonstrated that students in health-oriented academic programs, highly focused on nutrition and physical exercise, are more prone to develop orthorexia nervosa than students in other educational areas.

Objectives: Determine the prevalence of orthorexia nervosa in medical students and identify associated factors.

Methods: We conducted a cross-sectional, descriptive, and analytical study in the faculty of medicine of Sfax in Tunisia, between February and April 2023. We used ORTO-15 for the assessment of orthorexia.

Results: The research has enrolled 220 students. Their mean age was 21.40 ± 1.68 years, with female predominance (70%). The mean Body mass index (BMI) was 22.46 ± 4.15 kg/m². The prevalence of overweight (BMI ≥ 25 kg/m²) and obesity (BMI ≥ 30 kg/m²) were respectively 19.5% and 3.6%. Over a third of students (34.1%) were using means of weight control, of which the diet represented 62.66% of cases. The participants had consulted a nutritionist in 11.4% of cases. The ORTO-15 mean total score was 36.88 ± 6.76 , with a mean score of 12.95 ± 2.69 for cognitive dimension, 13.31 ± 2.70 for clinical dimension, and 10.61 ± 2.52 for emotional dimension. A total of 60% of participants had a score under the threshold.

Orthorexia was significantly associated with female gender ($p < 10^{-3}$), overweight or obesity ($p = 0.037$), the use of weight control methods

($p < 10^{-3}$), following a diet ($p < 10^{-3}$), and consulting a nutritionist ($p = 0.009$).

Conclusions: In our study, orthorexia seems to be quite widespread among medical students, particularly females, who are overweight or obese, and who use weight control methods.

Efficacy of transcranial direct current stimulation for controlling of food craving in subjects with overweight or obesity

J. Kim^{1*} and S. Yang¹

¹Psychiatry, Daegu Catholic University School of Medicine, Daegu, Korea, Republic Of

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.418

Introduction: This study investigates the effects of transcranial direct current stimulation (tDCS) on food craving improvement and changes in brain function associated with craving in overweight and obese subjects.

Objectives: Food craving disregards the homeostatic mechanisms related to appetite and nullifies the rewarding effects of food, directly contributing to body weight and eventually leading to obesity. In this study, we aim to explore the effects of transcranial direct current stimulation (tDCS) on food craving improvement and changes in brain function associated with craving by conducting a total of 10 sessions of tDCS over a period of 2 weeks on overweight and obese subjects.

Methods: A total of 86 patients who were overweight or obese (BMI ≥ 23 kg/m²) during the study period were included. The tDCS montage involved placing the anode over the left and the cathode over the right DLPFC. Weight, BMI, neuropsychological variables, and food craving-related variables were assessed. We measured absolute and relative EEG power in 19 channels and analyzed QEEG according to the following frequency ranges: delta (1–4 Hz), theta (4–8 Hz), alpha (8–12 Hz), beta (12–25 Hz), high beta (25–30 Hz), and gamma (30–80 Hz).

Results: After the application of tDCS, there was no significant reduction observed in weight and BMI. However, all measures related to food and eating showed a decrease in the intensity of cravings, and there was also a significant reduction in depression, anxiety, and perceived stress. In quantitative EEG analysis, an increase in theta waves was observed in the left frontal area (F7 and F3), an increase in alpha waves in the right parietal area (P4), and a decrease in beta waves in the frontal area (FP2) and occipital area (O1).

Conclusions: This study investigated the effects of tDCS on food craving in overweight and obese individuals, and it was found that there were improvements in psychological factors such as depression and anxiety. Additionally, using quantitative EEG, neurophysiological changes were observed, including an increase in theta waves and a decrease in beta waves.

The social determinants of depression: social support, loneliness, and the impact of the COVID-19 pandemic

A. Gabarrell-Pascuet*, J. M. Haro and J. Domènech-Abella

Sant Joan de Déu Research Institute, Sant Boi de Llobregat, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.419

Introduction: The COVID-19 pandemic involved stringent social restrictions, a surge in mortality, and significant economic consequences, affecting age groups differently and leading to increases in loneliness and mental health problems, particularly depression, which was already very common before the pandemic.

Objectives: Analyse changes and related factors of the relationship between loneliness and depression by age group from (1) before to the COVID-19 outbreak, (2) during the pandemic, and (3) after the last state of emergency. Moreover, we aim to (4) evaluate the effect of social support to alleviate feelings of loneliness and improve the course of depression.

Methods: We used data from three different cohorts, all representative of the Spanish adult population. (1) We longitudinally analysed the association between loneliness and depression with a sample interviewed before ($N = 1,880$) and during ($N = 1,103$) the pandemic. We used mixed-models to study changes in major depressive disorder (MDD) by age group and regression models to quantify the association between age and potential mediating effects. (2) We analysed data of 2,000 adults during the pandemic. Several regression models were constructed to assess the impact of pre-pandemic mental disorders on the main association by age group. (3) Out of those 2,000 participants, 1,300 were interviewed 9 months later, to determine group-based loneliness trajectories and its associated risk factors. (4) We analysed the relationship between loneliness, social support, and MDD over a 7-year period ($N = 404$ individuals aged 50+ having MDD). We tested cross-lagged panel models using structural equation modelling.

Results: During the pandemic the probability of having MDD increased significantly among younger individuals, and was partly explained by loneliness, low resilience, and worsened economic situation. Loneliness was associated with more depressive symptoms, and this association was stronger in younger adults without pre-pandemic mental disorders and in older adults with them. At the end of pandemic, three courses of loneliness were detected: invariant low loneliness (42.6%), decreasing medium loneliness (51.5%), and fairly invariant high loneliness (5.9%). Risk factors for worse trajectories were being younger, female, not married, and, notably, having pre-pandemic mental disorders. Among individuals with depression prior to the pandemic, lower social support predicted higher subsequent levels of loneliness, resulting in an increase in MDD recurrence.

Conclusions: Strategies to decrease the impact of loneliness on depressive symptoms should consider individuals' mental health background, address social determinants, and adopt an age-driven perspective.

Impact of intrinsic and extrinsic religiosity on cannabis use in adolescents: A structural equation modelling approach to data from the National Survey on Drug Use and Health (NSDUH) 2015–2019

G. Carrà^{1,2}, F. Bartoli¹, A. Canestro¹, C. A. Capogrosso^{1*}, P. E. Bebbington² and C. Crocamo¹

¹Department of Medicine and Surgery, University of Milano-Bicocca, Monza, Italy and ²Division of Psychiatry, University College London, London, United Kingdom

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.420

Introduction: Religiosity is believed to be a factor that may reduce the risk of addiction and substance use both in adults and in young people. It is a complex construct that is neither measurable nor objectifiable, thus it must be estimated from proxy characteristics. For this purpose, researchers differentiate between subjective religiosity (i.e., individual religious experience) and extrinsic religiosity, that is, participation to religious services (extrinsic-personal subtype) or to social activities consistent with religion-based principles (extrinsic-social subtype).

Objectives: This work aimed at exploring the role of different facets of religiosity – intrinsic (subjective), extrinsic-personal (service attendance), and extrinsic-social (church-based social activities) – in terms of deterring cannabis use among adolescents.

Methods: Aggregated data of NSDUH (2015-2019) on 68,263 adolescents between 12 and 17 years of age were analysed using a structural equation modelling (SEM) to determine pathways of intrinsic and extrinsic components of religiosity in cannabis use. Several covariates were considered in the analyses, including comorbid depression and civil volunteering activities.

Results: About 15% of participants admitted cannabis use in the previous year. Intrinsic and extrinsic-personal religiosity was reported by 66% and 25% of the sample, respectively. A percentage of fifty-seven of participants were involved in at least one faith-based activity, while 74% reported participation in secular community activities. Both intrinsic and extrinsic-personal religious components were likely to reduce cannabis use at the SEM regression model analysis controlling for putative confounders (cannabis use coeff.: -0.065, $p=0.001$; coeff.: -0.176, $p<0.001$, respectively). Considering the joint contribution of relevant covariates (community-based activities, lifetime MDE, sex, and poverty status), the outputs were similar. Cannabis use was not influenced by extrinsic-social component of religiosity, even though the involvement in non-faith based volunteering activities was protectively associated.

Conclusions: From a policy-makers perspective, the reduction of cannabis use among young people may be obtained by supporting secular volunteering programs, which seem to be a cost-effective strategy. Moreover, whilst promoting religiosity is beyond the scope of any preventive programs, religious practices should be considered relevant protective factors.

Evaluation of Problematic Technology Use in Preschool Children

M. Tepetaş^{1*}, A. Ünsal¹ and G. S. Tepetaş Cengiz²

¹Medical Faculty, Eskişehir Osmangazi University, Eskişehir and

²Mehmet Tanrıkulu Health Services Vocational School, Bolu Abant İzzet Baysal University, Bolu, Türkiye

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.421

Introduction: Individuals have difficulty controlling their use of technology, it constantly on their minds when they don't have access to it, it takes up too much time in their daily lives, and these situations negatively impact daily life are referred to as "problematic technology use". The widespread use of technology from a young age is leading to an increase in the number of children with problematic technology use. Problematic technology use negatively impacts children's development, especially their mental development. Important risk factors for problematic technology use include a long stay at home, a previous traumatic event, and low life satisfaction. In addition, it is possible that problematic technology use is more common in children with low social competence and low behavioral levels.

Objectives: The aim is to determine the level of problematic technology use in 48-72-month-old children receiving preschool education, to examine some variables thought to be related to it, and to assess their level of social competence and behavior.

Methods: The study was a cross-sectional research conducted between January and September 2023 among the parents of children studying in Eskişehir and Bolu. The study group consisted of the parents of 883 children. In our study, the Problematic Technology Use Scale for Young Children (PTUS-YC) and the Social Competence And Behavior Evaluation-30 Scale (SCBE-30) were used.

Results: The age of the parents ranged from 20 to 54 years (mean: 35.5 ± 4.8), 740 of them were women. The average age of the children was 63.2 ± 7.3 months and 442 of them were boys. The scores obtained from PTUS-YC ranged from 26-104 and the mean was 55.1 ± 14.9 points. Among the variables associated with problematic use of technology, those related to parents were place of residence, age and marital status, while those related to children were time spent at home with technological devices, parental control over content used, adaptation to school and ownership of a technological device. There is a weak positive correlation between children's scores on the PTUS-YC and the SCBE-30 ($r:0.336$; $p < 0.05$).

Conclusions: It can be said that problematic technology use in our study was at a moderate level. As the level of social competence and behavior increase, problematic technology use decreases. It is recommended to limit the time children spend with technological devices, ensure that parents control the content they use on technological devices, support their adaptation to school, and work on gaining social competence and positive behavior.

The Kids are not alright - When did we start getting more more distressed?N. Glozier^{1*}, R. Morris¹, F. Botha² and P. Butterworth³¹University of Sydney, Sydney; ²University of Melbourne, Melbourne and ³Australian National University, Canberra, Australia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.422

Introduction: Much has been made of the decline in population mental health over COVID but most studies show this just exacerbated a long term trend. This has predominantly been attributed to changes in adolescent mental health over the past decade but there has been little evaluation of whether this post Millenium cohort was the first to demonstrate such a decline.

Objectives: This study investigates to what extent mental health differs in people born in different decades – i.e., possible birth cohort differences in the mental health of the population over the past two decades. To remove the linear dependency and identify any differences in trends between cohorts, we model mental health for each cohort as a nonlinear smooth function of age in an age-cohort model.

Methods: This analysis draws on 20 annual waves of the Household Income and Labour Dynamic in Australia (HILDA) survey, is a nationally representative household panel that commenced in 2001 with 13,969 participants. The birth cohort of each person was defined by the decade of birth year (1940s, 1950s, etc). Mental ill health was assessed with the MHI5 from the SF36, in each wave and K10 from alternate waves. We estimate and compare penalized smooth trends in mental health for each cohort using restricted maximum likelihood (REML) using generalized additive mixed modelling (GAMM). Cohort effects are captured by directly estimating the differences between the smooth age trends of adjacent cohorts.

Results: Later cohorts were more likely to have poorer mental health, higher distress, more likely to be single and unemployed, and less likely to be chronically ill or disabled. Mental health was worse for younger age-groups in each survey year, and this discrepancy is much greater in more recent surveys - consistent with a birth cohort effect. Millennials (those born in the early 1990s) had a lower score at the same age as earlier generations, and the later cohorts do not show the age-related improvement seen in other earlier cohorts as they aged. At age 30 the average MHI-5 score of those born in the 1990s was 67, compared to 72.5 and 74 for people born in the 1980s and 1970s.

Conclusions: The deterioration in mental health over time which has been reported in large cross-sectional surveys, likely reflects cohort-specific effects related to the experiences of young people born in the Millennial generation and, to a lesser extent, those from the immediately prior cohort born in the 1980s. We need to understand whether later cohorts are less resilient to similar risk factors experienced by earlier cohorts or whether they experience more and/or a greater severity of risks for mental ill-health. Such evidence is critical if the deteriorating pattern of mental health is to be arrested.

The complex dynamics of therapeutic leave in Psychiatry

Â. S. Pinto*, T. P. Soares and A. Marques

Department of Psychiatry, Vila Nova de Gaia/Espinho Hospital Center, Vila Nova de Gaia, Portugal

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.423

Introduction: Therapeutic leave, the temporary and authorized absence of a patient from a psychiatric inpatient facility, is a practice rooted in the shift of mental illness towards more humane and recovery oriented care. This shift began to gain momentum in the mid-20th century, with the deinstitutionalization movement, which sought to treat psychiatric patients in less restrictive environments and facilitate their integration into the community. Today, therapeutic leave remains relevant in general psychiatry inpatient treatment facilities, and on an international level. It's additionally used as a way to assess the progress and the stability of the patient outside the controlled environment that is the hospital, and to provide a gradual transition back into independent living and potential stressors of the outside world. But it is administered more on tradition and perceived benefits than on solid scientific grounding, reflecting a practice guided by clinical experience rather than empirical data or guidelines.

Objectives: Our review aims to evaluate the existing body of research on therapeutic leave in general psychiatry inpatient units. We intend to identify the outcomes that have been studied, and assess the extent and nature of their impact.

Methods: This scoping review was conducted through a comprehensive search of academic databases, including Google Scholar, PubMed, Embase, Cochrane Library, and PsycINFO. Search terms were carefully selected to capture relevant publications, and the results were screened for their pertinence to the review's aims. Studies focused on forensic settings were excluded.

Results: The literature on therapeutic leave is notably limited, and the prevalence of its utilization in clinical practice remains unclear. Scientific publications primarily address readmission rates, with two indicating an increased risk in patients granted leave during their inpatient treatment. However, one report suggested a potential reduction. Length of stay (LOS) was negatively impacted, with prolonged hospitalization in these patients shown in one report. Post-discharge emergency room visits seem unaffected. A rise in readmission rates and LOS typically suggests higher subsequent healthcare costs. However, findings from another study contradict this expectation, with reduction of costs post-initial inpatient treatment. The literature also explores the hazards linked to therapeutic leave, highlighting that a significant portion, between 30 to 80%, of inpatient suicides transpire during such leave. Additional concerns extend to non-fatal self-harm, as well as the possibility of patients causing harm to others or to property.

Conclusions: Our review reveals a significant research gap in therapeutic leave's effects, with a reduced number of outcomes studied and inconclusive findings. Future studies should aim to clarify these outcomes and eventually define therapeutic leave protocols.

Volition and Perception: Why patients choose to continue or discontinue ADHD medication

K. B. Johannessen^{1*}, P. Ishøy¹, T. Houmann¹, E. Levin² and P. H. Thomsen³

¹Psychiatric Center Glostrup, Brøndby; ²Psychiatric Center Hillerød, Hillerød and ³Aarhus University, Aarhus, Denmark

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.424

Introduction: The present study examines self-reported factors related to discontinuation of ADHD medication in Danish adults. Based on insights from six patient interviews, a questionnaire was developed with themes such as perception of ADHD, perceived beneficial- and adverse effects of the medication, to examine patients' reasons for continuation or discontinuation of the prescribed medication.

Objectives: ADHD medication has proven effective for treating ADHD in adults. Large registry-based studies have generally shown high discontinuation rates over time and focused on different risk factors, such as comorbidity, gender and socioeconomic status. However, in the present study we explore patient reported reasons for continuation or discontinuation of ADHD medication as well as what drives their choice of living with or without medication despite ADHD.

Methods: The present research is a questionnaire study consisting of 1,050 Danish adults who redeemed a prescription of ADHD medication for the first time between 2017-2019. Questionnaires were sent out by Statistics Denmark to 4,748 adults, a representative sample from the 17,334 Danish adults who redeemed a prescription within that period. A gap of 12 months between redemptions was defined as discontinuation and questionnaires were sent out to an equal number of patients who continued or discontinued the ADHD-medication. Chi²-tests were performed to examine the differences between adults who continued vs. discontinued ADHD-medication in relation to different main themes.

Results: The patients who continued medical treatment more strongly perceived ADHD as a biological illness whereas patients who discontinued, more strongly perceived ADHD as an illness constructed by society. Furthermore, patients who continued medical treatment reported that the medication has a more positive influence on their lives whereas patients who discontinued the medication reported that the treatment involved more negative feelings and decreased the positive sides of themselves. Finally, patients who continued the prescribed ADHD-drugs reported more strongly that they continued the treatment for themselves, to be able to work and be social than the patients who discontinued the medical treatment.

Conclusions: The present findings suggest that the perception of ADHD as being either a biological or social construct is central to why patients choose to continue or discontinue ADHD-medication. Moreover, patients who continued the medical treatment generally reported more positive effects of the ADHD-drugs whereas patients who discontinued the medical treatment reported different negative effects of the medication. From a clinical perspective, these findings show the importance of understanding the individual patient's perception of ADHD. These perspectives should be addressed in the clinic alongside with awareness of how ADHD-drugs may have a positive and negative effect on the individual patient.

Improving mental wellbeing among families and friends of people with alcohol and drug use issues in Darwin, Australia

N. Tari-Keresztes^{1*}, N. Armstrong², H. Gupta¹, J. A. Smith¹, S.-A. Endemann² and S. Goding²

¹Rural and Remote Health, Flinders University and ²Northern Territory Lived Experience Network, Darwin, Australia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.425

Introduction: Families and friends of individuals with alcohol and other drug use (AOD) issues are highly stigmatised and vulnerable, which often leads to social isolation, decreased quality of life, psychosocial vulnerability, heightened distress, less access to social support, and development of maladaptive coping strategies and own mental health challenges and/or AOD use issues. While peer support for families is commonplace in Australia, in Darwin, psychosocial support activities delivered by peers are very sparse.

Objectives: The NT Lived Experience Network (NTLEN), in allyship with a team of researchers from Flinders University, has secured multiple fundings aimed to develop, implement, and evaluate a peer education and recovery program called Circles of Support (CoS) for families and friends of persons with AOD use issues.

Methods: The suitable evaluation approach was co-designed with live experience representatives from NTLEN and other local key stakeholders. It applied a mixed-method approach, including pre and post-program surveys (n=26) and individual interviews with program participants and the program delivery team (n=11). We also used a co-design approach to develop survey instruments to ensure they were strengths-based and recovery-oriented.

Results: While most participants showed sound stress management skills and understanding of stressors at the program start, about 30% did not think they could handle distress if it got worse and did not have the tools to live the life they wanted. Also, about 25% did not know when to ask for help. Many participants (40%) expressed that they were not hopeful about possible changes in their own family context, such as fewer experiences of stress. By the end of the program, participants reported lower stress levels and higher total empowerment scores. The qualitative interviews highlighted the complexities and challenges participant faced in their journeys. Among them, stigma was considered the most critical, especially among participants from culturally and linguistically diverse backgrounds. In some cases, perceived stigma prevented participants from joining the program. The program was well-received and successful in empowering families and friends and improving their own mental wellbeing. Their key learning and experiences included identifying the stage of their situation, learning to cope with challenges, reducing stress, developing hope, experiencing growth, creating a better and more supportive relationship with their loved ones, and implementing self-care on a regular basis.

Conclusions: Our findings emphasise the critical role of peer support for families and friends in improving their mental health and wellbeing. They also draw attention to improving help-seeking behaviours, which may be influenced by stigma, shame and prioritising the person's needs.

Effectiveness of “Mom Supports Mom” Peer Support Intervention in Reducing Prenatal Anxiety and Psychosocial Stress Levels

K. Hrdličková^{1,2*}, A. Horáková^{1,3}, M. Kuklová^{1,4,5}, H. Němcová^{1,2}, P. Knytl^{1,6}, L. Kostýlková^{1,6} and A. Šebela^{1,6}

¹National Institute of Mental Health, Klecany; ²Faculty of Arts, Department of Psychology; ³First Faculty of Medicine; ⁴Faculty of Science, Department of Demography and Geodemography; ⁵Second Faculty of Medicine, Department of Epidemiology and ⁶Third Faculty of Medicine, Charles University, Prague, Czech Republic

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.426

Introduction: The prenatal period poses a risk of both onset and relapse of mental health difficulties. Anxiety and depressive symptoms are the most common, with a prevalence of 10-20%. Untreated mental health difficulties can have serious consequences for the child’s development, the quality of the mother-child relationship, and the whole family system. Peer support can be an effective form of care for women at risk.

Objectives: The aim of the study is to examine the effectiveness of remote “Mom Supports Mom” peer support intervention in reducing prenatal anxiety, depression and psychosocial stress levels.

Methods: A randomized controlled trial was conducted. The Edinburgh Postnatal Depression scale (EPDS) was used to assess the risk of mental health difficulties in pregnant women. Women with EPDS score ≥ 10 were randomized 1:1 to control and intervention groups. The intervention group received the “Mom Supports Mom” peer support intervention. The control group received care as usual. Between group-differences in anxiety, depression and psychosocial stress levels were measured one month after the enrollment/the start of the intervention. The Perinatal Anxiety Screening Scale (PASS), the Edinburgh Postnatal Depression Scale (EPDS), and the Prenatal Psychosocial Profile (PPP) were used to assess the mental health difficulties.

Results: The study involved a total of 67 participants in the intervention group, and 77 participants in the control group. Levels of anxiety ($U = 2016$, $P < 0.05$) and psychosocial stress ($U = 1862$, $P = 0.001$) were significantly decreased in the intervention group, showing a medium effect size of the intervention (Cliff’s delta= -0.218 and -0.317, respectively). There was no significant difference in depression levels ($U = 2288.5$, $P = 0.243$; Cliff’s delta = -0.113); see Table 1.

Table 1 Between group differences in study outcomes (n=144)

Measuring instruments	Intervention group (n=67)		Intervention group 95% Confidence Interval		Control group (n=77)		Control group 95% Confidence Interval		U value / t value		p-value
	Median (IQR)				Median (IQR)						
EPDS (pre)	13 (4)		12.5	13.9	13 (4)		12.8	14.2	2429.5		0.545
PASS (pre)	36 (17)		32.0	38.0	36 (15)		34.0	39.5	0.846		0.399
PPP (pre)	18 (4)		17.8	20.3	17 (6)		16.9	18.8	2282.5		0.233
EPDS (dif)	-6 (6)		-6.7	-4.1	-5 (6)		-5.4	-3.0	2288.5		0.243
PASS (dif)	-7 (11)		-12.3	-6.8	-5 (13)		-7.3	-2.4	2016		0.024
PPP (dif)	-2 (4)		-4.0	-1.6	0 (4)		-1.2	0.5	1862		0.001

EPDS = Edinburgh Postnatal Depression Scale
PASS = Perinatal Anxiety Screening Scale
PPP = Prenatal Psychosocial Profile
pre = administered at baseline
dif = administered post-intervention
IQR = interquartile range

Conclusions: The remote “Mom Supports Mom” peer support intervention can be effective in reducing anxiety and psychosocial stress levels in at-risk pregnant women. Nevertheless, it didn’t show effectiveness in reducing depression levels.

Choking as Cause of Death Among the Mentally Ill: A Literature review

P. Papadopoulou and G. N. Porfyri*

Psychiatry Department, General Hospital of Papanikolaou, Thessaloniki, Greece

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.427

Introduction: According to data, choking is one of the principal causes of death in mental health units. Specifically, research reveals that psychiatric patients -compared to the general population- are 43 times more likely to die due to choking. Nevertheless, only a limited number of studies has been focused on the risk factors of choking among this category of patients. Interestingly, dysphagia and choking on food are underdiagnosed and underreported in the UK psychiatry departments while there is an important insufficiency of provided information in national guidance archives as well as in regional clinical settings for adults with mental health diseases.

Objectives: To explore the risk factors of choking among psychiatric patients and to highlight interventions of preventing choking-related incidents.

Methods: A review of 36 articles -from 2010 to 2023- on PubMed and Google Scholar regarding choking-related incidents among inpatients of mental health units. Articles exploring choking suicide-related incidents or choking as cause of neurological illness, were excluded from the research. Keywords: choking, psychiatric patients, death.

Results: Numerous risk factors of choking have been identified, such as:

- Antipsychotics,
- Anxiolytics,
- Bradykinetic dysphagia (extra-pyramidal syndrome),
- Intellectual disabilities,
- Dementia,
- Anxiety,
- Coughing while eating,
- Fast paced eating and cramming food,
- Mealtime-related stressors such as willingness of avoiding peers.

Conclusions: There is an absolute need for a specialized training of nurses, caregivers, mental health clinicians to prevent incidents and injuries of inpatients due to choking. Close supervision, routine screening during the mealtime, and detailed information from relatives about the patient’s eating habits are essential for the safety and the ameliorated quality of hospitalization for the mentally ill.

The Influence of Gender Roles on Eating Attitudes: A Study Among Female College Students

B. Ozel*, Y. Hosgoren Alici and O. M. Koçak

Department of Psychiatry, Başkent University, Ankara, Türkiye

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.428

Introduction: Eating disorders (ED) are serious mental and physical illnesses that involve complex and damaging relationships with eating, exercise, and body image. They emerge due to a multifaceted interplay of factors, including familial predispositions, personality traits, and cultural influences. While societal beauty standards are recognized as significant risk factors, it is hypothesized that the roles and responsibilities associated with adult womanhood may also contribute to their development. In particular, the unique challenges faced by women, especially in developing countries like Turkey, may lead to discontent with traditional gender roles.

Objectives: This study aims to explore the connection between eating disorders, female identity perceptions, body attitudes, expectations regarding women's roles within families, and their potential association with body dysphoria. We investigate whether eating disorders are linked to a form of sexual dysphoria and body dysmorphia related to femininity rather than solely driven by societal beauty ideals.

Methods: Data from 228 female college students, both undergraduate and graduate, were collected via online surveys. The survey instruments included a sociodemographic form, the Eating Attitude Test, the Gender Roles Attitude Scale, and the Multidimensional Body-Self Relations Questionnaire.

Results: The average age of the participants was 24.41 (18-33) years. Regression analysis revealed that age ($\beta = -0.155$, $p = 0.015$), the belief that physical appearance would be less important if they were male ($\beta = 0.292$, $p < 0.001$), and maternal criticism about weight ($\beta = 0.239$, $p < 0.001$) were influential factors in shaping eating attitudes. Surprisingly, no significant relationship was found between eating attitudes and traditional gender roles ($\beta = 0.072$, $p = 0.246$). However, we did establish a connection between aspiring to meet ideal thinness standards and perceiving women as disadvantaged in the workplace due to their traditional gender roles ($t(226) = 2.32$, $p = 0.021$), as well as with maternal criticism ($t(225) = 3.55$, $p < 0.001$).

Conclusions: Our findings suggest that the absence of a direct link between eating attitudes and traditional gender roles may be attributed to an individual's perception of their environment rather than their self-assessment of masculinity within an egalitarian context. Notably, maternal influences specifically their criticism regarding their daughters' weight and the roles assigned to mothers significantly shape these perceptions and, consequently, eating behaviors, aligning with existing literature (Ferreira *et al.* Archives of Clinical Psychiatry 2021;48,168–177). This underscores the need to consider eating disorders within a broader biopsychosocial framework, encompassing attitudes toward the world and one's role within it.

Domestic violence in Tunisian women during pregnancy and anxiety: which association?

R. Jbir*, L. Aribi, I. Chaari, S. Mohamed, G. Fatma, M. Ines, N. Messedi and J. Aloulou

psychiatry B, Hedi chaker hospital university, Sfax, Tunisia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.429

Introduction: Domestic violence is a major public health problem. The situation is alarming in Arab countries: the prevalence of domestic violence is 39.3% in Saudi Arabia, 55% in Morocco and 62.2% in Egypt.

In Tunisia, a national survey carried out by the national family planning office in 2010, published in July 2011, drew attention for the first time to the frequency of this phenomenon in Tunisia and the recurrent nature of this form of violence. Unfortunately, few studies have focused on domestic violence during pregnancy and its impact on the mental health of expectant mothers.

Objectives: To study the prevalence of domestic violence during pregnancy among Tunisian women consulting in the context of medical expertise and its association with anxiety.

Methods: Our study was descriptive and analytical cross-sectional, carried out with women examined in the context of medical expertise following domestic violence at 'Hedi Chaker hospital', Sfax, from May 2021 until January 2022.

An anonymous survey was asked to these ladies, it included a section for collecting socio-demographic data.

The HADS questionnaire was used to screen for anxiety.

Results: 122 responses were collected. The average age of victims was 35.66 ± 9.94 years.

All the women in our population study were married, and each one was a victim of at least one form of violence. The majority (86.1%) had children. Most of them had secondary (44.3%) or university (31.1%) level education.

More than half of the women (63.9%) had no occupation.

Sixty-five women (53.3%) were assaulted during pregnancy, 43% of whom suffered from complications of varying severity.

Different consequences on pregnancy were reported with decreasing prevalence: 16.9% hospitalization in a gynecological ward, 13.8% abortion, 6.2% fetal death in utero and premature delivery in 4.6% of cases.

According to the HADS, seventy-six of women surveyed (62.3%) had anxiety symptoms.

Anxiety was significantly associated with exposure to violence during pregnancy ($p = 0.03$).

Conclusions: Our results showed a significant incidence of domestic violence during pregnancy and a significant association with anxiety.

Different actions must be taken towards these anxious women such as: Identify a "referent" in maternity wards to screen for domestic violence and directing women to structures and shelters that can help and, above all, protect them.

EPP0239

Working memory capacity in naturally cycling women and oral contraceptive usersM. Kowalczyk^{1*}, M. Kornacka² and I. Krejtz¹¹Psychology, SWPS University, Warsaw and ²Psychology, SWPS University, Katowice, Poland

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.430

Introduction: Miyake and Friedman's model (2012) presents three core executive functions: inhibition, updating and shifting. Updating refers to working memory (WM) because it involves passive storage but also active manipulation of information. According to a review by Hampson (2018), the literature is consistent on the fact that 17 β -estradiol (the most prevalent type of estrogen in women of reproductive age) is associated with improved WM. Levels of estradiol are at their highest in the follicular phase of the menstrual cycle. The use of OC is linked with a noticeable decrease in levels of estradiol and progesterone (Hampson, 2020). Nevertheless, combined OC contain synthetic steroids, usually ethinylestradiol and progestins which can be androgenic or anti-androgenic. Androgenic progestins are derived from testosterone while anti-androgenic progestins block androgen receptors (Raudrant & Rabe, 2003). The review by Beltz (2022) concluded that the use of androgenic OC is linked to an enhanced performance in spatial WM whereas anti-androgenic OC are linked with an impaired performance. When it comes to verbal WM, OC use is related to an enhancement in performance, irrespective of androgenicity.

Objectives: To measure the differences in WM capacity between NC women and OC users at two time points in one menstrual cycle (follicular and luteal phases for NC women).

Methods: 78 women (18-45; $M = 28.93$, $SD = 6.81$), including one group of NC women ($N = 40$) and one group taking OC ($N = 38$), were tested twice over the course of one menstrual cycle. The NC women were tested during their follicular and luteal phases while the OC users were tested during the active phase of their OC. They completed an automated version of the Operation Span task (OSPAN; Unsworth et al., 2005). The OSPAN task involves completing simple math problems while simultaneously trying to remember a series of randomly generated letters.

Results: There was no difference in WM capacity between NC women and OC users. However, we found a significant difference in the number of math errors (speed or accuracy) made by NC women. The number of math errors was higher ($M = 5.12$) during the luteal phase than during the follicular phase ($M = 2.68$). Moreover, we also found a significant difference in the number of math errors made by OC users ($M = 4.00$) and NC women ($M = 2.68$) in their follicular phase. The difference disappeared when the OC users were compared to NC women in their luteal phase.

Conclusions: We found no difference in WM capacity between NC women and OC users. However, we found that NC women made more math errors during the luteal phase than during the follicular phase and that OC users made more errors than NC women in their follicular phase. The follicular phase has an increased level of estradiol whereas OC users experience a decrease in their levels of estradiol. Estradiol levels could be linked with math performance.

Bipolar Disorder in the Elderly: Clinical Insights and Therapeutic Challenges

A. F. Borges* and V. Domingues

Serviço de Psiquiatria e Saúde Mental, Centro Hospitalar de Leiria, Leiria, Portugal

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.431

Introduction: Bipolar Disorder (BD) is a mood disorder characterized by recurrent episodes of mania, hypomania, and depression. While it often manifests in early adulthood, it can persist or emerge in later life, posing unique diagnostic and therapeutic challenges in the elderly population. This abstract explores the clinical aspects, diagnostic intricacies, and therapeutic considerations of BD in older adults.

Objectives: This study aims to shed light on the epidemiology and clinical presentation of BD in the elderly, discuss the diagnostic challenges, and address the complexities of treatment and management in this age group.

Methods: A comprehensive review of the literature was conducted, encompassing epidemiological studies, clinical trials, case reports, and expert guidelines from the past decade. The search was performed using medical databases such as PubMed and Medline.

Results: BD in the elderly presents with a range of clinical complexities that differentiate it from presentations in younger adults. These complexities include atypical features as elderly individuals may exhibit less overt manic or hypomanic symptoms, resembling irritability rather than euphoria; depressive episodes can be more prevalent and prolonged, leading to potential misdiagnosis as unipolar depression; medical comorbidities: older adults with BD often have more medical conditions, complicating treatment; cognitive impairment: cognitive decline, including mild cognitive impairment and dementia, is common and distinguishing it from neurodegenerative conditions requires specialized assessment; mixed episodes, in older adults may experience mixed episodes, requiring intensive treatment; diagnostic challenges: overlapping symptoms with other disorders make accurate diagnosis challenging. Treatment includes mood stabilizers like lithium, valproate, or lamotrigine, and atypical antipsychotics like quetiapine or aripiprazole. Treatment response varies, requiring consideration of age-related pharmacokinetics, pharmacodynamics, and drug interactions. Non-pharmacological interventions, including psychoeducation, tailored cognitive-behavioural therapies, and psychosocial support, are essential.

Conclusions: In summary, BD in the elderly demands a customized, multidisciplinary approach to navigate diagnostic complexities and optimize treatment, considering comorbidities and cognitive factors. Enhanced clinical awareness and holistic care are essential for effective management in this population.

Role of Different Forms and Intensities of Physical Activity in Prevention of Dementia

I. Singh^{1*} and R. Chandra²

¹Mental Health, Central West Hospital & Health Service, Longreach and ²Grampians Health Services- Aged Persons Mental Health Services, Ballarat, VIC, Australia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.432

Introduction: Dementia is one of the greatest health challenges worldwide. According to the World Health Organisation (WHO) factsheet, currently more than 55 million people worldwide have dementia, with over 60% living in low- and middle-income countries. Every year, there are nearly 10 million new cases of dementia. WHO Global Status Report 2021 estimated growth of 139 million people with dementia by 2050. The estimated total global cost of dementia is likely to surpass US\$ 2.8 trillion by 2030. As one grows older, the risk of developing dementia, particularly Alzheimer's Disease, progressively increases. The Lancet Commission Reports 2017 and 2020 on dementia prevention, intervention, and care identified 12 modifiable risk factors, including physical inactivity, obesity, midlife hypertension, and diabetes. Addressing these lifestyle factors may significantly reduce the risk of dementia and its progression. While no curative or disease-modifying treatment is available for dementia at his stage, addressing modifiable risk factors may have a preventive role in reducing the risk of dementia.

Objectives: The objective of the literature review is to explore current evidence on Physical Activity (PA) in reducing the risk of developing dementia and its progression. The focus is also to see the association of different forms and intensities of PA and their intensities, including aerobic, strength-based, and leisure, with the risk and progression of dementia.

Methods: Narrative review

Results: Results from the reviewed studies showed that PA was found to be associated with a reduced risk of dementia, particularly Alzheimer's Disease. Studies comparing different intensities of PA indicate though all levels of PA decrease the risk of dementia, there is a linear relationship between the higher intensity PA and the increased beneficial effect in terms of reduced risk of dementia. Leisure-time PA also has a protective role against dementia in longitudinal studies. There is more consistent evidence in favour of aerobic PA; however, it has a ceiling effect. The combination of aerobic and strength-based experience provides optimum beneficial effects. The elderly population who started physical activity in their 80s experienced the beneficial effects of PA in reducing the risk of dementia. There is mixed evidence of the protective effect of PA on the population who have already developed cognitive impairment or have genetic vulnerabilities. The author will also include the results of any relevant study published by 31 March 2024.

Conclusions: The details of the literature results and conclusions will be discussed at the conference.

Disclosure of Interest: I. Singh Consultant of: The author declare that the review was conducted in the absence of any commercial or

financial relationships that could be construed as a potential conflict of interest., R. Chandra: None Declared

EPP0242

Evaluation of the Effect of Resilience and General Quality of Life on Frailty in the Elderly

M. Tepetaş^{1*}, A. Ay¹, E. Yücel¹, E. Kavlu¹, M. F. Önsüz¹ and S. Metintaş¹

¹Public Health, Eskişehir Osmangazi University, Eskişehir, Türkiye

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.433

Introduction: As the life expectancy at birth improved, the increase in the elderly population, one of the most vulnerable groups in society, brings about some problems. Frailty is a condition that increases the risk of progressive deterioration in physiological functioning, hypersensitivity to stress and adverse health outcomes. Frailty is quite common in older people. In frail older people, recovery from illnesses is delayed and the likelihood of sequelae is increased. If frailty is recognized early, the likelihood of disease sequelae and mortality can be reduced.

Objectives: This study was conducted to determine the relationship between psychological resilience and quality of life on frailty in individuals aged 65 years and older admitted to hospital.

Methods: The study group of this cross-sectional study consisted of 504 people who applied to an outpatient clinic at a university hospital. The Tilburg Frailty Scale, the Connor Davidson Psychological Resilience Scale Short Form and the EQ-5D-3L General Quality of Life Scale were used. The Kolmogorov-Smirnov test, the chi-square test, the Spearman correlation analysis and the multivariate logistic regression were used to analyse the data.

Results: 292 of the participants in the study group were men. Their ages ranged from 65 to 90 years, and the mean was 70.5 ±4.9 years. Scores on the Tilburg Frail Scale ranged from 0 to 14, and the mean was 6.3±2.7 points. In the study, 71.1% of participants were classified as frail. It was determined that there was a moderate negative correlation between the results of the Tilburg Frailty Scale and the results of the Connor Davidson Psychological Resilience Scale ($r = -0.436$) and the EQ-5D-3L VAS Scale ($r = -0.608$) and a strong positive correlation between the results of the EQ-5D-3L Index Scale ($r = 0.729$) (for each $p < 0.001$). According to multivariate logistic regression, people who did not exercise regularly were 2,33 times more frail than those who did, and people who had a health problem that required bed rest were 2,18 times more frail than those who did not.

Conclusions: It was found that the frailty of people aged 65 and over is at a moderate level. An improvement in psychological resilience and general quality of life as well as an improvement in general health reduces frailty. It is recommended that people aged 65 and over to be physically active and to protect from situations that may require prolonged bed rest.

EPP0243

A differentiated approach to the choice of a neuroprotective drugs during complex antidepressant therapy of elderly depressive patients in a hospital setting

V. Pochueva*, O. Yakovleva and T. Safarova

FSBSI "Mental Health Research Center", Moscow, Russian Federation

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.434

Introduction: The complex antidepressant therapy in combination with neuroprotectors increases the overall effectiveness of the treatment of depression in the elderly due to the group of the most difficult patients for therapy with ≥ 2 predictors of a low therapeutic response (LTRP), as well as in patients with complex (anxious, senesto-hypochondriacal, delusional) and prolonged (≥ 6 months) depressions.

Objectives: Development of a differentiated approach to the choice of types of neuroprotective drugs in the course of complex antidepressant therapy in depressive elderly patients.

Methods: We studied groups of hospitalized patients aged ≥ 60 years with mild, moderate and severe depression (according to ICD-10) who received antidepressant monotherapy (comparison group) for 28 days (43 people) or complex antidepressant therapy in combination with carnitin (20), cerebrolysin (20), citicoline (20), ethylmethylhydroxypyridine succinate (EMHPS) (25) and actovegin (25). Complaints about memory impairment, lonely living, and the presence of leukoaraiosis on brain CT were considered as LTRP. Efficacy of therapy (change in total HAMD-17 scores in %) was compared in subgroups with neuroprotectors and in the comparison group in patients with ≥ 2 LTRPs, as well as in patients with complex and prolonged depressions. Statistical analysis was performed.

Results: By the 28th day of treatment, all patients with ≥ 2 LTRPs in the subgroups with the addition of any neuroprotectors were responders ($\geq 50\%$ change) with a significantly higher efficacy of therapy than in the monotherapy group (36.0%, $p < 0.05$). The efficacy of therapy was significantly higher in the subgroup with the addition of actovegin than in the subgroups with cerebrolysin and citicoline (73.7% versus 55.6% and 52.0%, respectively, $p < 0.05$). In complex depression, the effectiveness of therapy in the subgroup with cerebrolysin did not statistically differ from the comparison group. In prolonged depression, no statistically significant difference in efficacy was found between the citicoline-supplemented subgroup and the monotherapy group. The highest efficacy in the treatment of complex and prolonged depression was observed in subgroups with the addition of actovegin and EMHPS ($p < 0.01$).

Conclusions: If there are indications for prescribing complex antidepressant therapy (≥ 2 LTRPs) in depressive patients of late age, all studied neuroprotective drugs demonstrated high efficiency

compared to monotherapy. In complex depressions, the combination of antidepressants with cerebrolysin turned out to be less effective, in protracted depressions - with citicoline. Neuroprotectors actovegin and EMHPS can be considered universal drugs of choice for complex therapy of the most difficult categories of elderly depressive patients in a hospital setting.

Unveiling the Perspectives on Sexual Unwellness: A Cross-National Qualitative Study with Older Adults from Mexico and Portugal

S. von Humboldt^{1*}, N. M. Mendoza-Ruvalcaba², J. A. Ribeiro-Gonçalves¹, A. Chávez-Rodríguez², E. D. Arias-Merino³, G. Low⁴ and I. Leal¹

¹William James Center for Research, ISPA – Instituto Universitário, Lisbon, Portugal; ²University of Guadalajara CUTONALA, Health Sciences Division, Guadalajara, Jalisco; ³Public Health Department, Universidad de Guadalajara CUCS, Guadalajara, Mexico and ⁴Faculty of Nursing, University of Alberta, Edmonton, AB, Canada

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.435

Introduction: Sexual unwellness (SU) has been linked to a lack of sexual satisfaction and to an incapacity to maintain sexual relations.

Objectives: The objective of this cross-cultural study is to shed light on older adults' perspectives on SU across cultures.

Methods: Eighty-three older participants (65 to 98 years of age) took part in this qualitative study. Participants lived in the community and were of two different nationalities (Portuguese and Mexican). Semi-structured interviews were conducted, and content analysis was then carried out.

Results: SU emerged in the findings of the content analysis through six themes: Dissatisfying Sexual Experiences; Feelings of Isolation; Spirituality; Medication; Unattractiveness and Pain. The most common theme among older Portuguese participants was 'Dissatisfying Sexual Experiences' (25.5%). 'Feelings of Isolation' was most common among older Mexican participants (13.7%).

Conclusions: A diversity of experiences of older adults in relation to SU was highlighted in this study. Moreover, cross-cultural research on the construct of SU is essential for understanding the cultural differences in the conceptualization of the construct and how these themes may influence the quality of sexual life in old age. Keywords: Cross-cultural; Older adults; Qualitative study; Sexual Unwellness.

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.436

Introduction: Numerous studies have explored the symptoms and course of depression and anxiety in breast cancer patients and identified various clinical, sociodemographic, and genetic factors associated with their evolution. Nevertheless, these studies have been limited in duration and have focused on specific time points during chemotherapy or post-treatment follow-up. Furthermore, these studies included patients receiving different treatment regimens and used different tools to assess symptoms.

Objectives: To assess the prospective evolution of depression in breast cancer patients over eight consecutive chemotherapy cycles, taking into account sociodemographic, clinical, biological, and genetic factors.

Methods: A prospective longitudinal study was conducted on 69 breast cancer patients treated with intravenous chemotherapy at the oncology outpatient unit of the Hôtel-Dieu de France hospital (2017-2019; Ethics: CEHDF1016). The Hospital Anxiety and Depression Scale (HADS) was used to evaluate anxiety and depression in patients. Genotyping was performed for several genes (*ABCB1*, *COMT*, *DRD2*, *OPRM1*, *CLOCK*, *CRY2*, *PER2*) using the Lightcycler[®] 2.0 (Roche).

Results: Univariate repeated measures analysis showed differences in the evolution of depression and anxiety over time. For depression, a polynomial linear contrast for HADS-D scores was noted from cycle 1 to cycle 8, with a significant increase in depression at cycles 7 and 8 compared with cycle 1 ($p\text{-value}_{\text{cycle}7}=0.004$ and $p\text{-value}_{\text{cycle}8}=0.009$; Figures 1 & 2). Repeated measures analysis for anxiety showed a decrease in anxiety scores between cycles 1 and 6 of chemotherapy, followed by an increase starting cycle 6 (a polynomial trend for contrasts) ($p\text{-value}_{\text{cycle}6 \text{ versus } 1}=0.038$; Figures 1 & 2). Multivariable analysis showed that higher anxiety and depression scores at baseline were both associated with higher depression and anxiety scores over time. Other clinical and genetic factors, including polymorphisms in the *OPRM1*, *PER2*, and *COMT* genes, were also significantly associated with higher depression and anxiety scores.

Image:

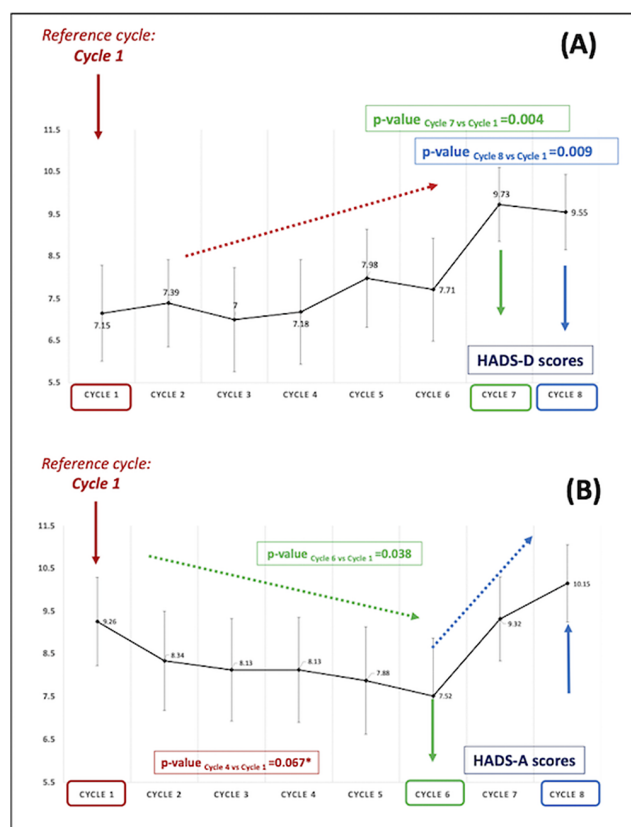

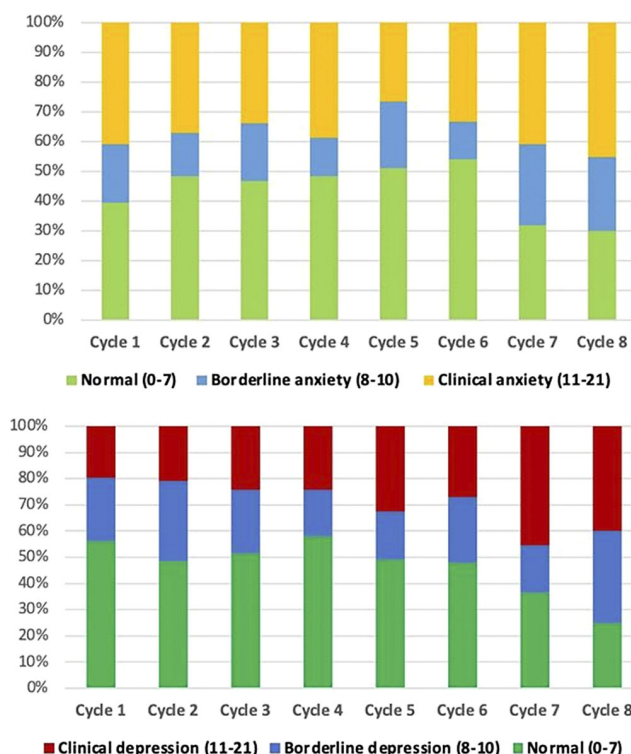

Image 2:

Conclusions: Our findings highlight the importance of understanding the trajectories of depression and anxiety over time in women with breast cancer and identifying the triggering factors. Such personalized approaches would improve patient quality of life.

Barriers in cancer care for patients with mental illness – a qualitative study

A. N. H. Vendelsøe^{1*}, M. Stie^{1,2}, P. Hjorth^{2,3}, J. Søndergaard⁴ and L. H. Jensen^{1,2}

¹Department of Oncology, Lillebaelt Hospital, Vejle Hospital, Vejle;

²Department of Regional Health Research, Faculty of Health Sciences, University of Southern Denmark, Odense; ³The Psychiatric Department in Vejle, Mental Health Services in the Region of Southern Denmark, Vejle and ⁴Department of Public Health, University of Southern Denmark, The Research Unit for General Practice, Odense, Denmark

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.437

Introduction: Patients with mental illness experience a substantial inequity when facing cancer treatment compared to patients without mental illness. They have a higher cancer mortality and are less likely to be referred for treatment following clinical guidelines. The cancer treatment can exacerbate mental symptoms, which may lead to discontinuation of the treatment. Other relevant specialities such as psychiatry and general practice are rarely involved.

Objectives: In this qualitative case study, the needs, barriers and facilitators of providing high quality, patient-centered care to patients with cancer and pre-existing mental illness were explored. Emphasis was on patients' experiences of being in the field between oncology, psychiatry, general practice and the municipality.

Methods: The study was anchored at the Department of Oncology, Lillebaelt Hospital, Vejle and data collection took place from January to June 2023. Through purposeful sampling five patients with cancer from adult psychiatric setting were included. Field studies were carried out inspired by the framework of Spradley, and involved following the patients during visits to the department of oncology and in the psychiatric setting. Formal interviews were performed using semi-structured interview guides inspired by Kvale and Brinkmann. Patient files were examined focusing on the awareness of the psychiatric diagnosis and treatment and communication between the departments and sectors.

Results: Our analysis showed one major theme: "Complexity on many levels", and five subthemes: "The impact of the cancer trajectory on mental illness", "The structure follows the disease, not the patient", "Fragmentation of the health care system", "Patient vulnerability" and "Importance of the patient-professional-relationship". Barriers included lack of a systematic approach to the patient group in the health care system and sparse collaboration between departments and sectors. The cancer trajectory often led to severe worsening of the psychiatric illness, resulting in psychiatric hospitalisation. Facilitators were specialized coordinators at the hospital or municipality, relatives, patients' resources and health professionals approaching the patient as a

person rather than a disease. Final results will be ready for presentation at the conference.

Conclusions: Despite intentions of reducing inequality, the Danish health care system is still not equipped to sufficiently help patients with cancer and pre-existing mental illness through their cancer treatment. This study will highlight relevant target points, paving the way for a new, feasible care model that improves continuity and patient-centered care for patients with cancer and mental illness.

EPP0248

A body beaten again: a narrative analysis of a series of cases of breast cancer survivors punctuated by violence

V. S. D. Melo^{1*} and C. Soares²

¹Psychiatry, Centro Hospitalar do Médio Tejo, Tomar and ²Psychiatry, Instituto Português de Oncologia - Porto, Porto, Portugal

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.438

Introduction: Various mechanisms have been identified to explain the relationship between gender-based violence, screening, and cancer. Biological mechanisms, primarily related to chronic stress and allostatic load, have been associated with high rates of chronic diseases among victims of violence, impairing the functioning of the immune and endocrine systems. Victims of abuse simultaneously show less initiative for screening exams, such as mammograms, as they perceive them as invasive and retraumatizing. They also demonstrate a greater tendency toward maladaptive coping behaviors and unhealthy lifestyles, such as abusive substance use. A significant number of these patients develop psychosocial dysfunction and body image disturbance during breast cancer treatments.

Objectives: This work aims to provide a descriptive and narrative analysis of body image and psychosocial changes in women breast cancer survivors with prolonged experiences of violence, supported by a non-systematic literature review on the central aspects under study.

Methods: For the introductory literature review, a search was conducted on search engines such as Google Scholar and PubMed, with no date limitations, using the following terms (or combinations): "intimate partner violence," "violence AND cancer," "body image AND psychosocial adjustment AND breast cancer." Additionally, a narrative analysis of body image and psychosocial changes in women breast cancer survivors with prolonged experiences of violence was conducted. For this purpose, participants were asked to complete two validated scales in the Portuguese language, and first-person testimonials were collected.

Results: The analysis of scale results and participant testimonials highlights a consensus on the significant impairment of psychosocial functioning and the experience of sexuality. There is evidence of avoidance behaviors in terms of affectionate and sexual contact due to feelings of fear, shame, and discomfort. The breast is valued as a sensual, erotic, and essential sexual element, and impactful changes in body image persist. However, in some cases, these changes are experienced as transformative and liberating, fostering a more generous view of the body, identity, and femininity.

Conclusions: Women with breast cancer should be screened for the possibility of being victims of violence, as this context predicts a

higher likelihood of emotional difficulties during surgical treatments, including psychological distress, post-traumatic stress, body shame, and self-blame. A significant number of women, including those in this study, consider the approach to self-image and sexuality in oncology consultations deficient. Psychological programs and interventions should be developed to empower patients to adjust to the sexual changes arising from treatments and disease progression and to promote positive intimate relationships and effective communication.

EPP0249

Development and psychometric testing of the Acceptability regarding Cognitive Rehabilitation Interventions Survey – Cancer Survivors (ACRIS-CS)

A. F. Oliveira¹, A. Bártoło^{1,2,3}, L. Loureiro⁴, I. M. Santos⁵ and A. Torres^{1*}

¹Department of Education and Psychology, Center for Health Technology and Services Research of the Health Research Network (CINTESIS@RISE), University of Aveiro, Aveiro; ²I2P - Portucalense Institute for Psychology, Portucalense University, Porto; ³Center for Global Studies, Open University, Lisboa; ⁴Department of Education and Psychology, University of Aveiro and ⁵Department of Education and Psychology, William James Center for Research (WJCR), University of Aveiro, Aveiro, Portugal

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.439

Introduction: Cognitive rehabilitation interventions (CRIs) for cancer-related cognitive impairment (CRCI) have shown promising results. However, the acceptability of CRIs in the context of CRCI treatment has not yet been assessed among cancer survivors. Due to the absence of suitable instruments designed to assess the acceptability of CRIs in this population, we developed the Acceptability regarding Cognitive Rehabilitation Interventions Survey for Cancer Survivors (ACRIS-CS).

Objectives: This study aimed to develop and test the psychometric properties of the newly created instrument, ACRIS-CS.

Methods: The study was conducted in two stages: (1) the creation of scale items derived from a comprehensive literature review, considering the Theoretical Framework of Acceptability (TFA); and (2) the assessment of the scale's psychometric properties with cancer survivors. At the end of stage 1, the questionnaire was revised by four clinicians and researchers with expertise in the field of CRCI, and the final item selection was determined by the authors, considering redundancy, item relevance, and face validity. The final scale comprised 11 items, answered on a 5-point Likert scale (ranging from "strongly disagree" to "strongly agree"). Higher scores indicated more positive perceptions related to the acceptability of CRIs. Data were collected online and analyzed using IBM SPSS Statistics (version 28.0). Construct validity (exploratory factor analysis, EFA) and reliability (internal consistency) analyses were performed.

Results: In this study, 154 cancer survivors were included. The Kaiser-Meyer-Olkin (KMO) measure of 0.847 confirmed the adequacy of sampling (KMO>0.5), and Bartlett's test of sphericity yielded statistical significance ($X^2(55) = 864.431, p < 0.001$),

validating the structure of the correlation matrix. The EFA results indicated the presence of three factors, each with eigenvalues exceeding the Kaiser criterion of 1. The scree plot confirmed the existence of three factors beyond the inflection point. All items demonstrated factor loadings higher than 0.40, indicating their relevance to the identified factors. This factor structure was conceptually justifiable. These factors were labeled as follows: 1) Affective attitude and effectiveness (6 items); 2) Perceived benefits and self-efficacy (3 items); and 3) Perceived burden (2 items). Collectively, these factors accounted for 68.7% of the total variance. The ACRIS-CS total scale and subscales demonstrated good internal consistency, with Cronbach's alpha coefficients ranging from 0.727 to 0.848.

Conclusions: The results of the EFA and internal consistency analysis were satisfactory. The ACRIS-CS appears to be a valid and reliable scale for assessing the acceptability of CRIs among cancer survivors.

doi: 10.1192/j.eurpsy.2024.440

Introduction: In the context of developmental disorders, it is frequently observed that atypical processes may yield seemingly unimpaired behavioural outcomes. Research has shown that children and adults with Autistic Spectrum Disorder (ASD) have intact statistical learning performance. Recent studies have indicated that learning can happen not only during practice but during ultrashort rests between practice blocks (that is, ultrafast offline learning) but no study to date examined these dynamics in ASD.

Objectives: This research aimed to unravel the effect of ASD on learning during and between blocks, also known as online and offline improvement.

Methods: We conducted a series of research with three different samples: 1) ASD children (N = 27), 2) ASD adults (N = 42), and 3) neurotypical adults with distinct positions on the autism spectrum, i.e., the severity of autistic traits (N = 174). Participants performed the Alternating Serial Reaction Time task, allowing us to measure statistical learning (the extraction of statistical knowledge) and general skill learning (speed-up regardless of probabilities) separately.

Results: Individual differences in online and offline improvements were observed. Results of individual studies further confirmed by

meta-analysis performed on the three above-mentioned datasets show that neither ASD nor the severity of autistic traits influences the dynamics of learning.

Conclusions: Our findings suggest that, not only learning but also the dynamics of acquisition of statistical knowledge are intact in autism.

Factors influencing the health-related quality of life among persons with lower limb amputation wearing a prosthesis

C. Papathanasiou^{1*} and A. Psoma²

¹Department of Psychology, Panteion University of Social and Political Sciences, Athens and ²School of Social Sciences, Hellenic Open University, Patras, Greece

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.441

Introduction: Limb amputation is often an unavoidable process in many diseases and accidents, leading to several limitations in social, professional, and recreational activities.

Objectives: To explore the perceptions of persons with lower limb amputation (PLLA) wearing a prosthesis regarding the health-related quality of life (HRQoL), and to examine the relationships between HRQoL, body image disturbance, and self-esteem.

Methods: The research sample consisted of 91 PLLA who were using a prosthesis. The data were collected through a questionnaire comprised of demographic information and the following scales: The Short Form Health Survey-12 (SF-12), the Amputee Body Image Scale (ABIS-R), and the Rosenberg scale (RSES), in order to assess HRQoL, body image disturbance, and self-esteem respectively. The SPSS statistical software (v.26) was used for the statistical analysis of the data.

Results: The mean SF-12 score of the participants was 70.31 (SD=16.74). The HRQoL was affected by the following sociodemographic factors: age, educational level, profession, income, marital status, and parenthood. It was also influenced by disability-related factors, such as amputation cause and years of prosthesis use. In particular, young participants reported a better level of HRQoL than the older participants ($p<0.001$). Participants with a higher education level presented better HRQoL than those with lower education level ($p<0.001$). Unemployed participants and students presented better HRQoL scores compared to all other professional categories ($p=0.001$). However, participants with lower incomes <10,000 € reported a lower level of HRQoL ($p=0.028$). Singles had the highest HRQoL score, while widowers had the lowest ($p=0.001$). Childfree participants experienced the highest level of HRQoL ($p=0.001$). Participants whose amputation resulted from an accident reported a better HRQoL compared to those who had an amputation due to Type 2 diabetes ($p<0.001$). As the years of prosthesis use increase, HRQoL decreases ($p=0.001$). Regarding the associations between HRQoL, body image disturbance, and self-esteem statistically significant relationships were recorded. More specifically, there is a significant positive relationship between RSES and SF-12 ($p<0.001$); as participants' self-esteem increases, so does their HRQoL. Conversely, a statistically significant negative

correlation emerged between SF-12 and ABIS-R ($p<0.001$); as HRQoL increases, body image disturbance decreases.

Conclusions: The aforementioned factors should be considered in the design and implementation of psychosocial interventions aimed at recovery. Qualitative studies are recommended to explore the lived experiences of PLLA in-depth.

Artificial Intelligence in Psychiatry: A New Paradigm

M. Gerantia

Center of mental Health and addiction prevention, Tbilisi, Georgia

doi: 10.1192/j.eurpsy.2024.442

Introduction: The advent of artificial intelligence (AI) and machine learning has sparked interest in its applicability in the mental health domain, offering potential improvements in the efficiency and personalization of psychiatric services.

Objectives: To characterize the methodological and technical approaches in studies utilizing machine learning and natural language processing (NLP) within mental health, to evaluate their potential and impact in psychiatric clinical practice, and to address the associated ethical concerns.

Methods: A systematic review, adhering to the PRISMA guidelines, was conducted across four primary medical databases. Emphasis was placed on studies that applied machine learning and NLP techniques to psychiatric contexts, extracting data from sources such as medical records and social media.

Results: From 327 identified articles, 58 were considered relevant. Major themes included symptom extraction, illness severity classification, therapy effectiveness comparison, and psychopathological insight derivation. Notably, most studies focused on specific populations like social media users, emergency room attendees, or those within medical databases. Methodological findings showcased a preference for efficient classifiers and Python as the primary platform.

Conclusions: Machine learning and NLP offer a promising new avenue for psychiatric research and clinical practice, enabling the extraction of previously inaccessible patient information and supporting the decision-making process. However, the field must address inherent limitations, ethical considerations, and ensure that the tools augment, rather than replace, clinical judgment.

Psychosocial risks in the practice of healthcare professionals: from the culture of stoicism to occupational suicide.

V. S. D. Melo^{1*}, I. A. Silva², A. F. Silva¹, A. Gouveia³ and C. A. Rodrigues¹

¹Psychiatry, Centro Hospitalar do Médio Tejo, Tomar; ²Psychiatry, ULSNA, Portalegre and ³Psychiatry, ULSBA, Beja, Portugal

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.443

Introduction: It is well known that healthcare professionals, in a somewhat generalized manner, work in stressful contexts that embrace emotional overload, highly hierarchical environments, and not always sensitive to the vulnerabilities that arise. Chronic professional stress in institutions, associated with the perception of low control and emotional exhaustion, acts as a trigger for eminently deleterious consequences, significantly affecting the most dedicated and perfectionist professionals.

Objectives: This work aims, through a non-systematic literature review, to analyze the psychosocial risks associated with the practice of healthcare professionals, as well as the mitigation strategies whose practical implementation may depend on and maintenance of a positive and protective occupational environment.

Methods: For the purpose of literature review, a search was conducted on search engines such as Google Scholar, Research Gate, and PubMed, with no date limitations, using the following terms (or combinations): “occupational psychiatry”; “psychosocial risks AND healthcare professionals”; “mitigation strategies”; “occupational risk management.”

Results: Healthcare sector professionals are the ones reporting exposure to higher levels of workload intensity, including parameters related to work speed (under time pressure), combined with prominent emotional demands and psychological suffering. In addition to the most commonly analyzed occupational stressors (workload, job fatigue, particularly draining emotional interactions, marked cognitive demands, complex decision-making, conflicts of a deontological nature), other relevant contextual factors emerge. Among these, predisposing personality traits (such as neuroticism), a sense of personal sacrifice with neglect of self-care, vicarious trauma, which is intimately related to compassion fatigue in the face of frequent and prolonged exposure to traumatic experiences (of various kinds) of the patients they accompany, and occupational violence, which can manifest as verbal or behavioral threats, mobbing, physical harm, and/or sexual abuse based on a tendentially gender-based and deeply hierarchical structure.

Conclusions: Undeniable consequences such as job dissatisfaction, psychological distress, the development of anxiety, depression, burnout, and post-traumatic stress disorder translate into a loss of capacity to perform occupational functions, with a higher risk of medical/clinical errors, conferring risks that should never be neglected to the safety of the users of healthcare institutions. On the darker side of this panorama, and in the face of chronic depletion, occupational suicide emerges. It is therefore urgent to requalify the work environment, aiming at creating and maintaining a positive occupational environment, or alternatively, a preventive approach to the risk of mental health problems originating or exacerbated in the workplace.

EPP0255

A scoping review of the literature on interventions to reduce stress and burnout among teachers.

A. Belinda* and Y. Wei

Department of psychiatry, University of Alberta, Edmonton, Canada

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.444

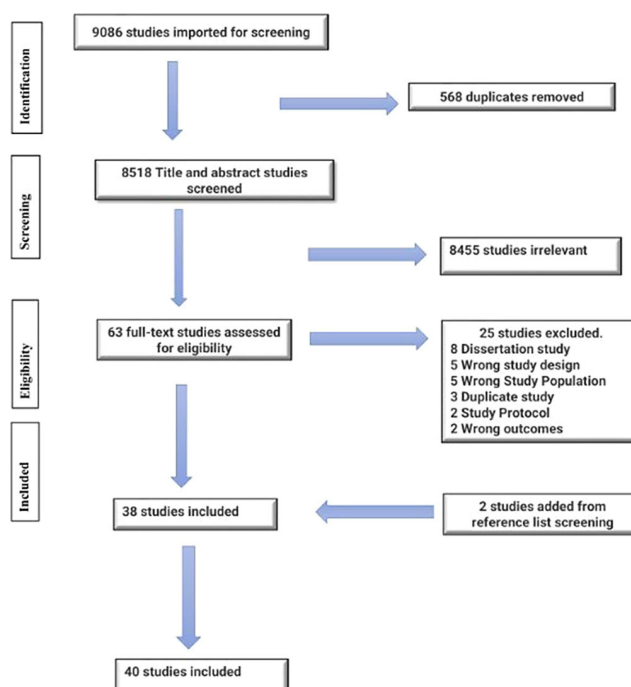

Introduction: Experience of chronic stress among professionals is a risk factor for poor mental and physical well-being. There is limited knowledge regarding the kinds of interventions, and outcomes achieved using different modalities to address stress and burnout among teachers.

Objectives: To undertake a scoping review of recent literature to determine psychological interventions and reported outcomes related to stress and burnout among teachers.

Methods: The PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses extension for Scoping Reviews) was followed. Relevant search terms were used to determine different interventions adopted to reduce teachers' stress and burnout. Articles published between 2018 and 2022 were identified using five bibliographic databases. Relevant articles were extracted, reviewed, collated, and thematically analyzed, and findings were summarized.

Results: Forty studies conducted in Asia, North America, Oceania, Europe, and Africa, met the inclusion criteria. Sixteen kinds of burnout and stress-reduction interventions were identified. The most popularly studied intervention were Mindfulness-Based Interventions alone or in combination with yoga or Cognitive Behavioural Therapy (CBT), followed by Rational Emotive Behavioral Therapy (REBT). Mindfulness-Based Interventions led to decreased overall Teacher Stress Inventory (TSI) and emotional exhaustion subscale scores. REBT, primarily used with special education teachers, especially in Africa, has also shown positive results. Other interventions reporting positive outcomes include Inquiry-Based Stress Reduction (IBSR), the Stress Management and Resiliency Training Program (SMART), Cyclic Meditation, Group Sandplay, Progressive Muscle Relaxation, Autogenic Training, Sport-Based Physical Activity, Emotional Intelligence Ability Models and Christian Prayer and Prayer-Reflection

Image:

Conclusions: Stress and burnout can have a negative impact on teachers and, very often, on the students they teach. Implementing suitable school-based interventions are necessary to improve teachers' stress-coping ability, reduce the likelihood of burnout and improve general well-being. Policymakers, governments, school boards and administrators should prioritize the implementation of school-based awareness and intervention programs to mitigate teacher stress and burnout.

Associations between Health-Related Quality of Life, Illness Perception, Stigmatization and Optimism among Hematology Patients: a Path Analysis

H. Kiss^{1*}, V. Müller², K. T. Dani³ and B. F. Pikó¹

¹Department of Behavioral Sciences; ²Doctoral School of Education and ³Department of Hematology, Department of Internal Medicine, University of Szeged, Szeged, Hungary

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.445

Introduction: Hematological diseases represent a diverse disease group ranging from benign to life-threatening conditions, with hematological malignancies being a major cause of mortality in the population worldwide. Although most hematological diseases require ongoing medical care making these conditions even more difficult for patients to endure. Since these diseases can pose many challenges by causing symptoms and limitations in various aspects of daily life, health-related quality of life (HRQoL) is a crucial aspect of their healthcare. Different dimensions of health-related quality of life are influenced by several psychological factors, including illness perception, stigmatization, and optimism: a more positive illness perception, along with optimism and reduced stigmatization, can contribute to a better HRQoL among hematology patients.

Objectives: Since hematological diseases often cause serious life changes, the current study aimed to explore the direct and indirect effects of illness perception on health-related quality of life among hematology patients in Hungary, including stigmatization and optimism as possible contributors.

Methods: In this cross-sectional study, 96 hematology patients (mean age = 56.45 years; SD = 15.55 years; 43.8% female) completed a self-administered survey including the following instruments: EORTC Quality of Life Scale, Brief Illness Perception Questionnaire, Stigma Scale for Chronic Illness, Revised Life Orientation Test.

Results: By creating two pathway models, illness perception had significant indirect effects on physical functioning ($\beta = -.205$, $p < .05$) through role and cognitive functioning while emotional functioning had significant indirect effects on social functioning ($\beta = .369$, $p < .01$) through illness perception and stigmatization, both effects moderated by optimism. After controlling for other factors, both illness perception and emotional functioning directly influenced physical and social functioning, respectively.

Conclusions: Our study supports previous research on the direct and indirect effects of illness perception on HRQoL. Based on our data, more optimistic illness perceptions and greater emotional functioning improve hematology patients' health-related quality

of life by facilitating an unbiased understanding of the disease. Optimism serves as a potential moderating mechanism by positively altering indirect effects. Healthcare professionals need to optimize patients' illness perception to improve physical and social functioning.

EPP0257

Factors Influencing the Mental Health of Caregivers of Children with Cerebral Palsy

R. Alhumaidah

College of Medicine, King Saud bin Abdulaziz University for Health Science, Jeddah, Saudi Arabia

doi: 10.1192/j.eurpsy.2024.446

Introduction: Cerebral palsy refers to a heterogeneous group of non-progressive neurodevelopmental disorders manifesting in infancy or childhood and varying in severity. It is characterized by impaired motor function, sensation, and depressed intellectual abilities. Functional limitations in patients with cerebral palsy may result in chronic dependency, thereby compromising caregivers' mental health and interfering with the integrity of the family structure.

Objectives: This study aimed to determine the different factors affecting the mental health of caregivers of children with cerebral palsy and to raise awareness among healthcare providers.

Methods: A cross-sectional study was conducted among caregivers of children with cerebral palsy in National Guard Health Affairs-Jeddah, Saudi Arabia, using the Depression Anxiety Stress Scale-21, a validated questionnaire assessing: depression, anxiety, and stress. This questionnaire was used to assess the mental health of the caregivers. In addition, factors reflecting child's health condition, such as visual impairment, number of emergency department visits, and number of Pediatric Intensive Care Unit admissions were reported to investigate the impact on the caregiver's mental health.

Results: The sample included 40 caregivers, of which 72.5% were mothers. According to the Depression Anxiety Stress Scale-21 score, 12.5% ($n = 5$) of the caregivers had moderate depression scores, 10% ($n = 4$) revealed extremely severe depression, and 10% ($n = 4$) showed moderate anxiety. Furthermore, 12.5% ($n = 5$), 15% ($n = 6$), and 7.5% ($n = 3$) of the caregivers have scored as moderate, severe, and extremely severe stress levels, respectively. Caregivers' depression, anxiety, and stress scores were significantly ($p \leq 0.05$) associated with the impact of vision of their dependent children, frequent hospital admissions, and frequent emergency department visits. Increased Pediatric Intensive Care Unit admissions in the past year were also significantly associated with higher caregiver anxiety scores.

Conclusions: To the best of our knowledge, the dimension of caregivers' stress and anxiety and their association with the children's dependency level is not well documented in our region. Caregivers of children with cerebral palsy reported having mental

health challenges associated with the children's vision, frequent need for acute medical care, and hospital admissions.

Healthcare workers should provide early and proactive planning of medical and social support for children and their families using a family-centered approach.

The relationship between parental reflective function, cognitive emotion regulation and parental perception of the infant

K. Hunyadi¹, M. Miklósi^{2,3,4} and B. Szabó^{2,3,5*}

¹Department of Developmental and Clinical Child Psychology, ELTE Eötvös Lóránd University Institute of Psychology; ²Department of Developmental and Clinical Child Psychology, ELTE Eötvös Lóránd Tudományegyetem University Institute of Psychology; ³Department of Clinical Psychology, Semmelweis University Faculty of Medicine; ⁴Heim Pál National Pediatric Institute, Centre of Mental Health and ⁵ELTE Eötvös Lóránd Tudományegyetem University, Doctoral School of Psychology, Budapest, Hungary

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.447

Introduction: The literature indicates that parental reflective functioning (PRF) is crucial to a good parent-child relationship. Furthermore, genuine parental mentalizing also promotes adaptive emotion regulation in attachment relationships. However, no prior study assessed the relationship between parental mentalizing, emotion regulation and object relation in the early years.

Objectives: We examined the relationship between PRF, cognitive emotion regulation and perception of the infant among parents of children up to five years old.

Methods: In our cross-sectional, non-clinical study, 136 parents completed the Parental Reflective Functioning Questionnaire, the Cognitive Emotion Regulation Questionnaire and the Mother's Object Relationship Scale - short form. In our 12 moderator models, we chose the subscales of the parental perception of the infant (invasiveness and warmth) as dependent variables, the subscales of adaptive and non-adaptive strategies of cognitive emotion regulation as independent variables, and the three subscales of PRF (pre-mentalization, interest and curiosity, certainty about mental states) as moderators.

Results: Warmth had a positive, weak correlation with adaptive strategies ($r(134) = 0.27, p < 0.007$), with certainty in mental states ($r(134) = 0.24, p < 0.007$) and interest and curiosity ($r(134) = 0.23, p < 0.007$); the correlation between interest and curiosity and non-adaptive strategies was moderate and positive ($r(134) = 0.32, p < 0.007$). None of the subscales of PRF moderated the relationship between the subscales of emotion regulation and the perception of the infant. The use of adaptive emotion regulation strategies was more likely to affect the perception of warmth ($B = 0.05 (t = 2.0584, p = 0.0415)$, $B = 0.04 (t = 1.7887, p = 0.0760)$), and the use of non-adaptive strategies was more likely to affect the perception of invasiveness ($B = 0.08 (t = 2.1333, p = 0.0348)$, $B = 0.09 (t = 2.3164, p = 0.0221)$).

Conclusions: Our results suggest that cognitive emotion regulation plays a role in object relation; therefore, we recommend promoting

adaptive cognitive emotion regulation strategies among mothers in the early years.

Perceived helpfulness of various sources of help for 5 mental illnesses

S. Shahwan*, E. H. Tay, S. A. Chong and M. Subramaniam

Research, IMH, Singapore, Singapore

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.448

Introduction: 1 in 8 people worldwide live with a mental illness (MI). This is expected to rise with increasing societal pressures. Despite the availability of evidence-based treatments, MIs remain undertreated. In Singapore, efforts such as the 'It's OK to Reach Out' campaign was launched to encourage help-seeking. Help-seeking behavior is complex; determined by an interplay of factors including perceptions towards help sources. As seeking ineffective sources contributes to unmet needs, understanding beliefs towards various sources of help is vital.

Objectives: The study aims to examine perceived helpfulness of various sources of help for 5 mental illnesses and changes in perceptions towards them over time.

Methods: The Mind Matters 2023 (M2) is an ongoing nationwide survey of mental health literacy among Singapore residents aged 18-65 years. Analysis is based on a preliminary sample (N=2500). Interviewers read a vignette depicting 1 of 5 randomly assigned MIs- depression (DP), schizophrenia (SZ), obsessive-compulsive disorder (OCD), alcohol abuse (AA) or dementia (DT). Respondents were asked to rate whether 10 Professional/Informal sources and 12 Actions were 'helpful', 'harmful' or 'neither' for the person in the vignette. Frequencies of helpful ratings were compared with the first Mind Matters study (M1) conducted in 2015 (N=3006).

Results: In M2, seeing a psychiatrist, psychologist and counsellor were rated helpful most frequently (79%-96%) while seeking traditional medicine and religious advisors were rated the least (12%-60%) across the vignettes, except for DT where doctor and close family (81%-85%) replaced psychologist and counsellor (66%-70%). Compared to M1, phone counselling saw an increase in helpfulness rating across all vignettes ($p < .05$) except AA. For Actions, reading about how others dealt with similar problems was rated helpful most frequently (76%-89%) while dealing with problems on one's own was rated the least across all vignettes (3%-11%) in M2. Compared to M1, being more social saw an increase in helpfulness ($p < .001$) rating for DP but a decrease for AA ($p < .001$). Admission to an institution was associated with a decrease in helpfulness rating for DP ($p = .006$) and OCD ($p = .04$) but increase for AA ($p = .03$).

Conclusions: The findings suggest recognition that MIs would be helped by professionals and self-reliance is ineffective to address these problems. Increased perceived helpfulness of telephone counselling was promising as studies have shown high client satisfaction coupled with its potential in reducing some barriers to care. Differences in directional changes in helpfulness rating for institutional care and socialising for DP and AA may represent understanding of the importance of behavioral activation and

stimulus control for these MIs respectively. Literacy regarding help-seeking sources has improved in Singapore over the last 8 years which may translate into increments in seeking appropriate care.

Cardiovascular risk associated with chronic treatment of paliperidone, olanzapine, risperidone and aripiprazole

A. L. Montejo^{1*}, C. Bermejo², J. Matías³, T. Martín³, J. Matías-Polo³, Y. Santana³, J. López-López³, R. de Alarcón¹ and J. M. Acosta²

¹Psychiatry, University of Salamanca. IBSAL; ²Neurociencias, IBSAL and ³Psychiatry, Complejo Asistencial Salamanca. IBSAL, Salamanca, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.449

Introduction: Weight gain, QT interval prolongation, and dyslipidemias associated with the chronic use of some antipsychotic medications can explain a higher prevalence of cardiovascular risk in these psychiatric population. The D'Agostino Index include some factors such as age, total cholesterol, high-density lipoproteins, systolic blood pressure increased, antihypertensive treatment, smoking, and diabetes, to estimate an individual's risk (low, moderate or severe) of developing a cardiovascular event through a period of 10 years or throughout the patient's lifetime.

Objectives: To compare the degree of cardiovascular risk using the D'Agostino Index, among different antipsychotic medications.

Methods: An estimation of cardiovascular risk (low, moderate, or high) was performed with the D'Agostino index in a sample of 144 patients (82 men and 62 women) mean age 45,2 +/- 10.13. All patients were treated for at least one year at a therapeutic dose and adhered to their treatment regimen correctly. Subjects with some relevant pre-existing unstable heart disease were excluded. All patients previously provided informed consent and were of legal age. Clinical data on medical history, concomitant medications, and risk factors were collected. A completed physical exam, waist circumference, lab sample, a lifestyle scale, and an evaluation of vital signs in accordance with European Society of Hypertension were evaluated. Statistical analysis was carried out using the statistical software SPSS version 26.0. A significance level $\alpha=0.05$ was considered throughout the study.

Results: The four most consumed antipsychotics were risperidone 9.72% (n=14), paliperidone 25.7% (n=37), olanzapine 14.6% (n=21), and aripiprazole 34.7% (n=50). Descriptively, it was observed that the drugs most associated with moderate or high risks were paliperidone (37.8%) and olanzapine (33.3%), risperidone (28.6 %). Aripiprazol (22%) was the less associated compound with moderate/high cardiovascular risk.

Conclusions: Subjects treated with olanzapine and paliperidone showed a higher association with cardiovascular risk. Predicting cardiovascular risk could provide individual benefits by enabling lifestyle modifications, pharmacological treatment changes, or closer monitoring to reduce cardiovascular risk.

Changes in clozapine dose and concomitant medication - a 10-year comparative study

A. V. Popa^{1,2*}, P. Petric^{1,2}, A. Teodorescu^{1,2} and P. I. Ifteni^{1,2}

¹Transilvania University of Brasov and ²Clinical Hospital of Psychiatry and Neurology of Brasov, Brasov, Romania

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.450

Introduction: Clozapine is an atypical antipsychotic approved for treatment-resistant schizophrenia. Although effective, possible side effects make its underutilization still a current problem. The type of titration and dosages used differ worldwide.

Objectives: To asses doses of clozapine and concomitant medications used in schizophrenia during 2012-2013 versus 2022-2023.

Methods: A retrospective observational study analysing clozapine doses and concomitant treatment used in schizophrenia from 2012-2013 compared to 2022-2023. Data were collected from the medical charts of patients admitted to the Clinical Hospital of Psychiatry and Neurology Brasov, Romania, during 2012-2013 and 2022-2023.

Results: In the total of 570 patients who were admitted in 2012-2013 with a diagnosis of paranoid schizophrenia, 69 (12,10%) of them were treated with clozapine. Of the 69 cases, 53,62% patients were females, mean age was 40,95 years (SD = $\pm 10,32$), with an average of onset age 23,17 (SD= $\pm 6,21$). The average length of stay for hospitalization was 24,97 days (SD= $\pm 12,65$). The mean clozapine dose was 393,47 ((SD= $\pm 183,69$), with a minimum dose of 100mg/day and a maximum dose of 800mg/day. 37,68% of patients received concomitant treatment with benzodiazepines, mood stabilisers or sedative-hypnotic drugs. None of the patients received concomitant treatment with another antipsychotic. Among the total of 356 patients admitted with the diagnosis of paranoid schizophrenia during the 2022-2023 period, 72 (20,22%) of the patients were treated with clozapine. 72,22% patients were females, mean age was 49,12 years (SD = $\pm 11,16$), with an average of onset age 25,04 (SD= $\pm 6,40$). The average length of stay for hospitalization was 18,58 days (SD= $\pm 13,78$). The mean clozapine dose was 275,34 (SD= $\pm 146,7$), with a minimum dose of 25mg/day and a maximum dose of 600mg/day. 72,22% of patients received concomitant treatment with benzodiazepines, mood stabilisers, sedative-hypnotic drugs or with another antipsychotic. Antipsychotics used in combination with clozapine were both oral (risperidone, amisulpride, quetiapine, aripiprazole) and long-acting injectable (aripiprazole, risperidone, paliperidone, flupentixol decanoate).

Conclusions: Clozapine remains the drug of choice in treatment-resistant schizophrenia even after 10 years, but its mode of administration has changed over time. While the doses of clozapine used have decreased, the percentage of patients receiving concomitant treatment has doubled. Although some side effects of clozapine are

dose-dependent, lowering doses and combining with other adjunct treatment is not always a better option, as polypharmacy and possible adverse effects combined can lead to reduced adherence. The decision to increase the dose of clozapine or to use concomitant (combination) treatment depends on individual factors, including the patient's clinical condition, response to treatment, and the assessment of potential risks and benefits.

Use of monthly extended-release risperidone injection in schizophrenia: clinical experience

E. de la Fuente Ruiz^{1,2*}, M. D. C. Blasco Fresco¹, C. Álvarez Sanagustín³ and L. T. Durán Sandoval¹

¹Psychiatry, Hospital Universitario Miguel Servet; ²Department of Medicine, Psychiatry and Dermatology, University of Zaragoza and ³Family and Community Medicine, Hospital Universitario Miguel Servet, Zaragoza, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.451

Introduction: Monthly extended-release injectable risperidone is the new antipsychotic formulation of risperidone available in doses of 75 mg and 100 mg, approved for the treatment of schizophrenia. It contains microcrystals of risperidone that are deposited following intramuscular injection. A fraction of the active ingredient of risperidone is already solubilized and rapidly enters the bloodstream, providing plasma levels similar to oral risperidone on the first day. The microcrystals continue to release risperidone steadily over a period of 4 weeks. No oral supplementation or loading doses are required.

Objectives: The objective of this study is to demonstrate the effectiveness of treatment with monthly extended-release injectable risperidone in patients with schizophrenia who are followed up as outpatients from the Mental Health Center. The study aims to show that this treatment improves symptoms associated with schizophrenia, leading to an enhancement in the quality of life for these patients.

Methods: Analysis and evaluation were conducted on 9 patients diagnosed with Paranoid Schizophrenia and treated with monthly extended-release injectable risperidone from a Mental Health Unit and the Hospital Emergency System during the months of January to April 2023. Among the nine patients, six were previously on oral risperidone treatment exceeding 4 mg, and three were on doses less than 4 mg. The first group received a monthly injectable dose of 100 mg of risperidone, while the second group received 75 mg.

Results: All nine patients showed improvement in positive and anxious symptomatology. Seven of them exhibited improvement in affective and cognitive profiles. None of the patients experienced significant metabolic alterations, and only one of them reported akathisia as a side effect. Furthermore, all patients improved their sleep patterns, and the seven who had behavioral disturbances with a tendency towards aggression no longer exhibited these behaviors.

Conclusions: Monthly extended-release injectable risperidone is beneficial in reducing positive and affective symptoms in patients with schizophrenia. It also improves anxious, cognitive, and behavioral symptomatology. It is considered effective, safe, and

well-tolerated for long-term treatment of this disease, regardless of its initial severity. Therefore, it is advisable to consider it as the first therapeutic option in patients with schizophrenia who have responded well to oral risperidone previously.

doi: 10.1192/j.eurpsy.2024.452

Introduction: The glucagon-like peptide-1 (GLP-1) receptor agonist Semaglutide has been widely used to manage type 2 diabetes due to its favourable effects on glycemic control and weight reduction. Proved to be safe in adults and elderly patients with renal or hepatic disorders demanding no dose modification. Affective symptoms are not listed as side effects in the product information. However, there is a recent investigation going on by the European Medicines Agency (EMA) after three flagged cases of suicidal thoughts in Iceland. In contrast, the Food and Drug Administration (FDA) recommend that patients with this treatment are monitored for suicidal thoughts or behaviour.

Objectives: This case study explores the possible relationship between Semaglutide treatment and the onset of a manic episode in a 57-year-old male with no history of psychiatric disorders.

Methods: We present a 57-year-old male with no psychiatric history of interests, with a previous good functioning. A one-week history of disruptive behaviours started, characterized by excessive cheerfulness, heightened euphoria, and reduced need for sleep. Family members describe a complex situation at home, with frequent outings by the patient, engaging in conversations with strangers, getting lost, and becoming more irritable with them. The patient and family relate this mood change after initiating Semaglutide for diabetes control, starting at 7mg doses. The temporal relationship between the initiation of Semaglutide therapy, precisely a dose escalation to 7mg, and the onset of manic symptoms prompted family members to notify the patient's endocrinologist. Due to the inability to manage the patient at home and his unpredictability, they sought help at the emergency department, resulting in a psychiatric admission. Imaging and analytical tests show no significant abnormalities.

Results: During his stay in the psychiatry department, semaglutide dosage was reduced, and treatment with Aripiprazole was initiated at doses of 5mg, given the metabolic profile associated with medical comorbidities (obesity, chronic renal failure and diabetes). Subsequent clinical observations showed a gradual resolution of manic symptoms and an improvement in the patient's overall mental state.

Conclusions: This case highlights the importance of monitoring and recognizing potential neuropsychiatric side effects associated with Semaglutide therapy, particularly in individuals without a

prior psychiatric history. Further research is warranted to elucidate the underlying mechanisms linking Semaglutide with mood disturbances and to identify risk factors that may predispose certain patients to develop manic states in response to this GLP-1RA. Clinicians should remain vigilant and consider alternative treatment options if such side effects occur, ensuring comprehensive management of patients receiving Semaglutide for diabetes control.

Exploring Cariprazine's Potential in Late-Stage Schizophrenia Treatment

P. Falkai¹, R. Csehi^{2*}, K. Acsai² and G. Németh²

¹Department of Psychiatry and Psychotherapy, University Hospital of Munich Ludwig Maximilian, Munich, Germany and ²Global Medical Division, Gedeon Richter Plc, Budapest, Hungary

doi: 10.1192/j.eurpsy.2024.453

Introduction: Schizophrenia is a chronic neuropsychiatric disorder that often requires long-term pharmacotherapy to manage symptoms and prevent relapse. There are important clinical differences between early-stage versus late-stage schizophrenia, like the predominant symptomatology. In later stages, negative, cognitive, and anxiety/depressive symptoms dominate the clinical picture, with relapses further potentiating the emergence of positive symptoms. Therefore, it is crucial to establish the efficacy of an antipsychotic medication in the later stages of schizophrenia as well. Cariprazine is a novel dopamine D3-preferring D3/D2 receptor partial agonist that has shown efficacy in treating schizophrenia across the symptom spectrum.

Objectives: The aim of this poster is to present the findings of cariprazine's efficacy in treating late-stage schizophrenia, especially in symptoms that are more commonly occurring in this phase of the disorder.

Methods: This poster reports the results of a post-hoc pooled analysis of three 6-week, double-blind, placebo-controlled trials (NCT01104766, NCT01104779, NCT00694707) that assessed the efficacy of cariprazine in schizophrenia. The primary outcome was the change in Positive and Negative Syndrome Scale (PANSS) Total Scores from baseline to endpoint. The analysis focused on patients with late-stage schizophrenia (defined as having an illness-duration of more than 15 years) who received cariprazine at doses between 1.5 mg/day to 6.0 mg/day. The changes in PANSS-derived Marder Factor Scores for Negative, Disorganised Thought (i.e., Cognitive) and Anxiety/Depression symptoms were further examined. The least square mean differences (LSMDs) between cariprazine and placebo groups were calculated using mixed-models for repeated measures (MMRM).

Results: Altogether, 128 placebo-, and 286 cariprazine-treated patients were identified as having schizophrenia for more than 15 years. The mean age of patients was about 45 years, while the mean illness-duration was about 24 years. The mean baseline PANSS scores were the same between the two groups. In the late-stage schizophrenia population, at Week 6, cariprazine yielded

statistically significantly greater reductions on the PANSS Total Score (LSMD -6.7, $p < 0.01$). Cariprazine further showed superiority over placebo in reducing negative (LSMD -1.4, $p < 0.05$), disorganised thought (LSMD -1.3, $p < 0.01$), and anxiety/depression (LSMD -0.9, $p < 0.05$) symptoms.

Conclusions: Cariprazine showed efficacy in treating patients with late-stage schizophrenia. It improved overall schizophrenia symptoms, as well as the negative, cognitive and anxiety/depression symptoms that are more prevalent in this phase of the disorder.

Different modalities of measuring life engagement in people living with schizophrenia spectrum disorders: A preliminary analysis

C. Cerati¹, I. Calzavara-Pinton^{1*}, G. Nibbio¹, A. Cicale¹, D. Zardini¹, M. Italia¹, L. Altieri¹, J. Lisoni², G. Deste^{1,2}, S. Barlati^{1,2} and A. Vita^{1,2}

¹Department of Biomedical Sciences and Translational Medicine, University of Brescia and ²Department of Mental Health and Addictions, ASST Spedali Civili di Brescia, Brescia, Italy

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.454

Introduction: The concept of "life engagement" encompasses several aspects of one's life, including personal well-being, contentment, purpose, and engagement in meaningful activities. In 2006, the group led by Scheier designed a 6-item scale to measure this concept in the general population: the Life Engagement Test (LET), however, this tool was never validated in clinical populations (Scheier *et al.* 2006 J Clin Psychiatry 2006; 29 291-298). In subjects living with schizophrenia life engagement can be measured through the Positive and Negative Syndrome Scale-Life Engagement (PANSS-LE), derived by isolating 11 items (i.e., N01, N02, N03, N04, N05, N06, G06, G07, G13, G15, G16) from the PANSS (Correll *et al.* 2022 J Clin Psychiatry 2022; 83-4) (Correll *et al.* 2022 J Clin Psychiatry 2022; 83-5).

Objectives: The aim of this study was to investigate the clinical and functional correlates of two different measures of life engagement in a cohort of individuals living with schizophrenia spectrum disorders (SSD).

Methods: Ninety-five subjects living with SSD recruited from the ASST Spedali Civili di Brescia (Italy) were included in the preliminary ad-interim analysis of the present study: for each patient information regarding the clinical presentation were measured with the Clinical Global Impression (CGI) scale, the Health of the Nation Outcome Scales (HoNOS), the Brief Negative Symptoms Scale (BNSS) and the PANSS; additionally, information related to the psychosocial functioning were collected through the Global Assessment of Functioning (GAF) scale; finally, life engagement was evaluated through the LET and the PANSS-LE. Spearman's

correlations were performed using SPSS v28 and p values < 0.05 were considered significant.

Results: Both the LET and the PANSS-LE were correlated with the CGI (p=0.002 and p<0.001 respectively), but only the PANSS-LE was found to be correlated with the GAF (p<0.001), the BNSS (p<0.001) and the HoNOS (p<0.001).

Conclusions: The concept of life engagement is of growing interest for healthcare professionals working in the mental health field, in line with the concept of reaching a full functional recovery and considering patient-reported outcomes. From our study it is evident that life engagement in individuals living with SSD is better characterized through the PANSS-LE rather than the LET, as the former is more specific to define the complexity of the SSD symptomatology.

Theta-burst rTMS in schizophrenia to ameliorate negative and cognitive symptoms: a double-blind, sham-controlled, randomized clinical trial

B. Orban Szigeti^{1*}, K. Farkas¹, L. Herman¹, R. Zsigmond¹, J. Rethelyi¹ and G. Csukly¹

¹Psychiatry, Semmelweis University, Budapest, Hungary

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.455

Introduction: Schizophrenia is a major mental disorder that affects approximately 1% of the population worldwide. Social cognition impairments and negative symptoms such as blunted affect or emotional withdrawal strongly contribute to the psychosocial functioning deficits and long-term disability in schizophrenia. The state-like and trait-like components of social cognition are impaired in schizophrenia

Objectives: Treatment effects of conventional approaches with antipsychotics or psychosocial interventions are limited when it comes to reducing negative and cognitive symptoms in schizophrenia. While there is emerging clinical evidence that new, augmented protocols based on theta-burst stimulation can increase rTMS efficacy dramatically in depression, data on similar augmented therapies are very limited in schizophrenia. The different patterns of network impairments in subjects may underlie that some but not all patients responded to given stimulation locations.

Methods: Therefore, we propose an augmented theta-burst stimulation protocol in schizophrenia by stimulating both locations connected to negative symptoms, namely the vermis of the cerebellum and the left Dorsolateral Prefrontal Cortex (DLPFC). Ninety subjects with schizophrenia presenting negative symptoms and aging between 18-50 years will be randomized to active and sham stimulation in a 1:1 ratio. The TBS parameters we adopted follow the standard TBS protocols, with 3-pulse 50-Hz bursts given every 200 ms (at 5 Hz) and an intensity of 100% active motor threshold. We plan to deliver 1800 stimuli to the vermis and 1800 stimuli to the left DLPFC daily in two 9.5-minute blocks for four weeks.

Results: The primary endpoint is the change in negative symptom severity measured by the Positive and Negative Syndrome Scale

(PANSS). Secondary efficacy endpoints are the change in cognitive flexibility measured by the Wisconsin Card Sorting Test and the change in social cognition assessed by the 'Reading the Mind in the Eyes', facial emotion recognition, and the 'Faux pas' tests. The safety outcome is the number serious adverse events.

Conclusions: In conclusion the aim of our study is to prove the safety and efficacy of theta burst stimulation for treating negative symptoms of schizophrenia.

Predictors of admission to an assertive outreach service for psychosis in Lebanon

G. Kassir¹, S. El Hayek², R. Charara³, M. Cherro¹, H. Itani^{1*} and J. El Khoury⁴

¹Psychiatry, American University of Beirut, Beirut, Lebanon;

²Psychiatry and Behavioral Sciences, University of Miami Miller School of Medicine, Miami; ³Center of Behavioral Health, Cleveland Clinic, Cleveland, United States and ⁴Psychiatry and Behavioral Health, American Hospital Dubai, Dubai, United Arab Emirates

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.456

Introduction: Schizophrenia is a chronic, debilitating mental illness that contributes significantly to the global burden of disease. Assertive outreach treatment for patients with schizophrenia and psychotic disorders has been implemented to improve treatment adherence and outcomes. The suitability of this model of care outside the western context has not been fully established. The Psychosis Recovery Outreach Program (PROP), staffed by a multi-disciplinary team that applies principles of early intervention and assertive outreach, was initiated in February 2016 at a leading psychiatric facility in Lebanon.

Objectives: The aim of this study is to identify and analyze clinical and demographic variables associated with patient enrollment in PROP, out of a typical clinical population attending a psychiatric outpatient department.

Methods: This retrospective study included patients above 18 y.o. at time of first point of care with a primary diagnosis of psychosis according to the International Classification of Diseases 10 (ICD-10), and who presented to the outpatient psychiatry department at the American University of Beirut Medical Center (AUBMC) and were following up in PROP. We collected twelve-month data and used logistic regression models to identify predictor variables for enrollment in the service compared to those receiving standard treatment.

Results: In total, 45 patients participated in the study. Patients were mostly males (77.8%), younger than 39 years (80%), of college or higher education (68.2%), and diagnosed with schizophrenia (46.7%) or schizoaffective disorder (48.9%). About one-quarter (22.7%) had a comorbid cannabis use disorder. A majority received more than one oral antipsychotic (75.6%) while half (51.1%) were maintained on a long-acting injectable (LAI) antipsychotic. The following variables were significant predictors of enrollment in PROP: having a comorbid cannabis use disorder (OR 2.83 [1.25 – 6.37]), being prescribed a LAI antipsychotic (OR 9.99 [4.93-20.24])

or more than one oral antipsychotic (OR 4.57 [2.22-9.39]), visiting the emergency department more than once (OR 8.7 [2.64-28.68]), and admission to the psychiatry unit (OR 13.91 [3.17-60.94]). In addition, those following up in PROP were younger and less likely to be in the oldest age group (over 54 years) [OR 0.11 (0.01-0.93)], less likely to be females (OR 0.39 [0.18-0.81]), and less likely to be diagnosed with “other psychotic disorder” as compared to schizophrenia (OR 0.14 [0.03 – 0.62]).

Conclusions: PROP was the first community treatment program to use the principles of assertive outreach in Lebanon. Our findings highlight that the assertive out-reach model of care is applicable to its target population in the context of psychiatric care in Lebanon, namely young individuals with psychosis, higher comorbidities and a severe course of illness.

Cascadic failure and preferential decay via pruning mediated percolation on interdependent networks: implications for schizophrenia

K. Szalisznyó^{1,2*}, P. Érdi^{2,3} and D. N. Silverstein⁴

¹Psychiatry, Uppsala University, Department of Medical Sciences, Uppsala University Hospital, Uppsala, Sweden; ²Computational Sciences Department, Wigner Research Center for Physics, Budapest, Hungary; ³Department of Physics and Department of Psychology, Kalamazoo College in Kalamazoo, Kalamazoo, United States and ⁴Agora for Biosystems, Sigtuna foundation, Sigtuna, Sweden

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.457

Introduction: During adolescence the brain is dynamically changing. Destabilization and acceleration of the normal adolescent synaptic pruning process is likely a contributing factor to the neuropathology of schizophrenia. Details on whether normal pruning effects weaker synapses more or uniformly all synapses with different strengths, needs to be further evaluated. Widespread impairment in structural connectivity in schizophrenic patients involving several cortical and subcortical areas, has been previously described. In this computational study, we investigated a stochastic percolation process in interdependent networks, motivated by pathological synaptic pruning. We examined preferential decay in the connectivity decremental process, as well as differential pruning in interconnected subnetworks. Finally, the speed of the percolation process, as well as the potential for pharmacological interventions of percolation in random networks was explored. Statistical structural properties of decaying networks pinpointed several network attributes which the disintegration and phase transitions qualitatively depended on.

Objectives: The following objectives were explored: 1.) Apart from a random percolation process, we investigated preferential decay of the connections. We introduced different percolation rules for various connection types. 2.) Based on previous experimental results, we assumed that different interconnected neural subpopulations prune differently, therefore we explored differential pruning process in the subnetworks. 3.) The speed of the percolation was

studied and the pharmacological synaptic connectivity change was also analyzed.

Methods: We considered two inter-connected randomly connected networks, where the connections were removed during the percolation process. Simulations were partially performed using Octave on a Lenovo Thinkpad running the Linux operating system and partially performed on a supercomputer at UPPMAX (NAISS Small Compute 2023 Dnr: NAISS 2023/22-102).

Results: We found that the coupled network system shows rich percolation behaviors with phase transitions for various coupling strength and coupling patterns. The phase transitions of both layers are altered qualitatively between discontinuous, mixed and continuous. Recursively developing percolation in interdependent networks can cause complete fragmentation of these networks, resulting in cascadic failure which might be related to schizophrenia symptoms.

Conclusions: This computational study analyzes the pruning-mediated percolation in interdependent neural networks. Consequences of the pathological overpruning were related to the attributes of the interdependent network properties. Implications for schizophrenia development and predictions for compensatory iatrogenic percolation was also pinpointed and discussed.

Deep brain stimulation and psychosis as side effect: A case study

M. Selakovic*, C. Panetsou, T. Karkatsoulis and D. Tsaklakidou

Department of Psychiatry, ‘Sismanoglio’ General Hospital, Athens, Greece

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.458

Introduction: Deep brain stimulation (DBS) of the subthalamic nucleus (STN) is a therapeutic method used for decades in neurological diseases such as Parkinson’s disease (PD), Huntington’s disease (HD) or dystonia. HD is a rare, inherited, neurodegenerative condition that causes progressive motor deficits, psychiatric symptoms, and cognitive impairment.

Objectives: Moreover, after DBS as a psychiatric side effect has been marked and the etiology of that side effect is not well-understood.

Methods: A case study of a 51 years old male is presented, who developed involuntary movements, for the first time at the age of 17, being diagnosed with Chorea Huntington, was treated with medication without improvement of the symptoms, such as rigidity and bradykinesia. After ten years, based on guidelines, he was treated with DBS, the outcome of which showed complete improvement of neurological symptomatology. Nevertheless, he started to present delusional ideas of reference with his siblings, sleep disturbance, dysphoria and agitation.

Results: Obviously, DBS improved neurological symptomatology permanently. The medical history of our patient has shown the recurrence of psychiatric symptoms as a few mandatory psychiatric

hospitalizations and his condition has improved with olanzapine 20 mg/ daily and L.A.I. of paliperidone (once /monthly).

Conclusions: By far, DBS, as a treatment modality, has great potential to modify disease outcomes and potentially cure the devastating genetic neurodegenerative disorder such as chorea. The cases with psychiatric side effects of DBS have been described so rarely, that it's difficult to formulate conclusions that can be applied to the whole population of patients treated with DBS. In our opinion, in some cases it is possible to effectively treat the psychotic symptoms without resignation from the benefits of DBS.

Psychotic experiences in university students: prevalence, correlates and association with non-specific psychological distress

N. Werbeloff* and N. Sobol

School of Social Work, Bar Ilan University, Ramat Gan, Israel

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.459

Introduction: Subclinical psychotic experiences (PEs) are far more prevalent than psychotic disorders, with an estimated prevalence of 7.2% (Linscott & Van Os. Psychol Med 2013;43 (6) 1133-1149). PEs are particularly prevalent in late adolescence and young adulthood, when obtaining academic education is one of the main developmental tasks. University students are at the peak age of onset of mental disorders, and often experience high levels of social and academic stress that may contribute to the onset of psychopathology. Hence, estimating the prevalence and correlates of PEs among university students is particularly important.

Objectives: To estimate the prevalence of PEs in a sample of Israeli students; assess whether rates of PEs differ by selected sociodemographic characteristics; and examine the association between PEs and non-specific psychological distress.

Methods: 150 students from universities and colleges in Israel participated in a cross-sectional online survey. All students were over the age of 18 and were not diagnosed with psychotic disorders. Participants completed self-report questionnaires, including the Prodromal Questionnaire - Brief Version (PQ-B), Kessler Psychological Distress Scale (K10) and sociodemographic details. The PQ-B yields a score for the total number of items endorsed (range 0–21), and a total distress score (range 0–105). A cutoff of ≥8 distressing symptoms was used to identify participants at high-risk for psychosis.

Results: 21 participants (14.0%) reported 8 or more distressing PEs. PEs were more common in males and among those with a psychiatric illness (Table 1). PEs were not associated with marital status, religiosity, or immigrant status. While a greater number of PEs was positively associated with non-specific psychological distress ($r=0.589$, $p<.001$), there was no association between distress caused by PEs and non-specific psychological distress ($r=0.145$, NS).

Table 1. Sociodemographic characteristics by group

		PEs-	PEs+	χ^2 , p
Sex	M	29.5%	52.4%	4.32, .038
	F	70.5%	47.6%	
Marital Status	Married	17.1%	23.8%	0.56, NS
	Unmarried	82.9%	76.2%	
Immigrant	No	89.9%	85.7%	0.34, NS
	Yes	10.1%	14.3%	
Religiosity	Secular	74.4%	57.1%	2.67, NS
	Other	25.6%	42.9%	
Psychiatric illness	No	87.6%	61.9%	8.87, .003
	Yes	12.4%	38.1%	

Conclusions: The findings confirm that self-reported PEs are much more prevalent than clinically diagnosed psychotic disorders, particularly among young adults. As PEs were found to be associated with non-specific psychological distress, and as they are known forerunners for severe mental disorders, it is important to address mental health issues in school settings and promote prevention and early intervention programs.

EPP0272

Retrospective Assessment of Metabolic Syndrome and Cardiovascular Disease Risk Following Monthly and Three-Month Long-Acting Paliperidone Palmitate Treatment in Schizophrenia

S. N. Ispir*, E. Yıldız, H. R. Demirel, H. Söylemez and M. Aydın
Psychiatry, Selcuk University Faculty Of Medicine, Konya, Türkiye

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.460

Introduction: Patients with schizophrenia exhibit a higher prevalence of metabolic syndrome and cardiovascular diseases compared to the general population, resulting in increased mortality rates. The extent of this risk may vary based on the specific treatment employed.

Objectives: This study aims to compare the risk assessments of metabolic syndrome and cardiovascular diseases in schizophrenia patients who transitioned from monthly long-acting paliperidone palmitate (PP1M) treatment to three-month long-acting paliperidone palmitate (PP3M) treatment during both treatment periods.

Methods: The research was conducted at the Psychiatry Clinic and Psychotic Disorders Outpatient Clinic of Selcuk University Faculty of Medicine. Eligible participants included patients under PP3M treatment for a minimum of 6 months and undergoing continuous monitoring in the psychotic disorders outpatient clinic. Sociodemographic and clinical data, scales, laboratory values, and measurements taken both before and during the use of PP3M and PP1M were retrieved from file records, encompassing assessments,

analyses, and examinations conducted in accordance with the “Psychotic Disorders - Treatment Monitoring Protocol.” Ethical approval was obtained from the Selcuk University Ethics Committee.

Results: Among the 31 patients transitioning from PP1M to PP3M treatment, 15 (48.4%) were female. The mean age of the patients was 44.4 ± 14.4 years. No statistically significant differences were observed in the mean values of clinical evaluation and side effect assessment scales, body mass index (BMI), waist-to-hip ratio, systolic blood pressure, glucose levels, cholesterol levels, prolactin levels, and thyroid-stimulating hormone (TSH) measurements between the pre- and post-treatment phases ($p > 0.05$). However, a significant difference was identified in the mean Qrisk3 values, a cardiovascular risk index, in two distinct measurements (10-year risk score: PP1M 3.7 ± 4.2 and PP3M 4.6 ± 4.8 , $p = 0.003$).

Conclusions: Our study, designed to investigate the impact of the monthly and three-month long-acting formulations of the same antipsychotic drug on patients' clinical status, side effects, and general health parameters, found that PP3M treatment did not significantly differ from PP1M treatment in terms of Qrisk3 values. Despite the lack of statistical significance between the parameters used in Qrisk3 calculation, the observed significant difference in Qrisk3 values is attributed to variations in age. In order to promote the widespread adoption of long-acting treatments in schizophrenia management, clinicians should engage in comprehensive comparative studies assessing both efficacy and side effects.

The Role of Partial Agonists and Specifically Cariprazine in Dual Disorders

Á. Barabássy*, Z. B. Dombi, R. Csehi, D. Djuric and G. Németh
Gedeon Richter Plc., Budapest, Hungary

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.461

Introduction: The treatment of dual disorders, the co-occurrence of a major psychiatric disorder and a substance use disorder, represents a great challenge. Recent articles recommend antipsychotics with a dopamine partial agonism as first line treatment for these patients. Studies also postulate that drugs targeting the dopamine D3 receptors specifically might have an advantage, as these receptors are involved in drug-related reward, drug-seeking, and drug-intake behaviour. One compound that has both, partial agonist- and D3- activity is cariprazine.

Objectives: To evaluate the real-world evidence of the effectiveness of cariprazine in patients with dual disorders.

Methods: We performed a systematic literature search on PubMed, looking for English language articles published between January 2017 - September 2023 with the following search terms: (cariprazine) AND (psychosis OR schizophrenia OR schizoaffective OR bipolar depression OR bipolar mania OR bipolar disorder

OR major depressive disorder) AND (“substance use disorder” OR cocaine OR alcohol OR cannabis OR heroin OR “double diagnosis” OR “dual diagnosis”) NOT (animal OR rat OR mouse) NOT (review or meta-analysis). An additional targeted hand search of congress reports, posters, and case reports was also conducted.

Results: The search yielded 8 articles with 11 case reports. Mental health disorders included psychosis, schizophrenia, schizoaffective disorder, PTSD, and bipolar disorder while the abused substances were methamphetamine, cannabis, alcohol, and cocaine. All case reports described an improvement in both the symptoms of mental and substance use disorder with reduced craving and drug use and in some cases even ceasing drug use all together.

Conclusions: In summary, evidence suggests that cariprazine seem to be a potential candidate for dual disorders as it improves symptoms of both mental and substance use disorders.

³Universitat de Girona; ⁴Departament d'Infermeria and

⁵Departament de Psicologia, Institut de Recerca sobre Qualitat de Vida, Girona, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.462

Introduction: This study examines the prevalence of drug use and substance dependence among university students majoring in Social Education at the University of Girona, aiming to comprehend its impact on the mental health of this population.

Objectives: To determine the prevalence of drug use and substance dependence among university students majoring in Social Education at the University of Girona and to examine gender differences in consumption patterns.

Methods: A cross-sectional, observational, and analytical design was employed. The study population consisted of 258 enrolled students in the program. Convenience sampling was used, with a sample size of 156 students, confidence level of 95%, and margin of error of 5%. The final obtained sample size was $n = 161$. An ad hoc questionnaire was used to collect data on general characteristics and drug use. Statistical analysis included Pearson's Chi-square tests and Student's t-tests.

Results: A total of 161 students participated (88.2% females, 11.2% males), with an average age of 21.61 years. Among them, 75.8% grew up in structured families, while 24.2% came from dysfunctional families. Regarding socioeconomic status, 4.3% considered themselves from a low-class background, 32.9% from

low-middle class, 51.6% from middle class, and 11.2% from upper-middle class.

Substance dependence was identified in 29.2% of the participants: alcohol (20.3%), MDMA (11.1%), cocaine (10.3%), psychopharmaceuticals (4.8%), and hallucinogenic mushrooms (4.0%). No significant differences were found in SDS scale scores for determining dependence thresholds for any substances except for cannabis (Males = 6.13 vs. Females = 1.80, $t = 3.886$, $df = 83$, $p < .001$). A total of 55.6% of males showed substance dependence compared to 25.7% of females ($X^2 = 6.853$, $df = 1$, $p = .009$).

Conclusions: This study highlights a concerning prevalence of drug use and substance dependence among university students majoring in Social Education at the university, with certain gender-based consumption pattern differences. These findings emphasize the urgency of intervention approaches targeting mental health and substance prevention in this specific population.

Unmasking the Dual Threat of Fentanyl and Xylazine Abuse in America

M. S. Bicho*, J. M. Coelho, B. Peixoto, C. Cruz, P. Baião and I. Ferreira

Psychiatry, Hospital do Divino Espírito Santo de Ponta Delgada, Ponta Delgada, Portugal

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.463

Introduction: The United States of America are currently facing a public health crisis characterized by the abuse of synthetic opioids, notably Fentanyl, and the veterinary sedative Xylazine. While each of these substances has been associated with significant risks, their current misuse presents a formidable challenge to healthcare professionals, law enforcement agencies and policymakers. While the opioid epidemic has long held the nation in its grip, the emergence of Xylazine as complementary agent in substance abuse has added a disturbing layer of complexity to an already terrible situation, due to its cost-cutting, an increase in its addictive properties and its ability to extend the duration of the opioid with which it is combined.

Objectives: The authors intend to review the relevant and current literature in order to extend the knowledge about this condition and find the best conducts for clinical practice.

Methods: Non-systematic literature review

Results: Various regions of the United States are facing a troubling surge in the co-abuse of Fentanyl, a potent synthetic opioid many times more potent than morphine, and Xylazine, a veterinary sedative and muscle relaxant, particularly in urban areas. The motivations for this combination appear to vary, ranging from the enhanced euphoria to cost-saving measures, further fueling its prevalence. However, the consequences are devastating. Both substances depress the central nervous system, with a sharp increase in overdose deaths and emergency medical services are strained to their limits in responding to these crises. Law

enforcement agencies are facing a daunting task in curtailing the distribution of these substances, often grappling with clandestine networks that exploit the accessibility of these drugs.

Conclusions: The concurrent abuse of Fentanyl and Xylazine represents a critical public health challenge in the United States of America, demanding immediate attention and a multidisciplinary response. Failure to address this issue comprehensively will have profound implications for the well-being of individuals, families and communities across the nation. It is imperative to mobilize resources, foster interdisciplinary collaboration and develop evidence-based policies to combat this dual-threat crisis. Novel intervention strategies, including community education programs, targeted outreach efforts, and supervised consumption facilities, are urgently needed to address this complex issue.

EPP0278

An LC-MS/MS method for the determination of W18 in urine samples

R. Quraishi* and A. Kumar

National Drug Dependence Treatment Centre, All India Institute of Medical Sciences, Delhi, India

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.464

Introduction: Synthetic drugs pose one of the most significant drug problems worldwide. In this category, W18 emerges as a potent drug of abuse chemically related to fentanyl. W18 has an analgesic potency 10,000 times greater than morphine. Recent in-vitro studies reported no activity of W18 towards opioid receptors. However, its presence in seized drug samples indicates its use as a precursor in fentanyl synthesis. This emphasizes the need to develop methods for its detection in developing countries dealing with emerging new drugs.

Objectives: To develop an analytical method for the determination of W18 in urine samples.

Methods: Standards with W18 concentrations ranging from 5-500 ng/ml were prepared in negative urine along with deuterated internal standard. The samples were diluted with methanol, centrifuged and the supernatant was subjected to Liquid chromatography-tandem mass spectrometry (LC-MS-MS) with time of flight (QTOF) analysis. For chromatographic separation, a C18 column with 50 degrees oven temperature was used. The mobile phase consists of formic acid, water, and acetonitrile. The TOF MS was operated in positive ion mode and multiple reaction monitoring was used for quantification.

Results: The retention time of W18 was obtained at 9.57 minutes. The parent ion with molecular weight 422.1 along with precursor ions Q1-273, Q2-111.0, Q3-150.0 g/mol were measured. The area of the standards ranges from 1 to 9.0 log 5 with R square of 0.99. The limit of detection (LOD) and quantitation were 5 and 20 ng/ml respectively. The recovery of W18 was estimated to be 96% from the from spiked urine standards.

Conclusions: The developed method is able to detect W18 presence in urine samples. This method has the potential to be used in clinical and research studies.

Assessment of the intensity of state-trait anxiety of children with cancer

G. Kyritsi¹, A. Zartaloudi^{2*}, H. Kyritsi², E. Dousis², E. Evangelou², C. Dafogianni², M. Polikandrioti², E. Vlachou² and I. Koutelekos²

¹Greek Health System and ²University of West Attica, Athens, Greece

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.465

Introduction: Children with cancer face many difficulties on a daily basis which place them at increased risk of developing anxiety and discomfort.

Objectives: To assess the intensity of state-trait anxiety in children with cancer.

Methods: The sample of the study consisted of 100 children from Greek Children's Hospital, aged 8-16 years, of which 56 had cancer, representing the study group while the control-group was 44 in an outpatient clinic with endocrinological problems. Data were collected by the completion of the questionnaire "State-Trait Anxiety Inventory for children" by Ch. Spielberger. Statistical package S.P.S.S. was used for statistical analysis. 22 and the statistical test, t-test and anova. The significance level was set at $p < 0.05$.

Results: Of the total sample, sarcoma 38%, brain Ca 14%, 48% endocrine problem, and the largest percentage (57%) were aged 8-10 years. Children with cancer in 44.6% were under treatment and 55.4% in remission or recovery. Body image change was experienced by the 44%. The mean value of the state anxiety was 30.3 ± 5.4 and trait was 35.3 ± 6.9 . Children with cancer experienced lower levels of state anxiety compared to control group, $p = 0.049$, and did not differ in terms of trait anxiety, $p = 0.060$. In the total sample, girls experienced trait anxiety of the highest intensity, $p = 0.018$ and children aged 14-16, $p = 0.020$. No statistically significant differences were found in relation to the type of cancer in both state and trait anxiety, $p = 0.096$ and $p = 0.424$, in relation to the phase of the disease and the change of body image, $p > 0.05$. Children whose fathers were of higher education experienced less anxiety and differed significantly from those of primary and secondary education, $p = 0.036$ and $p = 0.021$, respectively. Comparison between control group and study group in relation to gender, showed that girls with cancer experienced trait anxiety of higher intensity, $p = 0.029$ but children between 14-16 years from the control group experienced trait anxiety of higher intensity, $p = 0.030$.

Conclusions: Children of both groups experienced mild to moderate anxiety and its intensity was related to socio-demographic factors of the children and their parents.

Psychiatric disorders in patients with rheumatoid arthritis

A. Feki^{1*}, I. SELLAMI^{2,2}, I. Mnif¹, A. Abbes², Z. Gassara¹, S. Ben jema¹, M. Ezzeddine¹, M. H. Kallel¹, H. Fourati¹, R. Akrou¹ and S. Baklouti¹

¹Rheumatology and ²occupational medicine, Hedi chaker hospital, Sfax, Tunisia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.466

Introduction: Rheumatoid arthritis (RA) is a systemic inflammatory disease that can lead to significant morbidity and especially to psychiatric disorders. Depression and anxiety are common symptoms in RA patients, and seem to influence disease activity, pain, and treatment response.

Objectives: The aim of this study was to investigate the prevalence of depression and anxiety and their related factors in RA patients.

Methods: 100 patients diagnosed with rheumatoid arthritis according to ACR1987 or ACR/EULAR criteria 2010 were investigated. Demographic, clinical and laboratorial data were obtained from hospitals records.

The RA severity Disease Activity was assessed by the Disease Activity Score (DAS 28). Physical function was assessed by the Health Assessment Questionnaire-Disability Index (HAQ).

The Hospital Anxiety and Depression Scale (HAD a/d) was used to evaluate the depression and anxiety symptoms. Patients with results greater than 11 are considered depressed or anxious.

Results: The group studied included 87% of women and 13% of men. The median age was 55.2 years [27-83]. The median disease duration was 11.7 ± 8.9 years.

The majority of the patients were unemployed, they were housewives in 65% of the cases, retired in 6% and 2 % had taken sick leave. The median ESR was 44 ± 31.6 mm, and the median of CRP level was 26 ± 35.3 mg/l. The median disease activity (DAS 28) was 4.6 ± 1.4 . Forty-five % had moderate disease activity ($3.2 \leq \text{DAS } 28 \leq 5.1$), and 27% of the sample had high disease activity ($\text{DAS } 28 > 5.1$). The mean of the HAQ was 1.1 [0-3].

The anxiety and depression questionnaire (HAD a/d) showed means of 10.6 for depression, and 10.25 for anxiety respectively. Depression was presented in 46 % of RA patients. Anxiety was presented in 48 %.

There was a correlation of HAD a/d with employment status ($p < 0.05$), and functional disability (HAQ) ($p < 0.001$).

There was no significant association of anxiety and depression scales with RA disease activity.

Conclusions: Chronic inflammation impairs the physiological responses to stress, resulting in depression, anxiety which leads to a worse long-term outcome in RA.

Physical disability and social factors, are predictive of psychiatric disorders in RA. This fact must be taken into account when evaluating therapeutic response.

Gender differences in the association of dementia symptoms severity and hospital anxiety

K. Bosak^{1*}, S. Vuk Pisk¹, M. Grah¹, P. Folnegović Grošić²,
Ž. Bajić³ and V. Grošić¹

¹Psychiatric Clinic Sveti Ivan; ²Department of Psychiatry, University Hospital Centre and ³Research Unit "Dr. Mirko Grmek", Psychiatric Clinic Sveti Ivan, Zagreb, Croatia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.467

Introduction: Symptoms of anxiety can worsen cognitive decline in people with dementia, and symptoms of dementia and fears of further cognitive decline can cause anxiety. Advanced dementia is not necessarily associated with a loss of emotion, which means that people may still experience anxiety, but their ability to cope in a healthy way is reduced. The problem is exacerbated by the fact that hospital care alone can contribute to the severity of anxiety symptoms due to change in routine of daily activities, unfamiliar surroundings, uncertainty about health status, prognosis and various medical procedures. There are differences between women and men in the prevalence, course and manifestation of both dementia and anxiety disorders.

Objectives: To examine whether there are differences between women and men in the association of hospital anxiety with eight symptoms of dementia: difficulties with memory, orientation, judgement, problem solving, fulfilling social obligations, daily activities at home and with hobbies, or personal care, in patients with mild to moderate dementia.

Methods: A cross-sectional study was conducted at Sveti Ivan Psychiatric Clinic in Zagreb in June 2023. The target population were hospitalised patients diagnosed with dementia, both genders, aged 60-90 years, without psychotic disorder. Anxiety during hospitalisation was measured using the anxiety subscale of the Hospital Anxiety and Depression Scale (HADS-A), and the severity of dementia symptoms was measured using the Dementia Assessment Instrument (CDR). The hypothesis was tested using Wald test of differences between women and men in unstandardised linear regression coefficients of the HADS-A on individual dementia symptoms, after adjustment for age, education, presence of a married or stable non-marital partner and duration of current hospitalisation.

Results: We enrolled 65 women and 35 men of comparable age. There were significant gender-related differences in the association between hospital anxiety and difficulties with judgement ($P = 0.01$), fulfilling social obligations ($P < 0.001$), difficulties with home and hobbies ($P = 0.02$), and personal care ($P = 0.00$). In women, more pronounced difficulties with judgement and with home and hobbies were associated with higher anxiety, and in men the presence of these two symptoms of dementia was associated with lower anxiety. Difficulties with fulfilling social obligations are associated with lower anxiety in women and higher anxiety in men. Difficulties with personal care were associated with lower anxiety in both genders, but this effect was stronger in men.

Conclusions: There are differences between women and men in the association between anxiety during hospital treatment and the severity of individual dementia symptoms. These differences are present in difficulties with judgement, fulfilling social obligations, home, hobbies and personal care.

Methylomic signature of lithium response in bipolar disorder

C. BOURDON^{1*}, C. COURTIN¹, F. BELLIVIER^{1,2,3},
B. ETAIN^{1,2,3} and C. MARIE-CLAIRE¹

¹Université Paris Cité, Inserm, Optimisation Thérapeutique en Neuropsychopharmacologie; ²Hôpitaux Lariboisière-Fernand Widal, GHU APHP.Nord – Université de Paris, Département de Psychiatrie et de Médecine Addictologique, Paris and ³Fondation Fondamental, Créteil, France

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.468

Introduction: Bipolar disorder (BD) is a chronic and severe psychiatric disorder, characterized by the alternance of episodes of (hypo)-mania and major depression. Lithium (Li) is the first-line treatment for BD but unfortunately response to Li is highly variable: after at least two consecutive years of treatment, only a fraction of patients receiving Li will display significant improvement in the frequency and/or severity of mood recurrences. This interindividual variability of treatment response is difficult to predict, in the bipolar disorder context. This could be determined by genetic factors still misidentified by available genetic studies. In addition, no clinical or biological markers are available to reliably define eligibility criteria for a lithium treatment in bipolar disorder. A consequence is a long process of therapeutic trials (18-24 months) to phenotype Li response, delaying the stabilization.

Objectives: To identify objective biomarkers of the prophylactic response to lithium in order to improve patient care and propose therapeutic alternatives to patients who do not respond to lithium.

Methods: Using a genome-wide methylomic approach, and then logistic regressions incorporating as covariates the different types of treatments, we were able to identify differentially methylated regions (DMRs) whose methylation difference between responders and non-responders was not impacted by co-prescribed treatments. Then, we used Methylation Specific High-Resolution Melting (MS-HRM), a PCR based method than can be implemented in any medical laboratory at low cost and with minimal equipment, to estimate methylation proportion of 9 DMRs in 61 samples of bipolar patients.

Results: In the sample of 61 individuals with BD, the 9 MS-HRM-measured DMRs combined with clinical variables (age, sex, cigarette smoking status, lifetime number of hospitalizations, age at onset of BD, polarity at onset, psychotic symptoms at onset, family history of BD, lifetime alcohol/cannabis misuse, panic disorders, Li prescribed as the first mood stabilizer (vs 2nd or 3rd choice)) correctly classified 83,6% of individuals as good or non-responders ($n=61$, prophylactic response phenotype defined using the "Alda" scale). Excluding the partial responders, the percentage of correctly classified individuals is as high as 100% ($n=43$, 18 non responders and 25 responders). The AUC are respectively $AUC=0.913$ and $AUC=1.0$.

Conclusions: The MS-HMR method allow to identify the response status of individuals with BD with 9 DMR. These DMRs

discriminate good from non-responders and can be used in combination with clinical variables.

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.469

Introduction: A 10-15 years decrease in life expectancy has been observed in individuals with bipolar disorder (BD) and has been associated with premature cellular aging, but mechanisms involved remain unclear. Our team recently identified a subgroup of young individuals with prematurely shortened telomere length (TL).

Objectives: The aims of the present study were to replicate this observation in a larger sample and to analyze the expression levels

of genes associated with age or TL in a subsample of these individuals.

Methods: TL was measured by qPCR using peripheral blood DNA from 542 individuals with BD. Clustering analyzes were performed with age and TL as classification variables to identify similar groups.

Gene expression of 29 genes, including 20 associated with age and 9 with TL, was analyzed by RT-qPCR using peripheral blood RNA in a subgroup of 129 individuals. Gene expressions were compared between groups obtained from the previous clustering analyzes by Kruskal-Wallis and Mann-Whitney tests.

Results: Clustering analyzes identified 3 subgroups and replicated the clustering previously described: a subgroup of aged individuals with a low TL (mean age : 51.73 years ; mean TL : 2), a subgroup of young individuals with a high TL (mean age : 29.02 years ; mean TL : 4.36) and a subgroup of young individuals but with a low TL (mean age : 29.64 years ; mean TL : 1.96). None of the tested clinical variables were significantly associated with this subgroup.

Furthermore, gene expression level analyzes showed that only *POT1* expression was different between the two subgroups of young individuals, with a downregulation of *POT1* expression in the subgroup with a lower TL level. *POT1* is a protein involved in the maintenance of TL. *POT1* binds to another protein TPP1 allowing the recruitment of telomerase, the enzyme which extends TL. Our hypothesis is that in the subgroup presenting a lower *POT1* expression, the *POT1*-TPP1 complex cannot form and thus prevents telomerase recruitment and TL elongation.

Conclusions: This study confirms, on a larger sample, the existence of a subgroup of young individuals with BD presenting accelerated cellular aging. The observed decrease of *POT1* expression level suggests a newly described cellular mechanism in individuals with BD, that may contribute to telomere shortening.

Disclosure of Interest: None Declared

EPP0288

Telehealth Treatment of Patients with Bipolar Depression during the COVID-19 Pandemic: Comparative Safety, Patient Satisfaction, and Effectiveness to Prepandemic In-person Treatment

M. Zimmerman

Psychiatry, Brown University, Providence, United States

doi: 10.1192/j.eurpsy.2024.470

Introduction: The COVID-19 pandemic prompted a transition from in-person to telehealth psychiatric treatment. There are no studies of partial hospital telehealth treatment for bipolar disorder.

Objectives: In the present report from the Rhode Island Methods to Improve Diagnostic Assessment and Services (MIDAS) project, we compared the effectiveness of partial hospital treatment of patients with bipolar depression treated virtually versus in-person.

Methods: Outcome was compared in 76 patients with bipolar depression who were treated virtually from April, 2020 to December, 2022 to 130 patients who were treated from May, 2017 to January 2020. The patients completed self-administered measures of patient satisfaction, symptoms, coping ability, functioning, and general well-being.

Results: In both the in-person and telehealth groups patients with bipolar depression were highly satisfied with treatment and reported a significant reduction in symptoms from admission to discharge. Both groups also reported a significant improvement in positive mental health, general well-being, coping ability, and functioning. Suicidal ideation was reduced in both groups. No patients attempted suicide. A large effect size of treatment was found in both treatment groups. The length of stay and the likelihood of staying in treatment until completion were significantly greater in the virtually treated patients.

Conclusions: Telehealth delivery of partial hospital level of care for patients with bipolar depression was as safe and effective as in-person treatment.

Comparative analysis of self-stimulatory behaviors in ASD and ADHD

B. A. Oroian^{1*}, G. Costandache¹, E. Popescu¹, P. Nechita¹ and A. Szalontay¹

¹Institute of Psychiatry "Socola" Iasi, Iasi, Romania

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.471

Introduction: The phenomenon of self-stimulatory behaviors, commonly referred to as "stimming," presents a fascinating avenue of exploration within the context of neurodevelopmental disorders. While stimming behaviors are widely associated with ASD, there is emerging evidence suggesting that individuals with ADHD may also engage in similar behaviors. This study seeks to undertake a comprehensive investigation of the neurophenomenology of stimming in individuals diagnosed with ASD and ADHD, aiming to discern potential shared and distinctive characteristics.

Objectives: The principal objective of this research is to conduct an intricate neurophenomenological analysis of stimming behaviors in cohorts diagnosed with ASD (n=60) and ADHD (n=60), with a concurrent control group of neurotypical individuals (n=60). The study aspires to delineate the prevalence, typology, and neurophysiological underpinnings of stimming behaviors in both ASD and ADHD populations. Moreover, this study endeavors to identify whether particular stimming behaviors exhibit differential prevalence or intensity between the two disorders.

Methods: Participants underwent rigorous neurophenomenological assessments, incorporating structured interviews, validated self-report questionnaires and direct observations. Diagnostic confirmation was established through the administration of gold-standard instruments, such as the Autism Diagnostic Observation Schedule (ADOS-2) for ASD and the Conners' Parent Rating Scale for ADHD. Stimming behaviors were meticulously categorized (e.g., motor, vocal, sensory) and scrutinized for quantitative metrics, including frequency, duration, and complexity.

Results: Preliminary analyses have uncovered profound disparities in the manifestation of stimming behaviors between ASD and ADHD cohorts. Individuals with ASD displayed a significantly higher prevalence of stimming behaviors, with motor stimming

predominating, followed by vocal and sensory manifestations. In contrast, individuals with ADHD exhibited a comparatively reduced frequency and intensity of stimming, primarily within the motor domain, albeit notably less elaborate. Control group participants exhibited a negligible occurrence of stimming behaviors.

Conclusions: This multidimensional exploration illuminates the nuanced neurophenomenological distinctions in self-stimulatory behaviors between ASD and ADHD. Stimming emerges as a pivotal feature in ASD, while its presence in ADHD, though discernible, is markedly attenuated. This study's findings hold implications for precise diagnostic delineation and the prospect of personalized interventions for these complex neurodevelopmental conditions. Future avenues of research may delve into the neural substrates underpinning stimming behaviors, further enhancing our comprehension of these phenomena.

EPP0293

Systematically Informed Literature Review: What is the Prevalence of Borderline Personality Disorder (BPD) in Adolescents, 13-17, using DSM-5 Criteria?

S. Abdullah

Child & Adolescent Psychiatry, CNTW NHS Foundation Trust, Newcastle upon Tyne, United Kingdom

doi: 10.1192/j.eurpsy.2024.472

Introduction: In child & adolescent mental health settings, borderline personality disorder (BPD) is a dominant and substantial condition with high occurrence rates seen in community, crisis, and in-patient settings. Previously because of multiple concerns, BPD diagnosis in adolescents was considered questionable and was perceived to be invalid. However, in light of the evidence, recent guidelines and diagnostic manuals affirm the diagnosis in the under-18 population.

Objectives: Given its existence in adolescents and that DSM-5 (from 2013) allows diagnosing BPD in adolescents, a study was conducted in 2019 to explore what current literature had to say about its prevalence.

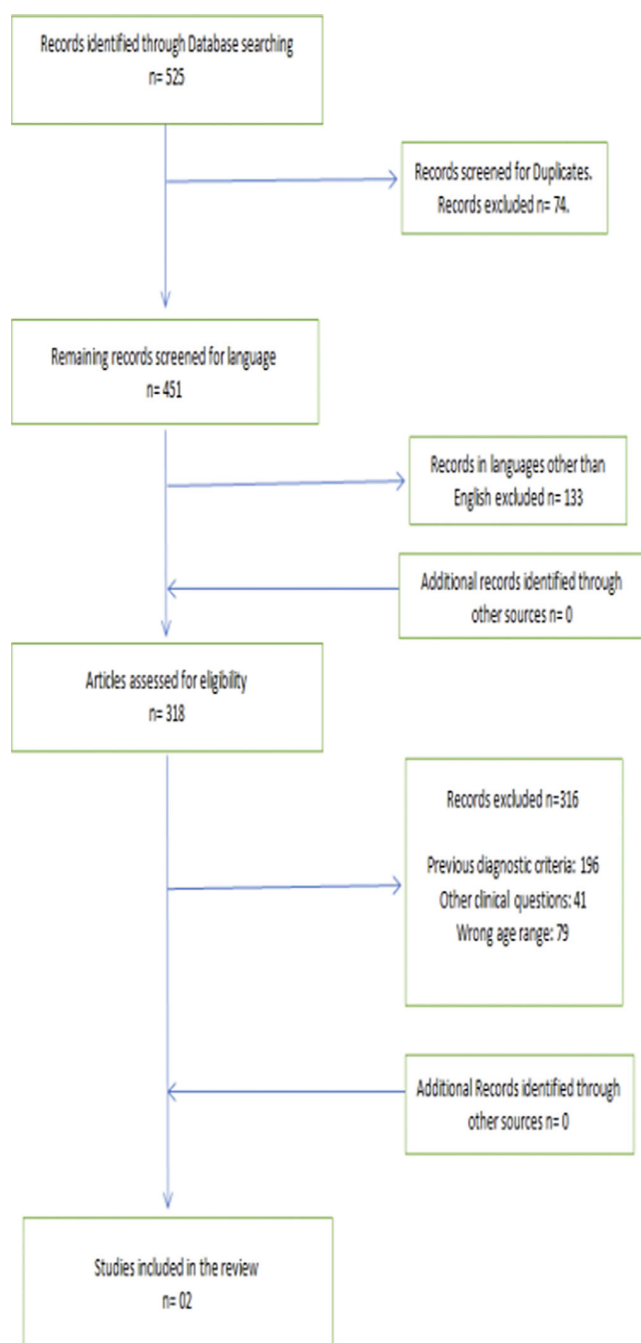

Methods: To answer this, a systematically informed literature review tried to look at the evidence. The hypothesis was that not many clinicians or researchers are aware of or using the opportunity to diagnose and thus manage BPD in adolescents, i.e., early in the course of this illness. Four databases were searched- PubMed, Embase, Medline, and Psycinfo- with the following inclusion & exclusion criteria:

1. Age: Adolescents (13-17).
2. BPD (disorder not traits or features).
3. Language – English, not just the abstract in English.
4. Time limit & diagnostic criteria (2013 onwards, DSM-5).
5. Full length articles not Abstracts alone.
6. No geographical limit.
7. Contacted academics personally for additional data.

Following search terms were used: Borderline Personality Disorder, BPD, EUPD, Emotionally Unstable Personality disorder, DSM V, DSM 5, Diagnostic and Statistical Manual of Mental Disorders 5, DSM-5, Prevalence, Rate.

Results: All searches yielded 525 results. Other sources didn't identify any other records to be included. Out of these 525 results, 74 were duplicates. The inclusion and exclusion criteria were applied on the remaining resources. Of the remaining records, 133 were in language other than English, and thus, were excluded. Remaining 318 articles were assessed for eligibility. Of these, 196 had used diagnostic criteria or rating scales based on previous diagnostic criteria, and thus were excluded. Furthermore, 41 articles had focused on a totally other clinical question than ours. 79 articles had the wrong age range as per our diagnostic criteria. Thus, the total number of articles which met inclusion and exclusion criteria was 02. The results showed higher rates of BPD in adolescents, especially in those exposed to online sexual solicitation (OSS) (355 vs 13%) and in females (80% of cases).

Image:

Conclusions: Despite the research and diagnostic allowance, there still seems to be reluctance among clinicians to diagnose BPD in adolescents. We advise consideration of BPD in adolescents if clinical picture indicates and application of the relevant criteria so patients can get appropriate treatment and support that they need.

Associations between general and specific psychopathology factors in parents and psychiatric, behavioral, and psychosocial outcomes in offspring: a Swedish population-based register study

M. Zhou^{1*}, H. Larsson¹, B. D'Onofrio¹, M. Landén¹, P. Lichtenstein¹ and E. Pettersson¹

¹Karolinska Institutet, Stockholm, Sweden

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.473

Introduction: Psychiatric conditions in parents are associated not only with the same condition in offspring, but also with virtually all other psychiatric conditions. However, it remains unknown whether this intergenerational transmission of psychiatric conditions was attributable to broader psychopathology comorbidity or to specific conditions.

Objectives: To estimate associations between general and specific factors of psychopathology in parents, and a wide range of register-based outcomes in their offspring.

Methods: Based on Swedish national registers, we linked 2 947 703 individuals born in Sweden between 1970 and 2000 to their biological parents (1 705 780 pairs of parents) and followed them to December 31, 2013. First, we estimated one general and three unrelated (specific) psychopathology factors (capturing internalizing, externalizing, and psychotic problems, respectively, independently of general psychopathology) based on nine parental register-based psychiatric diagnoses and violent criminal court convictions. Second, we regressed each offspring outcome on the latent general and three specific factors simultaneously.

Results: The general psychopathology factor in parents was significantly associated with all 31 offspring outcomes (mean Odds Ratio (OR) = 1.22; range: 1.08–1.40), which means that children whose parents scored one standard deviation above the mean on general psychopathology had, on average, a 23% higher probability of all outcomes. The specific psychotic factor in parents was primarily associated with psychotic-like outcomes (mean OR = 1.17; range: 1.05–1.25), and the specific internalizing factor in parents was primarily associated with offspring internalizing (mean OR = 1.11; range: 1.11–1.13) and neurodevelopmental outcomes (mean OR = 1.07; range: 1.02–1.10). The specific externalizing factor in parents was associated with externalizing (mean OR = 1.27; range: 1.21–1.32) and internalizing outcomes (mean OR = 1.10; range: 1.01–1.13).

Conclusions: The intergenerational transmission of psychiatric conditions across different types of spectra appeared largely attributable to a parental general factor of psychopathology, whereas specific factors were primarily responsible for within-spectrum associations between parents and their offspring. Service providers

(e.g., child psychologists, psychiatrists, teachers, and social workers) might benefit from taking the total number of parental mental health problems into account, regardless of type, when forecasting child mental health and social functions.

“Scan Me!”: a rehabilitation approach at the intersection between digital interventions and mountain-therapy

A. Barbieri

Department of Mental Health, ASL CN1, Cuneo, Italy
doi: 10.1192/j.eurpsy.2024.474

Introduction: Mountain-therapy is a therapeutic-rehabilitative approach aimed at secondary prevention, treatment, and rehabilitation of individuals with different pathologies or disabilities. Interventions in this field are based on potentially transformative dimensions of the mountain environment. Activities can include trekking, climbing, hiking, speleology, and winter sports. Benefits associated with these interventions are related to physical health as well as to rehabilitation in the domain of mental health and to the promotion of healthier lifestyles.

Objectives: The pilot project named “Scan Me!” has been developed by mental health services (*Centro Diurno*) of Cuneo (Italy), drawing on their long-standing experience with Mountain-therapy. The aim was to improve the efficacy of mountain-based activities, introducing elements of digitalisation able to actively engage service users and the broader community.

Methods: “Scan Me!” introduces an innovative activity of mapping, communicating, and digitising the mountain environment. The intervention includes: i) participatory identification of thematic areas (e.g. history of a place; local biodiversity; ancient practices); ii) exploration of the identified areas through readings, interviews and research; iii) preparing of messages (texts, pictures, videos) that the group wishes to convey; iv) creation of QR-codes containing the messages; v) positioning of QR-codes along mountain trails during dedicated excursions; vi) setting up of online surveys to get feedback from QR-codes’ users; vii) group discussion of feedbacks and the overall experience. The project includes monitoring and evaluation tools, such as activity forms (filled in with observational data by mental health professionals), self-administered questionnaires for participants, and engagement indicators.

Results: Findings show that the project enhances the therapeutic-rehabilitative value of mountain-based activities, such as increased self-esteem and self-efficacy that follow the completion of a route and relational skills developed within a group. The project shows encouraging results in the planning ability area (identification of themes, setting up of messages, creation and positioning of QR-codes). Being rooted in participants’ interests, the project promotes service users’ knowledge, its sharing with the group and with the general public (mountain visitors). Furthermore, the

project implies group reflection, commitment to a concrete objective, and attunement with the recipients of messages (which needed to be tailored for heterogeneous audiences – e.g.: hikers, students, tourists). Lastly, the project is youth-friendly, allowing services to engage a group they aim, but often struggle, to reach.

Conclusions: The pilot encourages further research to understand the potential of rehabilitation tools at the intersection between nature-based and digital mental health interventions.

Changing our way of working for a greater integration of mental health patients: The evolution of the Zamora’s Assertive Community Treatment over the last 10 years

L. Vicente Rodriguez^{1*}, L. Giménez Robert¹, L. Carrascal Laso¹, V. Saez Enguidanos¹, R. S. Gamonal Limcaoco¹ and M. A. Franco Martin¹

¹Psychiatrist Department, Complejo Asistencial Zamora, Zamora, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.475

Introduction: Since its beginning in the 1970s in Wisconsin, Assertive Community Treatment (ACT), has been adopted by numerous hospitals worldwide. It improves outcomes for people who are most at-risk of psychiatric hospitalization. The main goal is to provide a global attention with a focus on promoting maximum autonomy and facilitating integration into society. In 2012, the Health Care Complex of Zamora, Spain, adopted this pioneering approach to Mental Health. The main efforts were focused on creating a community network for individuals with severe mental disorders. It embraced a biopsychosocial model of intervention aimed at facilitating patient recovery, giving them tools to create a new life project based on their own autonomy.

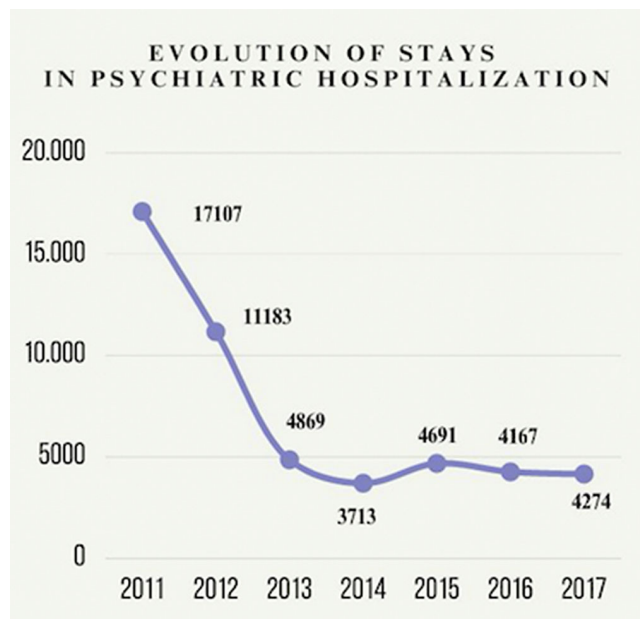

Objectives: The primary objective of this study was to assess the progress of the Assertive Community Treatment (ACT) since its introduction at the Health Care Complex of Zamora, with a specific focus on analyzing the number of hospitalizations as the dependent variable.

Methods: A quantitative analysis about psychiatry number of hospitalizations was conducted using the database of the Zamora’s Psychiatry Hospitalization Unit. SPSS Statistics for Windows was used to calculate statistical values related to number of hospitalization. The dataset covers the period from 2010 to 2017.

Results: The implementation of ACT has resulted in a significant reduction in hospitalizations reaching up to 75% in the Psychiatry Service of Zamora. It has been revealed a decrease from 17107 hospitalizations registered in 2011 to a total reduction to 4869 stances in 2013. A consistent trend in the reduction of hospitalizations has been observed (figure 1). A restructuration of the Hospitalization Unit was performed in order to implement the community model and reduce hospitalizations. Removal of more than 50% of the beds was developed. Besides, there has been

implemented a community subunit with the objective of regaining their autonomy after a psychiatric exacerbation.

Image:

Conclusions: Getting hospitalized in a Psychiatry Unit can have many different socio-laboral consequences. The ACT model has demonstrated a significative reduction in hospitalizations and it has evolved into a support network dedicated the integration of individuals that are usually left behind by society. Moreover, it presents itself as a positive cost-benefit intervention. ACT allows us to envision a future with fewer hospitalization and greater integration of mental health patients into modern society.

It is important to emphasize that the city of Zamora possesses unique characteristics that have facilitated the adaptation of this model. Not only are the rental prices for housing usually affordable, but the city's small size, which easy walking, allows for easy access to Community Mental Health resources and services.

Awareness of the disease and attitude to treatment in patients with various mental disorders at the initial stages of the disease

V. Mitikhin*, G. Tiumenkova and L. Alieva

Department of Mental Health Services, Mental Health Research Centre, Moscow, Russian Federation

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.476

Introduction: An important aspect in providing effective psychiatric care and treatment is the formation of an adequate perception of their mental disorder in patients and awareness of the need for treatment, especially at the initial stages of the disease. Patients' misunderstanding of their own psychopathological manifestations

can act as a serious obstacle to their compliance and lead to an increase in the frequency of exacerbations and repeated hospitalizations.

Objectives: To assess the attitude to the disease and treatment in patients with various mental disorders at the initial stages of the disease.

Methods: Clinical and psychopathological, psychological, statistical. The following scales were used: Drug Attitude Inventory (DAI, Hogan T.P. et al., 1983); Insight Scale for Psychosis (ISP, Birchwood M., 1994); Questionnaire "Style of self-regulation of behavior" (SSPM, V.I. Morosanova, 1988) and others. 17 patients with a diagnosis of bipolar disorder (BD, F31.xxx, ICD-10) were examined, the average age of patients was 25.52 ± 4.55 years and 39 patients with a diagnosis of schizophrenia (F20.1xx and F23.1xx, ICD-10), the average age of patients was 29.29 ± 9.71 . The duration of the disorder in both groups of patients was 0.5-3 years.

Results: A comparative analysis of the average scores of the scale of attitude to the disease revealed significant differences in the groups ($p \leq 0.01$). Patients with schizophrenia had a lower awareness of their disease (2.31 ± 0.91 points) than patients with bipolar disorder (3.59 ± 0.76 points). Correlation analysis revealed reliable connections ($p \leq 0.01$) between the scales of attitude to the disease and drugs and the self-regulation questionnaire. In patients with schizophrenia, deeper violations were found in the links of self-regulation, such as programming and planning when assessing the presence of a mental disorder and deterioration of their condition due to discontinuation of medication ($r=0.38$ and $r=0.36$, respectively). The low level of self-regulation in general and the rigidity of negative attitudes in awareness of the disease and the need for treatment also have a negative impact on compliance with the medication regimen. No such correlations were found in patients with bipolar disorder: they were more aware of the presence of a mental disorder and the need for treatment, but the degree of compliance with the medication regimen was not high enough.

Conclusions: The treatment of patients with mental disorders requires an integrated approach with the mandatory inclusion of a psychoeducational component in order to form an adequate model of their disease and an understanding of the expected risks when therapy is discontinued. Psychoeducation is especially relevant in the early stages of the disease, both for patients with schizophrenia and with BD.

Assessing the recovery process in a mobile rehabilitation team for people with severe mental disorders by using the Recovery Helm

S. Strkalj Ivezić^{1*}, M. Curkovic¹ and D. Štimac Grbić^{2,3}

¹Research, University psychiatric hospital Vrapce; ²Department for mental health, Croatian institute for public health and ³School of public health A Stampar, School of Medicine University of Zagreb, Zagreb, Croatia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.477

Introduction: People with severe mental disorder (SMD) determine the goals and paths of recovery with professional and non-formal supporters such as family and friends. It is crucial that these

people, as well as everyone who participates in the recovery process, are familiar with all the elements that contribute to the recovery of mental health in order to help people with SMD identify goals and assess their achievement. We have therefore created a Recovery Helm to assess the functioning in the various areas necessary for recovery to help us assess the needs and monitor the recovery process of people with mental health problems.

Objectives: The goal is to assess the initial state of mental health and monitor the effects of the mobile rehabilitation team program on the recovery of people with SMI through the use of the Recovery Helm.

Methods: We used the Recovery Helm: <http://shorturl.at/gyCDQ> as an instrument for the initial assessment of all areas crucial for recovery to determine the goals of recovery and interventions needed to achieve these goals of rehabilitation in 30 patients included in the program of the mobile rehabilitation team applying different psychosocial interventions according to the individual recovery plan made as a mutual agreement between patients and rehabilitation team. The status of recovery is evaluated after 3 and 6 months.

Results: The results indicate significant improvements in most areas of the recovery assessed at the Recovery Helm selected as individually important goal for a person included in the rehabilitation program

Conclusions: The Recovery Helm is an excellent clinical assessment instrument that helps determine recovery goals and rehabilitation interventions that promote recovery and monitor the achieved results.

Navigating the Professional Journey for Adults with Attention Deficit/Hyperactivity Disorder: Challenges and Strategies

S. A. Pinho* and F. Coutinho

Hospital de Magalhães Lemos, Centro Hospitalar Universitário de Santo António, Porto, Portugal

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.478

Introduction: Attention deficit/hyperactivity disorder (ADHD) is a neurodevelopmental disorder that affects approximately 5% of adults. Individuals with ADHD often display symptoms of inattention, including poor time management and difficulty concentrating and completing tasks. Hyperactivity frequently attenuates over time and transforms into inner restlessness, leading to workaholic behaviors. Impulsive symptoms, on the other hand, may manifest as irritability and low frustration tolerance.

Objectives: To describe the workplace challenges that adults with ADHD face and to explore strategies to improve their occupational outcomes.

Methods: A non-systematic review of the clinical literature available in PubMed was conducted using the keywords: "employment" and "attention deficit hyperactivity disorder".

Results: Individuals diagnosed with ADHD, in contrast to those without the condition, statistically exhibit poorer job performance and increased lateness, job instability, workplace injuries, particularly traffic accidents, comorbid diseases, and financial problems. Therefore, they often work harder to compensate for their

limitations however the findings regarding the health impact of such high job demands are inconsistent. Stimulant therapy during childhood is the main predictor of successful adult employment. Contrarily, risk factors for workplace impairment in ADHD include female gender, executive deficits, lower IQ, less education, combined/inattentive subtype, and history of substance abuse, depression, or anxiety. It was also demonstrated that ADHD individuals may thrive in manual and creative roles and hyperactivity can benefit self-employment. Psychiatrists should offer psychoeducation, along with psychostimulants if necessary, as it is the first-line treatment. Nonetheless, the long-term impact of pharmacological treatment on professional outcomes remains unclear. Although most employers lack ADHD knowledge, workplace strategies including well-defined duties, feedback, job control, and flexibility have been shown to effectively mitigate ADHD symptoms.

Conclusions: Evidence suggests that a significant amount of employees with ADHD face challenges in finding and keeping a job. Thus, identifying and treating ADHD in adulthood is imperative to help them selecting careers that align with their strengths and weaknesses, which are partially influenced by ADHD, and to promote optimal occupational health. This effort requires collaboration between psychiatry and occupational health professionals. Additionally, it is necessary to start implementing educational campaigns among workforce teams to effectively accommodate workers with ADHD. Further studies are needed to develop occupational programs and rehabilitating interventions tailored to this population.

Efficacy of Silexan in Patients with a Major Depressive Episode – First Results from a Multi-centre, Double-blind, Randomised, Placebo- and Reference-controlled Phase III Trial

S. Kasper^{1*}, E. Seifritz² and H.-P. Volz³

¹Molecular Neuroscience, Medical University of Vienna, Vienna, Austria; ²Psychiatry, University of Zürich, Zürich, Switzerland and

³Department of Psychiatry, Psychotherapy and Psychosomatic Medicine, Hospital OF PSYCHIATRY, Werneck, Germany

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.479

Introduction: Silexan [1], an essential oil from *Lavandula angustifolia* flowers, is the active substance of a medicinal product for oral use in the treatment of anxiety disorders. It has been shown to be effective in the treatment of patients suffering from mixed anxiety and depression.

[1] Silexan® is a special essential oil from *Lavandula angustifolia*, Dr. Willmar Schwabe GmbH & Co. KG, Karlsruhe, Germany

Objectives: The trial (ISRCTN36202964) was conducted to investigate the antidepressant efficacy of Silexan in patients with a major depressive episode compared to placebo and Sertraline.

Methods: Adult patients (≥18 years) suffering from a major depressive episode of mild to moderate severity according to ICD-10 were included. Further inclusion criterion was a total score of 19 –

34 points in the Montgomery-Asberg-Depression Rating Scale (MADRS). Randomised patients took 80 mg Silexan, 50 mg Sertraline, or placebo once daily over 8 weeks. Primary efficacy endpoint was the change of the MADRS total score between baseline and week 8. Response (a reduction of the MADRS total score $\geq 50\%$), remission (MADRS total score < 10 at the end of the treatment), the Patient Health Questionnaire PHQ-9, the Beck Depression Inventory, the Clinical Global Impressions, and the Sheehan Disability scale served as secondary endpoints.

Results: The full analysis set consisted of 498 patients. Between the start and end of treatment, the MADRS total score decreased by 12.1 (13.3, 11.0) points (adjusted mean, 95% confidence interval) in patients treated with Silexan, by 12.6 (13.7, 11.5) points in patients treated with Sertraline, and by 9.95 (11.1, 8.77) points under placebo. The confirmatory analysis proved that Silexan was significantly superior to placebo ($p < 0.01$, ANCOVA). Internal validity could be shown since the treatment effects of the active comparator Sertraline were also more pronounced compared to placebo ($p < 0.01$). There were no relevant differences between Silexan and Sertraline. Response was achieved by 53.5% of the patients in the Silexan group, by 54.0% of the patients in the Sertraline group, and by 41.5% of the patients in the placebo group. 44.4% of the patients treated with Silexan were remitter, compared to 45.2% under Sertraline and 32.6% under placebo. In both active treatment groups responder and remission rates were higher than in the placebo group ($p < 0.05$). Results of the secondary endpoints were in line with the results of the primary endpoint.

Conclusions: In a large phase III clinical trial, Silexan was more effective than placebo and not different to Sertraline in patients with a major depressive episode. Treatment effects were clinically relevant.

Ketamine enhanced ECT in refractory recurrent depression.

B. Arribas-Simon^{1*}, P. Martinez.Gimeno¹, M. Calvo-Valcarcel¹, C. Alario-Ruiz¹ and O. Martin-Santiago¹

¹Hospital Clinico Universitario, Valladolid, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.480

Introduction: Recurrent Depressive Disorder is a chronic condition that significantly impacts the quality of life. Despite various treatment options, some patients face severe and treatment-resistant relapses. This case is related to research on ketamine in Electroconvulsive Therapy (ECT) for RDD. One study highlighted

the efficacy and safety of ketamine compared to other anaesthetic agents in ECT for major depression. Additionally, another study explored subanesthetic doses of ketamine before each ECT session to improve therapeutic outcomes and sleep quality in patients with major depressive disorder.

Objectives: To present a clinical case of a patient with Recurrent Depressive Disorder (RDD) who improved following a change in the Electroconvulsive Therapy (ECT) protocol using ketamine as an anaesthetic inducer.

Methods: We examined the patient's medical records, including her medical history, previous treatments, and therapeutic responses.

Results: A 65-year-old childless woman with a history of stroke, bilateral carotid atheromatosis, and hypothyroidism suffered from RDD. Despite multiple prior treatments and ECT, she experienced a severe depressive relapse. Eight intensive ECT sessions were administered, with observed memory lapses. Due to the lack of response, the anaesthetic inducer etomidate was replaced with ketamine, resulting in a positive response. The patient continued pharmacological treatment with improved mood, but recent and evident memory alterations persisted, possibly related to antero-grade amnesia.

Conclusions: This case highlights the complexity of RDD in patients with comorbidities and treatment-resistant relapses. The change in the ECT protocol using ketamine was effective, emphasizing the importance of alternative therapeutic approaches in refractory cases. The successful treatment of RDD in this patient using ketamine in ECT underscores the need for personalized therapeutic options in treatment-resistant patients. These scientific resources reinforce the relevance of exploring therapeutic alternatives in contemporary clinical practice. We need more research to understand the underlying mechanisms and how this approach could be enhanced in similar cases.

Revealing complexity: beyond the whole—segmentation of hippocampal subfields in adolescents with depression and its relationships with cognition

Y. Zhang¹, X. Liu¹, Y. Yang², F. Xu², D. Yu³, X. Zhu⁴, K. Wang^{1*} and W. Zhang¹

¹School of Psychology, Shandong Normal University; ²Shandong Mental Health Center; ³Radiology Department of Qilu Hospital, Shandong University, Jinan, China and ⁴Institute of Health and Wellbeing, University of Glasgow, Glasgow, United Kingdom

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.481

Introduction: The occurrence of depression in adolescence, a critical period of brain development, linked with neuroanatomical and cognitive abnormalities. Neuroimaging studies have identified hippocampal abnormalities in those of adolescent patients. However, few studies have investigated the atypically developmental trends in hippocampal subfields in adolescents with depression and their relationships with cognitive dysfunctions.

Objectives: To explore the structural abnormalities of hippocampal subfields in patients with youth depression and examine how these abnormalities associated with cognitive deficits.

Methods: We included a sample of 79 first-episode depressive patients (17 males, age = 15.54 \pm 1.83) and 71 healthy controls

(23 males, age = 16.18±2.85). The severity of these adolescent patients was assessed by depression scale, suicidal risk and self-harm behavior. Nine cognitive tasks were used to evaluate memory, cognitive control and attention abilities for all participants. Bilateral hippocampus were segmented into 12 subfields with T1 and T2 weighted images using Freesurfer v6.0. A mixed analysis of variance was performed to assess the differences in subfields volumes between all patients and controls, and between patients with mild and severe depression. Finally, LASSO regression was conducted to explore the associations between hippocampal subfields and cognitive abnormalities in patients.

Results: We found significant subfields atrophy in the CA1, CA2/3, CA4, dentate gyrus, hippocampal fissure, hippocampal tail and molecular layer subfields in patients. For those patients with severe depression, hippocampal subfields showed greater extensive atrophy than those in mild, particularly in CA1-4 subfields extending towards the subiculum. These results were similar across various severity assessments. Regression indicated that hippocampal subfields abnormalities had the strongest associations with memory dysfunction, and relatively weak associations with cognitive control and attention. Notably, CA4 and dentate gyrus had the highest weights in the regression model.

Conclusions: As depressive severity increases, hippocampal subfield atrophy tends to spread from CA regions to surrounding areas, and primarily affects memory function in patients with youth depression. These results suggest hippocampus might be markers in progression of adolescent depression, offering new directions for early clinical intervention.

Interventions to promote social connection and their effect on depression: An umbrella review

L. De Risio¹, M. Pettorruso², A. D'Onofrio³, M. C. Vicinelli², C. De Troia², M. Santorelli⁴, M. Boffa³, P. Politi⁴, G. Martinotti², F. Zoratto³ and M. Borgi^{3*}

¹Department of Psychiatry and Addiction, ASL Roma 5, Colleferro;

²Department of Neuroscience, Imaging and Clinical Sciences, G. d'Annunzio University of Chieti-Pescara, Chieti; ³Center for Behavioral Sciences and Mental Health, Istituto Superiore di Sanità, Rome and ⁴Department of Brain and Behavioral Sciences, University of Pavia, Pavia, Italy

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.482

Introduction: Social connection (SC) is a multi-dimensional concept capturing both the structural-quantitative (e.g., number of social relations, social contact frequency, network structure) and the functional-qualitative dimension (e.g., social support) of social relationships. Although empirical evidence of the association between SC measures and depression has increased significantly in recent years (De Risio et al, *J Affect Disord* 2024; 345 358–368), very little is known about the extent to which interventions that build SC are effective in improving depressive symptoms.

Objectives: This umbrella review of systematic reviews/meta-analyses aims to synthesize evidence regarding the effectiveness of SC interventions on depression. Our primary focus is on interventions directly acting upon the natural social network, while indirect interventions that aim to improve social skills, or those

that provide professional (formal) or semi-professional support through health services, were excluded.

Methods: We provide a synthesis of the consistency and magnitude of the effectiveness of SC interventions on depression. We searched PubMed, PsycINFO, Cochrane Library, and EMBASE and 16 reviews/meta-analyses were included. Information on the effectiveness of SC interventions on depression were compared among different populations. The quality/certainty of evidence was assessed using AMSTAR-2 and GRADE tools.

Results: Included interventions were categorized into the following domains: social support (interventions increasing both perceived and enacted social support from family, friends, and others); social engagement (interventions aimed at strengthening social networks and contrasting social isolation); social inclusion (interventions promoting social integration and access to social capital); social identification (interventions enhancing participants' identification with a group). Overall, the evidence is rather mixed with some SC interventions resulting in little to no difference in depressive symptoms compared to usual care/other interventions. The most promising interventions appear to be those contrasting social disengagement and reducing social isolation in older individuals and in patients with depression, as well as social inclusion interventions for adolescents and young adults.

Conclusions: The broader implications of SC as a key determinant of depression call for a deep examination of the impact of interventions/preventive programs on the evolving psychopathology of depressive trajectories and inform on which targeted interventions are more effective, thus guiding public health policies.

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.483

Introduction: Major Depressive Disorder (MDD) is a complex mental health condition characterized by a wide spectrum of symptoms. According to the Diagnostic Statistical Manual 5 (DSM-5) criteria, patients can present with up to 1,497 different symptom combinations, yet all receive the same MDD diagnosis. This diversity in symptom presentation poses a significant challenge to understanding the disorder in the wider population. Subtyping offers a way to unpick this phenotypic diversity and enable improved characterization of the disorder. According to reviews, MDD subtyping work to date has lacked consistency in results due to inadequate

statistics, non-transparent reporting, or inappropriate sample choice. By addressing these limitations, the current study aims to extend past phenotypic subtyping studies in MDD.

Objectives: (1) To investigate phenotypic subtypes at baseline in a sample of people with MDD;

(2) To determine if subtypes are consistent between baseline 6- and 12-month follow-ups; and

(3) To examine how participants move between subtypes over time.

Methods: This was a secondary analysis of a one-year longitudinal observational cohort study. We collected data from individuals with a history of recurrent MDD in the United Kingdom, the Netherlands and Spain (N=619). The presence or absence of symptoms was tracked at three-month intervals through the Inventory of Depressive Symptomatology: Self-Report (IDS-SR) assessment. We used latent class and three-step latent transition analysis to identify subtypes at baseline, determined their consistency at 6- and 12-month follow-ups, and examined participants' transitions over time.

Results: We identified a 4-class solution based on model fit and interpretability, including (Class 1) severe with appetite *increase*, (Class 2), severe with appetite *decrease*, (Class 3) moderate, and (Class 4) low severity. The classes mainly differed in terms of severity (the varying likelihood of symptom endorsement) and, for the two more severe classes, the type of neurovegetative symptoms reported (Figure 1). The four classes were stable over time (measurement invariant) and participants tended to remain in the same class over baseline and follow-up (Figure 2).

Image:

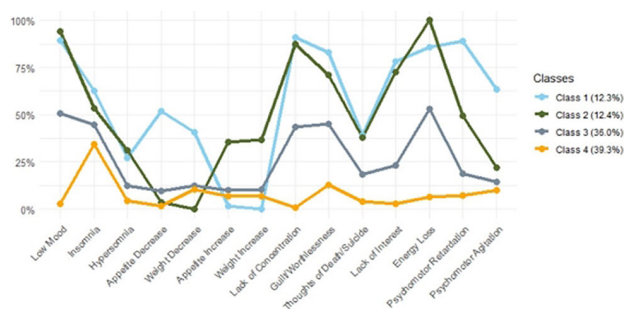

Figure 1. Probabilities of Endorsing Depressive Symptoms Derived from Baseline 4-Class Latent Class Analysis (N=619). Class sizes are presented as the percentage of this total.

Image 2:

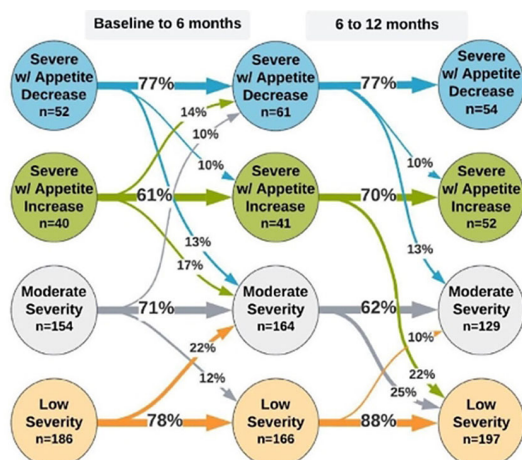

Figure 2. Transition probabilities and class sizes for three-step LTA model (N=432). Probabilities <10% are not shown.

Conclusions: We identified four stable subtypes of depression, with individuals most likely to remain in their same class over 1-year follow-up. This suggests a chronic nature of depression, with (for example) individuals in severe classes more likely to remain in the same class throughout follow-up. Despite the vast heterogeneous symptom combinations possible in MDD, our results emphasize differences across severity rather than symptom type. This raises questions about the meaningfulness of these subtypes beyond established measures of depression severity. Implications of these findings and recommendations for future research are made.

Eating Disorders

EPP0305

The presence of autistic traits might explain the relationship between sensory sensitivity and eating disturbances in a sample of young adults referring to a mental health clinic.

V. Nistico^{1,2,3}, G. Ingrosso¹, F. Lombardi¹, E. Chiudinelli¹, R. Faggioli⁴, A. Bertani⁵, O. Gambini^{1,3,4} and B. Demartini^{3,4*}

¹Health Science Department, University of Milan; ²Department of Psychology, University of Milan Bicocca; ³Aldo Ravelli Research Center for Neurotechnology and Experimental Brain Therapeutics, University of Milan; ⁴UO Psichiatria 51 e 52 and ⁵Centro Giovani Ettore Ponti, ASST Santi Paolo e Carlo, Presidio San Paolo, Milan, Italy

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.484

Introduction: The relationship between autistic traits and eating disturbances, although gaining considerably more attention in the last decades, is still unclear. Most of the studies up to date were conducted on individuals with a full diagnosis of Autism Spectrum Disorders (ASD) and/or of Eating Disorders (ED). One of the common features reported in both conditions is the alteration of sensory sensitivity, which is, in both cases, widely discussed in the literature, but mostly in the pediatric age.

Objectives: To investigate the association between sensory sensitivity, autistic traits, and eating disorders symptomatology in a group of young adults (18-24) who were referred, for the first time, to a mental health outpatient clinic.

Methods: 259 patients completed: the Eating Attitude Test (EAT-26), the Autism Quotient (AQ), the Ritvo Autism Asperger Diagnostic Scale-Revised (RAADS-R), the Sensory Perception Quotient - Short Form 35 item (SPQ-SF35) and the Swedish Eating

Assessment for Autism Spectrum Disorders (SWEAA), which investigates specific eating behaviour related to autism.

Results: 23.55% participants scored above the cut-off at the EAT-26, suggesting that they should be assessed for the presence of an eating disorder by a specialized clinician. The RAADS-R explained a great proportion of variance in the relationship between sensory sensitivity and both the SWEAA (Total Score and subscales) and the EAT-26 (Total Scores and subscales).

Conclusions: Our study revealed a substantial prevalence of potential eating disorders among young adults in our sample, with nearly one-fourth of participants surpassing the EAT-26 cutoff score. Additionally, we observed a noteworthy association between the presence of autistic traits and not only autistic-like eating behaviors but also a broader spectrum of eating disorder symptoms; this relationship was found in a cohort of young adult patients seeking clinical attention due to generalized distress, prior to receiving specific diagnoses of Autism Spectrum Disorder (ASD) or Eating Disorders (ED). These findings give rise to several intriguing inquiries. Could the existence of autistic traits, even when subthreshold, function as a mediator between alterations in sensory sensitivity and the emergence of maladaptive eating behaviors? Furthermore, if these traits exist at subthreshold levels, might they manifest in various psychiatric conditions, distinct from traditional categorizations, during episodes of acute distress? What potential precipitating factors should be considered in such cases?

EPP0306

The Evolution of Anorexia Nervosa in Singapore: A 30-year Demographic Analysis

H. Y. Lee* and V. K. H. Wong

Psychiatry, Singapore General Hospital, Singapore, Singapore

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.485

Introduction: New prevalence and time trend data from various Asian countries show that Eating Disorders (ED) are increasingly common in Asia. (Youl-Ri Kim. *Int J Eat Disord*. Dec 2020). A recent study estimating the prevalence of ED in Singapore found an alarming 6.2% screened positive for a clinical ED diagnosis, 19.5% were screened to be at high risk, and estimated the point prevalence of Anorexia Nervosa (AN) to be 0.9%. (Chua SN et al. *Int J Eat Disord*. Jan 2021).

The ED unit in Singapore General Hospital (SGH) was set up in 2003 as a National Treatment Programme for patients with ED.

Two local studies have been published to date on the demographics and clinical profile of patients with AN. The first study examined 126 patients from 1994 – 2002 (HY Lee et al. *Singapore Med J* 2005; 46(6): 275-281). The second study reported on 271 cases from our SGH ED unit from 2003-2010 (Kuek et al. *Singapore Med J* 2015; 56(6): 324-328). There have been no further studies in the last decade.

Objectives:

1. Study the demographics and clinical profile of patients who presented with AN to our ED unit from 2011-2022
2. Compare our data with the 2 previous studies and examine for any changes and trends in the past 30 years.

Methods: We conducted a review of the ED unit new case registry at SGH from 2011-2022. A total of 910 patients were diagnosed

with AN at presentation. The data was analysed with approval from the hospital institutional review board.

Results: A total of 910 cases presented with AN over 12 years. Comparing with the 2 previous studies, the number of new cases each year has continued to increase from <15 in the 1990s to hit a peak of 109 per year in 2022. 94% were females, with a mean presenting age of 19. 79.2% were Chinese, 5.2% were Indians and 2.9% were of Malay ethnicity. The Malay population continue to be under-represented whereas other ethnic groups continue to be over-represented, increasing from 3.2% to 7% in the previous studies to 11.1%. Referrals were mainly from tertiary healthcare intuitions accounting for 41.4% of cases. Self-referrals have decreased over the last decade whereas referrals from primary care has increased. The mean presenting body mass index (BMI) was 15.9. Compared to a previous study, there was a significant increase in presenting BMI (15.9+/- 0.78 vs 14.4 +/- 1.77, p value 0.0074).

Conclusions: The number of new cases of AN has seen an almost 10-fold increase in the last 30years. The Malay ethnicity continues to be under-represented – more research is needed if they are somehow culturally protected or if they are not coming forth for treatment. Majority of referrals are from tertiary healthcare institutions but referrals from primary care have increased, reflecting a possible increase in awareness amongst primary care doctors. The mean presenting BMI has increased – hopefully reflecting an increase in ED awareness such that patients are coming forward earlier for treatment.

The truth about modelling – disordered eating, body image, abuse and more: A content analysis among professional fashion models

N. Bogár^{1*}, F. Túry¹ and P. Kővágó²

¹Institute of Behavioural Sciences, Semmelweis University and

²Institute of Psychology, Pázmány Péter Catholic University, Budapest, Hungary

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.486

Introduction: The escalating demand for models to uphold a slim physique and extremely small measurements could play a pivotal role in contributing to the onset of eating disorders, in their clinical or subclinical forms.

Objectives: The study aimed to explore models' relationship with food, exercise, body image, industry members, experience of abuse and other related factors through self-narrated reports. To our knowledge, this study involved a larger number of multicultural female models than any previous qualitative research and is the first-ever study to use content analysis for the assessment of ED-like symptoms and body image disturbances in this population.

Methods: 87 models' data was analyzed. Snowball sampling was used. Semi-structured interviews targeted models' careers, attitudes towards the fashion industry, their body image, eating, exercising and dieting habits, etc. Thematic content analysis was performed on the transcripts of the interviews. A coding booklet was developed containing instructions on 31 codes. The codes developed for the analysis included calorie restriction, weight gain, loss of control,

laxative abuse, self-induced vomiting etc. They also included specific symptoms of eating and/or body image disorders. The analyses were conducted using relative frequencies. The absolute frequency of the codes was divided by the wordcount corresponding to the interview.

Results: The mean BMI of the subjects was 16.8 (SD= 1.30, range 13.58- 19.37). 44.7% of the models reported BMI of between 18.5 and 17.0, and 21.2% were under 17.0. Body image disorder symptoms were expressed by 63.10% of the models, and 36.90% have referred to eating disorders. The most referenced code was statements about the subjects' bodies (95.24% neutral, 89.29% negative, 64.29% positive statements). Statements about eating included 96.43% neutral and 45.24% negative claims. Monotrophic eating occurred in 27.38% of the answers, and 40.48% claimed to have used extreme calorie restriction. Juice fasting was occurrent amongst 3.57% of the interviewees. 22.62% have lost control over their food intake. 83.33% of the participants received criticizing comments on their bodies and such individuals talk negatively significantly more often about eating. Those individuals who engage in psychotherapy (16.67%) show significantly fewer signs of body image disorders, however, talk significantly more about eating disorder-related content.

Conclusions: The persistent expectation for thinness in the fashion industry elevates the likelihood of eating disorders and body image disorder development among models. The current study aims to offer insights into prevention strategies.

doi: 10.1192/j.eurpsy.2024.487

Introduction: Type 1 diabetes mellitus (T1DM) patients are treated via insulin which could result in weight gain. Studies have coined a new term, "Diabulimia" which refers to the limitation or skipping of insulin doses, with the objective of weight control. A previous meta-analysis has found that eating disorders (ED) are significantly associated with T1DM (Mannucci, E et al. J Endocrinol Invest 2005; 417-9), while a more recent one, has shown an insignificant association between ED and T1DM on analysis of diabetes-adapted questionnaires only (Young V, et al. Diabet Med. 2013:189-198)

Objectives: We aimed to re-analyze the association between ED and T1DM, whilst taking into account recently published literature and the type of questionnaire utilized.

Methods: A literature search of PubMed, Scopus, and Web of Science was conducted on 17th January 2023, using the key terms "T1DM", "Eating Disorders", and "Bulimia". Only Observational controlled studies were included.

Results: T1DM was associated with increased risk of ED compared to non-diabetic individuals (RR = 2.47, 95% CI = 1.84 to 3.32, p-value < 0.00001), especially bulimia nervosa (RR = 2.80, 95% CI = 1.18 to 6.65, p-value = 0.02) and binge eating (RR = 1.53, 95% CI = 1.18 to 1.98, p-value = 0.001), while no significant association was seen between T1DM and anorexia nervosa. Our sensitivity analysis has shown that increased risk of ED among T1DM persisted regardless of the questionnaire used to diagnose ED; DM-validated questionnaires (RR = 2.80, 95% CI = 1.91 to 4.12, p-value < 0.00001) and generic questionnaires (RR = 2.03, 95% CI = 1.27 to 3.23, p-value = 0.003). Furthermore, the Eating Attitudes Test-26 (EAT) showed a significant increase in the dieting subscale (MD = 2.95, 95% CI = 1.84 to 4.06, p-value < 0.00001) and bulimia subscale (MD = 0.78, 95% CI = 0.12 to 1.44, p-value = 0.02) among T1DM patients. Additionally, the Bulimic Investigatory Test, Edinburgh (BITE) showed a significant increase in the symptom subscale (MD = 0.31, 95% CI = 0.12 to 0.50, p-value = 0.001), however, no significant difference was detected between T1DM and controls in the severity subscale. Prevalence of insulin omission/misuse was 10.3% (95% CI = 8.1-13); diabetic females demonstrated significantly higher risk of insulin omission (RR = 14.21, 95% CI = 2.66 to 76.04, p-value = 0.002) and insulin misuse (RR = 6.51, 95% CI = 1.14 to 37.31, p-value = 0.04) compared with diabetic males. Analysis of other potentially unhealthy weight control behaviors showed insignificant associations between fasting, excessive exercise, dieting pills misuse, diuretics misuse, and T1DM.

Conclusions: T1DM patients are at higher risk of developing ED according to both generic and diabetes-validated questionnaires. Moreover, female diabetics are at higher risk of insulin misuse/omission. Subsequently, patients should be regularly screened and early psychiatric management is warranted.

Eating disorders in medicine university students in a city in the interior of the state of São Paulo Brazil

M. C. V. R. De Oliveira*, C. B. Soares de Oliveira, N. D. Rejali, M. B. Machado, M. H. Formaio and S. Umbelino da Silva

FACULDADE DE MEDICINA, UNOESTE, PRESIDENTE PRUDENTE, Brazil

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.488

Introduction: Eating disorders are characterized by a persistent disturbance in eating and/or eating-related behavior, resulting in altered food consumption or absorption, which can significantly compromise physical health as well as psychosocial functioning. These disorders are closely linked with stressful experiences which university students configure a group prone to development.

Objectives: The objective is to evaluate the impact of eating disorders on young people when entering and staying at university.

Methods: This is an observational, quantitative, analytical and cross-sectional study, in which 1300 (one thousand and three hundred) medical students were invited, of both sexes and over 18 years of age from the 1st (first) to the 12th (twelfth) year. period of the Medicine course at the University of Oeste Paulista (UNOESTE) with 91 students joining. A structured interview was applied via online, aiming at collecting sociodemographic and occupational data in conjunction with the application of the Periodic Eating Compulsion Scale - ECAP, assessing the existence and degree of eating disorders in medical students.

Results: Mean age 22.7 ± 3.9 years, predominantly female (76.9%) and white ethnicity (86.8%). Most live alone or with a parent (82.5%). With regard to eating habits, 81 (89.0%) said they did not follow a nutrition professional's diet, and 84 (92.3%) have at least 3 meals a day. Lunch is eaten by 100% of the participants, while supper is the least consumed meal (17.6%). A total of 24 (26.4%) participants said they had little time to eat, and almost half (46.2%) did not prepare their own meals, with 12.5% choosing to eat salted or not. eating a certain meal. The ECAP binge eating score had a median of 9 (11.5) points, with a minimum score equal to 1 and a maximum equal to 41. Sixty-eight (74.7%) of the participants were classified as having no binge eating, with moderate binge eating 15 (16.5%), and severe, 8 (8.8%).

Conclusions: There is a need for changes in lifestyle aspects in order to present healthier meals in appropriate amounts, in addition to an adequate therapeutic approach to these disorders. Research funding agency We also declare that we received financial support from the Institutional Program for Scientific Initiation Scholarships (PROBIC).

Endometriosis and depressive symptoms: The role of quality of life in endometriosis, chronic illness-related shame, self-compassion, and psychological flexibility

A. Galhardo^{1,2}, B. Simões¹, C. Pinto-Gouveia^{3*} and M. Cunha^{1,2}

¹Psychology, Instituto Superior Miguel Torga; ²CINEICC, FPCEUC, University of Coimbra and ³Psychiatry, Centro Hospitalar e Universitário de Coimbra, Coimbra, Portugal

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.489

Introduction: Endometriosis is a gynaecological pathology characterized by endometrial tissue similar to stroma and endometrium in extra endometrial and myometrial sites. This condition affects women's mental health and quality of life and can elicit shame feelings.

Objectives: To explore the role of quality of life in endometriosis, chronic illness-related shame, self-compassion, and psychological flexibility in depressive symptoms.

Methods: 260 people diagnosed with endometriosis, aged 18 years or older, were recruited through patients' associations. Participants completed an online sociodemographic and clinical questionnaire and the following self-report instruments: Anxiety, Depression, and Stress Scales (DASS-21), Endometriosis Health Profile (EHP-5), Chronic Illness-Related Shame Scale (CISS), Compassionate Engagement and Action Scales (EEAC-SC), and the Psy-Flex Scale.

Results: Regression analyses showed that years of education, endometriosis-related quality of life (pain, control, emotional well-being, social support, and self-image), chronic illness-related shame, and psychological flexibility were the significant predictors of depressive symptoms. On the other hand, endometriosis-related quality of life (work life, relationship with children, sexual life, relationship with healthcare professionals, treatment, and infertility) and self-compassion were not significantly associated with depressive symptoms.

Conclusions: The identification of chronic illness-related shame and quality of life related to endometriosis as relevant variables regarding the presence of symptoms of depression points to the relevance of early detection of these phenomena to prevent the development of depressive symptoms. Moreover, interventions targeting the development of psychological flexibility may contribute to the amelioration and prevention of depressive symptoms.

From Loss to Healing: Navigating Perinatal Grief with Enhanced Psychological Care

K. Razki*, Y. Zgueb, S. Ben Aissa, C. Najjar and U. Ouali

psychiatry department, Razi hospital, manouba, Tunisia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.490

Introduction: Several factors can influence the journey of perinatal grief in mothers, including the quality of care during this experience. The objective of our study was to investigate the factors influencing the perception of grieving women during the perinatal period and identify the role of medical and paramedical healthcare professionals in psychological support.

Objectives: To determine the factors influencing the perception of fetal loss in grieving mothers.

Methods: This was a descriptive, longitudinal, retrospective study conducted between July 2021 and March 2022 at the Fetal Pathology Department of the Center for Maternity and Neonatology in Tunis, Tunisia. The study included women who experienced perinatal loss and underwent fetal pathology examination.

The study was conducted in two stages: Initial consultation at the Fetal Pathology Department, five weeks after the date of expulsion, for perinatal grief counseling. Follow-up interview one year after the date of expulsion: The participants were contacted via telephone for an average duration of twenty minutes. The assessment of perinatal grief during both interviews was conducted using the shortened version of the Perinatal Grief Scale (PGS)

Results: The mean age of the patients was 31.41 years (± 5.15). The average gravidity was 2.47 (± 1.43). More than half of the patients had no living children ($n=41$). The majority of patients had no notable pathological history. Six patients had been followed in psychiatry, and five had a history of subfertility. The majority of patients ($n=61$) reported having good marital relationships.

Among the participants, 20% ($n=14$) had a high Perinatal Grief Scale (PGS) score ($\text{PGS} \geq 91$) at five weeks post-loss and were subsequently referred for psychiatric consultation.

At one year, all participants had a PGS score > 91 , demonstrating the effectiveness of psychiatric management. Multivariate analysis identified four independent factors associated with a high PGS score at five weeks: absence of living children ($\text{OR}=0.59$; 95% CI [0.36-0.98]; $p=0.04$), quality of marital relationship ($\text{OR}=1.2$; 95% CI [1.1-3.9]; $p=0.02$), family support ($\text{OR}=2.52$; 95% CI [1.55-4.12]; $p<0.001$), and quality of loss disclosure ($\text{OR}=2.52$; 95% CI [1.32-3.77]; $p=0.003$).

Conclusions: To identify patients at high risk of developing complicated grief and improve the quality of psychological care, it is necessary to implement appropriate protocols, provide training to healthcare personnel, and establish well-equipped healthcare facilities.

Covid-19 pandemics effects on postpartum depression in the Hungarian Baby-Mother-Father Unit

G. M. Mező*, C. Budinszki and T. Kurimay

Family Centred Buda Mental Health Centre, Saint John's Central Hospital, Budapest, Hungary

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.491

Introduction: Our Baby-Mother-Father Unit program in Saint John's Central Hospital (Budapest) offers mothers and fathers a unique opportunity to get better, receive psychiatric care (hospitalization or outpatient) without being separated from their babies. The Covid-19 pandemic had a strong impact on the whole population, including the parents of babies. During everyday operation the whole team experienced the increased need for health care, but we were not aware of the exact number of this change.

Postpartum psychiatric conditions have two main categories that stand out: postpartum psychosis and postpartum depression. As there are better quantifiable tools for measuring depression and strong scientific evidence supporting that the pandemic having increased mood disorders' intensity and numbers (Chen et al., 2022; Harrison et al., 2023), postpartum depression was chosen as the locus of investigation. Due to the respectively high numbers of parents with babies showing up at our Unit, we wished to get a clearer picture on pandemics effects on these people.

Objectives: Getting a more clear picture of pandemics effects on our Baby-Mother-Father Unit care. Defining numbers of patients, interactions and comparing test results of depression scales before and after the pandemic.

Methods: A retrospective study of years 2019 and 2022 was performed. The total number of patients (2019: 173, 2022: 278) and the total number of documented patient-doctor/psychologist interactions (2019: 963, 2022: 1919) were measured. Depression scales' (BDI, EPDS, PHQ-9), hopelessness scales (HS) results were compared. Due to our samples not showing normal distribution, a deeper analysis of test result categories was carried out by using Mann-Whitney test.

Results: The results showed that depression (BDI: $W=3165,5$ $p=0,17$; EPDS: $W=1693$, $p=0,42$; PHQ-9: $W=2502$, $p=0,39$) and hopelessness (RS: $W=976,5$, $p=0,52$) average points seem quite constant regardless of the pandemic and showed no significant differences. More detailed data analysis of result categories revealed pattern-like differences, which might tell us more about the subjective experiences of the individuals. The number of patients and patient-doctor/psychologists interactions increased dramatically. Furthermore the number of individual therapeutic sessions rose greatly (2019: 359; 2022: 1182), along with parents receiving therapeutic care (2019: 40, 2022: 95).

Conclusions: From our findings, assumptions can be made that besides the obvious rise of numbers of patients and interactions, during the pandemic postpartum depression's and hopelessness' structure changed.

Clozapine to treat aggression and agitation in advanced dementia

A. E. Michael¹, N. Michael², A. Erfurth^{3*} and M. Kujovic⁴

¹Johannes Wesling Klinikum Minden, Minden; ²Krankenhaus Elbroich, Düsseldorf, Germany; ³1st Department of Psychiatry and Psychotherapeutic Medicine, Klinik Hietzing, Vienna, Austria and ⁴LVR-Klinikum, Düsseldorf, Germany

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.492

Introduction: Agitation and aggression are a serious problem in clinical psychiatry, especially in multimorbid patients of advanced age, including those with dementia.

Objectives: We wanted to investigate to what extent clozapine could be an option in the treatment of selected refractory patients.

Methods: A retrospective study included patients with a diagnosis of dementia who were treated with clozapine in a specialist geriatric psychiatry unit between August 2018 and February 2022, and medical records were systematically reviewed. The Clinical Global Impressions Scale was used for the assessment of improvement and the Pittsburgh Agitation Scale for the assessment of symptom reduction. In addition, there was detailed documentation of side effects and clinical features.

Results: A total of 31 patients with a median age of 82 years were identified.

Conclusions: In conclusion, clozapine was effective and well tolerated in 23 patients. This suggests that low-dose clozapine may help alleviate the suffering of difficult-to-treat multimorbid patients with

advanced dementia and their carers. However, adverse effects, particularly in patients with cardiovascular and pulmonary impairment, should be carefully monitored.

School of Medicine, New-York, United States

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.493

Introduction: Growing clinical interest in psychedelic-assisted therapies has led to a second wave of research involving psilocybin, LSD, MDMA and other substances. Data suggests that these compounds have the potential to treat mental health conditions that are especially prevalent in older adults such as depression, anxiety, existential distress and post-traumatic stress disorder.

Objectives: The goal of this study was to quantify the prevalence of older adults enrolled in psychedelic clinical trials and explore safety data in this population.

Methods: A systematic review was conducted following the 2020 PRISMA guidelines. Search criteria included all trials published in English using psychedelic substances to treat psychiatric conditions, including addiction as well as existential distress related to serious illness. Articles were identified from literature searches on PubMed, EBSCO and EMBASE.

Results: 4,376 manuscripts were identified, of which 505 qualified for further review, with 36 eventually meeting eligibility criteria. Of the 1,400 patients enrolled in the 36 studies, only 19 were identified as 65 or older, representing less than 1.4% of all trial participants. For 10 of these 19 older adults, detailed safety data was obtained. No serious adverse events (AEs) occurred in any older adults and only transient mild-to-moderate AEs related to anxiety, gastrointestinal upset, and hypertension were reported during the psychedelic dosing sessions.

Conclusions: While existing data in older adults is limited, it suggests that psychedelic-assisted psychotherapy is safe and well tolerated in older adults. Therefore, psychedelic-assisted psychotherapy should be more rigorously investigated for the treatment of psychiatric conditions in this population.

Psychotropic Medication Prescriptions and Polypharmacy in Geriatric Patients Followed up in a Home-based Health Care Setting

S. Tanyeri Kayahan* and A. Kayahan

Psychiatry, Yalvaç State Hospital, Turkish Republic Ministry of Health, Isparta, Türkiye

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.494

Introduction: By 2050, one out of every six people in the world will be 65 years or older. Chronic diseases and associated multiple drug use are common in elderly. The use of five or more drugs is called polypharmacy and it's reported between 40-90% in the elderly. The Beers Criteria is the American Geriatrics Association's guide to current recommendations regarding the safety of pharmacotherapy in older age. Being a part of community-based health services in Türkiye since 2005, "Home-based Health Care Services" is a program in which patients, who are mostly elderly and have difficulty in accessing health institutions, access medical services at their homes.

Objectives: In our study, it was aimed to examine the chronic disease diagnoses and prescriptions of patients aged 65 and over, registered in a home-based health care unit, in terms of psychotropic drugs and polypharmacy, and to evaluate the compliance of their psychiatric prescriptions with the Beers Criteria.

Methods: Sociodemographic, psychiatric diagnosis and treatment prescription and home-based health service-specific data were collected from the electronic files of home-based health care unit patients. Chronic diseases were scored according to the Modified Charlson Comorbidity Index (mCCI). The last 6-month prescriptions obtained from the electronic patient files were scanned and included in the analysis. In statistical analysis using SPSS Version 25, a p-value of significance <.05 was determined.

Results: As of February 2023, 229(83.2%) of 275 patients aged 65 and over constituted the research sample. The mean age of the sample, half of whom were considered as oldest-old(85 years and older), was 83 ± 7.97 (median=86, IQR=10.75), 69.9%(n=160) were women and 97.8%(n=224) were diagnosed with at least one chronic disease. The mean mCCI scores were 5.30 ± 1.11 (median=5.50, IQR=1.0). Polypharmacy was detected in 78.6% of the sample(n=180), among half(n=114) of whom at least one psychotropic was prescribed, drugs not recommended to be prescribed according to the Beers Criteria in elderly patients were 46%(n=52). Prescription rates were as follows: anti-dementia- 21.5%(n=49), antidepressants- 31.1%(n=71), antipsychotics- 21.5%(n=49) and benzodiazepines- 5.3%. Most frequently prescribed antidepressant was escitalopram 49.2%, while most frequently prescribed antipsychotic was quetiapine 29.4%. The frequency of quetiapine prescription increased significantly in patients with dementia ($X^2(1)=29.54, p<.001$) and insomnia ($X^2(1)=13.11, p<.001$).

Conclusions: The frequency of polypharmacy was found to be closer to the higher values reported previously. Almost half of the sample had a prescription for psychotropic drugs, and one out of two of these prescriptions did not meet the Beers Criteria. Considering the aging population, it will be of great importance for clinicians to carefully evaluate psychotropic prescriptions and polypharmacy.

Disclosure of Interest: None Declared

Complex antidepressant therapy with the inclusion of various neuroprotectors in inpatient gerontopsychiatric practice

V. Pochueva*, T. Safarova and O. Yakovleva

FSBSI "Mental Health Research Center", Moscow, Russian Federation
*Corresponding author.

doi: 10.1192/j.eurpsy.2024.495

Introduction: Depressions are the most common mental disorders in elderly and senile patients. In these patients, there is a decrease in neurotrophic potential. Treatment of such patients with antidepressants alone does not always allow to achieve complete normalization of the secretion of neurotrophic factors and complete restoration of neurogenesis processes. In this regard, it is important to expand therapeutic opportunities to develop new therapeutic strategies for pharmacotherapy of late-age depression.

Objectives: Comparative evaluation of the effectiveness of two types of complex antidepressant therapy with the inclusion of different neuroprotectors (actovegin or cerebrolysin) in the treatment of late-life depression in the therapeutic regimen.

Methods: The study included 2 groups of patients with mild and moderate depressive episode (DE), comparable in basic demographic and clinical parameters.

The 1st group included 21 people, including 7 men (33.3%) and 14 women (66.7%), median age were 69 years [66; 76]. In 10 patients (47.6%), DE was diagnosed as part of recurrent depressive disorder (DDR), in 9 patients (42.9%) - as part of bipolar affective disorder (BAR), and in 2 patients (9.5%) is a single DE. Group 2 included 20 patients, 5 of them men (25%) and 15 women (75%), median age were 64 years [62; 70]. In 11 patients (55%), DE was diagnosed as part of DDR, in 6 patients (30%) - as part of BAR, and in 3 patients (15%) - single DE.

The 1st group of patients received complex antidepressant therapy with the inclusion of actovegin for one month, the 2nd group - with the inclusion of cerebrolysin. The effectiveness of the therapy was assessed on the HAMD-17 and HARS scales.

Results: A comparative study demonstrated the effectiveness of both types of complex antidepressant therapy used.

A comparative assessment of the effectiveness of the therapeutic response in two groups of patients showed no statistically significant differences in the reduction of depressive disorders after 2 weeks of therapy. Only by the end of the therapeutic course there was a more pronounced reduction of depressive disorders in the 1st therapeutic group (73.6% vs 63.6% ($p < 0.05$)).

Reduction of anxiety disorders, assessed on the HARS scale, was noted both by the 14th and 28th day of therapy in both therapeutic groups. However, it turned out to be more pronounced in the 1st therapeutic group: by the 14th day of therapy, the reduction of anxiety in the 1st and 2nd groups of patients was 36.4% and 30.0%, respectively ($p < 0.05$), and by the end of therapy - 77.7% and 60.0%, respectively ($p < 0.01$).

Conclusions: The augmentation of antidepressant therapy with drugs with multimodal activity, actovegin and cerebrolysin, should be considered as effective and it can be recommended for inclusion in the therapeutic regimen for the treatment of late-age depression in a psychiatric hospital.

Juxtaventricular and periventricular white matter hyperintensities (WMH) are associated with cognitive dysfunction in Patients with Alzheimer's DiseaseJ. H. Park^{1*}, H. J. Yang¹ and J. M. Song²¹Psychiatry, Jeju National University School of Medicine, Jeju National University Hospital and ²Psychiatry, Jeju Medical Center, Jeju, Korea, Republic Of

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.496

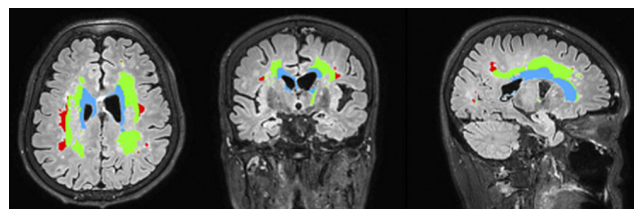

Introduction: White matter hyperintensities (WMH) is common among the elderly. WMH are associated with accelerated cognitive dysfunction and increased risk for Alzheimer's disease (AD). Although WMHs play a key role in lowering the threshold for the clinical expression of dementia in AD-related pathology, the clinical significance of their location is not fully understood.

Objectives: The aim of this study was twofold: 1) To investigate the quantitative association between WMH and cognitive function in AD; 2) To investigate whether there is any difference in the association between subclassified WMH and cognitive function in AD.

Methods: A total of 171 patients with AD underwent clinical evaluations including volumetric brain MRI study and neuropsychological tests using the CERAD-K neuropsychological assessment battery. WMH volume was calculated using automated quantification method with SPM and MATLAB image processing software. According to the distance from the lateral ventricular surface, WMH within 3 mm, WMH within 3-13 mm, and WMH over 13 mm were classified as juxtaventricular WMH (JVWMH), periventricular WMH (PVWMH) and deep WMH (DWMH), respectively. WMH volume data was logarithmically transformed because it was right-skewed.

Results: WMH volume in AD was 20.7 ± 18.2 ml. Total WMH volume was associated with poor performance in categorical verbal fluency test ($p = 0.008$) and word list memory test ($p = 0.023$). JVWMH volume was associated with poor performances on categorical verbal fluency test ($p = 0.013$) and forward digit span test ($p = 0.037$). PVWMH volume was associated with poor performances on categorical verbal fluency test ($p = 0.011$) and word list memory test ($p = 0.021$), whereas DWMH volume showed no association with cognitive tests. Total WMH and PVWMH volume were also related to Clinical Dementia Rating scale sum of boxes score ($p=0.022$).

Image:

Conclusions: Greater JVWMH and PVWMH are related with concurrent impairments in semantic memory and frontal function

independent of the hippocampal volume. However, DWMH volume is not associated with any cognitive function. Only PVWMH among subclassified WMH are related to the severity of AD.

Impulsivity profile analysis and its potential role in the differential diagnostics of adult Attention Deficit Hyperactivity Disorder and Borderline Personality Disorder

E. Kenézlői^{1*}, S. Somogyi¹, L. Balogh¹, E. Lévy¹, B. Bajzát¹, Z. Halmai², Z. S. Unoka¹ and J. Réthelyi¹

¹Psychiatry and Psychotherapy, Semmelweis University and ²Bhaktivedanta Collage, Budapest, Hungary

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.497

Introduction: Impulsivity is a complex construct, having at least three factors: 1) impulsivity as a personality trait, 2) impulsive action – waiting and stopping impulsivity and 3) choice impulsivity. Impulsive symptoms are present in Attention Deficit Hyperactivity Disorder (ADHD) and Borderline Personality Disorder (BPD) as well, even though impulsivity profile significantly differs.

Objectives: Our aim is to describe the impulsivity profile in adult ADHD (aADHD) and BPD in comparison with the control group, and describe a characteristic pattern, which associates with these disorders.

Methods: aADHD (n=100) and BPD Patients (n=63) were included, based on DSM-5 diagnostic criteria. Healthy control subjects (n=100) were screened using the Derogatis Symptom Checklist (SCL-90). Comorbid psychiatric disorders were assessed by structured clinical interviews and those who have both aADHD and BPD were excluded from the study. Participants were further investigated with online questionnaires: e.g. Barratt Impulsiveness Scale (BIS-11) Difficulties in Emotion Regulation Scale (DERS) and neuropsychological tests, like CANTAB Rapid Visual Processing, Stop Signal Task, and the Rogers' decision-making test.

Results: Based on the BIS-11 results, significantly higher attentional impulsivity was present in adult ADHD compared to BPD ($p<.001$) and healthy controls ($p<.001$). Emotional regulation difficulties, measured by DERS were significantly higher in BPD ($p<.001$) than aADHD, but the impulse control problems were more pronounced in the aADHD group, compared to BPD ($p<.001$). Using CANTAB neuropsychological test battery, strategy formulation difficulties ($p=0.16$) and stopping impulsivity ($p<.001$) were only present in aADHD compared to HC. BPD patients did not differ significantly from the control group in strategy formulation and in Stop Signal Reaction Time, a measure of stopping impulsivity. The significantly higher level of total false alarms, reflecting on waiting impulsivity were present both in aADHD and BPD.

Conclusions: According to our results these two disorders have different impulsivity profile characteristics, which can be useful in

differentiating these two disorders, and in building treatment plans. Stopping impulsivity, measured by SST was found in aADHD, but not in BPD. In BPD impulsive behavior is more likely attached to emotional dysregulation, a trait rooted in childhood traumatization.

This study was supported by the National Research, Development and Innovation Office grant K 129195 and K 135437.

The four abilities of emotional intelligence as predictors of health risk behaviour: what role do impulsivity and sensitivity to reward play in this relationship?

M. T. Sanchez-Lopez^{1*}, P. Fernández-Berrocal¹, R. Gómez-Leal¹, M. J. Gutiérrez-Cobo², R. Cabello² and A. Megías-Robles¹

¹Department of Basic Psychology and ²Department of Developmental Psychology, University of Malaga, Málaga, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.498

Introduction: Risky sexual relationships, reckless driving or initiating drug use are examples of health-related risk behaviours that are often related to poor emotional abilities (emotional identification, emotional understanding, facilitating thought and emotional regulation). However, the mechanisms by which this relationship operates have been relatively little studied. It is well known that certain personality traits such as impulsivity and sensitivity to reward are strongly related to risk-taking behaviour.

Objectives: The aim of this work was to explore the role of these two traits in the relationship between each of the different abilities/branches of emotional intelligence and health risk behaviour, as well as to identify the emotional ability that best predicts this relationship.

Methods: A community sample of 250 participants (Mage = 23.60; 72% women) was used to measure levels of emotional intelligence in each of its branches (through the performance-based ability test MSCEIT), and levels of health risk behaviour, impulsivity and sensitivity to reward.

Results: The results supported the existence of a negative relationship between the four emotional abilities and health risk-taking. Mediation analyses that included all four MSCEIT branches as predictors revealed an indirect effect of the “managing” branch on risk-taking, being the most important branch in predicting health-related risk-taking, due to its effects through impulsivity and sensitivity to reward.

Conclusions: Our results suggest that a strong negative relationship exists between emotional management ability and health risk-taking, highlighting that the emotional components of impulsivity and levels of sensitivity to reward have been shown to be among the mediating factors underlying this relationship. Further experimental research is needed to confirm the role of emotional intelligence, and in particular emotional management, as a protective factor for risk-taking behaviour.

“Engaging, interactive, not boring” – A new innovative tutorial programme for medical students with promising longevity at the University of East Anglia.S. Das^{1*} and J. Beezhold¹¹Norfolk and Suffolk Foundation Trust, Norwich, United Kingdom

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.499

Introduction: Medical students at the University of East Anglia (UEA) complete a psychiatry rotation in the fourth year of their MBBS degree. There are four rotations each academic year, in 2022-2023 there were 24 students per rotation. The rotation consists of two weeks of lectures, a four-week clinical placement, and then a further two weeks of lectures. Students are based across Norfolk and Suffolk for their clinical placements. Although case-based discussions occurred every Wednesday morning via Teams, there were no face-to-face small group teaching sessions during placement.

Objectives: To design an interactive set of tutorials for medical students covering a wide range of psychiatric topics which can be easily delivered by other facilitators.

Methods: Three 1.5 hour tutorials were created: 1) “Psychotic Bingo” – Students have a unique card with terms used in descriptive psychopathology to play Bingo, 2) “Medical ethics, mental health and the law” – Explores the case of Kerrie Woollerton to discuss the mental capacity act, advanced decisions, and the mental health act, 3) “Team Quiz” – Played in groups and covers the different specialties of psychiatry and pharmacology. Tutorials were only mandatory for students in Norwich (average 11 students per tutorial) due to a large geographical area across placements. Tutorials were delivered for three rotations between December 2022 – May 2023, the initial two rotations by the first author and the third rotation by other facilitators. Facilitators were provided with a tutorial guidance document to ensure consistency. The same feedback form was used to obtain qualitative and quantitative feedback from students at all tutorials.

Results: The table below shows that feedback from students was consistently high, and there was little difference in average students rating between tutorials delivered by the first author and other facilitators. The predominant qualitative feedback was that the tutorials were “very interactive”, “engaging” and “fun”.

Image:

Tutorial	Average score out of 10 for each student feedback domain							
	Delivered by first author				Delivered by others			
	Useful	Relevant	Interesting	Taught well	Useful	Relevant	Interesting	Taught well
Psychotic Bingo	9.09	9.48	9.17	9.52	9.31	9.69	9.15	9.23
Medical ethics	9.48	9.57	9.38	9.67	8.47	9.13	8.27	8.13
Team Quiz	9.50	9.67	9.50	9.50	9.36	9.64	9.45	9.36

Conclusions: This tutorial programme consistently received excellent feedback. The results show that the tutorials can be effectively delivered by other facilitators whilst maintaining a high standard, which ensures the programmes longevity. The tutorial programme

is being formally implemented for all medical students at UEA from October 2023.

Parental Experiences of Grief after Pregnancy Loss: systematic review of qualitative studiesM. R. Duarte¹, A. Torres^{1,2*} and P. S. Carvalho¹¹Departamento de Psicologia e Educação, Universidade da Beira Interior, Covilhã and ²CINTESIS@RISE, Aveiro, Portugal

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.500

Introduction: Gestational Loss represents a set of abrupt and unexpected losses throughout pregnancy or after childbirth. Every year, around two million babies die after 28 weeks of gestation, with between 14% and 20% of all pregnancies ending in loss. In most situations, pregnancy loss occurs in a pregnancy without signs of risk or irregularities, something that increases the shock and suffering felt by parents.

Objectives: The present study aims to understand the relationship between pregnancy loss and parents’ grief experiences after spontaneous abortion, stillbirth or neonatal death with qualitative evidence.

Methods: This review followed the principles of PRISMA, and the search was carried out in the Web of Science and Scopus databases, aiming to find relevant articles about parental grief experiences resulting from pregnancy loss, published between 2012 and 2022. After research and analysis Of the studies, 15 qualitative studies were included.

Results: The pain and sadness when experiencing the loss of a child was a common point in all the studies found. In this review, the majority of men revealed a duality in wanting to protect, physically and emotionally, their partner, while experiencing their own grief, something that led to the internalization of their emotions and the minimization of their pain. Grieving fathers and mothers report experiencing this process alone, describing the difficulty in expressing what they feel due to the lack of recognition of the loss. It was found that confrontation with other pregnant women leads bereaved parents to reveal jealousy and shame, as well as feelings of guilt. The farewell rituals, the process of writing and talking about their experience helped the women to not feel so alone and to find a purpose: to transform their pain and help other grieving mothers. Fathers and mothers who experienced pregnancy loss stated that the death of their child provided change and growth.

Conclusions: After Pregnancy Loss, adapting to the new reality is extremely painful, despite the work of mourning being necessary and crucial. This process is a search to integrate and accept the reality of the loss of the baby in a way that has meaning for the mother and father, it is the adaptation to a world without the lost child and to a relationship that had been built during the gestation period, which was violently broken. It is necessary for health professionals to be present and available to address these parents’ fears, provide advice and support.

Components of well-being and distress that foster resilience in medical students

A. Eöry^{1*}, K. T. Radvanyi¹, S. Kudrinko², G. Vajda², S. Rózsa³ and M. Kellermayer⁴

¹Family Medicine; ²Semmelweis Univerity; ³Personality and Health Psychology, Károli Gáspár University of the Reformed Church and ⁴Biophysics and Radiation Biology, Semmelweis Univerity, Budapest, Hungary

*Corresponding author.
doi: 10.1192/j.eurpsy.2024.501

Introduction: The shortage of medical professionals is becoming a nearly unsurmountable burden worldwide. Increasing uncertainties in the external environment require enhanced capacity for predicting future outcomes from the young adult population of medical students. **Objectives:** To find the level of resilience, the domains of psychological well-being and the symptoms of distress; and to identify associations between them in a cohort of medical students. **Methods:** Data were collected in the 2022-23 academic year among Hungarian and English medical students at Semmelweis Univerity. An online questionnaire was circulated via the official academic administration system (Neptun) with the incentive to provide personal results with available resources for those who requested it. Besides age and gender, we applied the short form of the Nicholson McBride Resilience Questionnaire (NMRQ), Ryff's Psychological Well-being Scales (PWB), and the Depression, Anxiety and Stress Scale (DASS). Additional to descriptive statistics, univariate analyses as well as multiple regression analyses (SPSS v.24) were used. (Ethics permission No: BM/5326-2/2023). **Results:** Altogether 318 students (132 Hungarians) filled the questionnaire, and 251 students requested personal answers. 114 males participated with a mean age slightly higher than that of females (24 (SD:4) ys vs 23 (SD:3) ys). Hungarians (H) demonstrated lower resilience (Mdn:37, IQR:32, 42) then international (I) students (Mdn: 41, IQR: 36, 47), U=15287, p<0.001. Both H and I students showed similar patterns on PWB, scoring highest on personal growth, purpose in life and positive relations with others; while reaching lowest scores on environmental mastery, and lower scores on autonomy and self-acceptance. However, they demonstrated differences in each of the domains (see table).

	Hungarian n=132 (Mn (SD))	International n=186 (Mn (SD))	t (316)	p
Autonomy (A)	34 (7.9)	36 (7.4)	-2.8	0.004
Environmental Mastery (EM)	32 (8.4)	34 (7.7)	-2,1	0.04
Personal Growth (PG)	42 (5.6)	40 (7.2)	2.9	0.004
Positive Relations (PR)	41 (8.4)	37 (7.7)	4.6	<0.001
Purpose in Life (PL)	42 (7.8)	38 (8.0)	3.5	<0.001
Self-Acceptance (SA)	36 (10.4)	36 (7.7)	0.2	n.s.

Higher prevalence of symptoms of depression, anxiety and stress were found in I students. Multiple regression analyses resulted in statistically significant models for both H (F(11, 121)=19.6; p<0.001; R²=0.641) and I students (F(12, 143)=8.98; p<0.001; R²=0.430) indicating that EM (t=4.7; p<0.001), PL (t=-3.2; p=0.002), SA (t=4.2; p<0.001), A (t=2.9; p=0.005), and anxiety (t=4.06; p<0.001) significantly predicted the strength of resilience in H, while autonomy (t=4.9; p<0.001) proved to be significant predictor in case of I students.

Conclusions: These single-centre results need to be further clarified on national and international level to stimulate interventions for strengthening resilience through establishing a caring network by universities for the fragile population of medical students.

The impact of family communication patterns on parent-child attachment and child quality of life

A. Z. Békefi^{1,4}, M. Miklósi^{2,3,5} and B. Szabo^{3,6,7*}

¹Department of Developmental and Clinical Child Psychology, ELTE Eötvös Lóránd University Institute of Psychology; ²Department of Developmental and Clinical Child Psychology, ELTE Eötvös Lóránd University Institute of Psychology; ³Department of Clinical Psychology, Semmelweis University Faculty of Medicine; ⁴Autism Foundation; ⁵Heim Pál National Pediatric Institute, Centre of Mental Health; ⁶ELTE Eötvös Lóránd University, Doctoral School of Psychology and ⁷Developmental and Clinical Child Psychology, ELTE Eötvös Lóránd University Institute of Psychology, Budapest, Hungary

*Corresponding author.
doi: 10.1192/j.eurpsy.2024.502

Introduction: Previous research has demonstrated stable patterns of family communication. The Revised Family Communication Pattern Instrument (RFCP) is a common measure of these patterns. It posits two orientations: conformity orientation, characterized by a tendency to seek agreement within the family and by authoritarian decision-making; and conversation orientation, characterized by shared decision-making with the child and frequent family discussion. **Objectives:** The primary aim of our research was to adapt the RFCP questionnaire to the Hungarian language. Based on previous research, we hypothesized a negative relationship of conversation orientation and a positive relationship of conformity orientation with parents' mentalizing problems, parental stress and burnout. According to our hypothesis, conformity orientation would predict both attachment anxiety and avoidance, whereas conversation orientation would decrease attachment anxiety. **Methods:** Parents of children aged 6–17 (N=269, female=86,2%, mean age=42,64 [SD=6,10] yrs) completed the following online questionnaires: Child Quality of Life Questionnaire (ILK) parent version, Reflective Function Questionnaire (RFQ-8), Experiences of Close Relationships Questionnaire (ECR-RS), Parent Burnout Questionnaire (PBA-HUN), Perceived Stress Questionnaire (PSS) and the RFCP instrument. We conducted a confirmatory factor analysis. Linear regression analyses predicting attachment anxiety and avoidance included two factors of the RFCP, the RFQ-8, the

PBA-HUN, and the PSS total score, as predictors. In addition, two factors of the ECR-R were included in the linear regression analyses predicting quality of life.

Results: The confirmatory factor analysis confirmed the original two-factor structure of RFCP ($\chi^2=5482.21$, $df=325$ $p<.001$, $\chi^2/df=16.86$, CFI=0.91, TLI=0.90, RMSEA=0.075 (90% CI 0.068–0.082)) and their internal reliability (Cronbach's alpha = .78 and .74). Attachment avoidance ($R^2=0.12$, $F(5)=7.38$, $p<.001$) was only predicted by conversation orientation ($\beta=-0.28$, $p<.001$), while attachment anxiety was predicted ($R^2=25.2$, $F(5)=17.7$, $p<.001$) by conformity orientation ($\beta=0.24$, $p<.001$), parental mentalization difficulties ($\beta=0.20$, $p<.001$) and parenting stress ($\beta=0.15$, $p=.015$). Parental report of the child's quality of life was predicted most strongly by attachment anxiety ($\beta=-0.28$, $p<.001$), followed by conversation orientation ($\beta=0.21$, $p<.001$) and attachment avoidance ($\beta=-0.18$, $p<.001$, $R^2=28.8$, $F(7)=15.17$, $p<.001$).

Conclusions: The Hungarian version of the RFCP questionnaire has proven to be a reliable questionnaire. The importance of family communication patterns is demonstrated by the fact that it explains both the quality of parent-child attachment and the parent's report on the child's quality of life.

Promoting mental health by peer education at the University of Debrecen

V. A. Molnár^{1*}, E. Ménes², K. Kósa¹ and L. I. Tóth³

¹Department of Behavioural Sciences; ²Department of Emergency Medicine and ³Internal Medicine Building "A", University of Debrecen, Debrecen, Hungary

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.503

Introduction: Medical students have been shown to experience mental health problems more frequently compared to their non-medical student peers. This can manifest in pathological levels of stress and depression, and can lead to substance abuse, reduced academic performance, or even suicide.

Objectives: A credit course on professional socialization is offered for medical students at the University of Debrecen in the form of peer education. Our goal was to evaluate experiences of this course delivered in the past 5 academic years.

Methods: After reviewing the relevant literature, the structure of a focus group interview was developed. The focus group consisted of 8 participants and was moderated by the course supervisor with the help of an assistant moderator. The group summarized the number of students completing the course, and narratives of teaching experiences between 2018/19 and 2022/23. They also revised relevant versions of the tutors' handbook containing the topics and methodology of the course. The duration of the interview was 90 minutes, and it was tape recorded by the assistant moderator, who also made notes in case the tape is inaudible.

Results: Between 2018/19 and 2022/23 61 students finished the course with the help of 23 tutors. The course is offered for students of general medicine, dentistry and pharmacy to improve their positive professional attitudes and social skills through group work and practical exercises. The medical curriculum includes

mandatory courses with practical opportunities for developing professional and social skills, but due to the limited number of contact hours and the varying levels of student interest and motivation, these skills are difficult to master. The credit course was developed using the concept of Balint groups, offering peer-supervised opportunities for motivated students above year 2 to practice their professional skills in controlled conditions while also receiving feedback from their peer group leaders. The course complements the traditional medical curriculum and sensitizes students in a protected environment in which they can observe their own communication more consciously and recognize unfavourable behaviour patterns. Developing the ability to work in a team, learning to listen, and practicing assertiveness during study years can also reduce performance-related stress and future medical errors along with increasing job satisfaction and patient adherence.

Conclusions: Based on the narrative summary of the focus group, both the experiences of participating students and peer teachers are positive, the handbook is a useful tool. The structured focus group provides a suitable method to evaluate the credit course which should be held once every academic year to evaluate the implemented course and explore options to improve future courses.

Dyslipidemia induced by antipsychotics: differences between schizophrenia and bipolar disorder

A. Tahirovic^{1*}, M. Zuko², I. Lokmic Pekic² and M. Arnautovic Tahirovic²

¹Psychiatric clinic, Clinical centre university of Sarajevo and

²Psychiatric hospital of Canton Sarajevo, Sarajevo, Bosnia and Herzegovina

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.504

Introduction: The introduction of antipsychotics, especially of newer generation, greatly affects the effectiveness of the psychiatric treatment of patients with schizophrenia (SCH) and bipolar disorder (BP). Patients suffering from SCH and BP often have metabolic syndrome (MetSy), as a result of taking antipsychotic therapy, especially in patients with abdominal obesity, there is an atherogenic fat profile that carries a high risk for the development of dyslipidemia.

Objectives: To investigate frequency and differences of somatic diseases in patients with SCH and BD depending on the presence of MetSy.

Methods: This five-year prospective study was conducted in the Psychiatric Hospital of Canton Sarajevo. We followed 135 patients with SCH and 135 patients with BD, aged 30 to 69 years, who were treated with antipsychotics for five years.

Results: Dyslipidemia was significantly more common in SCH patients (73.3%), compared to BD (54.1%) and was dominantly presented in women (61.4%). The frequency of dyslipidemia increased with the age of the patient. Associated risk factors in patients with SCH diagnosed with dyslipidemia were 73.5% smokers, 78.7% hypertensive patients, 69.7% patients with elevated

BMI and 83.0% with elevated blood glucose values, while slightly lower values were recorded patients with BP. 97.8% of patients with dyslipidemia had elevated CRP.

Conclusions: There are significant differences in dyslipidemia in patients suffering from SCH and BP. Adequate knowledge of the antipsychotic drugs is required in order to provide adequate psychiatric treatment, regarding minimalising adverse effects of antipsychotics will be reduced to a minimum. It is important to recognize high-risk patients and educate them about preventive measures.

Cariprazine as adjunctive treatment of catatonia in schizoaffective disorder: a case report.

D. Magalhaes* and L. Fernandes

Mental Health Department, Hospital Prof. Doutor Fernando Fonseca, Lisbon, Portugal

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.505

Introduction: Cariprazine is one of the most recent innovations in neuropsychopharmacology, with evidence for its efficacy in affective and psychotic spectrum disorders.

Objectives: To present a case that highlights cariprazine's potential use outside the regulatory approved indications.

Methods: Case report using CARE guidelines and a narrative review.

Results: We present the case of a 41-year-old male readmitted to a psychiatric inpatient unit due to three months of mutism and withdrawal. At admission, the patient did not communicate verbally or in writing, but he complied with simple orders, and his consciousness remained unimpaired. He scored 11 points on the Bush-Francis Catatonia Rating Scale (BFCRS), indicating immobility, mutism, staring, withdrawal, ambitendency, and automatic obedience. We observed psychomotor retardation and indirect signs of a depressive mood, including the omega sign. His medical history included ongoing psychiatric treatment since the age of 30, with two prior admissions to an acute inpatient unit. At the time of admission, he was treated with olanzapine 20 mg/day, lorazepam 2 mg/day (recently downtitrated), venlafaxine 150 mg/day, and bupropion 150 mg/day. At the start of the current episode, the patient's diagnosis was uncertain, with previous descriptions of psychotic, affective, and catatonic features. Due to suspicion of catatonia, we administered a high dose of lorazepam (8 mg/day), resulting in a partial response with a 4-point reduction in the BFCRS. We discontinued bupropion, increased venlafaxine to 225 mg, and switched from olanzapine to cariprazine using a taper, washout, and switch strategy. Psychotic symptoms briefly appeared when the patient was not taking a dopamine D2-receptor modulatory drug. We identified mild possible adverse drug reactions, including akathisia, transient insomnia, and daytime sleepiness. At a dose of 6 mg/day of cariprazine, we observed complete remission of catatonia (BFCRS=0) and significant improvement in affective and psychotic symptoms. The patient was discharged home with diagnoses of catatonia and schizoaffective disorder,

prescribed 6mg/day of cariprazine, 225mg/day of venlafaxine, and 2,5mg/day of lorazepam. At the 6-month follow-up, the patient continues to exhibit clinical stability.

Conclusions: This case emphasizes the safety and potential effectiveness of cariprazine in treating catatonia within the context of schizoaffective disorder. We consider that the partial agonist properties of cariprazine could theoretically reduce the risk of exacerbating catatonia, a risk typically associated with full D2-receptor antagonists. Other mechanisms of action, such as D3 partial agonism, may also contribute to the improvement or at least the non-aggravation of catatonic symptoms. Cariprazine's mood-stabilizing properties make it a promising off-label choice for treating schizoaffective disorder, especially when catatonic features are present.

Prolactin level changes according to atypical antipsychotics use: a study based on Clinical Data Warehouse

I. Sohn^{1*} and J.-H. Jeong²

¹Psychiatry, Keyo Hospital, Uiwang and ²Psychiatry, St. Vincent's Hospital, College of Medicine, The Catholic University of Korea, Suwon, Korea, Republic Of

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.506

Introduction: Antipsychotics are associated with increased serum prolactin. It depends on the type of the antipsychotics and gender. There are previous studies, but it is necessary to compare them including new drugs.

Objectives: Antipsychotic drugs are known as the major cause of non-neoplastic hyperprolactinemia. This study aimed to investigate the levels of serum prolactin elevation depending on the use of antipsychotic drugs in patients through the Clinical Data Warehouse

Methods: Our study included 118 subjects who were all diagnosed according to ICD-10 for schizophrenia, schizotypal and delusional disorders, manic episodes, and bipolar affective disorders. All the subjects were taking one of risperidone, blonanserin, amisulpride, and olanzapine. They had prolactin blood tests collected retrospectively through CDW.

Results: Among the 118 subjects included in the analysis, the mean serum prolactin level was 65.1 ± 54.7 ng/ml. Serum prolactin levels were significantly higher in subjects taking risperidone or amisulpride compared to blonanserin and olanzapine. The female subjects who took amisulpride or olanzapine had significantly higher prolactin levels, but there was no difference in prolactin levels between the sex in the subjects who took risperidone or blonanserin.

Conclusions: This study suggests the need for regular monitoring of serum prolactin levels in patients who are taking antipsychotics, especially in female patients. Further studies on the subjects with controlled confounding variables and larger sample groups are needed.

Protective effect of lithium pyruvate against oxidative damage to peripheral blood mononuclear cellsL. Smirnova^{1*}, E. Epimakhova^{1,2}, E. Plotnikov^{1,3} and I. Losenkov¹¹Laboratory of Molecular Genetics and Biochemistry, Mental Health Research Institute, Tomsk National Research Medical Center of the Russian Academy of Sciences; ²Division of Biology and Genetics, Siberian State Medical University and ³Research School of Chemistry & Applied Biomedical Sciences, Tomsk Polytechnic University, Tomsk, Russian Federation

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.507

Introduction: In recent years, there has been renewed interest in lithium therapy due to emerging evidence of the protective effects of lithium against neuronal death caused by a wide range of neurotoxic effects. Oxidative stress is a common pathway that is involved in various pathologies. In this regard, the development and study of new lithium compounds with combined antioxidant effects becomes relevant. Pyruvate has many potential benefits due to its positive effects on cellular metabolism.

Objectives: The purpose of this study was to study lithium pyruvate on blood cells of healthy donors under conditions of induced oxidative stress.

Methods: The study used blood from 20 healthy control group volunteers, aged 25 to 54 years. Venous blood was taken at baseline and then used for PBMCs extraction. After that cells were incubated during 24 hours in RPMI 1640 medium at 37°C and 5% carbon dioxide concentration. For oxidative stress induction hydroperoxide of trisubstituted butyl (HTB) was used in concentration of 50 µM. Cells were also incubated with lithium pyruvate in final concentration of lithium ions of 1.2 mM with or without HTB. Level of oxidative stress in culture was assessed by flow cytometer «Muse Cell Analyzer» (Merck Millipore, Germany) using «Oxidative stress» reagents kit (Merck Millipore, Germany). Statistical analysis was performed using the SPSS software, release 20.0 for Windows.

Results: Percentage of cells with reactive oxygen species (ROS) cultivated with HTB (65,33 (41,95-79,30) %) was statistically significant higher compared to intact cells (11,03 (7,93-15,53) %) ($p=0.001$). After addition of lithium pyruvate in culture statistically significant antioxidant effects were observed. In PBMCs incubated with HTB and lithium pyruvate statistically significant decreased percentage of cells with ROS (42,70 (16,73-58,70) %) ($p=0.001$)

Conclusions: A pronounced antioxidant effect of lithium pyruvate under induced oxidative stress on human peripheral blood mononuclear cells has been established. Lithium pyruvate can be considered as a promising psychotropic antioxidant for further experiments.

Case series and Literature review – Clozapine Induced Transient Myocarditis. Clinical characteristics and outcomes

U. L. Anyeji MD* and P. Bidkhanian MD

Psychiatry, BronxCare Health System, Bronx, United States

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.508

Introduction: Clozapine is a second-generation atypical antipsychotic medication used in patients with treatment-refractory schizophrenia. Its use is limited due to its associated adverse effects, including myocarditis. These adverse effects may have variable presentations, such as myocarditis transient or persistent, and a generalized inflammatory process. Thus, clinical monitoring to inform accurate diagnosis is essential to avoid unnecessary discontinuation of clozapine, leading to psychiatric decompensation.

Objectives: To review clinical features of clozapine induced Myocarditis and accurately identify signs and symptoms attributed to be most specific for myocarditis and determine at what stage clozapine should be discontinued.

Methods: We conducted a literature review on PubMed, MeSH, google scholar and Mount Sinai's Levy Library using keywords, clozapine, drug related side effects, adverse reaction, myocarditis, treatment resistant schizophrenia. Review of two cases series was done.

Results: A review of 15 articles that addressed the cardiac complications of clozapine was performed. This review provides a base on variable clinical characteristics and outcomes of clozapine – induced Myocarditis. It showed patients who had myocarditis ruled out, demonstrated high prevalence of systemic signs of inflammation such as fever, malaise, tachycardia and elevated c-reactive protein. However, despite clozapine maintenance in most, this systemic response subsided without any intervention. A nonspecific inflammatory response is common when initiating clozapine, this inflammatory “clozapine storm” occurs within the first month of initiation and is not necessarily predictive of myocarditis. These patients were monitored closely. Those confirmed with clozapine- induced myocarditis using echocardiography and cardiac magnetic resonance imaging were managed with dose reduction, laboratory monitoring, vital signs check, with early initiation of beta-blockers without discontinuation of clozapine, with improvement in their laboratory results and vital signs. Those with progressive clinical signs of myocarditis required immediate cessation of clozapine.

Conclusions: We are proposing a critical need for a multidisciplinary team of psychiatrists, cardiologists and pharmacists collaborating to prevent premature termination of clozapine in cases of treatment-refractory schizophrenia. Our cases showed middle aged patients with treatment - refractory schizophrenia, presenting with symptoms suggestive of clozapine induced- myocarditis, few weeks after initiation. Clozapine was continued with close monitoring, as symptoms resolved. Though clozapine is associated with myocarditis, with proper knowledge on guidelines for monitoring patients, it can mitigate unnecessary discontinuation of clozapine in those patients.

Gender differences in the effect of rtms with the H7-coil on physical and social anhedonia in schizophrenia spectrum disorder; a randomized, sham-controlled trialK. Matic^{1*}, I. Šimunović Filipčić², I. Orgulan¹, Ž. Milovac¹, Ž. Bajić¹ and I. Filipčić³¹Psychiatric Clinic Sveti Ivan; ²Department of psychiatry and psychological medicine, University Hospital Centre Zagreb, Zagreb

and ³Faculty of Dental Medicine, Josip Juraj Strossmayer University of Osijek, Osijek, Croatia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.509

Introduction: Studies of differences in the incidence and severity of physical and social anhedonia between women and men diagnosed with schizophrenia spectrum disorder (SSD) are often inconsistent, and gender differences in treatment response have not been well studied. Hormonal factors, such as those related to the menstrual cycle, pregnancy or menopause, as well as social and cultural patterns and roles, may influence treatment response. The incidence of affective or stress-related psychiatric comorbidities may be gender-specific, which could also complicate the treatment of anhedonia and other negative symptoms of SSD. Finally, there is no evidence of sufficient quality on gender differences in the effects of rTMS, but the results are intriguing and point to the need for further research.

Objectives: To investigate gender differences in the effect of rTMS with the H7-coil on physical and social anhedonia in patients diagnosed with SSD with dominant negative symptoms.

Methods: We conducted a randomized, sham-controlled trial during 2000-2023 in the population of patients diagnosed with SSD with primary negative symptoms defined as PANSS negative symptoms subscale score > 24, and PANSS positive symptoms subscale score < 20. The intervention was HF rTMS H7 coil (Brainsway Ltd. Jerusalem, Israel) once daily for 20 days applied to the prefrontal cortex (mPFC and ACC) at 100% motor threshold with a frequency of 18 Hz, and total of 39600 pulses. The outcomes were Physical and Social Anhedonia Scales (PAS, and SAS). We controlled for the large number of relevant covariates.

Results: We randomized 49 men and 29 women of similar age. The effect on physical anhedonia was statistically significant in women ($b = 9.04$; $p = 0.016$), but not in men ($b = 2.87$; $p = 0.272$). The effect on social anhedonia was similar, but the difference was smaller (for men $b = 3.71$; $p = 0.082$; for women $b = 5.42$; $p = 0.043$). However, the Wald test showed no statistically significant differences between the beta coefficients for women and men.

Conclusions: Based on this study, it is not possible to make valid and reliable conclusions about the existence of gender differences in the effects of rTMS treatment of anhedonia with the H7 coil. However, it is possible to claim that the treatment of anhedonia with this protocol is effective in women.

Development of a Patient-Centred Care Plan for Patients Requiring Maintenance Electroconvulsive Therapy Long-Term

X. Y. Seet^{1*}, X. E. Lee² and H. Rahman²

¹Department of Psychiatry and ²Tan Tock Seng Hospital, Singapore, Singapore

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.510

Introduction: Maintenance electroconvulsive therapy (ECT) can be effective and necessary in the long-term for patients with severe

and recurrent mood or psychotic disorders that are not amenable to any other forms of treatment. Patients with such treatment resistance affecting their ability to maintain minimal daily activities may eventually fall within the palliative psychiatric care domain in which advanced medical directives become an important beacon to direct care. There are Psychiatric Advance Directives which allow people with severe mental health conditions to consent to or refuse to consent to hospital admission and psychiatric treatment in the event they lose decision-making capacity and this can be especially important for a potentially controversial treatment such as ECT. However, the focus tends to be on enforcing involuntary treatment and less about a comprehensive long-term care plan. To our knowledge, there is no available framework to structure maintenance ECT as a patient-centred care plan.

Objectives: Our aim is to share the process of development of a patient-centred care plan for patients requiring maintenance ECT. Our objectives are:

1. Constant engagement with patients and family or caregivers
2. Regular reviews of clinical and consent aspects of treatment
3. Advocating for the welfare of patients and respect of values
4. Focus on dignity especially for patients who require treatment well into old age
5. Being prepared for termination of treatment if necessary

Methods: We reviewed our management of previous and existing patients on maintenance ECT and incorporated diligent consent-taking practices. Adopting good practices from known palliative approaches and involving the patient voice helped to form a framework for a patient-centred care plan.

Results: Our patient-centred care plan features half-yearly discussions about the risks and benefits of treatment, as well as an assessment of the patient's cognition and ability to consent which may change over time. Opportunities for them to share their values and expectations of care and engagement with their caregivers about their quality of life guide the continued treatment. A framework for discussing the disruption or eventual termination of ECT prepares for scenarios where older-aged patients may develop frailty or present with acute, prolonged or devastating medical concerns. This end-of-life care approach manages anticipated psychiatric-specific behavioural concerns and prepares for the possibility of death following the planned termination of ECT for patients who required long-term treatment throughout their life. Lastly, issues of grief amongst caregivers and ethical concerns from medical staff are addressed.

Conclusions: We hope that our patient-centred care plan provides a well-considered conversation and structure for the initiation, continuation and termination of maintenance ECT in the long-term.

Empowering Minds: A Comprehensive Study of ECT Treatment in a Reference Mental Health Center in Portugal

M. Barbosa Pinto^{1*}, M. T.D. Viseu¹, P. Frias Gonçalves² and E. Gomes Pereira²

¹CHUA, Faro and ²HML-CHUSA, Porto, Portugal

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.511

Introduction: Electroconvulsive Therapy (ECT) is one of safest and most effective treatments for severe mental illnesses. The ECT Unit of Centro Hospitalar Universitário de Santo António – Magalhães Lemos Hospital (CHUSA-HML) is a reference center for this treatment modality, providing support to the northern region of Portugal.

Objectives: This study aims to characterize patients undergoing ECT treatment from April to June 2023, at the ECT Unit of CHUSA-HML.

Methods: Retrospective study from April to June/2023. Social, demographic, epidemiological and clinical data were evaluated.

Results: Among the 55 patients who were treated there was a predominance in male sex (56%), the average age was 53 years old and only 9 completed higher education. Half of them were in a long-term relationship. Around 67% of patients are retired, predominantly (62%) due to psychiatric disability.

Most patients (78%) were referred through psychiatric consultation and the remainder came from psychiatric hospitalization (only 3 were never hospitalized). 41 patients were under maintenance treatment and 14 under acute treatment. Concerning the type of treatment 30 were submitted to bilateral ECT. For 33% it wasn't the first ECT treatment. Almost all patients improved their symptoms, only one patient had complications related to the procedure (tooth loss).

According to the international classification of disease (ICD11) the most frequent primary diagnosis was Schizophrenia or Other Primary Psychotic Disorders (58%). Neurodevelopmental disorders and substance use disorders were the most frequently comorbid diagnoses.

The results presented are preliminary, and other data that may be relevant are being collected and processed.

Conclusions: Severe mental illnesses profoundly impact patients, often imposing substantial limitations and suffering. These findings support the safety and effectiveness of ECT as treatment for severe mental disorders. Founding more specialized centers represents an important step toward enhancing mental health treatments. Access to controlled studies is crucial, fostering a deeper understanding of the ECT technique and long-term benefits.

Electroconvulsive therapy: the perspective of the informal caregiver in the decision-making process

P.-J. Geerts^{1*}, S. Abihi¹ and S. Verhaeghe²

¹az groeninge, kortrijk and ²ugent, Ghent, Belgium

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.512

Introduction: Despite the importance of electroconvulsive therapy (ECT) as treatment, it remains one of the most controversial and misunderstood treatments. Negative media representations, primitive practice in the past and fear for electricity results in fear that extends beyond other therapies. Research on the perspective and role of informal caregivers (IC) in the process of ECT is limited. Most research focuses on relatives' attitude or knowledge of ECT measured with questionnaires. However, profound understanding of their perspective can facilitate the role of physicians (or psychiatrists) in

guiding patients and their IC through the decision-making process of ECT.

Objectives: The aim of this study was to describe the perspective of informal caregivers in the decision-making process in ECT treatment.

Methods: A qualitative phenomenological study was set up. Semi-structured interviews were held with IC of patients who are treated with ECT. **Purposive sampling was based on maximum variation.**

All interviews were fully transcribed and thematic analyses took place. Trustworthiness was guaranteed by e.g. researcher triangulation

Results: In nine interviews were held with partners, children and parents of patients. The interviews had a mean duration of 102 minutes and interviewing proceeded until saturation of the most important themes was reached. During the interviews it became clear that the decision-making process of ECT is strongly influenced by the illness-trajectory and context of living with the mental health problems of the patient. IC describe their life and that of the patient as 'trying to survive'. The proposal of ECT is seen as a way out of this unendurable situation. The perceived responsibility of the IC in the informed consent process to ECT adds to this burden. The IC worry, feel uncertain and fear to do wrong. Nonetheless ECT seems to be a beacon of hope. Trust in the psychiatrist as a competent professional who wants the best for the patient seems more important than having an answer to all of their questions. After the ECT has been started, IC establish a framework to evaluate the side-effects and effectiveness of ECT. This framework is based on how they experience the patient in daily life and on what they define as 'the patient becoming a bit more himself again'. IC weigh the effects and side-effects to support the continuation of ECT. However, if patients clearly express that they experience side-effects that are too hindering, IC follow the patient if he or she wants to stop ECT.

Conclusions: Our study gives an insight in the perspective of the IC of patients undergoing ECT. It could be helpful for IC if the psychiatric team repeats information stepwise and takes the burden of responsibility perceived by the IC into account. The framework used by IC to evaluate the effects of ECT could be a valuable addition to the clinical evaluation of the ECT treatment.

Association between metabolic syndrome, cognitive dysfunctions, and peripheral inflammation in schizophrenia

A. Kancsev^{1*}, O. Kelemen^{2,3} and S. Kéri^{4,5,6}

¹Department of Psychiatry and Psychotherapy, SZSZBMK Jóna András University Teaching Hospital, Nyíregyháza; ²Department of Behavioral Sciences, Albert Szent-Györgyi Medical School, University of Szeged, Szeged; ³Department of Psychiatry, Bács-Kiskun County Hospital, Kecskemét; ⁴Department of Cognitive Science, Budapest University of Technology and Economics; ⁵National Institute of Mental Health, Neurology, and Neurosurgery, Budapest and ⁶Department of Physiology, Albert Szent-Györgyi Medical School, University of Szeged, Szeged, Hungary

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.513

Introduction: Metabolic syndrome (MetS) is of primary clinical interest because of its harmful impact on the general health and quality of life of patients with psychotic disorders. Paradoxically, MetS is associated with impaired cognitive functions in patients receiving antipsychotics primarily shown to improve cognition (e.g., clozapine and olanzapine).

Objectives: In this study, we aimed to investigate the relationship between MetS, cognitive functions, and peripheral inflammation.

Methods: The participants were 154 patients with schizophrenia. Fifty-seven patients met the criteria of MetS. We evaluated cognitive functions with the Repeated Battery for the Assessment of Neuropsychological Status (RBANS). The Positive and Negative Syndrome Scale (PANSS) quantified the clinical symptoms. We also measured the plasma levels of IL-6 and C-reactive protein (CRP). In addition to conventional statistics, we also calculated Cohen's effect size (d) and Bayes Factors (BF10).

Results: Results revealed that patients with MetS exhibited worse cognitive function relative to patients without MetS in attention ($d = 0.19$, $BF10 = 2.3$) and delayed memory ($d = 0.25$, $BF10 = 5.7$). No significant between-group differences existed in immediate memory, visuospatial functions, and language. The MetS and non-MetS groups did not differ in positive, negative, or general symptoms. Higher IL-6 levels were associated with worse delayed memory ($r = -0.56$, $BF10 = 34.6$).

Conclusions: Our results suggest that MetS-associated cognitive dysfunctions are less severe than reported in the literature: it was confined to two cognitive domains, the effect size was small, and the Bayesian evidence level was weak. Peripheral inflammation may mediate the association between MetS and long-term memory dysfunctions.

Sociodemographic profile and prescribing pattern of antipsychotic medication in patients with Schizophrenia

A. Palushaj^{1*} and V. Kola²

¹Neuroscience, "Ihsan Çabej" Hospital, Lushnje and ²Neuroscience, University Hospital "Mother Teresa", Tirane, Albania

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.514

Introduction: Schizophrenia is a complex psychiatric disorder that changes the patient's life by influencing how they think, behave, express emotions, percept reality and their interpersonal relationships.

Objectives: The aim of this study was to evaluate sociodemographic and therapeutic factors that act as risk and protective factors in the clinical outcomes of patients diagnosed with schizophrenia.

Methods: This was an observational retrospective study including patients diagnosed with schizophrenia, treated at the "Xhavit Gjata" Psychiatric Hospital, Tirane, Albania, who were discharged between May 1- October 30, 2022. The follow-up period was six months. Data on further hospitalizations during the follow-up were obtained from the Department of Statistics, QSUT, and confirmed

by family members for hospitalizations in other psychiatric hospitals in the country. Univariate and multivariate analyses were conducted to identify potential factors associated with emergency room stays, length of stay, and time until the next admission.

Results: A total of 158 patients were included in the study, 63 women and 95 men ($p = 0.03$). The average age of the patients was 42.9 years, with women averaging 45.3 years and men 40.6 years ($p = 0.01$). 43.7% of them had elementary education. The average age of disorder onset was 24.7 years. Haloperidol was the ambulatory therapy used in 54.3% of patients, while atypical antipsychotics were used in 75.1% of patients. The most commonly used atypical antipsychotic was Risperidone in 34.1% of patients, followed by Olanzapine in 17% of cases. Depo antipsychotics were used in 35.1% of patients. Clozapine was administered to 29.3% of patients, where 12.8% for the first time. 54.2% of patients starting Clozapine for the first time had three or more admissions. Clozapine was more frequently used in men, showing a significant difference from women ($p = 0.05$). In 44.7% of cases, monotherapy was prescribed. The average hospital stay was 21.9 days, ranging from 2-68 days. Living with a family member, male gender, and being "married" helped reduce the length of hospital stay. In the 6-month follow-up period, 31.4% were re-hospitalized. Significant factors affecting the reduction of time spent outside the hospital until the next hospitalization were social problems, the number of previous hospitalizations, civil status "not married," living arrangements, negative symptoms, and alcohol use (nearly significant). Protective factors included Clozapine, which reduced the prevalence of hospitalization by 57% compared to patients not taking it. Additionally, the use of Clozapine and Haloperidol increased the time spent outside the hospital.

Conclusions: Social and family support, positive compliance, and antipsychotic therapy such as Clozapine serve as protective factors for patients diagnosed with schizophrenia.

The impact of affective and negative symptoms on the development of psychosis in a six-year follow-up of a community-based population

C. Ergul^{1*}, T. Binbay², U. Kırılı³, H. Elbi³, K. Alptekin², J. van Os⁴ and M. Drukker¹

¹Maastricht University, Maastricht, Netherlands; ²Dokuz Eylül University; ³Ege University, Izmir, Türkiye and ⁴Utrecht University, Utrecht, Netherlands

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.515

Introduction: The Clinical High Risk (CHR) group for transition to psychotic disorders (PD) is usually defined by the severity of positive symptoms, help-seeking and impairment in level of functioning. However, the CHR concept has a limited transition risk to PD. Recent studies have shown that some of the risks might be attributable to other symptoms.

Objectives: This study investigates the association between affective and negative symptoms and the risk of transition to PD in a community-based population of 2185 participants in Turkey.

Methods: At baseline, psychotic and affective symptomatology were assessed. The same participants were contacted again 6-years later. The initial analysis aimed to assess the link between affective and negative symptoms, and the progression to PD. The independent variable, baseline symptomatology, was categorized into five groups: no Psychotic Experiences (PE)(reference), subclinical PE, subclinical PE accompanied by affective/negative symptoms, clinical PE, and clinical PE with affective/negative symptoms. In the subsequent analysis, the association between affective and negative symptoms at baseline and the onset of PE and PD at follow-up was evaluated. For this analysis, the baseline symptomatology was restructured into two categories: neither PE nor affective/negative symptoms (reference), and the presence of affective/negative symptoms without PE.

Results: The findings from the initial analysis indicated that being part of the 'subclinical PE only' group at baseline was not associated with an increased risk of developing PD at follow-up. Being part of the 'subclinical PE+affective/negative symptoms' group was not significantly associated with PD at follow-up, although a trend was observed (OR: 3.22; $z=1.90$; $p=0.057$). Moreover, being classified as having 'clinical PE only' (OR: 6.23; $z=2.57$; $p=0.010$) and 'clinical PE+affective/negative symptoms' (OR: 8.48; $z=4.17$; $p=0.001$) at baseline was associated with an increased risk of developing PD at follow-up. Results from the subsequent analysis showed that being in the 'affective/negative symptoms' group at baseline was associated with an increased risk of new subclinical PE (RR: 1.98; $z=3.20$; $p=0.001$), new clinical PE (RR: 3.14; $z=4.84$; $p=0.001$), and new PD (RR: 4.21; $z=2.17$; $p=0.030$) at follow-up, compared to the 'neither PE nor affective/negative symptoms' group.

Conclusions: The results confirm that baseline severity of positive symptoms is significant in predicting transition to PD. In addition, the findings imply that not only positive symptoms but also affective and negative symptoms might contribute to the risk of transition to PD as well as incident psychotic symptoms. Defining CHR groups based on a combination of positive, affective and negative symptoms instead of focusing only on positive symptoms likely will help more accurately predict the transition to psychosis.

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.516

Introduction: Auditory verbal hallucinations (AVHs) in schizophrenia have been suggested to arise from failure of corollary discharge mechanisms to correctly predict and suppress self-initiated inner speech. However, it is unclear whether such dysfunction is related to motor preparation of inner speech during which sensorimotor predictions are formed. The contingent negative variation (CNV) is a slow-going negative event-related potential that occurs prior to executing an action. A recent meta-analysis has revealed a large effect for CNV blunting in schizophrenia. Given that inner speech, similar to overt speech, has been shown to be preceded by a CNV, the present study tested the notion that AVHs are associated with inner speech-specific motor preparation deficits.

Objectives: The present study aimed to provide a useful framework for directly testing the long-held idea that AVHs may be related to inner speech-specific CNV blunting in patients with schizophrenia. This may hold promise for a reliable biomarker of AVHs.

Methods: Hallucinating ($n=52$) and non-hallucinating ($n=45$) patients with schizophrenia, along with matched healthy controls ($n=42$), participated in a novel electroencephalographic (EEG) paradigm. In the Active condition, they were asked to imagine a single phoneme at a cue moment while, precisely at the same time, being presented with an auditory probe. In the Passive condition, they were asked to passively listen to the auditory probes. The amplitude of the CNV preceding the production of inner speech was examined.

Results: Healthy controls showed a larger CNV amplitude ($p = .002$, $d = .50$) in the Active compared to the Passive condition, replicating previous results of a CNV preceding inner speech. However, both patient groups did not show a difference between the two conditions ($p > .05$). Importantly, a repeated measure ANOVA revealed a significant interaction effect ($p = .007$, $\eta_p^2 = .05$). Follow-up contrasts showed that healthy controls exhibited a larger CNV amplitude in the Active condition than both the hallucinating ($p = .013$, $d = .52$) and non-hallucinating patients ($p < .001$, $d = .88$). No difference was found between the two patient groups ($p = .320$, $d = .20$).

Conclusions: The results indicated that motor preparation of inner speech in schizophrenia was disrupted. While the production of inner speech resulted in a larger CNV than passive listening in healthy controls, which was indicative of the involvement of motor planning, patients exhibited markedly blunted motor preparatory activity to inner speech. This may reflect dysfunction in the formation of corollary discharges. Interestingly, the deficits did not differ between hallucinating and non-hallucinating patients. Future work is needed to elucidate the specificity of inner speech-specific motor preparation deficits with AVHs. Overall, this study provides evidence in support of atypical inner speech monitoring in schizophrenia.

Suicidology and suicide prevention

EPP0345

The link between personality dimensions, impulsivity, decision and coping style, and suicide attempts in affective patients.

J. M. Pawlak^{1*}, K. Bilśka¹, M. Skibińska¹, B. Narożna², P. Zakowicz¹, A. Rajewska-Rager¹, P. Kapelski¹ and M. Dmitrzak-Węglarz¹

¹Department of Psychiatric Genetics and ²Department of Pneumology, Pediatric Allergology and Clinical Immunology, Poznań University of Medical Sciences, Poznań, Poland

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.517

Introduction: Introduction: Affective patients, especially depressive, have an increased risk of suicidal behavior. Identifying individuals at increased risk remains a challenge. Among the correlates that may be crucial, the impact of personality is emphasized. Attention is paid to impulsivity, measured by subjective or objective tests. **Objectives:** Objectives: Comparative analyses were carried out to capture the differences and relationship between personality dimensions, impulsivity, and the decision-making style and coping with stress strategies in suicide attempters and non-attempters in the course of an affective disorder.

Methods: Methods: Data were obtained from 276 individuals diagnosed with unipolar and bipolar affective disorder, both sexes. The study group was disaggregated into a subgroup of patients with (N=95) and without (N=181) suicide attempts in an individual's history. The Temperament and Character Inventory (TCI) was used to assess personality dimensions. The Barratt Impulsiveness Scale version 11 (BIS-11) was used to measure impulsivity subjectively, and the Simple Reaction Time (SRT) test and the Continuous Performance Test (CPT) were objective assessment methods. The Coping Orientation to Problems Experienced (COPE) and Iowa Gambling Task (IGT) were applied to investigate coping and decision-making styles. Statistical analyses were performed in Statistica 13.3 StatSoft, Kraków, Poland.

Results: Results: In TCI, significant differences between suicide attempters and non-attempters concerned the following dimensions: harm avoidance (HA) ($p < 0.0000$), self-directedness (SD) ($p = 0.0001$), and cooperativeness (C) ($p = 0.0186$). In the CPT test, significant differences concerned correctly responded trials ($p = 0.0179$) and Bias response ($p = 0.0230$). In IGT, significant differences occurred in IGT block1_sum ($p = 0.0496$) only (Table 1). We did not observe any significant differences in other tests applied. In the Spearman rank correlation analysis in the group of suicide attempters, the following correlations ($p > 0.05$) with at least moderate strength $r > 0.4$ were revealed: Novelty seeking (NS), SD, and C correlated with several CPT parameters; Persistence (P) correlated with SRT variables; NS, HA and SD with BIS-11 variables.

Conclusions: Conclusions: Objective computerized tests (SRT; CPT; IGT) did not differentiate suicide attempters and non-attempters more clearly than self-reporting personality inventory TCI. Personality traits correlated with SRT and CPT variables. BIS-11 and COPE parameters did not enable to distinguish suicide attempters and non-attempters in the investigated group. This

suggests that tests used complement each other, and using a single tool may be insufficient to indicate patients at increased risk of suicidal behavior.

Mental health front-liners: Police officers' knowledge and attitudes towards suicide in Malta

D. Zammit* and M. Bezzina Xuereb

Mental Health Services, Mount Carmel Hospital, Attard, Malta

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.518

Introduction: Police-officers are in a strategic position of providing the first immediate response to a crisis as mental health frontliners.

Objectives: In this nation-wide cross-sectional study, we explored knowledge and attitudes towards suicide in the local police force, a crucial first step in the design and implementation of effective suicide prevention programmes.

Methods: An online, anonymous questionnaire was distributed to all local police-officers ($n = 2600$). It contained questions about their demographics and their experience with suicide while on duty, along with 34 statements from the validated tool Attitudes Towards Suicide (ATTS) (Renberg & Jacobsson. Suicide Life Threat Behav. 2003; 33 52-64), scored on a 5-point Likert Scale (1 = Strongly Disagree, 5 = Strongly Agree).

Results: The sub-scale "Suicide as a right" was positively correlated with "Tabooing" ($r(201) = .25, p < .001$), "Normal-common" ($r(201) = .29, p < .001$), and "Resignation" ($r(201) = .47, p < .001$), but negatively correlated with "Incomprehensibility" ($r(201) = -.26, p < .001$), and "Preparedness to Prevent" ($r(201) = -.19, p < .001$), meaning such individuals had a more permissive attitude towards suicide. On the other hand, the subscale *Preventability* was found to be positively correlated with *Incomprehensibility* ($r(201) = .21, p < .001$) and *Preparedness to Prevent* ($r(201) = .30, p < .001$).

Females scored higher in the sub-scale *Non-communication* ($M = 3.40, 95\% \text{ CI } [3.29, 3.51]$) while males scored higher in *Preventability* ($M = 3.35, 95\% \text{ CI } [3.27, 3.44]$). The higher the educational status of police-officers, the more they adopt a pro-prevention attitude to suicide ($M = 3.67, 95\% \text{ CI } [3.44, 3.89]$) and the more likely they are to appreciate that suicidal thoughts and behaviour can be common ($M = 3.40, 95\% \text{ CI } [3.20, 3.60]$). Participants with a mixed/different composition at home ($M = 4.05, 95\% \text{ CI } [3.86, 4.24]$) and/or have experienced only between 0 to 2 situations related to suicide in the past one year alone ($M = 4.05, 95\% \text{ CI } [3.94, 4.16]$), were the most likely to feel prepared to prevent suicide.

Conclusions: This study brings out different attitudes police-officers hold towards different aspects of suicide, influenced by their gender, educational background, personal life at home and total exposure to suicide during their career. Training programmes can help improve their knowledge and attitudes towards suicide, leading to a more positive behavioural response to individuals in crisis and create a safer environment. Malta, through an EU-funded programme, is currently investing its resources on drafting a national suicide prevention strategy, and such educational opportunities for our frontliners will ensure

we have the right tools in screening, identifying, treating, and saving more lives.

EPP0347

Preliminary results of “Choose Life!” - a county-wide programme for suicide prevention and mental health awareness

R. Wernigg

Department for Primary Care Planning and Development, National Directorate-General for Hospitals, Budapest, Hungary

doi: 10.1192/j.eurpsy.2024.519

Introduction: Suicidality and depression awareness still remains a concern in Hungary. This programme, based on the principles of the European Union Against Depression, implemented its five steps, such as: 1. improving family doctors' readiness to diagnose and treat depression, 2. increasing public awareness, 3. training stakeholders and community facilitators, 4. offering special help for risk groups, 5. facilitating self-help by the online tool “ifightdepression” in five of seven districts of Heves county from November 2014 until May 2016.

Objectives: We aimed to look at some clinical outcome measures of the programme, like diagnosis density of depression in primary care before and after the intervention; diagnosis density of depression in outpatient services; suicide attempts in specialised care; and completed suicide rates.

Methods: We extracted patient turnover data from the joint database of the National Healthcare Fund and the National Directorate-General for Hospitals. Raw patient turnover data were divided by the total patient turnover in order to obtain diagnosis density. For the diagnosis of depression, we used the sum of the ICD-10 diagnoses of F32 (depressive episode) to F33 (recurrent depression) plus F4120 (mixed anxiety-depressive disorder), as family doctors tend to use these diagnoses interchangeably. For suicide attempts, we used the diagnoses X60 to X84, plus Y8700. For completed suicides we used the same diagnoses with the “deceased” flag. Diagnosis densities were compared with concurrent national data and were standardised to the long-term average. In the case of outpatient services, we only could retrieve monthly data, which we smoothed out with three-monthly moving averages.

Results: Baseline diagnosis density of depression in primary care was already 44% above the national average when the program started and after the kickoff, it shortly went up to 53,3% and remained over the baseline for as long as until 2019. Also, the recognition rates of depression with no comorbidities in primary care increased by 6%, and steadily remained over the national average until 2019. For outpatient psychiatry, there was an 8% increase in depression turnover throughout the duration of the programme. As regards to suicide attempts treated in hospital, the rates went 20% below the national averages for the duration of the programme, and mostly remained there until 2020. Fatal suicidal events accounted for five to seven deaths a year per county, therefore, simple statistical methods could not uncover significant differences.

Conclusions: These early results indicate that the programme may have been effective in terms of reinforcing the diagnostic and treatment capacities of primary care for recognising a treating depression adequately, thereby eliminating suicide risk. Further statistical exploration of the data is still needed to confirm the magnitude and the validity of these results.

Improving Skills and Knowledge: Adapting a Core Competencies Suicide Risk Assessment Training Program to Support Mental Health Professionals in Hungary

M. Bérdi^{1*} and R. J. Cramer²

¹Psychiatry and Crisis Intervention, Peterfy Sandor Utcai Hospital-Clinic and Trauma Centre, Budapest, Hungary and ²Public Health Sciences, University of North Carolina at Charlotte, Charlotte, United States

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.520

Introduction: Competency and skill-based education and assessment have become increasingly significant in mental health professional training. The conventional approach of acquiring knowledge is now being supplemented by emphasizing practical skills and implementing best practices that prove effective in the field. This emphasis on competencies is particularly apparent in the instruction regarding suicide risk evaluation and management. Cramer and colleagues have identified ten core competencies essential for working with patients at risk of suicide and developed a training material (Cramer et al. 2013, Train. Educ. Prof. Psychol; 1 1-11).

Objectives: We aim to tailor Cramer et al.'s training program to the Hungarian setting and assess its efficacy among mental health experts, including psychiatrists, clinical psychologists, and social workers. Additionally, we aim to validate the Suicide Prevention and Assessment - Competency Assessment Form (SCAF-R), which comprises a ten-item survey to measure the ten core competencies' levels with Likert scales and textual ratings by observers. Through this training program, we aim to offer mental health professionals an educational framework to enhance their skills in evaluating and managing suicide risk. Our goal is to provide a comprehensive approach to suicide risk assessment and better equip professionals to handle this emotionally difficult clinical task.

Methods: We have created a Hungarian version of the core competencies training material tailored to the culture. We are assessing changes in attitudes towards suicide behavior and prevention by administering pre- and post-training psychometric measures, such as Willingness to Intervene against Suicide (WISE), Suicide Behavior Attitude Questionnaire (SBAQ), Attitudes Toward Suicide Prevention Scale (ASP), and Suicide Competency Assessment Form - Revised (SCAF-R). A quantitative analysis will be performed on the responses. The research was approved by Péterfy Hospital's Institutional Review Board (IRB): approval number 07-2023.

Results: The questionnaires' results will be summarized with standard statistical methods.

Conclusions: Improving mental health education in healthcare with up-to-date knowledge of evidence-based best practices is a top priority. Enhancing skills and knowledge can lower clinicians' anxiety in this emotionally challenging and burdensome task. There is a high demand for mental health workshop training among healthcare workers in both undergraduate and post-graduate education. We expect positive changes in attitude and self-perceived competencies in participants.

Basic beliefs about self and the world in people with suicidal ideation

T. I. Medvedeva¹, O. M. Boyko^{1*}, O. U. Vorontsova¹ and S. N. Enikolopov¹

¹Clinical psychology, Federal State Budgetary Scientific Institution "Mental Health Research Center", Moscow, Russian Federation

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.521

Introduction: Basic beliefs can be defined as a person's implicit, global, stable ideas about the world and about himself. The psychological features of people with suicidal ideas can be considered as characteristics of the value sphere of a person who is ready to choose a destructive way of solving problems.

Objectives: The relationship of basic beliefs regarding the general «Benevolence of the surrounding world», its «Meaningfulness» and «Worthiness of the Self» with the presence of suicidal ideas was investigated.

Methods: The study involved 140 people, (117 women). The Janoff-Buhlman World Assumptions Scale (WAS), the short Epstein Rational-Experiential Inventory (REI), Symptom Check List-90-Revised (SCL-90R), moral dilemmas (proposed by J.D. Green), as well as separate questions about the suicidal ideation, risk tendency were used.

For analysis, the subjects were divided into two subgroups: 98 people without thoughts of suicide; and 42 people answered that they had thoughts of suicide of varying severity. The subgroups did not differ by gender; in the group with suicidal ideation, the average age of the subjects was lower.

Results: In the subgroup with suicidal ideas, almost all indicators of basic assumptions, such as "Benevolence of the World" (average values of 16.10 ± 3.28 and 12.13 ± 4.80 for the control subgroup and the subgroup with suicidal ideas), were lower: "Benevolence of the People" (15.35 ± 3.07 and 12.42 ± 4.97), "justice" (12.46 ± 3.30 and 10.46 ± 3.60), "value of one's own self" (16.21 ± 3.93 and 11.83 ± 5.15), etc., with the exception of the "Self-controllability", which does not differ between subgroups. Also, in the subgroup with suicidal ideas, the indicators of "randomness" were increased (15.67 ± 3.64 and 18.67 ± 3.96). Indicators on the clinical scale "Hostility" of the SCL-90R questionnaire are also significantly higher in the group with suicidal ideation (average values 0.53 ± 0.5 and 1.29 ± 0.8). In the group with suicidal ideation, there is a higher tendency to take risks. At the level of a statistical trend, the rational method of decision-making in the

"Rational - Intuitive" questionnaire is lower (average values 14.3 and 13.0; significance level of differences 0.05). In the "Moral Dilemmas" test, in the subgroup with suicidal ideas, the ratio of choices in personal and impersonal dilemmas is statistically higher (0.67 and 0.93).

Conclusions: It was shown that the presence of suicidal ideas is associated with a reduced indicator of the Worthiness of the Self, the meaningfulness of the world and its benevolence, and with an increased sense of randomness as a principle for distributing ongoing events, which can manifest itself in a propensity for risk, impulsive decisions, devaluation of human life.

Relationship between childhood stressful events and drug consumption among university students

S. Rey-March¹, C. Giralt², S. Font-Mayolas³ and F. Calvo^{1*}

¹Departament de Pedagogia, Institut de Recerca sobre Qualitat de Vida;

²Institut Català de la Salut, Centre d'Atenció Primària Blanes 2 and

³Departament de Psicologia, Institut de Recerca sobre Qualitat de Vida, Girona, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.522

Introduction: The purpose of this study is to investigate the potential relationship between stressful events experienced in childhood and subsequent toxic substance consumption among university students majoring in Social Education at a Spanish university during the academic year 2022-2023.

Objectives: The primary objective is to analyze whether an association exists between stressful life events in childhood and patterns of substance consumption among university students.

Methods: A cross-sectional, observational, and analytical design was employed. The target population encompassed 258 students enrolled in the Social Education program in 2023. The final sample consisted of 161 students. A questionnaire incorporating the Childhood Trauma Questionnaire - Short Form (CTQ-SF) and the Severity of Dependence Scale (SDS) was administered to assess trauma history and substance consumption.

Results: A high percentage (95.03%) of students reported having consumed toxic substances at some point in their lives. The most common substances were alcohol (95.03%) and cannabis (52.8%). A statistically significant correlation was observed between childhood emotional abuse and increased alcohol consumption currently ($p = 0.015$). Furthermore, a significant relationship was identified between childhood sexual abuse and heightened alcohol consumption ($p = 0.015$). Moreover, positive correlations were found between sexual abuse and the consumption of specific drugs, such as cocaine and psychopharmaceuticals ($p < 0.05$).

No statistically significant differences were observed in drug consumption with regard to other forms of childhood maltreatment, such as emotional or physical neglect.

Conclusions: The results underscore the connection between childhood stress experiences and substance consumption among university students. Emotional and sexual abuse in childhood are linked to higher alcohol consumption and, in some cases, specific drugs like cocaine and psychopharmaceuticals. These findings emphasize the importance of considering traumatic experiences when addressing prevention and treatment strategies for substance consumption among young student populations.

Assessment of addictive behaviors in patients with schizophrenia

M. Kacem*, W. Bouali, H. Babba, F. Zouali and L. Zarrouk
Psychiatric department, Taher Sfar Hospital of Mahdia, Mahdia, Tunisia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.523

Introduction: Schizophrenia, a chronic and complex psychiatric pathology, can be isolated. However, it can be associated with other comorbidities and thus be accompanied by addictive behaviors that complicate their management.

Objectives: The objectives of our study were to estimate the prevalence and identify the characteristics of addictive behaviors in patients with schizophrenia.

Methods: A retrospective study of 151 patients with schizophrenia hospitalized in the psychiatry department of Taher Sfar University Hospital in Mahdia from January 2017 to December 2021.

Results: The mean age of the patients was 39.8 ± 11.23 years, with a predominance of the 36-45 age group (38.4%). All patients were male. Three quarters of the patients (75.5%) were users of psychoactive substances (PAS): nearly three quarters (72.8%) were addicted to tobacco, more than one third (39.7%) were addicted to alcohol, more than one quarter (29.1%) were addicted to cannabis and nearly one quarter (26.5%) were addicted to other PAS. In more than half of the cases (54.4%), the age of onset of substance use was between 16 and 25 years. The use of PAS preceded the onset of schizophrenia in 62.3% of cases. The relationship with the entourage was marked by hetero-aggressiveness in 77.5% of patients, withdrawal from the entourage in 16.6% of patients and conflict in 5.3% of patients. The impact on the relationship with oneself was marked by self-aggressiveness in 18.5% of patients. Concerning the professional impact, three quarters of the patients (76.1%) had to stop working. The majority of patients (84.1%) continued their usual treatment, while 15.2% of patients stopped it. Only one patient required an increase in dose.

Conclusions: Subjects suffering from schizophrenia are particularly vulnerable to addictions, mainly to tobacco and alcohol. They are thus a group more at risk of the deleterious effects of psychoactive substances and of the aggravation of the clinical and psychosocial evolution of their psychiatric disorders. Measures for early detection and treatment of their addictive behaviors even before the onset of schizophrenia should be proposed.

Repetitive transcranial magnetic stimulation (rTMS) is associated with increased abstinence in substance use disorders and comorbid depression

S. El Hayek^{1*}, H. Tolba¹, A. Elmougy¹ and W. Foad¹

¹Erada Center for Treatment and Rehabilitation in Dubai, Dubai, United Arab Emirates

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.524

Introduction: Substance use disorders (SUDs) are associated with high rates of comorbid depression. Finding effective treatments for many of the substances of abuse is still an area of developing research. Repetitive transcranial magnetic stimulation (rTMS) is an established treatment for depression, but its effects in SUDs are less conclusive.

Objectives: Therefore, we aimed to investigate the effect of rTMS in patients with SUDs and comorbid major depressive disorder (MDD).

Methods: We conducted a retrospective observational study of 55 patients with SUDs and comorbid MDD who were eligible for rTMS. Craving was measured using the Brief Substance Craving Scale (BSCS). Severity of MDD was measured using the Clinical Global Impression-Severity (CGI-S) scale.

Results: We found a statistically significant difference between baseline and posttreatment scores in patients receiving rTMS on both CGI-S scores and BSCS scores. The number of rTMS sessions significantly predicted increased days of abstinence in the community, even after controlling for confounders.

Conclusions: Patients with SUDs and MDD who received rTMS significantly improved in the areas of severity of depression and craving. The number of rTMS sessions significantly predicted increased abstinence.

Prevalence and correlates of psychoactive substance use in domestic and foreign university students

E. L. Nikolaev¹ and S. S. Fakhraei^{2*}

¹Department of Social and Clinical Psychology and ²Medical Faculty, Ulianov Chuvash State University, Cheboksary, Russian Federation

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.525

Introduction: Use of psychoactive substances is a risk factor for mental health. Studying the peculiarities of using psychoactive substances by university students is extremely important for organizing preventive health care

Objectives: To specify the frequency of smoking and alcohol drinking, as well as the peculiarities of the correlational interconnections, in domestic and foreign university students

Methods: The survey covered 546 undergraduate domestic and foreign university students of both genders and different religious backgrounds. As a tool, we used the Sociocultural Health Questionnaire (E. Nikolaev)

Results: It has been revealed that domestic students smoke cigarettes and hookahs surely more often ($p=.01$) than foreign students

(30.49% vs 19.08%). It is obvious that they also more often ($p=.01$) use electronic cigarettes or vaping drugs (25.24% vs 12.86%) and alcohol (54.42% vs 9.96%). Students in both groups denied using other psychoactive substances. Foreign students reveal positive correlational interconnections between smoking and alcohol drinking ($r=.44$), while there is no evidence of such interconnections in domestic students. Both groups show valid interconnections between the frequency of smoking and the level of stress ($r=.15$ и $r=.17$ correspondingly), the frequency of smoking and monthly financial expenses ($r=.21$ и $r=.22$ correspondingly). With domestic students, vaping negatively correlates with exercising in gyms ($r=-.12$), with foreign students it directly correlates with bodybuilding supplements consumption ($r=.15$). Those foreign students who drink alcohol more often point to the necessity of having a psychologist in the university ($r=.13$).

Conclusions: The revealed general and specific factors associated with domestic and foreign students' use of psychoactive substances call for the necessity of developing culturally differentiated preventive programs

Disclosure of Interest: None Declared

EPP0357

Psychological risk factors that predict social networking addiction in students

W. Abid^{1*}, F. Guermazi¹, M. Mnif¹, D. Mnif¹, I. Feki¹, I. Baati¹ and J. Masmoudi¹

¹psychiatry A department, Hedi Chaker university hospital, Sfax, Tunisia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.526

Introduction: Social networks (SN) addiction is a serious problem among young adults that requires increased attention.

Objectives: The aim of the study was to assess the relationships between internet addiction and selected psychological characteristics of university students.

Methods: This is a descriptive and analytical study, conducted over the period from November 2022 to January 2023, among students in various fields. SN addiction was measured using the Social Media Addiction Scale-Student Form (SMAS-SF). The Rosenberg scale was used to assess global self-esteem and the Social Self-Esteem Inventory was used to assess social self-esteem. The Big Five Personality-10 (BFI 10) scale was used to assess the 5 personality dimensions.

Results: A total of 116 students, with an average age of 25.49, took part in the study. Most students (91.4%) were over 20 years old. They were female in 78.4% of cases. They enrolled in postgraduate studies in 55.2% of cases. The majority of students (59.5%) studied medicine. According to the SMAS-SF scale, the average score was 75.87. The mean score for social self-esteem score was 122.03. Sixty-four participants (55.2%) had low and very low self-esteem. The dominant personality dimensions were extraversion and neuroticism in 15.5% each. Addiction to SN was significantly associated with very low global self-esteem ($p=0.028$) and a lower social self-esteem score ($p=0.011$). Low conscientiousness and neuroticism

were significantly associated with increased SN use ($p=0.007$, $p=0.004$ respectively).

Conclusions: This study provides a better understanding of the phenomenon of addiction to SN, and enables us to tailor prevention and care more effectively. The psychological factors associated with this behavior need to be more explored in future research.

EPP0358

12-Month Outcome Data for Buprenorphine-Naloxone Maintenance Treatment in Individuals with Opioid Use Disorder

Y. Taylan¹ and M. B. Sönmez^{2*}

¹Istanbul Sultanbeyli State Hospital, İstanbul and ²Trakya University School of Medicine, Edirne, Türkiye

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.527

Introduction: Buprenorphine/Naloxone (B/N) is a safe and effective treatment for the long-term stabilization of individuals with opioid use disorder (OUD). Patients undergoing opioid maintenance treatment experience reduced mortality rates, decreased substance use, and an overall improvement in their quality of life. Premature discontinuation of maintenance treatment increases the risk of relapse.

Objectives: Our primary objective was to assess patient compliance with maintenance treatment and to identify potential factors associated with treatment discontinuation and relapse.

Methods: The study involved 206 patients with OUD who initially enrolled in a 28-day abstinence-based inpatient program at our hospital. Following their inpatient treatment, they were subsequently admitted as outpatients for B/N maintenance treatment at the Alcohol and Substance Addiction Treatment Center in Trakya University School of Medicine (Edirne, Türkiye). The addiction profiles of patients were assessed using the Addiction Profile Index (API) Clinical Form during the baseline evaluation. Sociodemographic and clinical data were collected from the patients' records.

Results: After 3 months, 114 patients (55.3%) remained in treatment, and 52 patients (25.2%) were still in treatment at the end of 1 year. Factors associated with a higher likelihood of remaining in treatment for one year included older age ($z=-2.257$, $p=0.024$), longer length of education ($z=-2.270$, $p=0.023$), later onset of smoking ($z=-2.704$, $p=0.007$), later onset of substance use ($z=-3.597$, $p<0.001$), and a higher rate of completing the inpatient treatment program ($\chi^2=4.016$, $p=0.045$). Patients in the 1-year retention group had lower scores on the API anxiety ($z=2.767$, $p=0.009$), anger management problems ($z=2.754$, $p=0.011$), and novelty-seeking behavior ($z=2.634$, $p=0.043$) subscales. They also had a lower rate of having a criminal history ($\chi^2=5.349$, $p=0.021$). The duration of treatment retention was positively correlated with age ($r=0.160$, $p=0.021$), length of education ($r=0.158$, $p=0.023$), age of onset of smoking ($r=0.228$, $p=0.001$), and age of onset of substance use ($r=0.268$, $p<0.001$). It was negatively correlated with the duration of substance use ($r=-0.138$, $p=0.048$), the number of inpatient treatments ($r=-0.142$, $p=0.042$), and scores on the API

anxiety ($r=-0.167$, $p=0.040$), anger management problems ($r=-0.173$, $p=0.033$), and novelty-seeking behavior ($r=-0.209$, $p=0.010$) subscales.

Conclusions: Identifying the specific factors associated with treatment retention and dropout/relapse can be valuable in developing more effective and personalized treatment plans for individuals with OUD.

EPP0359

Exploring the role of the immune-neuroendocrine interplay during affective episodes and euthymia in bipolar patients to seek for a reliable biological signature of the disease

A. Berry^{1*}, M. Di Vincenzo², B. Collacchi¹, L. Giona¹, A. Giannini², D. D'Amico², F. Cirulli¹, A. Cirino² and M. Luciano²

¹Center for Behavioral Sciences and Mental Health, Istituto Superiore di Sanità, Rome and ²Department of Mental and Physical Health and Rehabilitative Medicine, University of Campania "Luigi Vanvitelli", Naples, Italy

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.528

Introduction: Bipolar disorder (BD) is characterised by heterogeneous phenotypic manifestations that may affect the achievement of a timely diagnosis delaying its therapeutic management. Increased circulating levels of pro-inflammatory cytokines and cortisol (CORT) have been observed in BD patients in addition to decreased levels of Brain-Derived-Neurotrophic Factor (BDNF) suggesting that the interaction among these mediators may play a role in the occurrence of affective episodes overall disrupting brain plasticity. However, knowledge on BD etiopathogenesis is still limited, including the causal relationship with inflammatory and neuroendocrine markers.

Objectives: To assess whether variations in peripheral neuroendocrine and inflammatory markers during acute phases of the disease and euthymia might predict the occurrence of affective episodes; to evaluate whether the interplay among these biomarkers might be exploited as a signature of BD.

Methods: We are currently recruiting BD patients during depressive or manic/hypomanic phases together with age- and sex-matched healthy controls (CTRLs). Complete blood count, pro-inflammatory, anti-inflammatory cytokines and BDNF will be assessed in serum; salivary cortisol awakening response test will be used to evaluate hypothalamic-pituitary-adrenal axis activity. MADRS, YMRS and HAM-A will be used to assess psychiatric symptoms, PSP and C-SSRS for global functioning and suicidal risk, IPSS and SRRS for stress levels and CIRS to evaluate physical comorbidities. All assessments will be carried out at the time of recruitment (T0) and after 3 (T1) and 6 (T2) months.

Results: Data have been so far collected on 28 BD patients (18 males, 10 females, age: 48.31 ± 11.3) and 26 CTRLs (16 males, 10 females, age: 46.82 ± 10.86). At T0, BD were characterised by a greater total number of white cells (7.83 ± 1.86 BD vs. 6.78 ± 1.87 CTRL, $p<0.05$), mean number of neutrophils (4.89 ± 1.49 BD

vs. 3.92 ± 1.45 CTRL, $p<0.05$) and neutrophil/lymphocyte ratio (NLR) (2.52 ± 1.1 BD vs. 1.9 ± 0.69 CTRL, $p<0.05$). Moreover, BD patients showed overall a greater BMI (30.5 ± 6.6 BD vs. 24.45 ± 3.86 CTRL, $p<0.001$). No difference was observed among groups with respect to sex and age.

Conclusions: Although preliminary, these results suggest that the active phases of BD are associated with a low-grade inflammatory state, potentially related to a different metabolic set-point in BD patients. Ultimately, this study will allow us to evaluate whether the presence of affective symptoms is correlated with fluctuations in the levels of inflammatory mediators, salivary cortisol and BDNF and to establish a reliable and highly predictive BD signature.

Serum Lithium Concentration and the Risk of Chronic Kidney Disease

G. Gislason^{1*}, Ó. S. Indriðason², R. Pálsson^{1,2} and E. Sigurðsson^{1,3}

¹Faculty of Medicine, University of Iceland; ²Division of Nephrology and ³Mental Health Services, Landspítali–The National University Hospital of Iceland, Reykjavík, Iceland

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.529

Introduction: Lithium is an important treatment option for individuals with mood disorders, but its use has been linked to the development of chronic kidney disease (CKD). Existing studies on this association have reported conflicting results.

Objectives: The aim of this study was to examine the risk of developing CKD with lithium use adjusting for common comorbidities.

Methods: This was a retrospective cohort study that included all individuals in Iceland receiving lithium therapy between 2008 and 2018. Lithium use was defined as at least one dispensed prescription for Lithium or at least one serum lithium concentration above the detection limit. Patients with affective disorders (ICD-10 codes F30-F39) attending the outpatient clinics of Landspítali–The National University Hospital Mental Health Services in 2014-2016, without lithium exposure, served as controls. CKD stages 3-5 were defined according to the Kidney Disease Improving Global Outcomes (KDIGO) guidelines for CKD as estimated glomerular filtration rate (eGFR) less than $60 \text{ mL/min/1.73 m}^2$. The eGFR was calculated using the serum creatinine (SCr) based on the *Chronic Kidney Disease Epidemiology Collaboration* (CKD-EPI) equation. Acute kidney injury (AKI) was defined according to the SCr component of the KDIGO criteria for AKI, and other comorbid diseases were defined based on ICD-9 and ICD-10 codes. Individuals with fewer than 2 SCr measurements during the study period and those with CKD stages 3-5 prior to 2008 were excluded. Cox regression analysis with time dependent variables was performed to assess the risk of CKD.

Results: The study included 2046 individuals exposed to lithium, of whom 221 (10.9%) developed CKD in the study period. Among the 1220 control subjects, 39 (3.2%) developed CKD. Lithium use was associated with CKD (hazard ratio [HR] 1.93, 95% confidence

interval [CI] 1.37–2.74) after adjusting for sex, age, and comorbid diseases. Other significant risk factors were age (per year, HR 1.03, 95% CI 1.02–1.04), initial eGFR (per mL/min/1.73 m², HR 0.92–0.96, 95% CI 0.90–0.99), presence of diabetes (HR 1.73, 95% CI 1.15–2.48) and history of AKI (HR 1.89, 95% CI 1.32–2.70). When compared to the control group not exposed to lithium, the risk (HR) of CKD was 1.24 (95% CI 0.81–1.89), 2.88 (95% CI 1.97–4.20) and 5.23 (95% CI 3.31–8.26) for groups with a mean lithium concentration of 0.3–0.59, 0.6–0.79 and 0.8–0.99 mmol/L, respectively.

Conclusions: Long-term lithium therapy seems to increase the risk of CKD in a concentration-dependent manner in individuals with bipolar and unipolar mood disorders. To mitigate this risk, it is essential to monitor blood levels carefully and use doses of lithium as low as possible for adequate mood stabilization and treatment.

Bipolar Disorder due to Cushing's Disease, with manic characteristics. Regarding a clinical case.

M. D. C. Blasco Fresco¹, S. Ciria Villar¹, L. T. Durán Sandoval¹, A. Perez Poza¹ and E. De La Fuente Ruiz^{1*}

¹Psychiatry, Miguel Servet University Hospital, Zaragoza, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.530

Introduction: The increase in cortisol can be exogenous or endogenous. As etiologies of endogenous increase we find: Cushing's disease, 68% of cases, generally due to an ACTH-producing pituitary tumor; Adrenal Cushing syndrome (17%); Ectopic Cushing syndrome (15%) due to lung tumor most frequently. It is relevant since among its symptoms one of the most notable are the psychiatric alterations it produces, among them mood disorders, depression being the most common, as well as psychotic symptoms, delirium and anxiety disorder.

Objectives: To carry out a correct differential diagnosis of the pathologies that could present with symptoms of a manic episode.

Methods: Clinical case description of a 52-year-old woman, who presented with manic symptoms in 2020, requiring hospitalization. Upon discharge from the acute care unit, she consulted with the endocrinologist due to weight gain, revealing an increase in abdominal diameter, hyperpigmentation, a moon-like face, and a hump. Free cortisol was measured in 24-hour urine, with a high result, followed by brain MRI, and pituitary microadenoma was confirmed.

Results: The patient underwent surgical resection of the microadenoma, which was partially effective, so she maintained high cortisol levels, even despite oral retreatment. In 2023 she had a new manic episode, with a cortisol value of approximately 300 nmol/day.

Conclusions: The importance lies in the correct diagnosis to provide appropriate treatment and avoid the chronicity of the disease and the patient psychiatrization. In this case and as in many other diseases, which present with psychiatric symptoms, it is important to differentiate whether it is a primary psychiatric disorder or are component symptoms of another disease that, upon receiving treatment, would resolve the psychiatric symptoms.

Affective temperament and emotional dysregulation in cyclothymia and adult ADHD: differential characteristics and clinical implications.

M. Moriconi^{1*}, D. Bartolini¹, U. De Rosa¹, M. Barbuti¹, E. Schiavi² and G. Perugi¹

¹Clinical and Experimental Medicine, University of Pisa and ²UO Psichiatria 2, Azienda Ospedaliero Universitaria Pisana, Pisa, Italy

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.531

Introduction: Emotional dysregulation is central to the problem of the overlap between attention-deficit/hyperactivity disorder (ADHD) and cyclothymia.

Objectives: We aimed to compare clinical characteristics, psychiatric comorbidity, affective temperament, and emotional dysregulation among subjects with attention-deficit/hyperactivity disorder (ADHD) and cyclothymia.

Methods: In this cross-sectional study, 187 participants were consecutively recruited between January 2018 and December 2019 at the outpatient clinic of the 2nd Psychiatry Unit of the University Hospital of Pisa. Eighty-one subjects were diagnosed with ADHD, 62 with cyclothymic disorder, and 44 with both conditions. Participating psychiatrists collected socio-demographic and clinical data, psychiatric comorbidities according to DSM-5 criteria, familiarity for psychiatric disorders, and any previous responses to antidepressant drug therapy. To study the temperamental characteristics of the participants, the short version of the Memphis, Pisa, Paris and San Diego Temperament Assessment (Brief-TEMPS-M) was administered, while emotional dysregulation was measured through the Reactivity, Intensity, Polarity, Stability questionnaire (RIPoS-40).

Results: Cyclothymic subjects, both with and without ADHD, were more often female ($p < 0.001$) than subjects with ADHD. Participants with ADHD showed significantly lower educational attainment than subjects without ADHD ($p < 0.001$). In addition, participants with ADHD alone showed comorbid substance use disorder more frequently ($p < 0.001$) than subjects with cyclothymia alone. On the other hand, the latter showed higher rates of eating disorders ($p = 0.033$) and familiarity for major depressive disorder ($p = 0.009$) and panic disorder ($p = 0.029$). Depressive and anxious temperament was significantly more represented in cyclothymic subjects without ADHD, as was negative emotionality, while hyperthymic temperament showed an opposite trend. No significant differences were observed between groups for cyclothymic temperament and overall negative emotional dysregulation, but patients comorbid with both conditions had the highest scores in these subscales.

Conclusions: ADHD and cyclothymia show high and overall similar levels of emotional dysregulation. However, cyclothymic patients may be more prone to negative emotionality ("dark cyclothymia"). It is possible that individuals with "sunny" cyclothymic features may escape clinical attention if ADHD is not present in comorbidity.

EPP0363

Alteration of cortical functional networks in mood disorders with resting-state electroencephalography

S. Shim

psychiatry, Soonchunhyang university hospital, cheonan, Korea, Republic Of

doi: 10.1192/j.eurpsy.2024.532

Introduction: This study investigated source-level cortical functional networks using resting-state electroencephalography (EEG) in patients with Bipolar disorder and Major depressive disorder, comparing the neuropathology of these disorders.

Objectives: This study investigated source-level cortical functional networks using resting-state electroencephalography (EEG) in patients with Bipolar disorder and Major depressive disorder, comparing the neuropathology of these disorders.

Methods: A total of 116 participants (35 patients diagnosed with bipolar disorder(BD), 39 patients diagnosed with Major depressive disorder(MDD), and 42 people who are healthy-control groups(HC)) were enrolled for this study. Depression and anxiety were evaluated with using State-Trait Anxiety Inventory (STAI) and Beck Depression Inventory (BDI). Graph theory-based source-level weighted functional networks were assessed via strength, clustering coefficient (CC), and path length (PL) in six frequency bands.

Results: At the global level, patients with BD and MDD showed higher strength ($p = 0.001$) and CC ($p = 0.001$), and lower PL ($p < 0.001$) in the high beta band, compared to HCs. At the nodal level, compared to HCs, patients with BD showed higher high beta band nodal CCs in the right precuneus($p < 0.001$), left isthmus cingulate($p < 0.001$), bilateral paracentral($p < 0.001$), and left superior frontal($p < 0.001$); however, patients with MDD showed higher nodal CC only in the right precuneus($p < 0.001$) compared to HCs. Although both MDD and BD patients had similar global level network changes, they had different nodal level network changes compared to HCs.

Conclusions: This study suggest that both patients have similar network changes at the global level, but they have different network changes at the nodal level. Also, the higher nodal CCs in the high beta band might indicate the regions became more connected with their neighbors in accordance with the severity of depressive and anxious states. This study found a significant correlation between cortical network state and anxiety-related psychological measure in BD patients. Our source-level cortical network indices might contribute to the understanding of the neuropathological mechanisms in these two disorders.

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.533

Introduction: Predicting acute affective episodes in individuals with Bipolar Disorder (BD) remains a clinical challenge. Specific environmental stressors, including air pollution, noise, and temperature variations might worsen affective symptoms or sleep in the general population, but their role in BD relapses is often overlooked. Indeed, they might exacerbate BD by perturbing circadian rhythms – fundamental aspects of BD.

Objectives: We thereby present the protocol of this pilot study and future preliminary data. We aim to longitudinally assess sleep alterations, mood fluctuations, and environmental exposure to several factors (air pollutants, climate, noise, artificial light-at-night, green space access) in patients with BD and to check the association of these variables with BD relapses.

Methods: In this pilot study, we will recruit 40 patients with BD in a 6-month prospective study. Patients were assessed during baseline, at 3 and 6 months. Data recollected will consist of a subjective (questionnaires) and objective (through meteorological stations) evaluation of physical environmental factors around the home residence; clinical assessment of mood and circadian rhythms, and continuous tracking of sleep-wake patterns, energy, and movement using actigraphy.

Results: Expected results will show that exposure to a worse environment (higher pollution, noise, light exposure, climate) will be associated with worse BD outcomes (i.e., relapse, mood symptoms, sleep alterations).

Conclusions: We will be sharing preliminary data from our ongoing study, offering insights into early patterns and findings that shed light on our objectives.

Korean Medication Algorithm for Bipolar Disorder: changes in preferred medications for mania over 20 years

D.-I. Jon^{1,*}, Y. S. Woo², J.-H. Jeong², J.-S. Seo³, J. G. Lee⁴, B.-H. Yoon⁵, I. Sohn⁶ and W.-M. Bahk²

¹Hallym University Sacred Heart Hospital, Anyang; ²The Catholic University; ³Joongang University, Seoul; ⁴Inje University, Busan; ⁵Naju National Hospital, Naju and ⁶Kyeyo Hospital, Euwang, Korea, Republic Of

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.534

Introduction: Majority of international guidelines for bipolar disorders are based on evidences from clinical trials. In contrast, the Korean Medication Algorithm Project for Bipolar Disorder (KMAP-BP) was developed to adopt an expert-consensus paradigm which was more practical and specific to the atmosphere in Korea.

Objectives: In this study, preferred medication strategies for acute mania over six consecutively published KMAP-BP (2002, 2006, 2010, 2014, 2018, and 2022) were investigated.

Methods: A written survey using a nine-point scale was asked to Korean experts about the appropriateness of various treatment strategies and treatment agents. A written survey asked about the appropriateness of various treatment strategies and treatment agents commonly used by clinicians as the first-line.

Results: The most preferred option for the initial treatment of mania was a combination of a mood stabilizer (MS) and an atypical antipsychotic (AAP) in every edition. Preference for combined treatment for euphoric mania increased, peaked in KMAP-BP 2010, and declined slightly. Either MS or AAP monotherapy was also considered a first-line strategy for mania, but not for all types of episodes, including mixed/psychotic mania. Among MSs, lithium and valproate are almost equally preferred except in the mixed subtype where valproate is the most recommended MS. The preference of valproate showed reverse U-shaped curve. This preference change of valproate may indicate the concern about teratotoxicity in women. Quetiapine, aripiprazole, and olanzapine were the preferred AAP for acute mania since 2014. This change might depend on the recent evidences and safety profile. In cases of unsatisfactory response to initial medications, switching or adding another first-line agent was recommended. The most notable changes over time included the increasing preference for AAPs.

Conclusions: The Korean experts have been increasingly convinced of the effectiveness of a combination therapy for acute mania. There have been evident preference changes: increased for AAP and decreased for carbamazepine.

The morbidity and prevalence of mental pathology in children and adolescents in the kyrgyz republic for 2005-2020

A. Nurali Kyzy^{1,2,3*} and T. M. Kadyrova^{1,3}

¹medical psychology, psychiatry and addiction, I.K. Ahunbaev Kyrgyz State Medical Academy; ²childrens department, Republican Center for Psychiatry and Narcology and ³member, Kyrgyz Psychiatric Association, Bishkek, Kyrgyzstan

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.535

Introduction: One of the principles of healthcare is preventive focus, that is, the implementation of measures to improve the hygienic education of the population and maintain a healthy life-style. The scientific rationale for carrying out primary prevention activities is based on an analysis of morbidity and prevalence rates and their dynamics.

Objectives: to conduct a comparative analysis of the primary incidence and prevalence of mental pathology in children and adolescents (0-17 years) in the Kyrgyz Republic for 2005-2020 .

Methods: statistical data from the Republican Center for Electronic Health and the National Statistical Committee of the Kyrgyz Republic were used (<http://www.stat.kg/ru/rss/>), (<http://cez.med.kg/>).

Results: primary incidence of mental pathology among children and adolescents in 2005, 2010, 2015 and 2020 amounted to 66.2, 44.1, 44.8, 51.1 respectively (based on 100,000 the child population). The prevalence of mental pathology for 2005-2020 was 418.4, 317.0, 312.5, 400.0 respectively (based on 100,000 the child population). That is, morbidity and prevalence rates show higher numbers in 2005 and in 2020 (Diagram №1). In the gender aspect, morbidity rates were higher in males 40.0, 28.0, 31.3, 31.0 compared to females 26.3, 16.1, 17.1, 20.1 (based on 100,000 the child population; (Diagram №2).

Image:

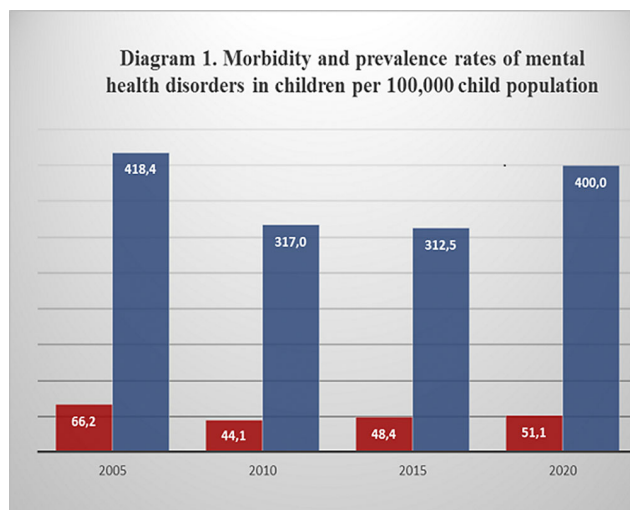

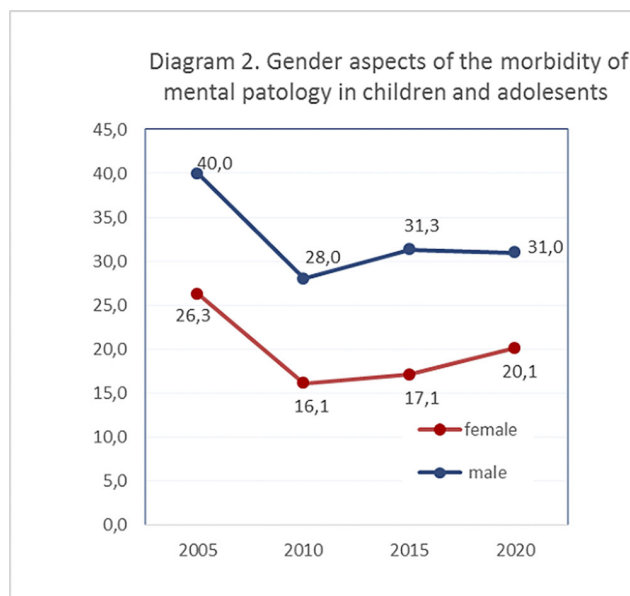

Image 2:

Conclusions: the variability of the obtained indicators of morbidity and prevalence of mental pathology in children and adolescents is due to difficulties in providing specialized psychiatric care to the child population due to the lack of child psychiatrists in the regions

of the country, the processes of population migration, and the phenomenon of stigmatization. In this regard, measures and educational programs are needed to improve the provision of psychiatric care to the child population at the level of primary medical and social care.

Sexual exploitation of male youth: background characteristics and needs from a life-course perspective

G. Mercera¹, S. Leijdesdorff¹, E. Heynen² and T. van Amelsvoort^{1*}

¹Psychiatry and Neuropsychology, Maastricht University, Maastricht and ²Clinical Psychology, Open University, Heerlen, Netherlands

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.536

Introduction: Sexual exploitation is a human rights violation that has a detrimental impact on the psychological-, physical- and social well-being of victims. Sexually exploited male youth are prevalent, yet underrepresented in clinical practice, policy and research. There are multiple barriers that often prevent male youth to disclose and to seek or receive support, such as gender norms, limited awareness of victimization and feelings of guilt and shame.

Objectives: By gaining more insight into the background and clinical characteristics of male victims and their care and support needs, this study aims to raise awareness and to better inform policymakers, care- and educational professionals on adequate prevention and intervention efforts.

Methods: Twenty-six male youth at high-risk or victims of sexual exploitation participated in this qualitative study. By means of semi-structured interviews and case-file analyses, data was collected by to identify risk and protective factors in their life-course and care and support needs.

Results: Results indicate that several vulnerabilities (e.g. previous experiences of abuse and neglect, mental health problems, household dysfunction, social rejection, running away, substance use) and a lack of positive and supportive relationships led male youth into high-risk situations. Among these were involvement in pay dates, survival sex and criminality, which contributed to victimization. Experiences of stigmatization were often a barrier to express vulnerabilities and to disclose victimization. There was a wide variety in care and support needs, including peer-to-peer support, therapy, support with day-to-day practices and anonymous support.

Conclusions: These results will contribute to adequate prevention and intervention strategies and meet the unique needs of male youth at risk for, or victim of sexual exploitation.

EPP0375

Mental health of children in Ukraine. risks and challenges today

M. Markova*, T. Aliieva and O. Piontkovska

Kharkiv National Medical University, Kharkiv, Ukraine

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.537

Introduction: Today, the most vulnerable group of Ukrainians are children. Their physical and mental health has been tested since 2020, from COVID-19 to 2022, the start of a full-scale-russia's war against Ukraine. The children of Ukraine were the first to feel the changes, since a complete change in life and the principles of acquiring primary adaptive skills of social interaction were distorted by COVID-19. Subsequently, new challenges in the form of war deformed the idea of life, happiness and the future.

Objectives: Studying the level of adaptation potential in children and adolescents living in the front-line zone in Ukraine.

Methods: The examination included the use of clinical-psychological, psychodiagnostic and psychometric research methods.

Results: The study in 2021 involved 217 children and adolescents with signs of maladjustment. In 2022, 378 children and adolescents with signs of maladjustment, of which 285 children are still in the frontline zone of Ukraine, 93 children, at the time of 2022, were taken abroad and returned to Kharkov in 2023.

During the initial analysis of the results, it was revealed that children with low adaptive resources are more susceptible to showing signs of maladjustment. One of the main factors of an adaptation resource is interaction with others (direct communication). It was this criterion that became the primary frustrating factor for children in the first months of the war. External isolation has led to a lack of communication between children and everyone in Ukraine, who during COVID-19 have adapted to a way of communicating while staying at home in physical isolation. War is a powerful independent psychogenic factor for the formation of maladaptation, but in today's realities it has also become an additional trigger for a previous psychogenic event in the life of Ukrainians.

Parents, for their part, note a sharp deterioration in the well-being of their children, frequent complaints of headaches (89.4%), overwork, aggressiveness (81.5%), closed-mindedness (78.6%), health complaints (74.5%), which is why they have to often consult a doctor and endlessly carry out diagnostics in search of reasons for deterioration (72.3%), weight loss (64.5%). The data indicate the frustration of being in the front-line zone, which aggravates mental health and triggers the process of disruption of adaptation and mental health of children and adolescents.

Conclusions: The study is aimed at developing a psychorehabilitation program for children and adolescents with a low level of adaptive resource.

Depressive Disorders

EPP0376

The Impact of Severe Wildfires on Mental Health: Prevalence of Major Depressive Disorder and Related Factors among Residents in Alberta and Nova Scotia, Canada.

W. Mao^{1*}, R. Shalaby¹, B. Agyapong¹, G. Obuobi-Donkor², R. Dias² and V. I. Agyapong^{1,2}

¹Psychiatry, University of Alberta, Edmonton and ²Psychiatry, Dalhousie University, Halifax, Canada

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.538

Introduction: Hundreds of fires have been burning from coast to coast across the country since March 2023, putting Canada on track to experience the worst wildfire season ever. From East to West, provinces such as Quebec, Ontario, Nova Scotia, Alberta, and British Columbia have been particularly affected by large and uncontrollable wildfires.

Objectives: This study aimed to determine the prevalence and predictors of depression symptoms among residents of Alberta and Nova Scotia during the Canadian wildfires of 2023.

Methods: This study conducted a cross-sectional quantitative survey for data collection. In the period between 14th May and 23rd June 2023, an online survey was administered using REDCap. Through the Text4Hope program, participants subscribe to receive supportive SMS messages daily. After the first message, participants were invited to complete an online questionnaire, containing demographic information, wildfire-related information, and responses to the Patient Health Questionnaire-9 (PHQ-9) for depression assessment. SPSS version 25 was used to analyze the data. Descriptive, univariate, and multivariate regression analyses were employed.

Results: A total of 298 respondents completed the online survey out of 1802 who accessed it, resulting in a response rate of 16.54 %. Most of the respondents were females (85.2%, 253), below 40 years of age (28.3%, 84), employed (63.6%, 189), and in a relationship (56.4%, 167). A historical depression diagnosis (OR = 3.15; 95% CI: 1.39–7.14) was a significant predictor of moderate to severe MDD in our study. While employment status did not significantly predict MDD, unemployed individuals were two times more likely to report moderate-to-severe symptoms of MDD than employed individuals (OR = 2.46; 95% CI: 1.06–5.67). Among the total sample population, the moderate to severe MDD prevalence was 50.4%, whereas it was 56.1% among those living in wildfire-affected areas.

Constant		-.967	.677	2.038	1	.153	.380		

Conclusions: As a result of our study, the development of moderate to severe MDD symptoms during wildfire disasters was significantly associated with a history of depression diagnosis. Although employment status did not significantly predict MDD, unemployed individuals had a greater likelihood of experiencing moderate-to-severe symptoms than employed individuals. Further research is necessary to ascertain reliable predictors of mental health issues among those who have experienced disasters, as well as to offer appropriate interventions and treatment options to the communities and individuals who are most vulnerable.

Real-world effectiveness and safety of esketamine intranasal spray combined with treatment-as-usual in psychiatric inpatients

E. Kavakbasi^{1*}, M. Yilmaz¹, Ö. Bulut¹, H. Berndt¹ and B. T. Baune^{1,2,3}

¹Department of Psychiatry, University Hospital Münster, University of Münster, Münster, Germany; ²Department of Psychiatry, Melbourne Medical School, The University of Melbourne, Melbourne and ³The Florey Institute of Neuroscience and Mental Health, The University of Melbourne, Parkville, Australia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.539

Introduction: Esketamine intranasal spray has been approved in both the USA and EU as a novel treatment in patients with treatment-resistant major depression (TRD) and for the management of acute depressive emergencies during the course of major depressive disorder (MDD). Real-world data on the effectiveness and safety of esketamine nasal spray in clinical use are limited.

Objectives: To investigate the clinical effects and safety of esketamine nasal spray on depression severity and suicidal ideation during inpatient treatment in $n=76$ patients in a German university hospital.

Methods: In this retrospective chart review, we analyzed the change in depression severity and safety after a treatment series with esketamine nasal spray combined with treatment-as-usual in patients with treatment-resistant depression (TRD) in inpatient treatment setting of a University Hospital. Depression severity has been rated with the Montgomery–Åsberg Depression Rating Scale (MADRS) as well as with the BDI-II (Beck Depression Inventory-Second Edition) before and after the treatment series. The intensity of suicidal ideation has been evaluated using MADRS item 10 on suicidal thoughts.

Results: A total of 76 patients have been included (women 55.3, $n=42$) in this analysis. Mean BDI-II pre-treatment was 37.6 and mean MADRS was 33.6 corresponding to severe depression. Mean score on item-10 pre-treatment was 2.4 (median 2.0). On average patients received 10.9 sessions (standard deviation 4.2, median 11.0) of esketamine nasal spray (min 1, max. 19 sessions). There was clear improvement after the treatment series in both the BDI-II (mean change -10.1, $p < 0.001$) as well as in MADRS score (mean reduction -10.0, $p < 0.001$). Suicidal ideation on item-10 also decreased significantly (-0.9, $p < 0.001$). The effect sizes were large for all three measures: Cohen's d 1.050 for BDI-II; 0.986 for MADRS and 0.742 for changes in suicidal ideation. Overall, esketamine treatment was well tolerated. In five cases esketamine treatment has been terminated early (after a mean of 3.4 sessions) due to dissociations ($n=4$; 5.3%) or due to non-response ($n=1$).

Conclusions: Esketamine nasal spray is a novel effective and safe treatment option, which leads to significant decrease in depression severity as well as in suicidal ideation. More data from real-world patients are needed to position esketamine in the algorithm of depression treatment. Rate of treatment discontinuation due to side-effects in this study was comparable to those in other esketamine studies (4.2% in Reif et al, NEJM, 2023).

Introduction: Treatment-resistant depression (TRD) lacks a universally consistent definition due to varied interpretations despite

attempts to define it based on inadequate response or remission despite sufficient antidepressant treatment. There's a crucial demand for a uniform definition and staging to streamline its effective management amid diverse treatment options and the complex nature of resistance. Five methods have emerged to define and classify treatment resistance reliably.

Objectives: The aim of this study is to compare the five staging methods (Thase&Rush SM (T&R), European Staging Method (ESM), Maudsley Staging Method (MSM), Massachusetts General Hospital Staging Method (MHG-s), Conway Staging Method(Conway)) in assessing treatment resistance within a single sample.

Methods: Retrospective analysis involved medical records of inpatient psychiatry clinic admissions at Hacettepe University between October 2012 and October 2014. Patients with a primary diagnosis of bipolar affective disorder, schizophrenia, other chronic psychotic disorders, dementia or cognitive disorders, alcohol and substance use disorders, and those with missing data were excluded.

Results: Initial screening yielded a total of 115 patients. 64 patients were included in the study, 13 patients were excluded due to missing data, and 38 patients were excluded due to comorbidity.

Characteristic	Total (N=64)	Last Episode Characteristics	Total (N=64)
Female - N(%)	44 (69)	Episode duration – month (mean ± SD)	13.75 ± 16.09
Age – yr (mean ± SD)	48.39 ± 18.81	Psychotic symptoms – N(%)	20 (31)
Married – N(%)	41 (64)	Anxiety symptoms – N(%)	24 (38)
Secondary school and over – N(%)	38 (59)	Suicidal attempt – N(%)	19 (30)
Employed – N(%)	16 (25)		

TRD definition and staging method (N=55)	T&R	ESM	MSM	MGH-S	Conway
Not resistant by this method	26 (47.3)	45 (81.8)	0 (0)	27 (49.1)	43 (78.2)
Identified by this method	29 (52.7)	10 (18.2)	55 (100)	28 (50.9)	12 (21.8)
Exclusively identified by this method	0 (0)	0 (0)	21 (38.2)	0 (0)	0 (0)
By this and one other method	27 (49.1)	0 (0)	11 (20)	5 (9.1)	0 (0)
By all methods	10 (18.2)	10 (18.2)	10 (18.2)	10 (18.2)	10 (18.2)
Identified as TRD					
Age of onset (mean ± SD)	40.28 ± 17.42	35.6 ± 18.27	40.44 ± 18.38	40.07 ± 17.9	38.17 ± 17.71
ATHF score (mean ± SD)	7.55 ± 5.46	12.1 ± 6.51	4.93 ± 4.98	7.43 ± 5.69	11.08 ± 6.47
Last episode duration (month) (mean ± SD)	17.11 ± 17.25	22.10 ± 20.96	14.22 ± 17.08	16.33 ± 17.66	20.83 ± 19.25

Conclusions: There is no universally agreed-upon definition for treatment resistance. In this sample, different definition and staging methods were employed to examine the similarities and differences in the clinical and treatment related characteristics of groups with TRD identified with each. The reasons and possible implication of concurrence and discordance between the methods will be discussed.

Exploring the Interplay Between Early Maladaptive Schemas and Depression: A Comparative Analysis

A.-G. Zanfir^{1,2*}

¹Prof. Dr. Alexandru Obregia Clinical Psychiatry Hospital and ²Faculty of Psychology and Educational Sciences, University of Bucharest, Bucharest, Romania

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.541

Introduction: Depression, a pervasive mood disorder, significantly impairs one's quality of life. Early Maladaptive Schemas (EMS), ingrained thought patterns stemming from early life experiences, play a pivotal role in shaping adult beliefs and behaviors. This study delves into the relevance of specific EMS domains—Emotional Inhibition (EI), Negativity/Pessimism (NP), and Social Isolation/Alienation (SI)—in influencing the severity of depression among medical students and diagnosed patients.

Objectives: Our primary goal was to assess the correlation between specific EMS domains and depression severity in medical students and clinically diagnosed patients. We aimed to elucidate whether these schemas could serve as indicators for potential depressive tendencies or if they had a stronger association in those already diagnosed with depression.

Methods: We conducted a prospective cross-sectional analysis involving 73 medical students and 61 diagnosed depression patients (aged 18-32). Four key variables—Depression, EI, NP, and SI—were measured using the Beck Depression Inventory-2 and The Young Schema Questionnaire-Short-form-3 in the Romanian context. Statistical analyses, including correlation coefficients and t-tests, were employed to explore the relationships between EMS domains and depression severity.

Results: In the non-clinical sample, we identified moderate, statistically significant correlations between depression and EI ($r=0.63$), NP ($r=0.71$), and SI ($r=0.59$). Conversely, the clinical sample exhibited slightly weaker, yet significant correlations (EI- $r=0.42$, NP- $r=0.39$, SI- $r=0.29$). Notably, significant differences emerged between the groups in all measured variables. These findings imply that while a positive correlation between EMS variables and depression exists in both samples, the association weakens in diagnosed patients, indicating that these schemas may be less predictive in this population.

Conclusions: Our study underscores the importance of understanding EMS domains in assessing depression severity. While specific schemas—EI, NP, and SI—correlate with depression in both medical students and diagnosed patients, this link is notably weaker in the latter group. Elevated EMS variables suggest a potential for future subclinical depression in medical students, but they

might not strongly predict depression in those already diagnosed. These nuanced insights have implications for preventive interventions and therapeutic approaches tailored to individuals at different stages of depression, thereby enhancing targeted mental health care strategies.

DNA methylation signatures support the role of neutrophils and monocytes in depression

E. Atil^{1*}, E. Van Assche¹, C. Hohoff¹ and B. T. Baune²

¹University of Münster and ²University of Münster, Münster, Germany

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.542

Introduction: Research repeatedly linked inflammation with major depressive disorder (MDD). The presence of an inflammatory subtype of depression is supported by molecular findings as well as imaging reports. We investigated the cell type composition estimated by using epigenome-wide DNA methylation markers in a sample of depressed individuals showing high or low inflammation levels measured by hsCRP. We aimed to understand the connection between depression and inflammation, specifically differences in cell type compositions between high and low inflammation groups at baseline.

Objectives: 119 individuals with MDD were included for this analysis. Following quality control procedures, 113 participants were included in the analysis ($M_{age}=47$ years, 57.98% women). The sample consisted of 37 individuals with high hsCRP ($hsCRP > 1.5$, $M_{age}=45$, $M_{hsCRP}=8.2$, $M_{MADRS}=28$, 70% women) and 76 individuals with low hsCRP ($hsCRP < 1.5$, $M_{age}=44$, $M_{hsCRP}=0.99$, $M_{MADRS}=28$, 49% women).

Methods: The Illumina Infinium MethylationEPIC 850k BeadChip was used for analyzing whole blood derived DNA. Data processing and cell type estimation was conducted using the RnBeads package. We applied the Houseman method to estimate cell type composition through epigenome-wide DNA methylation signatures, resulting in six cell types: neutrophils, natural killer cells, B cells, CD4+ T cells, CD8+ T cells and monocytes. Comparisons between both groups were tested using ANOVA.

Results: High and low hsCRP groups were compared for each of the six cell types estimated. A statistically significant difference was seen for monocytes ($p=0.0316$) and a trend for neutrophils ($p=0.0742$). The mean values for neutrophils in patients without inflammation were found to be 60%, while in patients with inflammation, it was 63%. For monocytes, the mean values for patients without inflammation and those with inflammation were 10% and 9.4%, respectively, with a smaller range (4.5%-14.3%) for individuals with inflammation as compared to patients without inflammation (5.3%-20.7%). None of the other four cell types showed a statistically significant difference.

Conclusions: We identified differences in the cell type composition between groups of depressed patients with high versus low inflammation. These results align with the existing body of knowledge reported in established academic literature. Our study

emphasizes the role of specific cells like neutrophils and monocytes in inflammation and depression. These findings offer valuable insights for improving depression treatment strategies as inflammation state may be relevant for treatment response. We also show the merit of DNA methylation signatures for the profiling of patients' inflammation status, i.e., immunomethylomics.

Personality Traits in Patients with Depression: Association with Symptoms of Depression and Anxiety

S. Galnaitytė^{1*} and V. Adomaitienė²

¹Faculty of Medicine, Vilnius University, Vilnius and ²Clinic of Psychiatry, Lithuanian University of Health Sciences, Kaunas, Lithuania

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.543

Introduction: The symptoms of depression and anxiety, which are frequently comorbid, may be significantly impacted by the individual's personality, even considering the complex etiology of depression. Several studies have shown that while certain personality traits may act as protective factors, others may increase vulnerability to depression and anxiety. Understanding these relationships may be important since personality traits have gained attention as potential determinants of symptom severity and treatment outcomes.

Objectives: To identify and evaluate the association of personality traits with symptoms of depression and anxiety in patients with depression.

Methods: The study involved 80 inpatients (≥ 18 years), hospitalized in University psychiatry department with depression diagnosis based on the ICD-10-AM classification. Subjects were asked to fill the Overall Anxiety Severity and Impairment Scale ("OASIS"), the Big Five Personality Dimensions scale and the Patient Health Questionnaire-9 (PHQ-9). Data analysis included descriptive data, Shapiro-Wilk test, Spearman correlation, Kruskal-Wallis test and Chi-Square test, with a significance threshold of $p < 0.05$.

Results: Severe (26.3%) and very severe (41.3%) depressive symptoms were the most prevalent. Extraversion was associated with minimal ($p = 0.002$), conscientiousness with mild ($p < 0.001$), neuroticism with very severe depressive symptoms ($p = 0.003$). The majority of depressed patients had severe (33,75 %) or very severe (32,5 %) anxiety symptoms. Anxiety symptoms were associated with more severe depressive symptoms ($r = 0.704$, $p < 0.001$). The association of conscientiousness and moderate anxiety symptoms was found ($p = 0.004$). In the presence of expressed neuroticism, most of the respondents showed very severe anxiety symptoms, in the absence of neuroticism – moderate anxiety symptoms ($p < 0.001$).

Conclusions: The results showed that personality traits were associated with severity of depression and anxiety symptoms in psychiatry inpatient with depression. Therefore, recognition of predominant personality traits in patients with depression may be helpful in selecting treatment and predicting treatment outcomes.

The impact of ruminative thought style on the maintenance of depressive mood

V. Misić¹, T. Vukosavljević Gvozden¹ and B. Batinic^{2*}

¹Department of Psychology, University of Belgrade, Faculty of Philosophy and ²University Clinical Centre of Serbia, Clinic of Psychiatry, University of Belgrade, Faculty of Philosophy, Department of Psychology, Belgrade, Serbia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.544

Introduction: Ruminations are a cognitive style of "thought recycling", which involves passively and repeatedly focusing on disorder and distress symptoms, or their causes, without attempting to alleviate them. They are a significant indicator of cognitive vulnerability, predicting the emergence, maintenance, and recurrence of depressive symptoms.

Objectives: To estimate the impact of the ruminative thought style on the maintenance and escalation of depressive mood.

Methods: The research sample consisted of 60 students between the ages of 19 and 30 ($M = 23$), divided into two experimental groups with 30 participants each. The participants took part in a 5-minute experiment that involved recalling an autobiographically sad event, assessing their mood on the Scale for Self-Assessment of Emotions (EAS) before and after the induction, and then splitting into two groups of 30 participants for random ruminating or distraction. The Beck Depression Inventory-II, the Ruminative Response Scale, the Ruminative Thought Style Questionnaire, and the EAS were used as research instruments. The progressive group relaxation approach was used at the end of the experiment with all participants to promote relaxation and lessen the psychophysical tension brought on by the experimental induction (10 minutes total).

Results: The experimental groups did not differ in mood intensity prior to the induction of sadness. Both experimental groups experienced significant impacts on depressed mood following the induction of sadness ($F(1,58) = 92.05$, $p < 0.001$): participants who ruminated demonstrated persistence in their negative mood, whereas participants who engaged in distractions demonstrated a decrease in their negative mood, even below the initial level ($F(2,116) = 12.69$, $p < 0.001$).

Conclusions: This result provides an additional experimental validation of the phenomenon of maintaining a depressive mood through ruminations. An essential psychotherapy goal should be the treatment (metacognitive therapy, rumination-focused CBT, mindfulness, cognitive bias correction, etc.) of such mechanisms, recognized as crucial for the maintenance of depression.

Assessment of various dimensions of impulsivity and their expression in unipolar and bipolar affective disorder

M. Dmitrzak-Weglarz^{1*}, K. Bilski¹, M. Skibińska¹, B. Narożna², P. Zakowicz¹, A. Rajewska-Rager¹, P. Kapelski¹ and J. M. Pawlak¹

¹Department of Psychiatric Genetics and ²Department of Pulmonology, Poznan University of Medical Sciences, Poznan, Poland

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.545

Introduction: Impulsivity is the tendency to take quick and rash actions without the ability to assess their consequences, resulting in an increased frequency of risky behaviors. In recent years, it has been indicated that impulsivity is a multidimensional construct with different ways of expression in various mental illnesses. Moreover, personality traits might predispose do different psychiatric diagnoses and impact its course.

Objectives: Because differences in the manifestation of impulsivity can be observed at several levels (e.g., behavioral/motor, cognitive, attention, or emotionally related), we applied several tools to check whether they would allow for the differentiation of unipolar (UD) and bipolar (BD) affective disorders.

Methods: The study used data from 282 patients with affective disorders and 95 healthy controls of both sexes. Among the patients, we distinguished a subgroup diagnosed with UD and BD. We included a homogeneous group of patients in euthymia state at the end of hospitalization due to the last depressive episode. The following tools were used: subdimension novelty seeking (NS) of The Temperament and Character Inventory (TCI) and The Barratt Impulsiveness Scale version 11 (BIS-11) to assess various dimensions of impulsivity. The Coping Orientation to Problems Experienced (COPE) was used to assess the strategy of coping with stress. Statistical analyses were performed in Statistica 13.3 StatSoft, Krakow, Poland.

Results: We observed significant differences in BIS-11 dimensions such as motor (MI) ($p=0.0006$), nonplanning (NP) ($p=0.0249$), and the sum of impulsivity ($p=0.0095$) between UD and BD patients. We found no significant differences in the intensity of impulsivity measured by the NS subdimension, regardless of the type of affective disorder. In the Spearman rank correlation analysis, the following correlations of novelty seeking were revealed ($p>0.05$):

NS with BIS-11 MI ($r_s=0.3877$, $p=0.0001$), BIS-11 NP ($r_s=-0.2926$, $p=0.0042$) and COPE-planning ($r_s=-0.2552$, $p=0.0191$) dimensions. Moreover, a unique and strong correlation of NS with COPE - focus on and venting of emotions was revealed in BD patients ($r_s=0.5402$, $p=0.0461$).

Conclusions: The obtained correlation results confirm the multi-dimensional nature of impulsivity. The relationship between NS and the motor and nonplanning dimensions comes to the fore. Among the tests used, BIS-11 best differentiated unipolar and bipolar patients.

The Slovenian version of the Cardiac depression scale – validity and reliability

A. Kokalj Palandacic^{1,2,*}, S. Uzman¹, M. Lainscak^{2,3} and B. Novak Sarotar^{1,2}

¹University Psychiatric Clinic Ljubljana; ²Faculty of Medicine, University of Ljubljana, Ljubljana and ³Department of Internal medicine, Cardiology division, General Hospital Murska Sobota, Murska Sobota, Slovenia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.546

Introduction: Cardiovascular diseases (CVD) were the cause of 40% of all deaths in Slovenia in 2016, and are the seventh most common cause of visits to the general practitioner. The prevalence of depression in people with CVD is high and is a strong predictor of mortality and additional cardiac events. In patients with coronary artery disease, depressive symptoms contribute to a lower quality of life and to physical limitations.

Objectives: The purpose of this study was to translate the Cardiac Depression Scale into Slovenian (S-CDS) and to assess its psychometric properties on Slovenian patients with heart disease.

Methods: After obtaining the consent from the original authors, the Cardiac depression scale was translated by three bilingual Slovenian native speakers with medical knowledge. Afterwards, they worked jointly to reach consensus on one version, which was then back-translated (Slovenian to English) by two independent English translators unfamiliar with the original version. The original authors approved the final draft. The S-CDS was then applied to a total of 272 patients with heart disease that underwent elective coronary angiography. At the same time the Spielberger State Anxiety Inventory (STAI-S) and the Center for Epidemiologic Studies Depression Scale-20 (CES-D) were used. An exploratory and confirmatory factor analysis, internal consistency, test–retest reliability and concurrent validity were performed.

Results: The total scale had Cronbach's alpha 0.92 and test–retest reliability 0.71. Six factors were confirmed by the exploratory factor analysis, accounting for 60.88% of total variance. A two and one factor solution indicated by the confirmatory factor analysis had acceptable goodness-of-fit measures. A one factor solution was kept, considering a high correlation between the two factors and the theoretical background in previous studies. A moderate to strong correlations were confirmed by concurrent validation against the CES-D and the STAI-S.

Conclusions: The S-CDS with 25 questions is a reliable and valid instrument for measuring depressive symptoms in Slovenian patients with heart disease.

EPP0385

A comparative study of depression, anxiety, loneliness, well-being and self-esteem among patients with and without Inflammatory Bowel Disease

V. Efstathiou¹, I. Theodoridou², A. Karvouni², E. Kaloudi², P. Bali² and A. Papadopoulou^{2,*}

¹Psychology Department, National and Kapodistrian University of Athens and ²Second Department of Psychiatry, National and Kapodistrian University of Athens, "Attikon" University General Hospital, Athens, Greece

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.547

Introduction: Individuals diagnosed with Inflammatory bowel disease (IBD) often experience recurring and painful symptoms, which can significantly affect their daily life, while hospitalization and/or surgery may be needed when they present complications. During the course of the disease, IBD patients may experience

feelings of anxiety and/or depression and present decreased well-being.

Objectives: The aim of the present study was to investigate depression, anxiety, loneliness, well-being and self-esteem in patients with IBD in comparison to individuals without IBD (healthy controls), while taking into consideration demographic and clinical parameters

Methods: The study included 164 participants and in particular 98 patients with IBD and 66 healthy controls matched for sex and age. All participants completed Hospital Anxiety and Depression Scale (HADS) to assess depression and anxiety, UCLA Loneliness Scale to assess feelings of loneliness, Mental Health Continuum Short Form (MHC-SF) to assess well-being and Rosenberg Self-esteem Scale (RSES) to assess self-esteem, while socio-demographic and clinical data were additionally recorded.

Results: According to the results, statistically significant differences were observed in all psychological parameters with IBD patients presenting higher depression ($p<0.001$), higher anxiety ($p=0.002$), higher loneliness ($p=0.002$), lower well-being ($p=0.019$) and lower self-esteem ($p<0.001$) compared to healthy controls. Among IBD patients, higher well-being was independently associated with higher self-esteem and lower anxiety, but not with depression, loneliness or patients' sex and age.

Conclusions: The findings highlight the importance of investigating and timely detecting psychological symptoms among patients with IBD, with a view to providing them an integrative physical and mental health care.

Exploring the Interplay of Humor and Quality of Life in Adults Confronting Chronic Diseases: A Comprehensive Systematic Review

E. Bartzou^{1*}, E. Tsiloni², S. Mantzoukas³, E. Dragioti¹ and M. Gouva¹

¹Research Laboratory Psychology of Patients, Families & Health Professionals, Department of Nursing, School of Health Sciences, University of Ioannina, Ioannina; ²Department of Educational Sciences and Social Work, University of Patras, Patra and ³Research Laboratory of Integrated Health, Care and Well-being, Department of Nursing, School of Health Sciences, University of Ioannina, Ioannina, Greece

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.548

Introduction: Chronic diseases, often referred to as non-communicable diseases (NCDs), stand as the leading global cause of mortality. Individuals grappling with chronic ailments frequently experience a decline in their overall quality of life (QoL), encompassing psychological, social, and physical dimensions of well-being.

Objectives: Recognizing that humor has demonstrated the potential to engender favorable effects on QoL, this systematic review seeks to explore the correlation between humor and QoL among adults contending with chronic health conditions.

Methods: A thorough examination of quantitative data was conducted in strict adherence to the PRISMA 2020 guidelines. PubMed/MEDLINE, PsycINFO, and CINAHL were comprehensively

searched from their inception until June 22, 2023. Furthermore, the reference lists of the included datasets and relevant review articles were exhaustively scrutinized (Figure 1). The Newcastle-Ottawa Scale (NOS) was employed to assess the quality of eligible studies.

Results: A total of eighteen studies met the inclusion criteria, encompassing a diverse spectrum of chronic disease categories, including cardiovascular diseases and various types of cancer, among others. Collectively, these studies involved a participant cohort comprising 4,325 individuals. Noteworthy findings emerged, indicating a substantial association between distinct facets of humor—such as one's sense of humor, coping humor, humor styles, and laughter—and psychological QoL. Nevertheless, the relationship between humor and physical QoL exhibited a more intricate pattern, characterized by mixed outcomes (Figure 2).

Image:

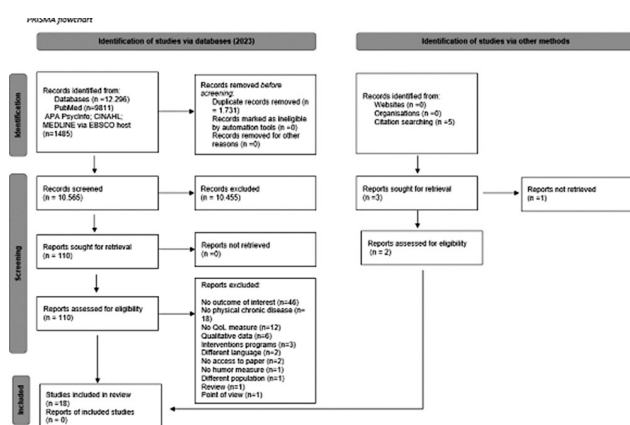

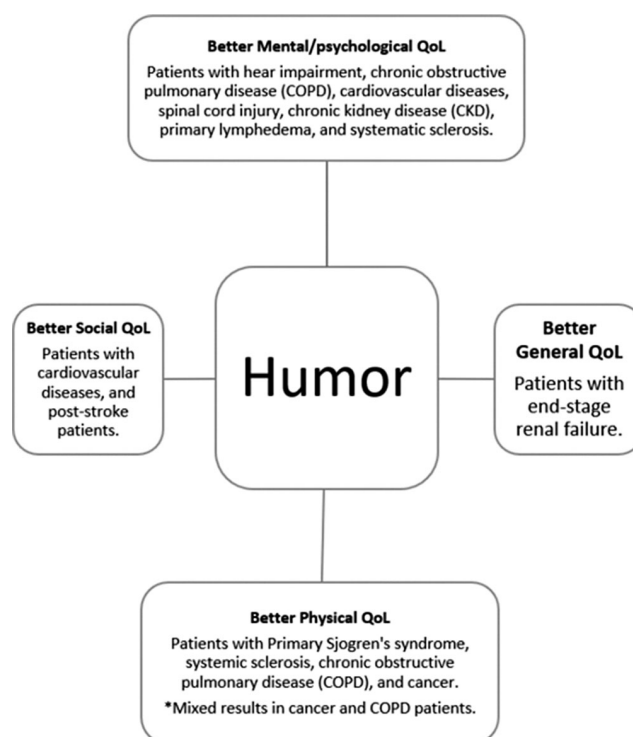

Image 2:

Conclusions: Despite the limited and inconsistent evidence across studies, humor appears to exhibit a positive association with QoL.

Peduncular Hallucinosi: Clinical characteristics, etiology, and a case report

J. Garde Gonzalez*, A. Oliva Lozano, P. Herrero Ortega and M. A. Morillas Romerosa

Psychiatry, La Paz University Hospital, Madrid, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.549

Introduction: Visual hallucinations are a relatively common neurological complaint. Peduncular hallucinosis (PH) stands out as a distinct entity, characterized by complex visual hallucinations resulting from structural lesions in the brainstem or diencephalon.

Objectives: We aim to provide an overview of the clinical features, etiological factors, and management strategies associated with PH, incorporating a unique case study.

Methods: Clinical case report and brief literature review.

Results: Clinical Characteristics: PH is marked by detailed, colorful, vivid, and occasionally emotionally charged visual hallucinations. These hallucinations encompass people, animals, or objects and may be mistaken for reality. While primarily visual, they may occasionally involve other sensory modalities. Crucially, patients with PH maintain insight, distinguishing it from primary psychotic disorders.

Etiological Factors: PH is most commonly associated with structural brainstem lesions, particularly in the midbrain. Potential instigators encompass ischemic strokes, vascular anomalies, tumors and infections. Disruption of the reticular activating system in the brainstem is implicated in the pathogenesis. Advanced imaging techniques have unveiled cases with subtle presentations, broadening our comprehension of PH.

Pathogenesis: PH may involve the disturbance of serotonergic inhibitory pathways and the reticular activating system. A plausible link with hypnagogic hallucinations hints at a mechanism related to rapid REM sleep transitions.

Case Report: Mr. J., a 30-year-old patient, suffered recurrent mesencephalic strokes attributed to Sneddon's syndrome, ADA-2 deficiency, and protein C deficiency, leading to malacic lesions in the hemimesencephalon and right hemipons. He experienced complex visual hallucinations, primarily geometric patterns and animals, mainly at night. Importantly, he maintained insight into their hallucinatory nature. Mr. J. also had diplopia, visual impairment, recurrent headaches, and left hemiparesis.

Reactive anxiety and depression due to functional loss followed his recurrent strokes. Initially, antipsychotics were used to manage sensory-perceptual disturbances, but were later discontinued due to reduced interference with daily functioning. Antidepressant and psychological therapy was continued throughout the follow-up to address mood symptoms.

Conclusions: Peduncular hallucinosis is an intriguing phenomenon characterized by complex visual hallucinations. Understanding its clinical features, etiology, and possible mechanisms is essential for accurate diagnosis and management. This case report emphasizes PH's clinical aspects and the importance of a multidisciplinary

approach, including pharmacological intervention and psychological support. Understanding its features, causes, and management is essential for accurate care. Further research is needed to improve our comprehension and optimize treatment strategies.

Analysis of the demand for mental health consultation and liaison programmes: a comprehensive view.

F. Garcia Lazaro* and F. Gotor Sanchez-Luengo

Hospital Universitario Virgen del Rocío, Sevilla, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.550

Introduction: The mental health consultation and liaison programme plays a crucial role in comprehensive medical care by addressing psychiatric co-morbidities in hospitalised patients.

Objectives: The aim of this study is to analyse demand and assess referral patterns to the mental health consultation and liaison programme in order to identify areas for improvement and optimise the provision of care.

Methods: A descriptive cross-sectional study was conducted by analysing records of referrals to the mental health consultation and liaison programme over a one-year period. Demographic data, origin of demand, type of request, episodic diagnosis, psychiatric diagnoses, follow-up and discharge referral were collected.

Results: A total of 1180 referrals to the mental health consultation and liaison programme were reviewed. Most of the episodic diagnoses were related to anxious-depressive symptomatology, acute stress reaction and acute confusional syndrome. The majority of patients followed up did not require further referral to mental health facilities.

Conclusions: Analysis of the demand for the mental health consultation and liaison programme helps us to optimise care on psychiatric co-morbidities. These results support the importance of integrated care that addresses both medical and psychiatric aspects of inpatient health. Strategies to improve collaboration between different services should be implemented to ensure optimal care and provide a holistic approach.

Suicide risk in patient with diabetes varies by the duration of diabetes: The Korea National Health and Nutrition Examination Survey

Y.-C. Kim, Y.-H. Um, H.-J. Seo and J.-H. Jeong*

Psychiatry, St. Vincent's Hospital, The Catholic.ac.kr, Suwon, Korea, Republic Of

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.551

Introduction: Suicide has a complex relationship with several factors, and it is known that identifying high-risk groups of suicide and managing crisis in advance can help prevent suicide. Moreover in a previous study, it showed that people with chronic diseases often suffer from psychological difficulties such as depression and anxiety, which can influence one to commit suicide. Based on many studies about the relationship between diabetes and depression, 10% of diabetic patients experience major depression, and diabetic patients experience twice as much depression as the general population. But, there are few studies examining the relationship between diabetes and suicide risk, and most of them were targeted for type 1 diabetes only.

Objectives: The objectives of this study were to investigate the suicide risk in diabetic patients, and evaluate the suicide risk varies by the duration of diabetes, using a large population sample in South Korea

Methods: Using the 2019 Korea National Health and Nutrition Examination Survey data, 6,296 adults (aged 19 years or older) were included. Suicidal ideation, suicidal plan, and suicidal behavior of diabetic patients were compared with the general population. After classifying the patients into ≤ 1 year, 2 to 9 years, and 10 years \leq for the duration of diabetes, we evaluated the relationship between the duration of diabetes and the risk of suicide.

Results: Diabetic patients had higher prevalence of suicidal ideation (9.1%, $P < 0.001$) and suicidal plan (3.6%, $P < 0.001$) than general population. After adjusting for potential confounding factors, suicidal plan (aOR = 3.011, 95% CI = 1.392-6.512) was significantly associated with diabetes. In the 2 to 9 year group of diabetes, we found an increase in risk of suicidal ideation (aOR=2.068, 95% CI=1.219-3.510), suicidal plan (aOR=3.640, 95% CI=1.592-8.320), and suicidal behavior (aOR=6.222, 95% CI=1.759-22.008) after adjusting covariates. However, increase in suicide risk was not observed in the ≤ 1 year and 10 years \leq groups after diagnosis of diabetes.

Conclusions: In adults, diabetes is associated with increase in suicide risk. Suicide risk in diabetic patients shows an 'inverted U-shaped' depending on the duration of diabetes.

The Effect of the COVID-19 Pandemic on Suicide Attempts and Self-Harm in Teenagers and Young Adults: An Analysis of Regional Emergency Medical Center Data of a Metropolitan City in South Korea

S. M. Bae^{1*} and N. Ku²

¹psychiatry, Gachon University Gil Medical Center and ²College of Medicine, Gachon University, Incheon, Korea, Republic Of

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.552

Introduction: The COVID-19 pandemic has had a wide-ranging impact on economic and social phenomena worldwide, particularly affecting mental health. However, these impacts have varied significantly across countries. Previous studies have shown that the groups more vulnerable to mental health problems also differ across countries and societies (Gunnell *et al.* Lancet Psy 2020; 7(6) 468-471, Pirkis *et al.* Lancet Psy 2021; 8(7) 579-588, Nomura *et al.* Psy Res 2021; 295 113622). Therefore, by examining changes in self-harm and suicide attempts, which constitute mental health emergencies, at the community level, we can explore the COVID-19 pandemic's impact on the deterioration of mental health in various age groups within the region and identify the groups most vulnerable to mental health problems.

Objectives: The aim of this study is to examine the relationship between the COVID-19 pandemic and changes in the number of emergency room visits due to suicide attempts or self-harm in teenagers and young adults in Incheon, a metropolitan city in the capital area of South Korea.

Methods: We conducted a retrospective data analysis on the medical records of patients who visited the regional emergency center of Incheon Medical Institution from January 2018 to December 2022 due to suicide attempts or self-harm. As our statistical method, we employed interrupted time series analysis to determine whether the COVID-19 pandemic has a statistically significant correlation with the trend changes in the number of emergency room visits related to suicide attempts or self-harm. This study was approved by the Institutional Review Board of Gil Medical Center, Gachon University of Korea (IRB approval number GFIRB2022-335).

Results: The data of 4,030 subjects (35.8% male; $n=1,443$) who visited the regional emergency center during the study period were analyzed. A total of 556 (13.79%) of the study participants were minors under the age of 19, and a total of 1,789 (44.39%) were young adults aged 20-39. The analysis revealed an increasing trend in the number of emergency room visits due to elevated suicidality in teenagers and young adults (20-39 years old) following the COVID-19 pandemic (figure 1 & figure 2).

Image:

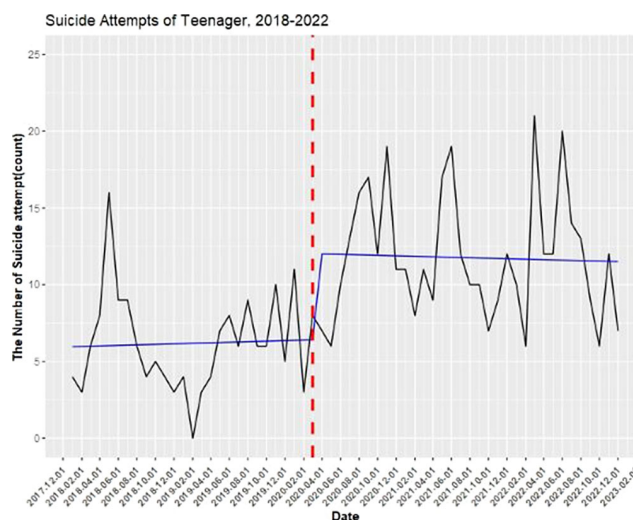

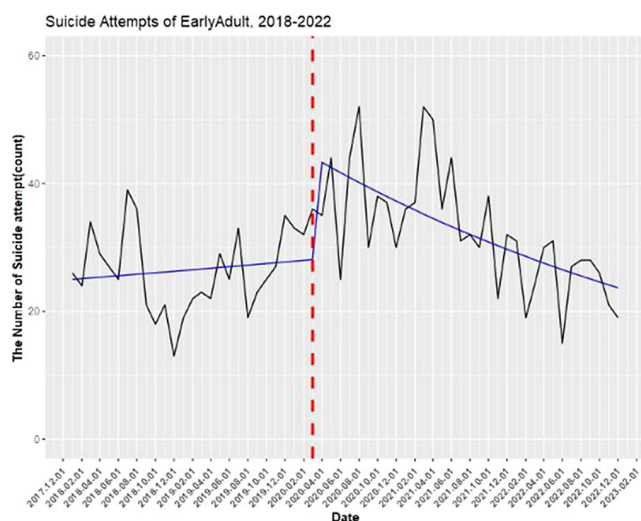

Image 2:

Conclusions: While suicide attempts and visits to the emergency room due to self-harm increased both before and after COVID-19, it is noteworthy that past suicide attempts are the most significant risk factor for future suicide attempts. Therefore, the data on vulnerable groups presented in this study can be instrumental for effective prevention and follow-up management of suicide attempts within the field of community psychiatry.

Perceived vulnerability, fear of covid-19, and psychological distress of military hospital healthcare workers

C. Papathanasiou^{1*} and D. Christodoulis²

¹Department of Psychology, Panteion University of Social and Political Sciences, Athens and ²School of Social Sciences, Hellenic Open University, Patras, Greece

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.553

Introduction: The healthcare workers of military hospitals are actively involved in the fight against covid-19, as part of the national healthcare systems. Therefore, these health professionals may experience symptoms of psychological distress.

Objectives: The study of sociodemographic characteristics and pandemic-related psychosocial factors that affect the psychological distress of healthcare professionals in a military hospital.

Methods: 134 health professionals participated (- 34.3% doctors, 53% nurses and 12.7% other staff). A cross-sectional study was conducted using the DASS-21, PVDS, and FCV-19S questionnaires. Demographic variables were also collected. The data was analyzed using student's t-test and Mann-Whitney test, analysis of variance and Kruskal-Wallis test, Pearson's correlation coefficient and Spearman's correlation coefficient, as well as multivariate linear regression.

Results: 21.64%, 17.91%, and 16.42% of the sample showed symptoms of depression, anxiety, and stress respectively. A significant

correlation emerged between all three dimensions with perceived infectibility and fear of covid-19. Contact with a possible covid-19 patient, female gender, marriage, underlying diseases, increased working hours were found as stressors. The mean values of perceived infectibility and germs aversion were 3.4 and 4.9, respectively. A significant correlation was found between the two subscales with fear of covid-19 ($p=0.001$ and <0.001 respectively). Participants who had undergone psychotherapy in the past had a higher score of perceived infectibility ($p=0.024$). Women and staff in the pathological sector showed greater aversion to germs ($p=0.040$ and 0.001 respectively). Educational level and working hours were negatively correlated with germs aversion ($p=0.037$ and 0.044 respectively). The mean of fear of covid-19 was 14.5, with 14.2% of the population being above the scale average. Fear of covid-19 showed a positive correlation with female gender, age, family, contact with a possible positive case. It was negatively correlated with the medical staff, the educational level, and the employees in a covid-19 clinic. According to the results of the multivariate linear regression analyses: (i) The increase in educational level was associated with a decrease in the fear for covid-19 score ($p=0.026$); (ii) The increase in perceived infectibility score was associated with an increase in the fear for covid-19 score ($p<0.001$); (iii) The increase in germs aversion score was associated with an increase in fear for covid-19 score ($p=0.014$).

Conclusions: The findings confirm the presence of psychological distress on the healthcare workers of the hospital and its dependence on perceived infectibility and fear of covid-19.

Translation and validation of the Greek versions of the Coronavirus Anxiety Scale, the Obsession with COVID-19 Scale and the Coronavirus Reassurance-Seeking Behaviors Scale

M. Bakola¹, K. S. Kitsou¹, V. Angelidou², A. Giannakopoulos³, M. Drakopoulou¹, K. Mavridou¹, P. Kalianezos¹, K. Argyropoulos¹, C. Petropoulos³, G. Charalambous², P. Gourzis^{4*}, S. A. Lee⁵ and E. Jelastopulu¹

¹Department of Public Health, School of Medicine, University of Patras, Patras, Greece; ²Postgraduate Program of Health Management, Frederick University of Nicosia, Nicosia, Cyprus; ³Department of Mathematics; ⁴Department of Psychiatry, University of Patras, Patras, Greece and ⁵Department of Psychology, Christopher Newport University, Newport News, United States

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.554

Introduction: Understanding coronaphobia, or the heightened fear and anxiety related to the COVID-19 pandemic, involves assessing physiological, cognitive, and behavioral measures.

Objectives: We aimed to develop a Greek version of the Coronavirus Anxiety Scale (CAS), the Obsession with COVID-19 Scale (OCS), and the Coronavirus Reassurance-Seeking Behaviors Scale (CRBS), to identify groups that appear vulnerable to this form of pandemic-related anxiety.

Methods: We conducted a cross-sectional online study from February to April 2021 in Greek-speaking people living in Cyprus. Participants completed sociodemographic questions and questions related to COVID-19, the CAS, OCS, and the CRBS. All three scales

are rated on a 5-point scale, from 0 (not at all) to 4 (nearly every day). For CAS, a score ≥ 9 indicates probable dysfunctional coronavirus-related anxiety, for OCS a ≥ 7 score indicates probable dysfunctional thinking about COVID-19, and for CRBS score ≥ 12 suggests above-average reassurance-seeking activity.

Results: A total of 405 adults (66.4% women) from Cyprus participated in this study. The results of this study demonstrate that these Greek adapted measures have adequate reliability (Cronbach's alphas >0.70) and factor structure (exploratory and confirmatory factor analysis support). However, only the CAS demonstrated both convergent and divergent validity. Education personnel, housekeepers, and older adults were also found to have higher coronavirus anxiety relative to their counterparts.

Conclusions: The findings of this research support the use of these coronaphobia scales in Cyprus and other Greek-speaking populations. Assessing the potential for fear-driven behaviors may be of great benefit to both clinicians and researchers, helping to identify individuals at risk, adapt interventions, and improve our understanding of the psychological consequences of surviving a public health emergency.

Comparing Psychiatric Admission Following Suicidal Presentations to the Emergency Department pre-COVID and During the COVID era

S. Crowley^{1*} and E. Cassidy²

¹Clare Psychiatry of Later Life, HSE Mid West, Ennis and ²Department of Liaison Psychiatry, Cork University Hospital, Cork, Ireland

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.555

Introduction: Suicide is one of the leading causes of death worldwide, (Centiti et al. 2020). Presentations to the emergency department (ED) with suicidal ideation (SI) or deliberate self-harm (DSH), and admissions following same, are a major part of unscheduled adult mental health service activity.

Objectives: To evaluate how suicidal presentations to the emergency department (ED), and admission following same have been affected by the COVID era thus far. To evaluate how key patient characteristics affect admission during the COVID era and pre-COVID, namely whether presentations were with suicidal ideation (SI) or deliberate self-harm (DSH), whether the patient was previously known to a community mental health team (CMHT), and whether the patient was intoxicated at the time of presentation.

Methods: Data is routinely collected on all adults presenting with SI/DSH to the ED. We looked at presentations, admissions and key patient characteristics over the 12 months of the COVID era thus far (March 2020-February 2021) and compared them to the preceding 12 months.

Results: Presentations over the two 12 month periods were similar (pre-COVID n=819, COVID era n=823). However, admission increased by 27% (139 to 177) over the COVID era as a whole. For nine months of the COVID era monthly numbers of admissions were higher than their pre COVID comparison. Admission rates during the COVID era were found to be increased across all patient groups examined, but were particularly increased in those presenting sober or with SI. Admission rates rose equivalently for those known or unknown to a CMHT.

Image:

Socio-Demographic Information	Pre-COVID	COVID era
Total	819	823
Gender		
Female	403 (49%)	421 (51%)
Male	416 (51%)	402 (49%)
Age		
18-19	66 (8%)	69 (8%)
20-25	180 (22%)	212 (26%)
26-29	98 (12%)	98 (12%)
30-39	179 (22%)	161 (20%)
40-49	139 (17%)	129 (16%)
50-59	93 (11%)	81 (10%)
60-64	21 (3%)	39 (5%)
65 or older	43 (5%)	34 (4%)

Image 2:

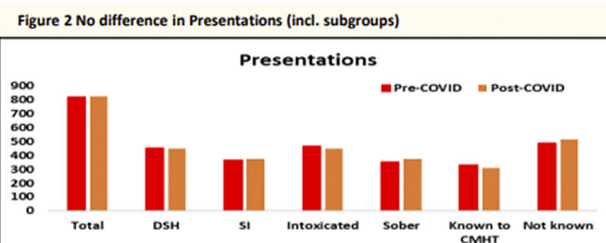

Figure 3 Rise in Admissions during COVID era (esp. SI, Sober)

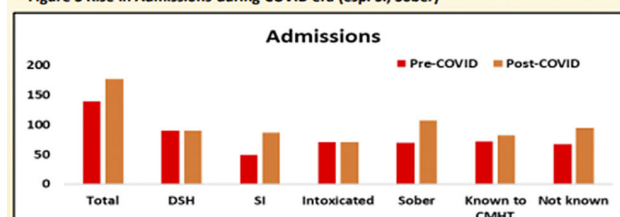

Figure 4 Admission Rate higher in COVID era (esp. SI, Sober)

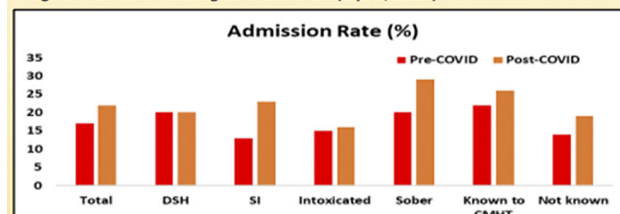

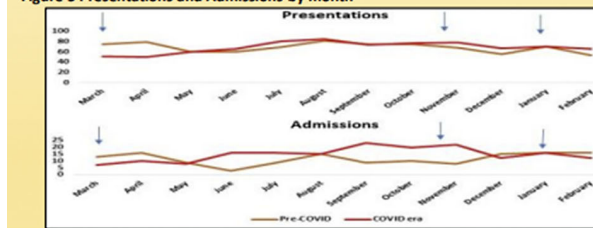

Figure 5 Presentations and Admissions by month

Conclusions: The number of admissions following suicidal presentations to the ED has risen significantly in the COVID era. This may be due to more severe presentations in terms of risk of suicide without admission or increased psychiatric morbidity requiring admission. Limitations of service provision in the community due to COVID era restrictions may also partially explain these findings.

EPP0396

Anxiety and subjective assessment of cognitive functions after COVID-19.

T. I. Medvedeva, O. M. Boyko*, S. N. Enikolopov and O. U. Vorontsova

Clinical psychology, Federal State Budgetary Scientific Institution "Mental Health Research Center", Moscow, Russian Federation

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.556

Introduction: Wide circulation of the COVID-19 has led to the high occurrence of a longcovid in which the complaints of violations of cognitive functions and affective disorders often occur.

Objectives: The aim of this study was to assess the relation of anxiety and subjective appraisal of the states of cognitive functions.

Methods: The data of 1233 respondents of internet-research who were divided into the four groups according to their COVID-19 status and the level of anxiety. Group 1 (didn't have COVID before, low level of anxiety) – 689 people (mean age 40,6), group 2 (didn't have COVID before, High level of anxiety) – 364 people (mean age 39,8), group 3 (had been ill COVID-19, low level of anxiety) – 102 people (mean age 41,2), group 4 (had been ill COVID-19, High level of anxiety) -130 people (mean age 35,5). Methods include the questions about the states of their cognitive functions (attention, memory, working capacity), a question about COVID-19 status. There are the results of comparing the groups that was carried out using the Kruskal-Wallis test. A pairwise comparison was carried out using the Mann-Whitney test for two groups of people who were not ill; two groups who were ill; two groups with a low level of anxiety; two groups with a high level of anxiety. To correct multiple comparisons, the adjusted significance level calculated by the formula ($p = 1 - 0,951^{1/n}$) was used, which was $p=0,017$ for 4 pairwise comparisons.

Results: Results are shown in table.

	Group 1	Group 2	Group 3	Group 4
Trouble remembering things	0,50 (*2)	0,99 (*1,*4)	0,77 (*1,*4)	1,30 (*2,*3)
Feeling low in energy or slowed down	0,74 (*2,*3)	1,77 (*1,*4)	1,23 (*1,*4)	2,34 (*2,*3)
Having to do things very slowly to insure correctness	0,27 (*2)	0,88 (*1)	0,31 (*4)	1,00 (*3)
Difficulty making decisions	0,63	1,63	0,82	1,67

Continued

Continued

	Group 1	Group 2	Group 3	Group 4
	(*2)	(*1)	(*4)	(*3)
Your mind going blank	0,34 (*2,*3)	1,12 (*1)	0,64 (*1,*4)	1,36 (*3)
Trouble concentrating	0,58 (*2)	1,55 (*1,*4)	0,72 (*4)	1,86 (*2,*3)
Feeling everything is an effort	0,43 (*2)	1,47 (*1,*4)	0,56 (*4)	1,81 (*2,*3)

An entry in parentheses such as (2*) means that this group for this parameter statistically significant differs from group 2.

As indicated in the table, respondents with the high level of anxiety have higher levels of the subjective assessment of cognitive functions regardless of their COVID-19 status.

Conclusions: A possible explanation may be the disorganizing effect of anxiety on the cognitive functions. When combined with possible organic disorders caused by the transferred COVID-19, the most marked indicators of cognitive decline are observed. An effective rehabilitation of cognitive functions after COVID-19 requires to diagnose the level of anxiety and to seek psychological and psychiatric assistance for people with a high level of anxiety.

Divergent risk of SARS-CoV-2 infection, severe COVID-19 and mortality across psychiatric disorders: analysis from electronic health records in Catalonia

A. Monistrol-Mula^{1*}, M. Félez-Nobrega¹, I. Giné-Vázquez¹ and J. M. Haro¹

¹Epidemiology of mental disorders and ageing, Institut de Recerca Sant Joan de Deu, Sant Boi de Llobregat, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.557

Introduction: People with psychiatric disorders are particularly vulnerable to SARS-CoV-2 infection and its associated complications. However, current literature show that not all psychiatric disorders are equally vulnerable to COVID-19.

Objectives: This study aimed to assess whether individuals with distinct psychiatric disorders exhibit different risk of SARS-CoV-2 infection, COVID-19 hospitalization, and mortality.

Methods: We conducted a case-control study using data of electronic health records from Catalonia. Cases included adults with a hospital admission between 2017 and 2019 for non-affective psychosis, bipolar disorder, depressive disorder, stress-related disorders, neurotic/somatoform disorders, and substance misuse. These were matched to patients without a diagnosis by sex, 5-year age band, and living area. Outcomes included SARS-CoV-2 infection, hospitalization, and COVID-19-related death up to December 2021. Logistic regression analysis were employed to test the association between the six groups of psychiatric disorders and COVID-19

outcomes, controlling for age, sex, smoking, being in a nursing home, and physical comorbidities.

Results: 785,378 subjects were included. Preliminary findings showed that patients diagnosed with psychosis and bipolar disorder had lower risk of infection [OR: 0.85 (95% CI: 0.79-0.92), $p < 0.001$; OR: 0.84 (95% CI: 0.76-0.92), $p < 0.001$], whereas individuals with stress-related and neurotic/somatoform disorders had higher risk of infection [OR: 1.08 (95% CI: 1.04-1.14), $p < 0.001$; OR: 1.06 (95% CI: 1.03-1.10), $p < 0.001$]. People with depressive, stress-related, and neurotic/somatoform disorders had lower risk of COVID-19 hospitalization [OR: 0.87 (95% CI: 0.78-0.97), $p = 0.01$; OR: 0.71 (95% CI: 0.61-0.84), $p < 0.001$; OR: 0.67 (95% CI: 0.60-0.76), $p < 0.001$]. In line with these results, individuals with stress-related disorders also experienced lower mortality [0.49 (95% CI: 0.33-0.70), $p < 0.001$]. Conversely, people with psychosis, bipolar disorder, and substance misuse exhibited higher risk of COVID-19-related death [OR: 2.9 (95% CI: 1.68-3.1), $p < 0.001$; OR: 1.95 (95% CI: 1.30-2.81), $p < 0.001$; OR: 1.82 (95% CI: 1.49-2.20), $p < 0.001$].

Conclusions: We found different risks of SARS-CoV-2 infection, COVID-19 hospitalization, and COVID-19 mortality for psychiatric disorder groups. Differences in vulnerability to COVID-19 among people with psychiatric disorders might be explained by factors such as shared living facilities, physical comorbidities, psychotropic medications, and difficulties in accessing high-intensity medical care. Special attention should be directed towards individuals with psychosis, bipolar disorder, and substance misuse.

Clozapine and the Risk of Severe COVID-19: A Retrospective Cohort Study

I. Yaich^{1,2*}, A. Touiti^{1,2}, C. Ben Said^{1,2} and N. Bram^{1,2}

¹Forensic Psychiatry Departement, Razi Hospital, La Manouba and ²Faculty of Medicine of Tunis, Tunis El Manar University, Tunis, Tunisia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.558

Introduction: Clozapine is the standard treatment for managing treatment-resistant schizophrenia (TRS). However, concerns arise due to potential hematologic side effects, such as agranulocytosis, especially during the COVID-19 pandemic.

Objectives: This study aims to investigate the association between clozapine treatment and an increased risk of severe COVID-19 infection in patients with TRS.

Methods: A retrospective study reviewed clinical records of forensic patients with TRS from 2020 to 2022 at Razi Hospital's forensic psychiatry department in Tunisia. Twenty-five patients, including 18 on clozapine treatment, were included.

Results: All patients were male, with an average age of 39.7 years. Twenty-three patients received at least one vaccine dose. Twenty-two patients contracted COVID-19. Among those treated with clozapine, two required intensive care unit admission and oxygen therapy without intubation. Clozapine treatment remained uninterrupted, with no dose escalation during infection episodes. Lymphopenia was the most commonly reported hematologic abnormality.

Conclusions: While there may be an association between clozapine use and an increased risk of COVID-19 infection, no clear correlation with infection severity and antipsychotic treatment was established in this study. Further research is needed to explore this potential association comprehensively.

The influence of the COVID-19 pandemic on the occurrence of depressive symptoms in the Croatian adult population

J. Dumic¹, I. Miskulin², M. Kristic², J. Kovacevic², I. Vukoja², L. Dumic² and M. Miskulin^{2*}

¹Department of Dental Medicine, Faculty of Dental Medicine and Health Osijek and ²Department of Public Health, Faculty of Medicine Osijek, Osijek, Croatia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.559

Introduction: The COVID-19 pandemic has led to a worsening of mental health among the Croatian general population. However, the overall prevalence of population depressive symptoms in Croatia over the COVID-19 pandemic is still unknown.

Objectives: This study aimed to investigate the influence of the COVID-19 pandemic on the occurrence of depressive symptoms among Croatian adults.

Methods: This cross-sectional questionnaire study was conducted from mid-February to mid-May 2022 period. A validated, anonymous questionnaire that contained questions regarding demographic data, as well as the Zung Self-Rating Depression Scale was self-administered to a convenient sample of adults from the city of Osijek in eastern Croatia.

Results: The study sample included 500 subjects with a median age of 34 years (interquartile range 26-53), 42.4% males, and 57.6% females. According to the Zung Self-Rating Depression Scale, there were 16.2% of subjects with mild or moderate depressive symptoms. Depressive symptoms were more frequent among older subjects (61 years or older) ($p = 0.001$), among subjects with a lower level of education (subjects with or without elementary school) ($p < 0.001$), among subjects who were retired ($p = 0.005$), among subjects who considered their socioeconomic status as under average ($p < 0.001$), and among subjects who experienced death of close family member caused by COVID-19 infection ($p = 0.004$).

Conclusions: The COVID-19 pandemic increased the prevalence of depression in the Croatian general population where some sociodemographic characteristics of study subjects seem to put those subjects at greater risk considering the occurrence of depressive symptoms. Development of appropriate supportive programs that enhance the mental health of the Croatian general population during pandemics is needed to potentially prevent the occurrence of depressive symptoms and to help the general population successfully overcome this important mental health challenge.

The causes of negative countertransference in its cultural aspect among psychiatric residents in Tunisia

D. Mezri*, S. Walha, S. Hamzaoui, K. Mahfoudh, A. Ouertani, U. Ouali, A. Aissa and R. Jomli

Avicenne, Razi hospital, Manouba, Tunisia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.560

Introduction: Negative countertransference in psychiatry refers to the therapist's unfavorable emotional reactions to the patient, such as anger and frustration, which can hinder the therapeutic relationship and the client's progress. This is why it is imperative to study the causes of this negative counter-transference, such as cultural causes, to ensure effective treatment, appropriate care and better comfort for psychiatry residents during their professional practice.

Objectives: To study the cultural causes of negative countertransference among psychiatric residents in Tunisia and their coping behavior.

Methods: This cross-sectional study was carried out among Tunisian residents working in psychiatric departments, using a questionnaire deployed via Google Forms.

Results: The study involved 26 residents with 23 females. The average age was 27.57 years with extremes ranging from 26 to 32. The participants were family doctors practicing in psychiatric wards (26.9%), first year psychiatry residents (15.4%), second year psychiatry residents (23.1%), third year psychiatry residents (19.2%), fourth year psychiatry residents (11.5%) and child psychiatry residents (3.8%). The majority of residents admitted having had a negative transference towards a patient (88.5%). The level of frustration felt by residents during this counter-transference on a scale of 100 varied from 1 to 100 with an average of 61.9. Substance abuse was the primary cause in 52.17% of cases. The second cause was the patient's ideology, with a percentage equal to 43.47%. The same percentage of 17.39% was for traditions, socio-economic level and membership of a particular political group. In 82.6% of cases, residents tried to analyze this counter-transference and 65.2% of them managed to deal with their frustration. The feeling of guilt was experienced by 56.52% of practitioners and the same number of residents tried to avoid the patient. Among the participants, 43.47% discussed this difficulty with their supervising physician and only 4 residents asked to change patients.

Conclusions: In conclusion, our study identified the cultural causes of negative countertransference in Tunisian psychiatry residents, including substance abuse, ideology, traditions, socio-economic level and politics. Understanding these causes is essential to resident training but also to the delivery of quality care in psychiatry. By integrating this knowledge into training, we can help residents recognize and manage negative countertransference, in order to improve the quality of care they provide to their patients.

Unveiling Koro's diverse conceptualizations across cultures

D. Seabra^{1*}, I. Lopes¹, J. Moura¹, J. Leal¹, T. Rocha¹, J. Cunha¹, S. Torres¹, D. Santos¹, G. Santos¹ and N. Ramalho¹

¹Psychiatry and Mental Health, Centro Hospitalar Barreiro Montijo, Barreiro, Portugal

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.561

Introduction: Koro, also known in Cantonese as *Shook Yang*, which literally translates to "shrinking penis", has its roots in a cultural belief that a mythological figure would steal the penis of his victims. Predominantly reported in Southeast Asia, it involves an acute fear of genital retraction, often accompanied by the belief that this retraction may lead to death. Over the last two centuries, Koro has undergone several attempts to establish its definition and classification, without a true consensus having been reached.

Objectives: This study aims to explore the cultural nuances surrounding Koro and reflect on the various conceptualizations that modulated its definition and nosological classification, from Ancient China until the present.

Methods: A non-systematic literature review with the keywords "koro" and "culture" was conducted.

Results: Koro was only introduced to the Western world during colonial expansion, drawing the attention of several psychiatrists who, in Asian territory, reported numerous cases in natives, making the very first attempts at a nosological classification, whether as an anxiety neurosis, or as an obsessive-compulsive disorder. The literature reveals significant cultural variations in the manifestation of Koro, challenging the traditional psychiatric understanding rooted in Western diagnostic categories. Cultural factors, including societal beliefs, religious practices, and regional variations, emerged as influential contributors to the prevalence and presentation of Koro. Additionally, the study identified instances of Koro evolving in response to cultural shifts and globalization, emphasizing the dynamic nature of this syndrome.

Conclusions: This review underscores the need for a comprehensive understanding of Koro that acknowledges its diverse conceptualizations across cultures. Its occurrence, not only in multiple parts of the world, but also in close relation with various comorbidities, has contributed to the dissolution of its primary identity as a culture-bound syndrome, turning Koro into a moving target.

Pregnancy, postpartum and breastfeeding: beliefs about women's sexuality during this period

S. Bader^{1*}, Z. zran¹, M. aloulou¹, A. Abdelmoula², A. Bouaziz¹ and W. abbes¹

¹Psychiatry and ²obstetric gynecology, University Hospital of Gabes, Gabes, Tunisia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.562

Introduction: Pregnancy, postpartum and breastfeeding is a very challenging period in the women's life. Many shared false beliefs and perceptions about this period can influence a pregnant woman's sexual life and couple.

Objectives: to explore sexual satisfaction, misconceptions and beliefs about sexuality during pregnancy and postpartum in women.

Methods: It was a cross-sectional study established over a period of 3 months from the June 1st, 2023 to August 31, 2023. This study focused on a population of pregnant postpartum and breastfeeding women recruited from outpatient consultations and inpatient of the obstetric gynecology department at the university hospital of Gabes, Tunisia. We used a pre-established sheet exploring socio-demographic data, medical and gynecological history, informations concerning the marital relationship and the woman's sexual activity and eight questions (yes or no / choosing an option) to explore the beliefs and perceptions about sexuality during pregnancy and postpartum. We administered the validated Arabic version of the Arizona Sexual Experiences Scale (ASEX) to assess sexual functioning.

Results: Fifty-eight women were included. The average age was 35.6±5.5 years, they had a university level in 40% and they were unemployed in 74.2%. They were from an urban origin in 75%. They were pregnant in the first, second and third trimester in (15.6%, 15.6% and 25% respectively). They were in postpartum in 43.8% of cases with a cesarean delivery in 73.3% and breastfeeding in 56%. All women reported being on good terms with their spouses and satisfied with their sexuality. The usual frequency of sexual relations (SR) was (1/day: 22.6%, 1/week: 74.2%, 1/month: 3.2%). Only 3.4% masturbated and 5.17% had sexual fantasies. Among women, 55.1% believed that RS is not allowed in the first trimester, and 67.8% believed that it can harm the baby. Only 25% of women believed that RS is permitted throughout pregnancy. 58.1% believed that RS in the third trimester could induce early delivery, and 30% believed that it could harm the baby. They all believed that post-partum SR is only authorized after 40 days. Among the sample 22.6% believed that SR is not allowed during breastfeeding, and that it can harm the baby in 13% of cases. The mean ASEX score was 13 ± 4.3 and 47% had sexual dysfunction. Regarding the frequency of SR, 25% reported wanting to reduce the frequency, 3.4% wanting to increase the frequency and 71.6% were neutral.

Conclusions: A better understanding of the misconceptions and beliefs about sexuality during pregnancy and the post-partum period is needed to reduce restriction imposed on sexual activity during a normal pregnancy and to enhance marital harmony and the sexual life of the couple.

EPP0406

Risks of mental health of foreign medical residents who study in Ukraine

M. Markova^{1*}, A. Kaafarani¹ and T. Aliieva¹

¹Kharkiv National Medical University, Kharkiv, Ukraine

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.563

Introduction: The high level of psycho-emotional stress today significantly increases the moral burden on the mental health of

medical workers. One of the most vulnerable groups of medical specialists in Ukraine are foreign resident doctors. Since in Ukraine this contingent of doctors is faced with extraordinary problems of high psycho-emotional stress, such as COVID-19 around the world and the Russian war against Ukraine. Raising the issue of resident doctors, the main issue becomes not only their professional identity, but also the formation of the necessary stress resistance in different conditions of professional activity.

Objectives: To study the level of tolerance to stress and uncertainty among foreign resident doctors in unusual conditions of performing professional duties.

Methods: The examination included the use of clinical-psychological, psychodiagnostic and psychometric research methods.

Results: As of the beginning of 2020, 395 foreigners were studying. During the first phase of the pandemic, 118 foreigners left Ukraine. By the beginning of 2022 (before the full-scale war), 302 medical residents were trained. As of the beginning of 2023, 167 doctors are studying, of which only 61 people are on the territory of Ukraine. The primary analysis of the clinical-psychological study showed that the most common complaints among foreign resident doctors are: increased levels of feelings of tension (in 75.4%), decreased motivation for activity (73.2%), anxious (72.7%) and depressive symptoms (69.3%), frequent headaches (68.6%), constant feelings of irritation (65.4%), manifestations of aggression in relation to colleagues (63.9%) and patients (61.4%), a feeling of fear for the future (60.1%), conflicts in the family (59.5%).

The study of factors that influence the increase in the level of stress among foreign resident doctors were sorted according to the principle of ordinary and extraordinary. Ordinary stress factors include: the nature of the specialty, the conditions of professional activity, a foreign country, relationships in the team. Extraordinary factors include new working conditions (professional challenges of COVID-19, war on the territory of Ukraine), increased risks of responsibility for the patient's life (search for a treatment solution against the background of COVID-19), nature of assistance (providing assistance due to combat injuries).

Conclusions: At the end of the study, a comprehensive program will be created for the early detection of signs of adaptation disorder, which will be aimed at reducing emotional distress, tension in the learning process, support in the first years of training for medical residents.

Developing a support intervention for family members of people treated under the Mental Health Act

I. Wells^{1*}, K. Wintsch² and D. Giasco¹

¹University of Warwick, Coventry and ²Queen Mary University of London, London, United Kingdom

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.564

Introduction: In England, a national Mental Health Act (MHA) review was carried out, providing recommendation for policy and practice changes. One of these recommendations was to provide support to family members (FMs) of patients who have been involuntarily hospitalised. In response to this review, the National

Institute for Health and Care Research (NIHR) provided funding for research to address policy questions, for example what support may be most relevant to FMs during their patients' treatment. The study presented here was funded as part of this initiative and has explored what support FMs wish to receive.

Objectives: To explore FMs' experiences and views around support they would have liked during their patients' involuntary hospitalisation and wider stakeholder views on what a family support programme in England should involve. This information can be used to develop a support programme for FMs.

Methods: One-to-one interviews were conducted online as part of two work packages. The first work package explored FMs' experiences and views of support. The second work package explored views on what should be included in a family support programme in England from FMs, patients and professionals. Interviews took place at three sites across England. Audio recordings of the interviews were transcribed, and data were analysed using thematic analysis.

Results: 22 FMs were recruited to the first work package, where four key themes were identified: (1) heterogeneity in the current support for families; (2) information about mental health and mental health services; (3) continuous support; and (4) peer support and guidance. FMs reported receiving support from professionals, peers and relatives, but the extent of this support varied. FMs consistently reported wanting a named contact to provide information and personal continuity of support. 5 FMs, 4 patients and 10 professionals took part in the second work package, where four main themes were also identified: (1) development of a support programme; (2) delivery of a support programme; (3) factors limiting accessibility or engagement; and (4) benefits of a support programme. Information about the MHA and strategies to promote effective communication between FMs and professionals were identified as important to include in the programme and its delivery should include a combination of face-to-face, written and online methods. Potential benefits of the programme include improved FM knowledge and wellbeing.

Conclusions: FMs of involuntarily hospitalised patients should receive information around the MHA and strategies to promote effective communication with professionals. FMs should also be allocated a named contact person to offer information and personal continuity of support through various methods, for example through online, face-to-face or written contact.

Palestine-Israel War Coping Strategies of Tunisian People

N. Messedi¹, F. Guerhazi¹, A. Samet¹, I. Chaari¹, M. Sehli^{1*}, F. Charfeddine¹, L. Aribi¹ and J. Aloulou¹

¹Psychiatry B, Hedi Cheker University Hospital, Sfax, Tunisia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.565

Introduction: The war in Gaza is a stressful life event. Due to its significant human and financial losses, it affected the mental health of people around the world including the middle east citizens.

Objectives: To study the coping strategies of Tunisian people toward Palestine-Israel war in its first month and the factors associated with them.

Methods: It was a cross-sectional, descriptive and analytical study, conducted among Tunisians. Data were collected during October and November 2023, through an anonymous online questionnaire, spread throughout social media (Facebook/Instagram), using the Google Forms® platform. We used a socio-demographic and clinical data sheet and the "Brief-COPE" to assess coping strategies.

Results: A total of 1091 participants completed the questionnaire. Their mean age was 32,7± 9.8 years, with a sex-ratio (F/M) of 3.5. Among participants, 46,1% are married, 42,5% have children and 19,5% have a psychiatric follow history. Sport's practitioners represent 23,3% of the participants and 10,6% increased their use of sports after the war news.

In terms of coping strategies: problem focused coping was the most used strategy (mean= 2,02) followed by emotional focused coping (mean= 1,98) and avoidant coping (mean= 1,63). Tunisians rely the most on religion, accepting reality and planning as coping mechanisms (score= 2,85; 2,4 and 2,23 respectively). Substance use was the last resort option (score= 1,11).

Our survey revealed significant associations between coping mechanisms and several factors: Venting, humor and behavioral disengagement were significantly correlated with sex gender (p=0,000 ; 0,000 ; 0,000 respectively); Substance use coping mechanism was significantly correlated with participants having a psychiatric follow history (p=0,001); Avoidant coping subscale was significantly correlated with having children (p=0,000); Self distraction was significantly correlated with the increase use of sport among Tunisians (p=0,000).

Conclusions: These findings underscore the need for healthcare and productive coping strategies for Tunisians and middle east people during the Palestine-Israel war.

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.566

Introduction: The postpartum period poses a risk of both onset and relapse of mental health disorders in mothers, which can impact maternal-child relationships and development of children. Timely intervention is crucial, especially considering that majority of at-risk women do not seek professional help.

Objectives: This study aims to evaluate the effectiveness of Mom Supports Mom, a remote peer support intervention, in improving the mental health of postpartum women.

Methods: A randomized controlled trial with 488 Czech postpartum women with depressive symptoms (Edinburgh Postnatal Depression Scale, EPDS score ≥ 10 shortly after giving birth) assessed the impact of Mom Supports Mom on depressive and anxiety symptoms (EPDS and Perinatal Anxiety Screening Scale, PASS) and health-related quality of life (Assessment of Quality of Life, AQoL-8D) at 6 weeks postpartum. The Mini-International Neuropsychiatric Interview 5 (MINI) was used to assess psychiatric diagnoses.

Results: The intervention significantly reduced depressive (Cohen's $d = 0.30$; $p = 0.003$) and anxiety symptoms (Cohen's $d = 0.29$; $p = 0.003$) and improved health-related quality of life (Cohen's $d = 0.27$; $p = 0.008$) at 6 weeks postpartum. No significant difference was observed in psychiatric diagnoses between the intervention and the control group.

Conclusions: Mom Supports Mom intervention reduces postpartum depressive and anxiety symptoms and enhances health-related quality of life. These findings support the integration of peer support into perinatal mental health care, addressing barriers that women face in seeking help.

Psychological and Pharmacological Interventions to Reduce Alcohol Use Disorder (AUD) in the inpatient units. A General Review.

E. Owusu^{1*}, R. Shalaby¹, N. Nnamdi¹, L. A. Mobolaji¹ and V. I. Agyapong^{1,2}

¹Psychiatry, University of Alberta, Edmonton and ²Psychiatry, Dalhousie University, Halifax, Canada

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.567

Introduction: According to the World Health Organization, around 2 billion people worldwide are estimated to drink. Alcohol intake results in 25% of the 3.8% of worldwide fatalities and 4.6% of global disability-adjusted life years that may be attributed to alcohol.

Objectives: This review seeks to synthesize data on psychological and pharmacological treatments for Alcohol Use Disorder (AUD) available in the inpatient setting.

Methods: A comprehensive and narrative review of studies and research on psychological and pharmacological interventions for patients with alcohol use disorders in inpatient treatment units was performed. Data was extracted from electronic bibliographic databases, including Medline, EMBASE, PsycINFO, Global Health, HealthSTAR, and Cumulative Index for Nursing and Allied Health Literature (CINAHL) via EBSCOhost. This review included both qualitative and quantitative studies.

Results: Overall, after an initial title, abstract screening, and subsequent full-text screening, seven out of 1245 extracted studies met the eligibility criteria and were included in the review. This review

suggests that a combination of pharmacological interventions such as naltrexone, nalmefene, acamprosate and brief psychological interventions were effective in treating AUD.

Conclusions: This review suggests that pharmacological and psychological approaches, when used together, are efficacious in treating AUD. There is a need to adopt both pharmacological and psychological interventions in the treatment of AUD.

Effects of a transition care program on depression, self-efficacy, and self-care behaviors in heart failure patients

H.-S. YEH^{1*} and Y.-F. TSAI²

¹Cardiology, Chang Gung Memorial Hospital at Linkou and ²Nursing, Chang Gung University, Tao-Yuan, Taiwan, Province of China

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.568

Introduction: Heart failure is a progressive and unpredictable heart disease. How to work with these patients to decrease their psychological distress and promote their self-care behaviors is important. Transition care is the continuity of medical care for heart failure patients returning home from the hospital. Intervention through transition care may improve the continuity of medical care for patients with heart failure but it has not been examined in clinical settings in Taiwan.

Objectives: The aims of this study were to explore the effects of a newly developed transition care program on depression, self-efficacy, and self-care behavior of heart failure patients.

Methods: Using an experimental research design and block randomization, participants were divided into the experimental group (received transition care and routine care) and the control group (received routine care only). The Patient Health Questionnaire-9 (PHQ-9), the General Self-Efficacy Scale (GSES), and the Self-Care of Heart Failure Index (SCHFI version 6.2) were used to collect data before discharge and the first month after discharge.

Results: A total of 20 patients with heart failure were recruited. No significant differences were found between the experimental ($n=10$) and control groups ($n=10$) in the degree of depression ($Z=-.077$, $p=.938$), self-efficacy ($Z=-1.214$, $p=.225$), and three self-care behaviors subscales (self-care maintenance $Z=-1.214$, $p=.225$; self-care management $Z=-.401$, $p=.689$; self-care confidence $Z=-.436$, $p=.663$) at discharge. After the one-month posttest, only self-efficacy ($Z=-2.545$, $p=.011$) and three self-care behaviors subscales (self-care maintenance $Z=-3.097$, $p=.002$; self-care management $Z=-2.595$, $p=.009$; self-care confidence $Z=-3.671$, $p<.001$) reached a statistical difference between the two groups.

Conclusions: Based on the preliminary results, heart failure patients can improve their self-care behavior and self-efficacy but not depression through transitional care intervention.

Latent classes based on clinical symptoms of military recruits with mental health issues and their clinical responses to treatment over 12 months

D.-I. Jon*, J. Eo, E. H. Park and H. J. Hong

Psychiatry, Hallym University Hospital, Anyang, Korea, Republic Of
*Corresponding author.

doi: 10.1192/j.eurpsy.2024.569

Introduction: In South Korea, all men at the age of 18 or older are required to serve at military for a certain period as an obligation. These recruits should be able to withstand psychological stress and pressures of rapid adaptation of the unique and new environment in military. The number of military recruits facing adaptation issues has been on the rise, necessitating an evaluation for active service. In our previous study (Park et al., in press 2023), we classified the military recruits with mental issues according to latent profile analysis (LPA) and examined the treatment response during six months.

Objectives: In this study, we further examined clinical characteristics over the next six months.

Methods: Ninety-two participants were analyzed with LPA using MMPI-2 clinical profiles in the previous study. The three classes were identified: mild maladjustment (Class 1, n=14), neurotic depression and anxiety (Class 2, n=36), high vulnerability and hypervigilance (Class 3, n=42). At 12 months, Clinical Global Impression-Severity and Global Assessment of Functioning were assessed to test their long-term changes.

Results: While Class 1 and 2 significantly improved over 6 months, Class 3 showed little or no improvement even with more medications in our previous study. During the 6-month follow-up period, 50% of Class 1, 38.9% of Class 2, and 41.5% of Class 3 were dropped. It was during this period that their level of military service was decided. Class 1 and 2 which showed marked improvement up to initial 6 months, did not demonstrate substantial further improvement during follow-up period with a considerable portion stopped visiting hospital. Subjects in Class 3, who showed little or no improvement during initial 6 months, demonstrated continued improvement in this study, although their symptoms still appeared relatively severe.

Conclusions: This study suggests clinical implications for treatment plan and intervention of each subgroup classified based on MMPI-2 clinical profiles of military recruits who might show maladjustment to serve. The long-term continuous treatment for Class 3 patients will be needed, even after exemption from active duty.

Older Adults' Knowledge of Geriatric Depression and Its Related Factors

Y.-F. Tsai^{1*} and S.-H. Lee²

¹School of Nursing, Chang Gung University and ²Department of Psychiatry, Chang Gung Memorial Hospital at Linkou, Tao-Yuan, Taiwan, Province of China

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.570

Introduction: Even though depression is a severe health issue among older adults, few studies have explored their knowledge of geriatric depression.

Objectives: This study aimed to explore older adults' knowledge of geriatric depression and its related factors.

Methods: A cross-sectional survey was conducted. Older adults were recruited by convenience from outpatient clinics of three hospitals in Taiwan.

Results: A total of 327 older adults participated in this study. Their mean score of knowledge was 7.73 (SD=2.12, Range=2-12) on an 18-item knowledge scale, indicating poor knowledge of geriatric depression. Females had significantly higher geriatric depression knowledge scores than males ($t=2.50$, $p=0.01$). Junior and senior high school graduates had significantly higher geriatric depression knowledge scores than illiterate and primary school graduates ($F=10.23$, $p<0.01$). In addition, their geriatric depression knowledge scores also differed by religious belief ($F=4.91$, $p<0.01$), living status ($F=8.64$, $p<0.01$), and perceived health condition ($F=8.81$, $p<0.01$). Buddhists had significantly higher geriatric depression knowledge scores than Taoists. Living with partners and perceiving their health status as fair and good tended to have higher geriatric depression knowledge scores than their counterparts. However, their geriatric depression knowledge scores did not significantly correlate with their mean scores of social distance toward older adults with depression.

Conclusions: Older adults tended to have poor geriatric depression knowledge. Improving their knowledge shall be an urgent task. Our results may serve as references for developing further depression prevention.

The biology of mental pain: a systematic review to map the different expressions, definitions, hypotheses, experimental paradigms, investigation methods and candidate biomarkers of mental pain in human subjects

E. K. Duranté^{1,2*}, A. Ribeiro^{1,2}, L. Gaspard-Boulinc³,
C. Lemogne^{1,2,4}, I. Boutron^{1,2} and A. Chevanec^{1,2}

¹METHODS Team, Université de Paris Cité, CRESS, INSERM UMR 1153; ²Centre d'Épidémiologie Clinique, Hôpital Hôtel Dieu, AP-HP; ³IBENS, École Normale Supérieure and ⁴Department of Psychiatry, Hôpital Hôtel Dieu, AP-HP, Paris, France

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.571

Introduction: Mental pain is a transdiagnostic symptom, predictive of suicide and reported as a critical outcome by patients. A previous systematic review of epidemiological and clinical research has shown a lack of consensual definition of mental pain in clinical research and high heterogeneity across the different measurement instruments of mental pain. Up today there is no systematic review synthesizing all published biological investigations on mental pain.

Objectives: This study aims to map the field of biological investigations of mental pain in human to identify what and how

biomarkers are investigated with a meta-research approach, by providing a critical appraisal of the terms and definitions of mental pain, the studies' hypotheses, the experimental paradigms used to induce or mimic mental pain and the measurement instruments used to measure mental pain.

Methods: We conducted a systematic review (compliant with PRISMA guidelines) of all primary research reporting to investigate candidate biomarkers of mental pain in human subjects as stated by the authors. We searched from inception to June 23rd, 2022, the 3 databases MEDLINE, Web of Science and EMBASE. We extracted the study characteristics (e.g., year of publication, population, etc.), the terms used for meaning mental pain, the definition of mental pain, the method to induce mental pain and its rationale, the hypotheses and aims, the measurement instruments of mental pain, the candidate biomarkers, and their method of investigation. We performed descriptive statistics of the sample's characteristics and the extracted data, a qualitative analysis of the definitions, hypothesis, aims and experimental paradigms, and a data visualization linking candidate biomarkers, experimental paradigms, and their investigation methods.

Results: The search retrieved 5685 papers of which we included 72 primary research publications constituting 78 distinct research studies. Only 37.5% of studies reported a definition of mental pain. 11.5% of studies did not show a measurement instrument of mental pain. The Cyberball (a social exclusion paradigm) was the most frequently used paradigm in experimental studies (62.7%). The cingulate cortex was the most frequently investigated biomarker category (15.3% of all candidate biomarkers), with fMRI as the most frequent investigation method (53.7% of all investigation methods).

Conclusions: The field of biological investigations on mental pain shows a marked heterogeneity of definitions, terms, hypotheses, experimental paradigms, and measurement instruments, with an over-representation of the construct of social pain and the Cyberball. These could compromise the comparison and combination of studies results in evidence synthesis and their translation into clinical practice.

*Corresponding author.

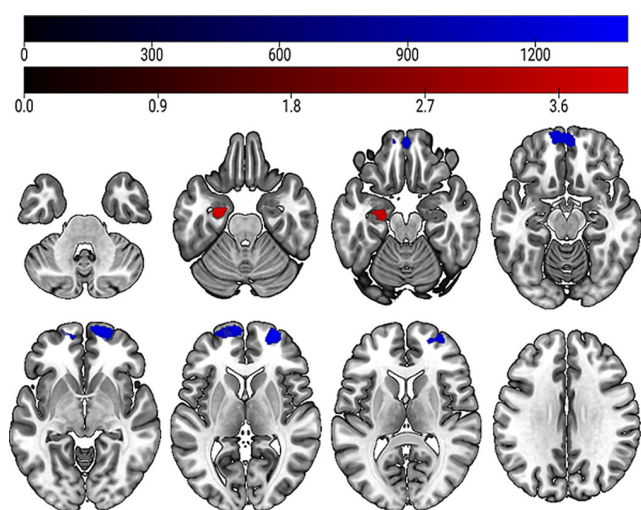

doi: 10.1192/j.eurpsy.2024.572

Introduction: The clinical high-risk state for psychosis (CHR) is associated with alterations in grey matter volume (GMV) in various regions such as the hippocampus (Vissink *et al.* BP:GOS 2022; 2(2) 147-152). Within the scope of the North American Prodrome Longitudinal Study (NAPLS-2; Cannon *et al.* AM J Psychiatry 2016; 173(10), 980-988), a publicly available risk calculator based on clinical variables was developed to assess the likelihood of individuals to transition to psychosis within a 2-year period.

Objectives: In the current study, we aim to examine the association between GMV and NAPLS-2 risk scores calculated for individuals with CHR and recent-onset depression (ROD), taking a transdiagnostic approach on the transition to psychosis.

Methods: The sample consisted of 315 CHR ($M = 23.85$, $SD = \pm 5.64$; female: 164) and 295 ROD ($M = 25.11$, $SD = \pm 6.21$; female: 144) patients from the multi-site Personalised Prognostic Tools for Early Psychosis Management (PRONIA) Study (Koutsouleris *et al.* JAMA Psychiatry 2018; 57(11), 1156-1172). Risk scores were calculated using the six clinical and neurocognitive variables included in the NAPLS-2 risk calculator that were significant for predicting psychosis. Further, we derived smoothed GMV maps from T1-weighted structural magnetic resonance imaging using a full width at half maximum kernel size of 8 mm. We employed a multiple regression design in SPM12 to examine associations between risk scores and GMV. On the whole-brain level, we calculated permutation-based threshold-free cluster enhancement (TFCE) contrasts using the TFCE toolbox. Additionally, we calculated t-contrasts within a region-of-interest (ROI) analysis encompassing the hippocampus. All results were thresholded at $p < 0.05$ with family wise error correction to address multiple comparisons.

Results: Our analysis revealed that linear GMV increases in the right middle and superior frontal gyrus ($k_E = 2726$ voxels) were significantly associated with higher risk for psychosis transition within two years (see figure 1, highlighted in blue). In the ROI analysis, we found a significant negative linear association between GMV decreases in the left hippocampus ($k_E = 353$ voxels) and higher risk for psychosis transition (see figure 1, highlighted in red).

Image:

Conclusions: GMV reductions in the hippocampus have frequently been observed in CHR and psychosis patients (Vissink *et al.* BP:GOS 2022; 2(2) 147-152), therefore our results further highlight the crucial role of this region in the progression of the disease. There is limited evidence on GMV increases in CHR patients. However, the GMV increase we found in the frontal pole may reflect compensatory mechanisms of the brain in the development of psychosis. In addition, we were able to provide biological validation of the NAPLS-2 risk calculator and its assessment of risk for transition to psychosis.

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.573

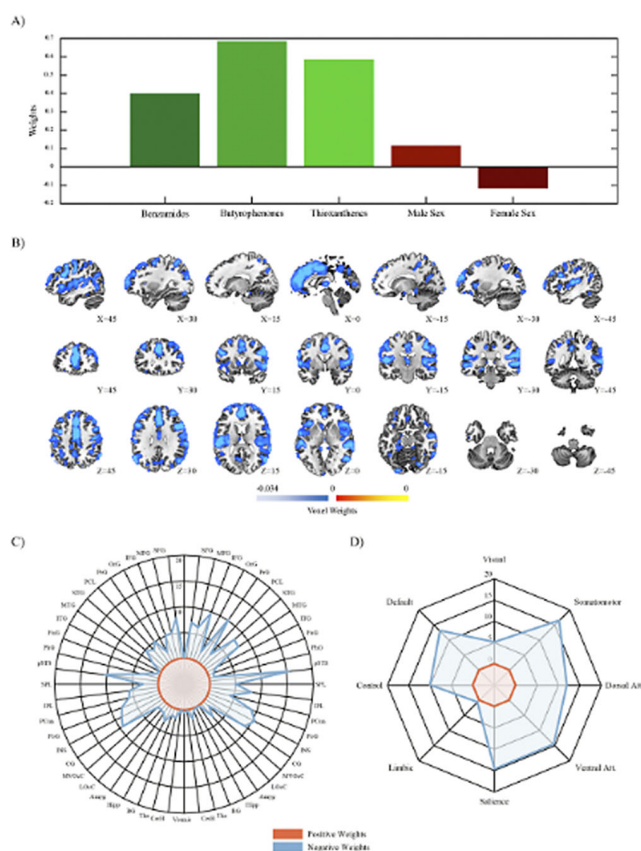

Introduction: Psychiatric drugs, including antipsychotics and antidepressants, are widely prescribed, even in young and adolescent populations at early or subthreshold disease stages. However, their impact on brain structure remains elusive. Elucidating the relationship between psychotropic medication and structural brain changes could enhance the understanding of the potential benefits and risks associated with such treatment.

Objectives: Investigation of the associations between psychiatric drug intake and longitudinal grey matter volume (GMV) changes in a transdiagnostic sample of young individuals at early stages of psychosis or depression using an unbiased data-driven approach.

Methods: The study sample comprised 247 participants (mean [SD] age = 25.06 [6.13] years, 50.61% male), consisting of young, minimally medicated individuals at clinical high-risk states for psychosis, individuals with recent-onset depression or psychosis, and healthy control individuals. Structural magnetic resonance imaging was used to obtain whole-brain voxel-wise GMV for all participants at two timepoints (mean [SD] time between scans = 11.15 [4.93] months). The multivariate sparse partial least squares (SPLS) algorithm (Monteiro *et al.* JNMEDT 2016; 271:182-194) was embedded in a nested cross-validation framework to identify parsimonious associations between the cumulative intake of psychiatric drugs, including commonly prescribed antipsychotics and antidepressants, and change in GMV between both timepoints, while additionally factoring in age, sex, and diagnosis. Furthermore, we correlated the retrieved SPLS results to personality domains (NEO-FFI) and childhood trauma (CTQ).

Results: SPLS analysis revealed significant associations between the antipsychotic classes of benzamides, butyrophenones and thioxanthenes and longitudinal GMV decreases in cortical regions including the insula, posterior superior temporal sulcus as well as cingulate, postcentral, precentral, orbital and frontal gyri (Figure 1A-C). These brain regions corresponded most closely to the dorsal and ventral attention, somatomotor, salience and default network (Figure 1D). Furthermore, the medication signature was negatively associated with the personality domains extraversion, agreeableness and conscientiousness and positively associated with the CTQ domains emotional and physical neglect.

Image:

Conclusions: Psychiatric drug intake over a period of one year was linked to distinct GMV reductions in key cortical hubs. These patterns were already visible in young individuals at early or sub-threshold stages of mental illness and were further linked to childhood neglect and personality traits. Hence, a better and more in-depth understanding of the structural brain implications of medicating young and adolescent individuals might lead to more cautious, sustainable and targeted treatment strategies.

Humanitarian Love in Values-Based Practice and Health Professionals' Psychosocial Outcomes: Systematic Review

A. L. Batiridou^{1*}, E. Dragioti¹, S. Mantzoukas² and M. Gouva¹

¹Research Laboratory of Psychology of Patients, Families and Health Professionals, Department of Nursing, School of Health Sciences and
²Research Laboratory of Integrated Health, Care and Well-being, Department of Nursing, School of Health Sciences, University of Ioannina, Ioannina, Greece

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.574

Introduction: The literature on Values-Based Practice often neglects the significance of love in therapeutic interactions, sometimes treating it as taboo or crossing professional boundaries.

Objectives: This systematic review investigates the role of humanitarian love in the lives of healthcare professionals and its psychosocial impact, aiming to establish it as a core value in values-based practice.

Methods: We conducted a PRISMA 2020-compliant systematic review, searching databases (CINAHL, PubMed, Scopus) from inception to April 3, 2023, using PEO elements: health professionals (P), love (E), psychosocial impact (O). Two independent reviewers conducted screening, data extraction, and bias assessment. A narrative synthesis of the data was applied. The selection process is presented in Figure 1.

Results: Eight articles met the inclusion criteria, comprising 1,948 participants (median age: 28.55). Humanitarian love encompassed compassionate love, self-compassion, and affection. Humanitarian love showed a negative correlation with burnout, compassion fatigue, self-judgment, and secure attachment, while positively correlating with professional well-being, professional commitment, self-care, patience, diversity acceptance, spirituality, self-kindness, and ethical values. Humanitarian love significantly influenced healthcare professionals' psychosocial well-being. The main outcomes are presented in Figure 2.

Image:

Figure 1. PRISMA flowchart of selection process

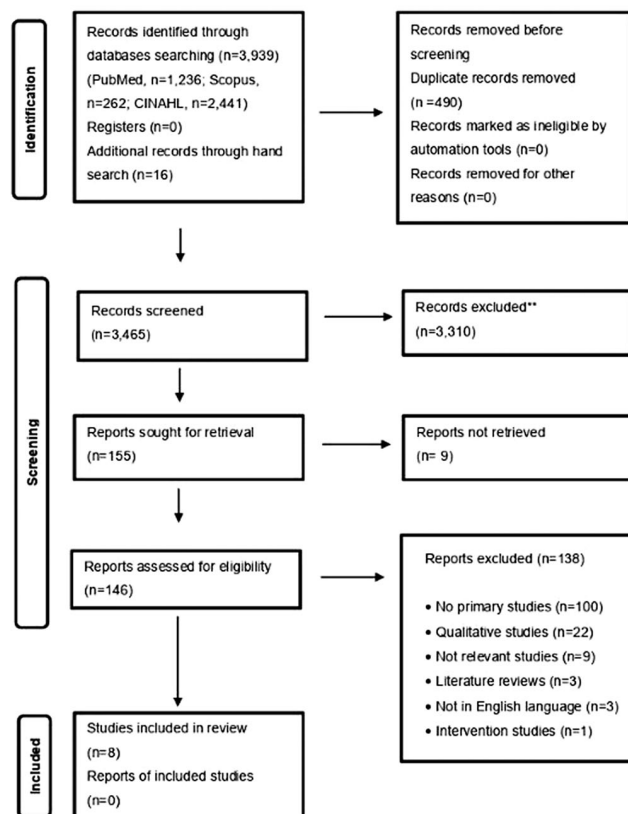

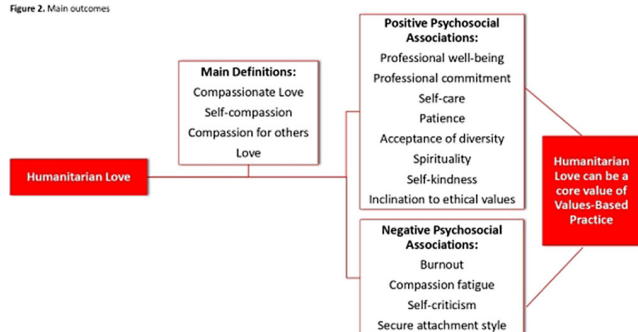

Image 2:

Figure 2. Main outcomes

Conclusions: This review highlights humanitarian love's potential to enhance the psychosocial well-being of healthcare professionals and emphasizes its significance as a core value in values-based practice. Cultivating humanitarian love among healthcare professionals through research and interventions could bolster their resilience, job satisfaction, and overall fulfillment in their roles.

Treatment adherence across different psychiatric disorders: findings from a large patient cohort

N. Girone^{1,*}, B. Benatti^{1,2}, M. Cocchi¹, F. Achilli¹, C. Viganò¹, M. Vismara¹ and B. Dell'Oso^{1,2,3}

¹Department of Mental Health, Sacco University Hospital; ²Center for Neurotechnology and Brain Therapeutic, "Aldo Ravelli" Center, University of Milan, Milan, Italy and ³Department of Psychiatry and Behavioral Sciences, Bipolar Disorders Clinic, Stanford University, California, United States

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.575

Introduction: Medication adherence was defined by the WHO as "the extent to which a person's behavior coincides with the medical advice given" (WHO, 2003). Existing literature indicates that approximately 49% of patients with major psychiatric disorders do not fully adhere to their prescribed psychopharmacological therapy (Colom et al, 2002). Non-adherence can lead to partial therapeutic responses or treatment resistance, increased risk of relapse, re-hospitalization, elevated suicide risk, and overall poorer functioning, thereby compromising the patient-doctor therapeutic relationship (Garcia et al, 2016).

Objectives: The aim of the present study was to assess potential differences in terms of clinical features related to adherence to treatment in a large cohort of psychiatric patients of an Italian psychiatric department.

Methods: The study included 307 psychiatric patients, of any gender or age, diagnosed with unipolar depression (UD), bipolar

depression (BD), anxiety disorders (AD), schizophrenic spectrum disorders (SS) or a primary diagnosis of personality disorders (PD), based on DSM-5 criteria. Patients were consecutively recruited from the Department of Psychiatry at Luigi Sacco University Hospital, in Milan. The patient's adherence to treatment was evaluated using the Clinician Rating Scale (CRS), with a cut-off of ≥ 5 defining adherence subgroups (A+: score ≥ 5 ; A-: score < 5). Comparative and predictive analysis were performed for the whole sample and the two adherence subgroups.

Results: Overall, nearly one-third of the whole sample reported suboptimal medication adherence. Specifically, rates were approximately 35.3% and 32.7% for BD and SS, respectively, followed by 30.8% for PD, 28% for AD and, 20.3% for UD (see Figure 1). Patients with A- showed significantly higher current substance abuse (17.8% vs 4.5%, $p < .001$), along with a higher rate of lifetime substance abuse, although with a trend towards significance (31.5% vs 20.5%; $p = .057$). Moreover, the A- group had a significantly higher number of lifetime hospitalizations (1.35 ± 1.8 vs 0.73 ± 1.11 ; $p < .001$) and higher rate of previous psychotropic treatment dropouts compared to the A+ group (90% vs. 36.2%; $p < .001$, see Figure 2).

Image 2:

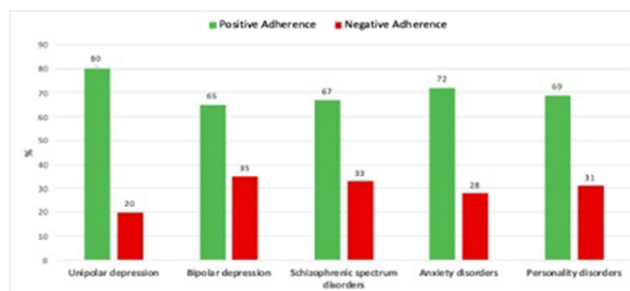

Image 2:

Conclusions: Approximately one-third of the whole sample reported a suboptimal medication adherence, with varying rates across different diagnoses. Current and lifetime substance abuse appears to be an unfavorable transdiagnostic factor. Additionally, severe outcomes such as increased hospitalizations and a more

acute disease presentation are linked to poorer adherence. Recognizing the characteristics of adherence patterns within specific diagnostic categories is crucial for designing precise interventions to enhance patient outcomes and optimize the overall effectiveness of treatment.

Linking Digital Traits from Facial Expression, Voice, and Head Motion to Montgomery–Åsberg Depression Rating Scale Subscales

Z. Zhu¹, Y. Wu¹, J. Seidel², D. Roy¹ and E. Salzmänn^{2*}

¹Boehringer Ingelheim Pharmaceuticals, Inc., CT, United States and

²Boehringer Ingelheim International GmbH, Ingelheim am Rhein, Germany

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.576

Introduction: The 10-item Montgomery–Åsberg Depression Rating Scale (MADRS) measures different dimensions of depression symptomatology. Digital traits may generate deeper understanding of the MADRS subscales and provide insights about depression symptomatology.

Objectives: To identify digital traits that predict specific MADRS subscales and ascertain which digital traits are important for which MADRS subscales.

Methods: During a Phase II decentralised clinical trial in major depressive disorder (MDD), patients completed the MADRS and used AiCure (LLC, New York, NY, USA), a smartphone application, to complete image description tasks at baseline. Digital measurements identified from the literature as relevant to MDD symptomatology were conducted using audio and video data derived from the image description tasks. Digital measurements included speech (rate, sentiment and first-person singular pronouns), vocal acoustics (intensity, pause fraction and fundamental frequency), facial expressivity (regional facial movement) and head pose (Euclidean and angular head movement). Digital traits analysis involved data pre-processing followed by machine learning (ML) using Elastic Net, Decision Tree, and Random Forest models; model performance was evaluated using 5-fold cross-validation and mean absolute error (MAE). Important digital traits were calculated by percentage change in MAE after permuting a specific variable. Important digital traits for the MADRS Apparent Sadness subscale score were mapped to defined, interpretable domains.

Results: The ML model predictions varied for different MADRS subscales (Table). Overall, Elastic Net and Random Forest models

outperformed Decision Tree across all subscales scores other than suicidal thoughts. Half of the literature-based digital traits contributed to the prediction of ≥ 1 MADRS sadness sub-scale score. The important digital traits for the Apparent Sadness subscale score could be mapped to 4 domains (Figure); this aligned with findings from the literature.

Image:

Table. Machine learning model performance on MADRS Total Score and subscale scores, MAE (standard error)

MADRS Scales (baseline)	Elastic Net	Decision Tree	Random Forest
Apparent Sadness	0.80 (0.10)	1.07 (0.20)	0.83 (0.10)
Concentration Difficulties	0.80 (0.26)	1.01 (0.13)	0.84 (0.10)
Inability to Feel	0.79 (0.16)	1.04 (0.22)	0.81 (0.18)
Inner Tension	0.82 (0.33)	1.05 (0.31)	0.82 (0.33)
Lassitude	0.78 (0.20)	0.92 (0.30)	0.77 (0.16)
Pessimistic Thoughts	0.87 (0.16)	1.03 (0.21)	0.85 (0.22)
Reduced Appetite	0.85 (0.32)	0.75 (0.08)	0.75 (0.26)
Reduced Sleep	0.82 (0.11)	0.81 (0.24)	0.81 (0.13)
Reported Sadness	0.61 (0.24)	0.72 (0.25)	0.60 (0.27)
Suicidal Thoughts	0.97 (0.13)	0.88 (0.22)	0.98 (0.08)
MADRS Total	0.83 (0.14)	0.96 (0.20)	0.85 (0.17)

Green text indicates best performance (MAE [SE]) across the three machine learning methods for each subscale; highlighted text indicates subscales with top three lowest total MAE (SE).

MADRS: Montgomery–Åsberg Depression Rating Scale; MAE, mean absolute error; SE, standard error

Image 2:

Figure. Important traits for MADRS Apparent Sadness subscale score at baseline

Conclusions: Digital traits collected from patients with MDD were able to predict certain MADRS subscales better than others.

Philosophy and Psychiatry

EPP0427

Exploring the Philosophy of Mind and Its Implications for Psychiatry

M. Gomes^{1*}, A. Fernandes², P. Veloso¹ and V. Santos³

¹Psychiatry; ²Hospital de Braga, Braga and ³Psychiatry, Centro Hospitalar Universitário Cova da Beira, Covilhã, Portugal

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.577

Introduction: Philosophy of mind grapples with fundamental questions concerning the Consciousness, the Mind-body problem, the Identity, and Free will (as opposed to Determinism). In the context of psychiatry, this philosophical groundwork provides a conceptual framework for comprehending the intricate workings of the human psyche.

Objectives: We aim to discuss how the philosophical investigation of the mind influence and enhance psychiatrists understanding of psychiatric disorders and patient-centered care.

Methods: Review of the literature.

Results: Philosophy of mind explores what it means to be conscious and the nature of subjective experience. This includes questions about the “hard problem” of consciousness, that refers to the difficulty of explaining why and how physical processes in the brain give rise to subjective, first-person experiences (or qualia). The “hard problem” posits that even if we knew everything about the brain’s physical processes and how they relate to cognitive functions, we would still lack an explanation for why these processes give rise to subjective consciousness. Psychiatry often deals with individuals who experience disturbances in their subjective conscious experiences, so the “hard problem” perspective allows psychiatrists to appreciate the diversity of conscious experiences and to empathize with their patients’ unique mental worlds.

Related with the previous topic is the mind-body problem. The elucidation of this problem highlights the challenge of reconciling mental phenomena with neurobiological processes. Integrating philosophical notions of dualism, materialism, and emergentism into psychiatric practice is essential for addressing the holistic nature of mental health.

Concerning to philosophical perspectives on personal identity, questions about the continuity of identity, selfhood, and the role of narrative in shaping one’s sense of self contribute to a deeper understanding of disorders like dissociative identity disorder, borderline personality disorder and even psychosis.

Furthermore, philosophical discussions on free will and determinism are pertinent to psychiatric ethics and the treatment of individuals with behavioral disorders, informing the ethical considerations surrounding involuntary psychiatric hospitalization, medication administration, and the delicate balance between autonomy and paternalism in psychiatric care.

Conclusions: Philosophy of mind provides psychiatry with a rich conceptual landscape, offering insights into the nature of mental phenomena. As our understanding of the brain and consciousness continues to evolve, the philosophy of mind remains an evolving area of philosophical inquiry.

EPP0429

Teaching clinical phenomenology in a post-graduate medical training program

L. Mehl-Madrona

Native Studies, University of Maine, Orono, United States

doi: 10.1192/j.eurpsy.2024.578

Introduction: Patient care suffers when practitioners do not understand the patient’s experience of the illness. This is especially true in psychiatry relative to patients having learned the jargon and studying the diagnostic criteria for various mental disorders using internet search engines, especially Google. Patients more commonly present with a list of symptoms that match the checklist for their self-diagnosis. Their experience may be quite different from the words they use to present their symptoms to medical personnel. More than ever, psychiatric providers need to unpack the words their patients use to discover the actual experience. K. Toombs has written exquisitely about clinical phenomenology in the context of her diagnosis of multiple sclerosis and her negotiation of a medical system that largely ignored her lived experience. This algorithmic, checklist approach to human suffering derives from an understanding of clinical practice in which the practitioner applies scientific knowledge of the bodily processes of diseases, recognizing those diseases by inquiring about the presence of symptoms characterizing those diseases and then rendering treatments based upon statistical studies (preferably randomized, controlled trials) of large groups of individuals. Within this approach, little need exists to encounter the person with the disease as an actual human being, an Other in the sense of Levinas. This approach suffers because even history-taking requires an encounter with an Other in which the internal, private experience of this Other must be heard and made part of the clinical process. This approach can ignore the role of the doctor-patient relationship and the clinical encounter in symptom relief.

Objectives: To describe an educational program in clinical phenomenology that was well received by trainees who rated that it improved their practice.

Methods: In this presentation, we will describe our efforts at teaching clinical phenomenology and psychiatry within a residency training program, in which we encourage trainees to develop deeper listening skills through conducting life story interviews, motivational interviewing techniques, and narrative approaches in which they search for the metaphors underlying the patients’ illness. We will describe factors influencing trainees’ acceptance or rejection of these approaches and the change in the culture of our training program and clinic that have arisen from their implementation.

Results: One hundred and twenty residents have taken this course. Eighty-eight percent reported improved clinical skills and ability to relate to patients.

Conclusions: The practice of medicine does not exist independently from the relationships in which medicine is practiced and a thorough understanding of the lived experience and experience of the patient is necessary for accurate diagnosis, psychiatric or medical, and for discovery of a treatment approach with the patient.

Antioxidant and metabolic adjunctive treatment in late onset psychosis

T. Prokhorova*, I. Boksha, O. Savushkina, E. Tereshkina, E. Vorobyeva and G. Burbaeva

FSBSI "MENTAL HEALTH RESEARCH CENTRE", Moscow, Russian Federation

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.579

Introduction: Basing on our previous findings of significant additional gain obtained from usage of adjunctive antioxidant medicine added to antipsychotic+antidepressant therapy in late-onset schizophrenia-like psychoses (LOP), the group often suffering of comorbid pathologies and experiencing substantial side-effects of drugs, we spread our approach to try "metabolic" medicines as adjunctives in LOP.

Objectives: To reveal biochemical parameters of the blood cells which might be used for distinguishing subgroups of patients suffering with LOP for whom various adjunctive therapy (antioxidant, metabolic) would be advantageous.

Methods: The study included 59 patients 50-89 years old, with LOP (onset after 40 years), and 38 healthy peoples 51 – 84 years old. The activities of glutamate dehydrogenase (GDH), glutathione reductase (GR), and glutathione S-transferase (GST) were determined spectrophotometrically in erythrocytes and platelets. Scores by PANSS were evaluated twice: before and on the 28-th day of antipsychotic treatment.

Results: Samples from control group were used for determination of the control ranges for levels of studied enzymatic activities. Enzymatic activity levels were analyzed in three groups of patients: group Gr1 (n=16) treated without adjunctive therapy, and two other groups (Gr2 and Gr3) treated with adjunctive medicines: antioxidant 2-ethyl-6-methyl-3-hydroxypyridine succinate (Gr2, n=20), or "metabolic" medicines citicoline/cerebrolysin/cortexin/actovegin/gliatilin (Gr3, n=23).

As compared with controls, activity of erythrocyte GR was decreased at baseline and after the treatment course in all patients' groups ($p < 0.01$); in Gr2 significant decreases in baseline platelet GDH and GST activities were observed ($p = 0.005$). Different significant links between biochemical parameters and scores by clinical scales before treatment were observed: in Gr1, erythrocyte GST activity positively correlated with scores by PANSS-Neg ($R = 0.61$, $p = 0.012$), by PANSS-Psy ($R = 0.54$, $p = 0.032$), and by PANSS ($R = 0.62$, $p = 0.010$), in Gr2, erythrocyte GST activity positively correlated with scores by PANSS-Pos ($R = 0.53$, $p = 0.016$), by PANSS-Psy ($R = 0.52$, $p = 0.015$), and by PANSS ($R = 0.60$, $p = 0.005$), in Gr3, platelet GR activity positively correlated with PANSS-Pos ($R = 0.50$, $p = 0.014$).

Conclusions: We have confirmed the additional favor (decrease in side-effect severity) obtained by distinct patient groups when treated with adjunctive antioxidant or "metabolic" therapy. Moreover, correlations revealed in the patient subgroups between enzymatic activities and scores by psychometric scales enable revealing those biochemical markers measurement of which facilitate

differentiating the patients for whom the adjunctive medicines to antipsychotic+antioxidant treatment can positively influence the treatment outcome.

M2 macrophage-derived soluble factors enhance neuronal density in the frontal cortex of depression-like mice

E. Markova^{1*}, I. Rashchupkin¹, E. Shevela¹, E. Serenko¹, T. Amstislavskaya², A. Ostanin¹ and E. Chernykh¹

¹State Research Institute of Fundamental and Clinical Immunology and ²State Research Institute of Neurosciences and Medicine, Novosibirsk, Russian Federation

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.580

Introduction: Chronic inflammation in depression is associated with decreased levels of neurotrophic factors and suppressed neurogenesis. We have previously shown that intranasal therapy with soluble factors from M2 macrophages polarized by interaction with apoptotic cells in serum deprivation conditions (M2(LS); LS - low serum) and characterized by anti-inflammatory and pro-regenerative activity leads to the correction of the behavioral pattern in mice with a depression-like state.

Objectives: The present study focuses on the effect of M2(LS) macrophages on neuronal density in the frontal cortex and hippocampus of depression-like mice.

Methods: Depressive-like state was formed in passive male mice (CBAx57Bl/6J) as a result of repeated experience of defeat in agonistic interactions with aggressive partner during 20 days (the sensory contact model). Depression-like mice were then treated intranasally with M2(LS) macrophages conditioned medium for 7 days. After that, the number of mature neurons in the frontal cortex and hippocampus was assessed using Nissl staining.

Results: The neuronal density in the pyramidal layer of the frontal cortex was significantly lower in depression-like mice than that in the intact control group of mice ($p = 0.047$). At the same time, the number of neurons in the experimental group of mice that received soluble M2(LS) factors, was higher than that in depressive-like untreated control mice ($p = 0.003$) and was comparable to that in the intact group of mice. At the same time the neuronal density in the CA1 and CA3 hippocampal areas did not change in depression-like mice following intranasal treatment with conditioned medium of M2(LS) macrophages.

Conclusions: The data obtained may indicate the neuroprotective effect of M2(LS) macrophages in the stress-induced depression model, which is realized through soluble factors and manifests itself in an increase of the pyramidal neurons density in the frontal cortex.

*Corresponding author.
doi: 10.1192/j.eurpsy.2024.581

Introduction: Increased plasma concentrations of proinflammatory cytokines are found in chronic schizophrenia patients, patients with first episode and in individuals with high risk for psychosis. The most replicated findings are increased concentrations of IL-6, TNF-α and IL-1β through different phases of the disorder while the results for two important proinflammatory cytokines IL8 and IFN-γ were not consistent.

Objectives: Primary objective of this study was to assess differences in concentrations of IL-8, IFN-γ and IL-1β between schizophrenia patients and healthy controls, Secondary objective was to explore differences in first episode drug naïve patients.

Methods: We measured plasma concentrations of IL-8, IFN-γ and IL-1β in 64 healthy controls and 64 schizophrenia patients during acute exacerbation and remission phase. 25% were drug naïve first episode schizophrenia patients. The patients were matched by age, sex and body mass index and exclusion criteria included obesity class 2 or higher, any concomitant organic mental or neurological disorder, acute or chronic inflammatory disease, and use of immunomodulatory drugs or psychoactive substances.

Results: Levels of IL-8 were significantly lower in patients with schizophrenia in acute phase and remission compared to healthy controls (p=0,009 for acute phase and p=0,020 for remission). There was no significant difference in the levels of INF-γ and IL-β between schizophrenia in acute phase and remission and healthy controls (p>0,05). In schizophrenia patients there was no difference in the levels of INF-γ, IL-β and IL-8 between acute phase, remission and healthy controls (p>0,05). There was no difference in plasma levels of IL-8, IFN-γ and IL-1β between first episode drug naïve and previously treated schizophrenia patients.

Conclusions: Our research did not find disturbance of plasma levels of IFN-γ and IL-1β in schizophrenia patients, although the increase of IL-1β was the most replicated finding up to date. Interestingly and contrary to expected the finding of significantly decreased levels of IL-8 in schizophrenia patients requires further research since IL-8 plays a vital role in the inflammatory pathway and may be implicated in cognitive dysfunction.

¹Psychiatry, Ankara University, ANKARA, Türkiye; ²Psychiatry, Specil Psychiatric Hospital Department of Psychiatry Podvrsanska, psychiatry, Vrsac, Serbia and ³Psychiatry, mamak devlet hastanesi, ANKARA, Türkiye

*Corresponding author.
doi: 10.1192/j.eurpsy.2024.582

Introduction: A growing body of evidence has shown the association between autoimmune thyroiditis and mental illness (Rege *et al.* AUS N J S Psychiatry 2013; 300 141-154). Identifying the neuropsychiatric features associated with thyroid antibody positivity could have significant implications for diagnostic and therapeutic strategies. However, the link between anti-thyroid antibodies and precise underlying pathophysiology requires future research.

Objectives: The aim of the present study was to conduct a retrospective evolution in patients diagnosed with schizophrenia spectrum disorder and affective disorder who were screened for anti-thyroid antibodies at the time of their hospitalization and to investigate neuropsychiatric features of anti-thyroid antibody-positive patients.

Methods: A total of 143 inpatients diagnosed with schizophrenia spectrum disorders and affective disorders between 2021 and 2023 were screened for anti-thyroid antibodies such as thyroid peroxidase (TPO) and thyroglobulin (TG). All patients were women. In order to elucidate the subsequent neuropsychiatric clinical features of individuals with positive anti-thyroid antibodies, the retrospective examination was conducted based on Neuropsychiatric Inventory-Q (NPI-Q) and DSM-V diagnostic criteria utilized at the time of hospitalization.

Results: The main age of the patients was 48.2 (SD 10.4). A total of 143 inpatients with schizophrenia spectrum disorders and affective disorders were screened for anti-thyroid antibodies at the time of their hospitalizations. %23.1 (n=33) tested positive for at least one of the anti-TG or anti-TPO. All patients were euthyroid. The neuropsychiatric diagnoses are shown in Table 1. The most common neuropsychiatric features assessed by NPI-Q are shown in Table 2. 12.1% (n=4) of all patients were treated with IV steroid Pulse therapy.

Table 1. Neuropsychiatric syndrom-level diagnostic patterns according to DSM-V

Patients with positive thyroid autoantibodies (n=33)	
Manic syndrome	10 (30.3%)
Psychotic Syndrome	19 (57.6%)
Depression syndrome	5 (15.2%)
Catatonia	10 (30.3%)
Exited	6 (18.2%)
Stuporus	2 (6.1%)
Fluctuating	2 (6.1%)

Table 2. The most common clusters of Neuropsychiatric features

NPI-Q	Positive Thyroid Autoantibodies (n=33)
Delusion	15 (45.4%)
Agitation/Aggression	14 (42.4%)
Irritability	14 (42.4%)
Motor abnormality	14 (42.4%)
Sleep disorder	15 (45.4%)
Appetite/Eating	14 (42.4%)

Conclusions: In particular, in a subset of schizophrenia spectrum disorder or affective disorder patients with positive anti-thyroid antibodies may indicate autoimmunity, especially in cases where catatonic symptoms dominate the clinical presentation.

Features of the spectrum of immune markers in patients with juvenile depression with clinically high risk of psychosis

S. A. Zozulya*, M. A. Omelchenko, I. N. Otman, Z. V. Sarmanova, V. V. Migalina, V. G. Kaleda and T. P. Klyushnik

Mental Health Research Centre, Moscow, Russian Federation

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.583

Introduction: Identification of biomarkers associated with the risk of psychosis manifestation in juvenile patients with depression may contribute to a better understanding of the pathogenesis of mental disorders and early diagnosis.

Objectives: To determine the level of pro-inflammatory and anti-inflammatory cytokines and other inflammatory indicators in the plasma of juvenile patients with depression and clinically high risk of psychosis, and to study the correlation of these markers with the severity of psychopathologic symptoms.

Methods: 80 young men aged 16-24 years with the first depressive episode (F32.1-2, F32.38, F32.8) were examined. Based on the severity of attenuated psychotic symptoms (APS) in the structure of depression according to the SOPS scale, all patients were divided into two groups - with clinically high risk of psychosis (n=58) and with depression without APS (n=22). The HDRS-21 and SANS scales were also used for psychometric assessment. Serum level of cytokines TNF- α , IL-6, IL-8, IL-10, TNF- α /IL-6 ratio, TNF- α /IL-10 ratio, leukocyte elastase (LE) and α 1-proteinase inhibitor (α 1-PI) activity, C-reactive protein (CRP) concentration, and the level of autoantibodies to S-100B protein were determined.

Results: Both groups of patients showed a high level of inflammation assessed by LE and α 1-PI activity ($p>0.05$). Significantly higher level of IL-6 ($p=0.03$), CRP concentration ($p=0.026$) and TNF- α /IL-10 ratio ($p=0.032$) were found in patients with clinically high risk of psychosis. This group was also characterised by high level of autoantibodies to the S-100B protein compared to patients with depression without APS ($p=0.048$).

In the high clinical risk group, correlations were found between the SOPS positive subscale score and the level of TNF- α ($R=0.32$, $p=0.017$), IL-8 ($R=-0.3$, $p=0.034$), TNF- α /IL-6 ratio ($R=0.30$, $p=0.021$) and TNF- α /IL-10 ratio ($R=0.32$, $p=0.014$). The SOPS negative subscale score correlated with CRP concentration ($R=0.3$, $p=0.043$). The SOPS total score correlated with TNF- α /IL-10 ratio ($R=0.31$, $p=0.021$). In this group of patients, the level of IL-10 was found to correlate with the duration of the disease ($R=0.48$, $p<0.001$). In patients with depression without APS, the level of IL-6 was correlated with the severity of depression according to the HDRS scale, and the level of TNF- α was associated with the duration of the depressive episode ($R=0.51$, $p=0.029$).

Conclusions: The obtained results confirm the involvement of inflammation in the development of juvenile depression. Qualitative and quantitative characteristics of the spectrum of immune markers and the cytokine profile, and correlations with the severity of psychopathologic symptoms were revealed in patients with clinically high risk of psychosis.

Immunological predictors of rhythmic transcranial magnetic stimulation (rTMS) efficiency in patients with treatment-resistant schizophrenia

S. A. Zozulya*, A. N. Pomytkin, D. V. Tikhonov, V. G. Kaleda and T. P. Klyushnik

Mental Health Research Centre, Moscow, Russian Federation

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.584

Introduction: Model and clinical studies demonstrate the efficiency of rhythmic transcranial magnetic stimulation (rTMS) in diseases associated with neuroinflammation. The therapeutic potential of rTMS is related to modulation of neuroplasticity in the CNS, activation of neurogenesis and reduction of neuroinflammatory processes. Presumably, one of the factors that determines the efficiency of rTMS can be the features of the immune status of patients.

Objectives: To reveal the features of the spectrum of inflammatory markers in patients with treatment-resistant schizophrenia with different efficiency of rTMS.

Methods: 31 male patients aged 16 to 47 years (mean age 29.9 ± 8.4 years) with treatment-resistant schizophrenia who developed a first psychotic episode in adolescence (19-25 years) were examined. The course of rTMS was conducted for 3 weeks (15 sessions). Depending on the dynamics of clinical and psychometric parameters after the course of rTMS, the patients were divided into three groups: group 1 - with worsening of clinical condition (n=8); group 2 - without therapeutic effect (n=12); group 3 - with good therapeutic response (n=11). Before rTMS, leukocyte elastase (LE) and α 1-proteinase inhibitor (α 1-PI) activity, and the levels of autoantibodies to S-100B protein and myelin basic protein (MBP) in the plasma of patients were determined. The parameters of 18 healthy male donors without clinical signs of psychiatric and somatic pathology were used as controls.

Results: All groups of patients were characterised by moderate and high levels of immune system activation, determined by a complex of inflammatory and autoimmune markers. At the same time, the high level of immune system activation in patients with low MTR efficiency was associated with low LE activity in plasma (within the reference range or below the lower limit - 200.6 (168.5- 220.3) nmol/min·mL), which was not consistent with the overall level of inflammation. This group of patients also showed high levels of antibodies to MBP compared to control values ($p < 0.05$). The low LE activity can be explained by the transmigration of neutrophils from the blood to the brain due to a critical increase in the permeability of the blood-brain barrier, which is largely controlled by LE.

Conclusions: The study confirmed the participation of immune mechanisms in the formation of therapeutic resistance in schizophrenia and revealed the characteristics of the spectrum of immune markers in patients with low efficiency of rTMS.

Disclosure of Interest: None Declared

doi: 10.1192/j.eurpsy.2024.585

Introduction: The data of current research indicate the participation of systemic inflammation in the pathogenesis of endogenous psychoses. Changes in the level of peripheral immune markers are associated with the development of neuroinflammation and correlate with the severity of psychopathological symptoms detected in patients. However, the association between individual components of the immune system involved in the development of endogenous psychosis remains poorly understood.

Objectives: To study the connection between molecular and cellular components of the immune system in women with endogenous psychoses with depressive-delusional symptoms.

Methods: 32 female patients aged 23 [17; 36] years with endogenous psychoses within different nosologies (F20, F21, F31, depressive-delusional conditions) and 17 women without clinical signs of psychiatric pathology were examined. The activity of leukocyte elastase (LE), $\alpha 1$ -proteinase inhibitor ($\alpha 1$ -PI), the proportion of four subpopulations of monocytes (classical CD14+CD16-, intermediate CD14++CD16+, nonclassical CD14+CD16+ and transitional CD14+CD16-) in plasma, activity of cytochrome-c oxidase (COX), glutamate dehydrogenase (GDH), glutathione s-transferase (GST) and glutathione reductase (GR) in platelets and functional activity of complement system (faCS) in serum were determined. The PANSS scale was used to assess the severity of psychopathological symptoms.

Results: Increased activity of the inflammatory markers LE ($p = 0.033$) and $\alpha 1$ -PI ($p = 0.02$) was found in the plasma of the patients. Increased percentage of pro-inflammatory monocytes

(intermediate and transient) in plasma ($p = 0.003$) was confirmed by negative correlations between CD14++CD16- and CD14+CD16+ ($R = -0.685$, $p = 0.00002$), CD14++CD16- and CD14+CD16- ($R = -0.608$, $p = 0.0002$), CD14++CD16- and CD14+CD16+ ($R = -0.424$, $p = 0.002$). A decrease in GDH activity ($p = 0.0079$), GST activity ($p = 0.002$) and GR activity ($p = 0.0006$) was observed in patient platelets, which can reflect changes in the activity of intracellular metabolic pathways. A positive correlation was found between COX activity and $\alpha 1$ -PI ($R = 0.51$, $p = 0.025$). A significant decrease in faCS compared to control ($p = 0.0003$) and a negative correlation between faCS and GST activity ($R = -0.496$, $p = 0.011$) were observed. faCS was positively correlated with the degree of reduction in the PANSS score ($R = 0.416$, $p = 0.038$).

Conclusions: The revealed connection between molecular and cellular components of the immune system in patients with endogenous psychoses reflect activation of the systemic inflammatory response accompanied by changes in the ratio of monocyte subpopulations and impaired regulation of the complement system. The data obtained can be used to develop methods of monitoring patients taking into account their immunological features.

Logistic regression model for the prediction of asthenia development in schizophrenia based on inflammatory blood markers

S. A. Zozulya*, A. N. Simonov and T. P. Klyushnik

Mental Health Research Centre, Moscow, Russian Federation

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.586

Introduction: According to a number of authors, inflammation is involved in the development of asthenic syndrome in different diseases. The results of our own studies indicate that the main feature of the spectrum of inflammatory markers in patients with asthenic syndrome in schizophrenia is low enzymatic activity of leukocyte elastase against the background of high levels of other inflammatory markers. Presumably, the decrease in LE activity may be associated with functional exhaustion of neutrophils and/or their transmigration to the brain through the disrupted blood-brain barrier due to a long-term chronic inflammatory process.

Objectives: To create a logistic regression model for predicting the development of asthenia in schizophrenia based on the analysis of the association between leukocyte elastase (LE) and $\alpha 1$ -proteinase inhibitor ($\alpha 1$ -PI) activity in blood plasma.

Methods: A database including clinical and demographic parameters (ICD-10 diagnosis, duration of the disease, psychometric evaluation according to the PANSS and MFI-20 scales, sex and age) and immunological parameters (enzymatic activity of LE and functional activity of $\alpha 1$ -PI in blood plasma) of 95 patients from 22 to 55 years old with paroxysmal-progressive (F20.x1) and paranoid (F20.00) schizophrenia was used to construct the model. An asthenic symptom complex was diagnosed in 61 patients.

Results: A binary logistic regression model linking the probability of developing asthenia to LE and $\alpha 1$ -PI activity was constructed by analyzing a database of patients with schizophrenia.

$P = 1 / (1 + \exp [-(11.71 - 0.057 \cdot LE + 0.027 \cdot \alpha 1\text{-PI})])$ (2), where

P is the probability of asthenia development; exp is the base of the natural logarithm; 11.71 is the regression constant; 0.057 is the coefficient for LE; 0.027 is the coefficient for α 1-PI.

This model adequately describes the clinical data and has good predictive ability (sensitivity - 93.44%, specificity - 76.47%, AUC - 0.89).

Conclusions: A binary logistic regression model was created to predict the development of asthenia in schizophrenia using immunological parameters LE and α 1-PI. The model is highly effective and can complement clinical examination of patients with schizophrenia, contributing to the objective diagnosis of asthenic syndrome and, consequently, timely therapeutic correction.

Hungarian adaptation of the Honest Open Proud program

D. Őri^{1,2*} and P. W. Corrigan³

¹Institute of Behavioural Sciences, Semmelweis University;

²Department of Mental Health, Heim Pal National Pediatric Institute, Budapest, Hungary and ³Department of Psychology, Illinois Institute of Technology, Chicago, United States

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.587

Introduction: The Honest, Open, Proud (HOP) program is an effective peer-led group program to support people with mental health problems in their disclosure to manage self and public stigma. The HOP program will be integrated into the National Anti-stigma Program in Hungary, which was initiated in 2020.

Objectives: Our goal was to develop the Hungarian version of the HOP program. We conducted the following measures to achieve our aim.

Methods: The adaptation process was conducted using community-based participatory research (CBPR) between September 2022 and January 2023. Over ten sessions, a group of eight individuals, consisting of both males and females with varying mental health conditions (mean age = 39.6 ± 8.5), participated in the online-led CBPR. The adaptation process was systematically documented, and regular supervision was provided.

Results: The program comprises three lessons and a follow-up section. We have translated the text of the manual and workbook into Hungarian and adjusted the tone, language, locations, and examples as per the Hungarian context. Although our adaptation process did not involve changes to the content and implementation strategies, we will perform structural modifications and adjustments to ensure the content is suitable for the predefined number of sessions and Hungarian participants.

Conclusions: The HOP could be feasibly implemented in the National Anti-stigma Program in Hungary; both online and in-person programs are planned. Given the lack of such a program

in Hungary, it will likely be warmly welcomed and strongly supported for the benefit of people with mental health problems.

Gestational age and sex interaction and risk for autism spectrum disorder in extremely preterm newborns: an 18-month follow-up study

L. Pina-Camacho^{1*}, J. Merchan-Naranjo¹, E. Rodriguez-Toscano¹, L. Martin¹, C. Romero¹, L. Boada¹, S. Zeballos², M. Arriaga² and D. Blanco-Bravo²

¹Department of Child and Adolescent Psychiatry, Institute of Psychiatry and Mental Health, Hospital General Universitario Gregorio Marañón, CIBERSAM, IiSGM, School of Medicine, Universidad Complutense and ²Neonatology Service, Hospital General Universitario Gregorio Marañón, IiSGM, School of Medicine, Universidad Complutense, Madrid, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.588

Introduction: Extremely preterm newborns - EPTN (born ≤ 28 weeks gestational age) are at increased risk of developing autism spectrum disorders (ASD). Demographic and perinatal risk factors associated with ASD risk in EPTN are understudied.

Objectives: (i) In EPTN and born at full-term healthy controls (HC), to characterize the emergence of ASD traits and autistic symptom load at age 18 months; (ii) in EPTN, to identify the influence of perinatal characteristics such as sex and gestational age on autistic symptom load at corrected-age 18 months.

Methods: Observational, longitudinal, prospective, 18-month follow-up study. We recruited a cohort of n=113 EPTN and n=47 HC (the PremTEA cohort); n=57 EPTN and n=42 HC successfully completed the 18-month follow-up visit. We assessed autistic symptom load & risk at 18 months using the M-CHAT-R/F questionnaire. For all EPTN and HC, we collected demographic and perinatal data. Using GLMs, we assessed, in EPTN, the association between demographic/perinatal variables and 18-month autistic symptom levels.

Results: At 18 months, EPTN children showed higher autistic symptom levels than HC (M-CHAT-R/F score, mean (SD) [range] = 2.21 (3.23) [0-12] in EPTN vs. 0.33 (0.57) [0-2] in HC; $d=.873$, $p=.001$). In EPTN, we identified differences by gestational age and sex in autistic symptom levels at 18 months ($aR^2=.517$, $p=.006$). In particular, female EPTNs born with lower gestational age showed higher autistic symptom load at age 18 months.

Conclusions: Our findings support the need for early screening of ASD symptomatology in EPTN infants, particularly in higher-risk subgroups, such as female patients born with lower gestational ages.

Comparative Financial Implications of Outpatient and Inpatient Service of the Psychiatric Department in General Hospital during the COVID-19 Pandemic in Taiwan: Case Report

W.-Y. Su¹ and S.-C. Wang^{2*}

¹National Yang Ming Chiao Tung University, Taipei City and ²Tao Yuan General Hospital, Ministry of Health and Welfare, Tao Yuan City, Taiwan, Province of China

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.589

Introduction: The COVID-19 pandemic has stressed global healthcare systems, with Taiwan's National Health Insurance (NHI) playing a crucial role in prevention and treatment. Like other countries, Taiwan grappled with managing the virus alongside regular healthcare services, resulting in notable financial strain on hospitals after COVID-19 pandemic.

Objectives: This study explores the financial implications of the psychiatric department at a medical center in Taiwan, highlighting the changing dynamics of healthcare costs and revenue during this period.

Methods: Data were collected monthly between January 2020 and September 2022, including the number of outpatient visits, inpatient patient-days, medical revenue, medical costs, and gross medical profit. Multivariate linear regression analysis confirmed the assumptions of the model and validated the findings.

Results: Regression analysis revealed a significant correlation between the number of patients and financial indicators (USD¹). Medical revenue (**Table. 1**), grew by 82 USD for each outpatient visit ($p < 0.001$, 95% CI: 41–122), and grew by 70 USD for each inpatient-days ($p = 0.001$, 95% CI: 31–108). Medical costs (**Table. 2**), increased by 59 USD for every inpatient-days ($p = 0.01$, 95% CI: 15–102). Finally, the gross medical profits (**Table. 3**) increased by 72 USD for each outpatient visit ($p = 0.003$, 95% CI: 27–117).

Table 1. Multiple linear regression analysis of the impact of medical service on medical revenue.

Revenue	Coef.	SE	t	p	[95% Conf. Interval]	
Outpatient (Visits)	82	20	4.136	.000	41	122
Inpatient (Patient Days)	70	19	3.664	.001	31	108

Table 2. Multiple linear regression analysis of the impact of medical service on medical cost.

Cost	Coef.	SE	t	p	[95% Conf. Interval]	
Outpatient (Visits)	9	22	0.422	.676	-36	55
Inpatient (Patient Days)	59	21	2.757	.010	15	102

Table 3. Multiple linear regression analysis of the impact of medical service on medical gross profit.

Gross Profit	Coef.	SE	t	p	[95% Conf. Interval]	
Outpatient (Visits)	72	22	3.261	.003	27	117
Inpatient (Patient Days)	11	21	0.501	.620	-33	54

¹All values were converted from TWD to USD using the rate as of 2023/08/15.

In summary, outpatient visits significantly augmented revenue and gross profit, whereas inpatient days led to heightened revenue and costs.

Conclusions: During the COVID-19 outbreak, healthcare systems, including those in Taiwan, were tested for unparalleled service challenges. This study found that while outpatient services boosted profits, rising inpatient admissions strained finances, given their higher costs and staffing needs. After the pandemic, psychiatric departments should reconsider resource allocation to balance expenses and revenues. Effective management is crucial for patient outcomes, emphasizing the need for quality care and fiscal control. Future research must focus on fortifying healthcare resilience.

Conduct problems, hyperactivity, and screen time among community youth: Can mindfulness help?

S. Kim^{1,2*}, S. Munten¹, N. J. Kolla^{1,3,4} and B. Konkoly-Thege^{1,4}

¹Waypoint Centre for Mental Healthcare, Penetanguishene;

²McMaster University, Hamilton; ³Centre for Addiction and Mental Health and ⁴University of Toronto, Toronto, Canada

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.590

Introduction: While technology continues to evolve and the prevalence of screen-based activities is rising, limited studies have investigated the effect of various types of screen time on youth behavioural problems. Further, the influence of mindfulness intervention programs on behavioural problems beyond hyperactivity is largely understudied.

Objectives: This study aims to address a research gap by examining the associations between four types of screen time and hyperactivity and conduct problems among community youth during the pandemic. The current study also aimed to investigate the efficacy of a mindfulness-based intervention in reducing hyperactivity and conduct problems.

Methods: Community youth aged 12-25 from Ontario, Canada, were recruited between April 2021 and April 2022 ($n = 117$, mean age = 16.82, male = 22%, non-White = 21%). The Mindfulness Ambassador Program, a structured, 12-week, evidence-based intervention program, was offered live, online and led by two MAP-certified facilitators. We conducted linear regression analyses using pre-intervention data to examine the unique association between the four types of screen time and behavioural problems (hyperactivity and conduct problems). The efficacy of the MAP

on adolescent hyperactivity and conduct problems was examined considering the three survey time points (pre-, post-, and follow-up) using a series of linear regression models utilizing the Generalized Least Squares (GLS) Maximum Likelihood (ML), unstructured model.

Results: The average score for conduct problems was classified within the normal range, while the average score for hyperactivity was considered borderline at baseline. More than 5 hours of playing video games were significantly associated with increased conduct problems [$\beta = -1.75$, 95% CI = -0.20 – 3.30, $p = 0.03$]. Accounting for age, sex, baseline mental health status, and screen time, the mindfulness intervention program significantly contributed to decreased hyperactivity at post-intervention compared to the baseline [$\beta = -0.49$, 95% CI = -0.91 to -0.08, $p = 0.02$]. It was maintained at follow-up [$\beta = -0.64$, 95% CI = -1.26 to -0.03, $p = 0.04$].

Conclusions: Our findings suggest an adverse impact of excessive video gaming on behavioural problems among community youth and confirm that the trend remains the same. Considering the simplicity, brevity, non-invasive nature and other mental health benefits of the mindfulness intervention, we argue that the results are promising and worthy of further study and larger-scale implementation. Clinicians, parents, and educators should work collaboratively to provide developmentally appropriate strategies to moderate screen time spent on video games among youth.

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.591

Introduction: Globally, mental disorders account for almost 20% of disease burden and there is growing evidence that mental disorders are associated with various social determinants. Tackling the United Nations Sustainable Development Goals (UN SDGs), which address known social determinants of mental disorders, may be an effective way to reduce the global burden of mental disorders.

Objectives: To examine the evidence base for interventions that seek to improve mental health through targeting the social determinants of mental disorders.

Methods: We conducted a systematic review of reviews, using a five-domain conceptual framework which aligns with the UN SDGs (PROSPERO registration: CRD42022361534). PubMed, PsycInfo, and Scopus were searched from 01 January 2012 until 05 October 2022. Citation follow-up and expert consultation were used to identify additional studies. Systematic reviews including interventions seeking to change or improve a social determinant of mental disorders were eligible for inclusion. Study screening, selection, data extraction, and quality appraisal were conducted in accordance with PRISMA guidelines. The AMSTAR-2 was used to assess included reviews and results were narratively synthesised.

Results: Over 20,000 records were screened, and 101 eligible reviews were included. Most reviews were of low, or critically low, quality. Reviews included interventions which targeted socio-cultural ($n = 31$), economic ($n = 24$), environmental ($n = 19$), demographic ($n = 15$), and neighbourhood ($n = 8$) determinants of mental disorders. Interventions demonstrating the greatest promise for improved mental health from high and moderate quality reviews ($n = 37$) included: digital and brief advocacy interventions for female survivors of intimate partner violence; cash transfers for people in low-middle-income countries; improved work schedules, parenting programs, and job clubs in the work environment; psychosocial support programs for vulnerable individuals following environmental events; and social and emotional learning programs for school students. Few effective neighbourhood-level interventions were identified.

Conclusions: This review presents interventions with the strongest evidence base for the prevention of mental disorders and highlights synergies where addressing the UN SDGs can be beneficial for mental health. A range of issues across the literature were identified, including barriers to conducting randomised controlled trials and lack of follow-up limiting the ability to measure long-term mental health outcomes. Interdisciplinary and novel approaches to intervention design, implementation, and evaluation are required to improve the social circumstances and mental health experienced by individuals, communities, and populations.

The nurses' assessment of the psychiatric care quality and the development of measures to improve it

V. Mitikhin^{1*}, T. Solokhina¹, L. Burygina² and L. Alieva¹

¹Department of Mental Health Services, Mental Health Research Centre and ²Psychiatric clinical hospital № 4 named after P.B. Gannushkin, Moscow, Russian Federation

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.592

Introduction: The development of the methodology for the psychiatric care quality managing is associated with the implementation of criteria and standards, systematic evaluation and the continuous improvement of the care quality. Important role in assessing the care quality belongs to the specialists of the psychiatric

services, who are both “providers” and “internal consumers” of care. At the same time, it is especially significant to take into consideration the opinion of nurses, as the largest group of specialists working in psychiatric institutions and directly providing treatment and care for patients.

Objectives: To assess the quality of care by nurses of psychiatric institutions and to develop evaluation criteria and measures to improve the quality of care.

Methods: Questionnaire «Assessing the satisfaction with quality of care by medical staff of psychiatric institution», including 78 questions about the quality of the structure, process and results of activities (Solokhina et al., 2014); adapted questionnaire «Assessment of the burden of psychiatric staff working in psychiatric institution», including 52 questions (WHO, 1994). The study involved 35 nurses of inpatient and outpatient services of Moscow psychiatric hospital № 4 named after P.B. Gannushkin.

Results: It was found that 76,5% of respondents were satisfied with the quality of provided care in general and 78,2% of them were satisfied professional level of medical staff. The lower satisfaction was obtained when the other aspects were assessed. For example, only 58,6% of respondents were satisfied by relations with colleagues, 55,9% – by support from administration correspondingly. Dissatisfaction of nurses was related with working conditions, salary, excessive control by administration, insufficient professional training and lack of participation in the assessment of the institution's activities.

It was revealed that the integral index of professional burden of nurses was at the average level ($1,47 \pm 0,26$). Inverse correlations between burden of staff and satisfaction with quality of care and institution's activities were established. This allows to consider the professional burden as criterion in assessing the quality of care. Using obtained results, a training aimed at improving the communicative competence of medical personnel was developed and implemented in practice (Trushkina, Solokhina, 2019). For today more the 60 nurses have taken part in this training. The results demonstrate the professional growth of the participants and their communication patterns expansion.

Conclusions: Nurses' satisfaction and indicators of professional burden both can be used as criteria of assessment of the psychiatric care quality. It is also necessary to introduce in psychiatric institutions training aimed at continuous professional skills improving.

and Psychology Service, Hospital Clinic de Barcelona; ³Tobacco control Unit, Institut Català d'Oncologia - IDIBELL; ⁴IDIBAPS; ⁵Department of Child and Adolescent Psychiatry and Psychology, SGR-881, Hospital Clinic de Barcelona and ⁶CIBERSAM, Barcelona, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.593

Introduction: Cannabis use poses a significant risk to the psychological wellbeing of youth, affecting academic performance and potentially triggering the onset of mental health issues. Providing young people with comprehensive information about patterns of cannabis use and specific factors that increase an individual's health risks is crucial. The ability to critically assimilate this information is known as health literacy (HL).

Objectives: To design a psychoeducational intervention to increase HL on risky cannabis use among students aged 16-25, and to assess its usability and feasibility.

Methods: We designed a psychoeducational intervention based on the outcomes of a 3-hour co-creation session involving healthcare professionals and students. 29 university students and 25 high-school students completed this intervention and assessed its usability and feasibility with the SUS (System Usability Scale), PSSUQ (Post-Study System Usability Questionnaire) and additional open questions regarding the most and less-liked aspects of the intervention.

Results: The design phase resulted in an informative website (<http://www.cahlyclinic.cat/>) and a 1-hour structured onsite educator-facilitated session, comprising 3 group activities (completed on paper or online) addressing three dimensions of cannabis HL: searching for, interpreting and applying reliable information. Usability of the intervention was rated as excellent (SUS mean score >80). PSSUQ results indicate that students were satisfied with the intervention; found the HL information clear, relevant, and adequate for their needs; found the interface of the digital version pleasant and usable without support; and would recommend it to other students.

Conclusions: We propose an innovative structured and usable intervention, designed using a participatory approach, which aims to disseminate information on risky cannabis use to a key target population, namely young people.

EPP0446

From ADHD to well-being: The Role of Rejection Sensitivity in college life

V. Müller^{1*} and B. Pikó²

¹Doctoral School of Education and ²Department of Behavioral Sciences, University of Szeged, Szeged, Hungary

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.594

Introduction: Rejection-sensitivity is a prevalent yet understudied emotional symptom often associated with adult ADHD. While ADHD research typically focuses on behavioral and cognitive facets, emerging evidence highlights the significance of emotional symptoms. Emotional dysregulation in ADHD impacts psychological well-being and mental health. Our study examines how ADHD symptoms relate to rejection sensitivity, considering factors like resiliency, self-regulation, and overall well-being.

Objectives: Our study seeks to establish a direct connection between ADHD scores and rejection sensitivity among college students. We also investigate the mediating role of well-being, creative executive efficiency, self-regulation, and resilience, while exploring the moderating role of savoring capacity.

Methods: Between February and May of 2023, we conducted a cross-sectional study using an online questionnaire, gathering data from 304 Hungarian higher education students aged 18 to 35. The majority, 78.0%, were female, and 71.4% were full-time students. Most participants were pursuing a bachelor's degree (56.6%), followed by undivided master's (21.7%), doctoral studies (13.8%), and traditional master's degrees (6.9%). We administered the Adult ADHD Self-Report Scale (ASRS-v.1.1.1), The Mental Health Test (MHT), and the Rejection Sensitivity Questionnaire (A-RSQ) for our research.

Results: First, the ADHD scores were significantly associated with each mediator (well-being: $\beta = -.343$, $p < .001$; creative and executive efficiency: $\beta = -.183$, $p < .01$; self-regulation ($\beta = -.230$, $p < .001$; and resilience: $\beta = -.321$, $p < .001$). There was a direct effect of ADHD scores on rejection sensitivity scores ($\beta = .466$, $p < .001$). Finally, we also detected the indirect effects of ADHD scores on rejection sensitivity scores through the four mediators ($\beta = .227$, $p < .001$). Savoring capacity significantly moderated the relationship between ADHD and rejection sensitivity scores ($\beta = -.244$, $p < .001$).

Conclusions: ADHD scores in our study population significantly correlate with well-being, creative and executive efficiency, self-regulation, and resilience. Furthermore, these scores directly influence rejection sensitivity, suggesting a heightened vulnerability to perceived rejection among those with higher ADHD scores. The indirect effects emphasize that the relationship between ADHD and rejection sensitivity is mediated by the aforementioned positive psychological constructs. This underscores the need for holistic interventions in ADHD populations, addressing not just core ADHD symptoms but also enhancing well-being, cognitive efficiency, self-regulation, and resilience to potentially mitigate rejection sensitivity.

The mediating role of social stress sensitivity on the relationship between hostile attribution bias and paranoia: An experience sampling study

A. K. C. Chau^{1,2*} and S. H.-W. So¹

¹Department of Psychology and ²Institute of Health Equity, The Chinese University of Hong Kong, Hong Kong, Hong Kong

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.595

Introduction: Heightened affective responses to daily life stressors, referred to as elevated affective reactivity to stress (or 'stress sensitivity'), have been proposed as a putative mechanism of schizophrenia. Previous studies on stress sensitivity mainly used a case-control design; given that schizophrenia is heterogeneous its relationship with specific symptoms (e.g. paranoia) is yet to be addressed.

In view of the continuum approach of understanding psychotic symptoms, the relationship between stress sensitivity (especially 'social stress sensitivity') and paranoia in the general population is important. Supported by emerging evidence of the relationship between hostile attribution bias (i.e. a tendency to interpret others' actions as hostile and intentional) and paranoia, we hypothesized that social stress sensitivity mediates the relationship between hostile attribution bias and momentary experiences of paranoia.

Objectives: Using experience sampling method, this study aimed to examine the association between social stress sensitivity, hostile attribution bias and momentary paranoia in non-clinical young adults. We also tested the role of social stress sensitivity as mediator of the relationship between hostile attribution bias and momentary paranoia.

Methods: Consented participants free from any past and current psychiatric diagnoses (confirmed with the Structured Clinical Interview for DSM-IV Disorders) completed the measure of hostile attribution bias (i.e. abbreviated Ambiguous Intentions Hostility Questionnaire). Participants then filled in an ESM questionnaire measuring momentary levels of paranoia, social stress (i.e. pleasantness of and preference for being alone or with others) and negative affect on a mobile phone app repeatedly, ten times per day over six days. Social stress reactivity was calculated as the within-moment correlation between social stress and negative affect. The associations between social stress sensitivity, hostile attribution bias and momentary paranoia, and the mediating role of social stress sensitivity, were tested with multilevel modelling.

Results: The final sample consisted of 131 participants (57.3% female, mean age= 20.36 (SD= 2.93)). The mean compliance rate was 71.9% (SD= 0.16). Social stress sensitivity was positively associated with momentary paranoia ($B = 0.03$, $p = .002$). Hostile attribution bias was associated with momentary paranoia ($B = 0.41$, $p < .001$), as well as social stress reactivity ($B = 0.10$, $p = .003$). The mediating effect from hostile attribution bias to momentary paranoia via social stress sensitivity was significant ($ab = 0.05$, 95% CI [0.03-0.07]).

Conclusions: Social stress sensitivity was related to momentary paranoia, as well as hostile attribution bias. Our finding suggests social stress reactivity as a potential mechanism underlying the relationship between hostile attribution bias and paranoia.

Retrospective evaluation of sociodemographic and clinical characteristics of patients with schizophrenia receiving clozapine monotherapy and clozapine combined with different antipsychotics

E. Yıldız*, S. N. İspir, H. R. Demirel, S. Odabaş Ünal and M. Aydın
Department of Psychiatry, Selçuk University, Faculty of Medicine, Konya, Türkiye

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.596

Introduction: Schizophrenia is a chronic mental disorder and clozapine is an atypical antipsychotic that can be used in treatment-resistant schizophrenia patients. However, treatment-resistant schizophrenia may also include patients with an inadequate response to clozapine.

Objectives: In our study, we retrospectively analysed the socio-demographic and clinical characteristics of patients receiving clozapine monotherapy and patients receiving clozapine in combination with different antipsychotics. In this way, we aimed to evaluate the factors that influence the response to clozapine.

Methods: Clozapine monotherapy and clozapine in combination with different antipsychotics were identified by retrospective chart review of patients followed up at the Schizophrenia and Other Psychotic Disorders Outpatient Clinic, Department of Psychiatry, Faculty of Medicine, Selçuk University. Sociodemographic and clinical characteristics were recorded and subjected to statistical analysis. The study was approved by the Ethics Committee of Selçuk University.

Results: Of the 143 patients whose data were analysed, 60 (42%) were female. The mean age of the patients was 40.2 ± 12.0 years and the mean duration of training was 10.4 ± 4.3 years. 62 patients (43.4%) used long-acting antipsychotics. 90 patients (62.9%) were using clozapine, 52 (36.4%) were using clozapine as monotherapy, 5 (3.5%) were using clozapine together with another oral antipsychotics drug, and 33 (23.1%) were using clozapine together with a long-acting antipsychotic. No statistically significant difference was found when comparing mean age, age at first antipsychotic initiation, age at clozapine initiation and mean clozapine dose between patients using clozapine monotherapy ($n=52$) and patients using different antipsychotics in combination with clozapine ($n=38$). When the two groups were compared, a significant difference was found in the mean number of antipsychotics used before starting clozapine and the mean number of hospitalisations, with a lower number in the monotherapy group (3.1 ± 1.4 vs 4.1 ± 2.0 , $p=0.01$ and 2.8 ± 2.2 vs 4.5 ± 3.2 , $p=0.006$, respectively).

Conclusions: It is important to assess the concept of treatment resistance appropriately in the treatment of schizophrenia patients. The results of our study suggest that starting clozapine treatment promptly in treatment-resistant patients may increase the likelihood that patients will benefit from clozapine and reduce the need for additional treatments. Although our data and criteria for evaluating response to treatment are limited, it is important to draw attention to the clinical results of proceeding in accordance with the guidelines in the treatment of schizophrenia. Evaluating the response to clozapine treatment needs studies with stronger data and larger sample sizes.

A specialized unit for women with schizophrenia: Results from the healthcare model Observatories-Monitoring Stations and Interventions.

J. P. Paolini San Miguel^{1*}, M. Natividad¹, M. V. Seeman², E. Román¹, A. Balagué¹, B. Palacios³, N. Bague¹, E. Izquierdo¹, E. Rial¹, J. A. Monreal¹ and A. González Rodríguez¹

¹Mental Health, Mutua Terrassa University Hospital. University of Barcelona, Terrassa, Spain; ²Psychiatry, University of Toronto, Toronto, Canada and ³Clinical and Health Psychology, Autonomous University of the State of Morelos, Cuernavaca, Mexico

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.597

Introduction: There are many theoretical reasons to implement gender-specific care for schizophrenia. For all these reasons, the Mutua Terrassa-Functional Unit for Women with Schizophrenia was inaugurated in January 2023 in the context of a community mental health service.

Objectives: Our aim today is to describe the health care model applied in this newly initiated unit.

Methods: We created a healthcare model in our new unit consisting of A) Five observatories of Health (somatic morbi-mortality, hyperprolactinemia-HPRL, substance use disorders, social exclusion/discrimination, and drug safety); B) Monitoring stations or vigilance teams (reflecting the 5 observatories); and C) resulting actions (specific interventions). The observatory teams each meet monthly. In this presentation, according to the healthcare model we implemented, we first describe data about the original patient recruitment and then focus on the observatories of somatic morbi-mortality and hyperprolactinemia.

Results: From 265 potentially eligible women, 42 were included in the 5 observatories. (A) of the 11 women in the observatory of somatic morbi-mortality, 10 women had died within the last 24 months. Causes of Death: (1) respiratory tract disease ($n=5$; 45.4%), (2) cancer ($n=3$; 27.3%): lung cancer ($n=1$), pancreatic cancer ($n=1$), kidney cancer ($n=1$), (3) ischemic colitis ($n=1$; 9%), (4) Alzheimer disease ($n=1$; 9%). 2) Morbidity. One woman had an ongoing glioblastoma. (B) Observatory of HPRL. Eight women with moderate/severe HPRL were included. Strategies for lowering prolactin levels were discussed with neuroendocrinologists. Interventions: adjunctive aripiprazole ($n=3$), switch to aripiprazole ($n=2$), lowering antipsychotic doses ($n=2$), and adjunctive cabergoline ($n=1$).

Conclusions: Designating special teams to focus on specific problems of women with schizophrenia will reduce morbidity and improve outcomes in this vulnerable population.

NADPH-dependent peroxidase activity of antibodies in patients with schizophrenia

L. Smirnova^{1*}, D. Kazantseva¹ and E. Kornetova²

¹Laboratory of Molecular Genetics and Biochemistry and ²Affective States Department, Mental Health Research Institute Tomsk National Research Medical Center Russian Academy of Sciences, Tomsk, Russian Federation

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.598

Introduction: The development of oxidative stress in patients with schizophrenia is associated with changes in the level of activity of antioxidant enzymes. It is likely that catalytically active antibodies (abzymes) can take on these functions. Abzymes are antibodies with enzymatic activity. Catalase and SOD activity of abzymes was previously detected in patients with schizophrenia. But NADPH-dependent peroxidase activity has not been studied. The present work discusses the protective role of abzymes against reactive oxygen species within the pathogenesis of schizophrenia.

Objectives: The aim of the study was to investigate the NADPH-dependent peroxidase activity of IgG in patients with paranoid

schizophrenia in the exacerbation phase and in the remission phase.

Methods: A total of 124 patients were examined during the work. Of them, 82 patients with paranoid schizophrenia (F20.0) had a mean age of 33.6 ± 5.12 years (52 males, 30 females), disease duration averaged 8.9 ± 4.62 years. Patients with schizophrenia included 42 patients with acute schizophrenia and 40 patients with schizophrenia in therapeutic remission. The control group included 42 sex- and age-matched patients. IgG was purified by affinity chromatography on columns with proteinsepharose on an AKTA purifier chromatograph (GE). The homogeneity of isolated IgG preparations was checked by Lemilly electrophoresis in a gradient of 4-18% PAAG. Gel filtration under pH-shock conditions was performed on a Superdex-200 HR 10/30 column. NADPH-dependent peroxidase activity of IgG was determined on a SPECORD M-40 spectrophotometer (Carl Zeiss) at 340 nm by NADPH oxidation in the conjugated glutathione reductase reaction of tertiary butyl hydroperoxide reduction. Statistical processing of data was performed in Statistica 12.0 program.

Results: It was proved that IgG from patients with schizophrenia had NADPH-dependent peroxidase activity, and this activity is an intrinsic property of the investigated antibodies. The NADPH-dependent peroxidase activity in IgG patients in the exacerbation stage was increased 3-fold ($p=0.0001$) compared to the studied activity in the group of healthy individuals, and it was increased 2-fold ($p=0.017$) in the group of patients in therapeutic remission compared to the activity in healthy individuals. Also NADPH-dependent IgG peroxidase activity in patients in remission was 1.7 times lower than in patients during the exacerbation period ($p=0.012$).

Conclusions: It was established for the first time that abzymes from patients with schizophrenia and healthy individuals have NADPH-dependent peroxidase activity and can decompose lipo and hydroperoxides. We hypothesize that these abzymes help cope with generalized oxidative stress. Under the influence of neuroleptic therapy in patients in remission, the level of oxidative stress and NADPH-dependent peroxidase activity of abzymes decrease.

Cardiovascular Risk Assessment in Psychotic Disorders: A Comparative Analysis of Plasma Atherogenic Index between Remitted Patients and Healthy Control

M. T. Ergün^{1*}, B. Sağlıyan¹, Ö. Bayırlı¹, S. Kaya¹ and M. Aydın¹

¹Department of Psychiatry, Selçuk University Faculty of Medicine Hospital, Konya, Türkiye

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.599

Introduction: Psychiatric patients have a higher risk of premature mortality primarily due to cardiovascular diseases (CVD). One significant contributing factor is the presence of dyslipidemias. Current studies are shifting focus towards lipoprotein ratios, believed to better reflect cardiovascular risk. These studies have demonstrated that ratios associated with high-density lipoprotein (HDL) are stronger predictors for CVD compared to traditional

lipid parameters. One of these ratios is the logarithmic transformation of the triglyceride (TG) to HDL ratio, known as the plasma atherogenic index (PAI).

Objectives: Our study aimed to compare the PAI between patients diagnosed with psychotic disorders who presented to our outpatient clinic and healthy control groups.

Methods: Fifty patients diagnosed with psychotic disorders, including 50 residing in a nursing home and 50 outpatient in such facilities, presented to our psychiatric outpatient clinic and were included in our study. Additionally, a healthy control group consisting of 49 individuals was recruited. A socio-demographic data form was administered to all groups. Peripheral blood levels of HDL, Triglycerides (TG), and LDL were recorded for each participant included in the study. Ethical approval for the study was obtained from the local ethics committee.

Results: The patient groups were compared in terms of age and gender. While there was no statistically significant difference in gender between the groups, a significant difference was observed in terms of age ($p=0.099$, $p=0.004$). When examining the age distribution of the groups, it was observed that the care facility group was older compared to the other groups. The age and gender distributions of the groups are shown in Table 1 and Table 2.

Psychotic patients in the outpatient group and the nursing home group were compared in terms of age and atherogenic index. Age was statistically significant, indicating that the nursing home group was significantly older ($p=0.001$, $p=0.478$). In the comparison of the control group with psychotic patients, there was no statistical difference in age, but a significant difference was found in terms of the atherogenic index ($p=0.510$, $p=0.001$). The statistical analysis and data between psychotic patients and the control group are presented in Table 3.

Image:

Table 1. Gender Distribution of Groups

	Female	Male	Total	p
Out Patient Group	20(40.0%)	30(60.0%)	50(100.0%)	0.099*
Nursing Home Group	14(28.0%)	36(72.0%)	50(100.0%)	
Control Group	24(49.0%)	25(51.0%)	49(100.0%)	
Total	58(38.9%)	91(61.1%)	149(100.0%)	

The calculations were performed using the Pearson Chi-Square test

Table 2. Age Distribution of Group

	Patient Age			p
	Minimum	Maksimum	Median	
Out Patient Group	19	64	38.48	0.004*
Nursing Home Group	23	64	46.06	
Control Group	23	64	41.08	

The calculations were performed using the Kruskal-Wallis test.

Table 3. Comparison of Age and Atherogenic Index Between Patients Diagnosed with Psychosis and the Control Group

	Control Group	Psychosis Group	p
Age (Mean, \pm SD)	41.08(\pm 11.4)	0.49 (\pm 0.20)	0.510*
AI (Mean, \pm SD)	42.27(\pm 11.7)	0.63 (\pm 0.24)	0.001*
Number of Patients	49	100	

AI: Aterojenik Index

The calculations were performed using the Mann-Whitney U test

Conclusions: This study, examining the comparison of Plasma Atherogenic Index (PAI) in patients diagnosed with psychosis with healthy controls, represents a significant step in understanding the cardiovascular health profile of this population and developing

appropriate treatment strategies. Future research will further contribute to a deeper understanding of the impact of psychiatric disorders on cardiovascular health and aid in the development of effective interventions to minimize these effects.

Medication choice and psychosis Hospital readmissions: A two-year comparative study

O. Martin-Santiago*, M. Calvo-Valcarcel, P. Martinez.Gimeno, C. Alario-Ruiz and B. Arribas-Simon

Hospital Clinico Universitario, Valladolid, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.600

Introduction: Hospital readmissions in psychosis are a critical concern, with medication choice playing a vital role. Oral antipsychotics, though common, rely on patient adherence and can lead to relapses if not followed. Long-acting injectable atypical antipsychotics (LAIA) provide an alternative, ensuring consistent medication release and reducing relapse risk due to missed doses. Studies indicate that LAIAs result in fewer readmissions due to improved adherence. Tailoring treatment to individual needs is essential. Medication choice significantly influences hospital readmission prevention in psychosis. LAIAs, which could offer greater adherence to treatment and symptom control, present a promising option. Individualized treatment decisions are a priority for long-term recovery.

Objectives: This study aimed to compare the hospital readmission rates within two years post-discharge among two groups of patients diagnosed with schizophrenia and other psychotic disorders who received either oral antipsychotic treatment or LAIAs.

Methods: We collected sociodemographic and hospitalization data from 155 patients, 90 receiving oral antipsychotics and 65 receiving LAIAs, following their discharge from a psychiatric unit.

Results: There were 90 patients in the oral treatment group, and 65 in the LAIA group, with 67.6% receiving paliperidone and 26.1% receiving aripiprazole. There were no significant differences in age or gender between the two groups. However, patients in the LAIA group had *longer stays in the hospital* ($M=14.7$; $SD=10.2$ vs $M=11.1$; $SD=6.4$; $t_{(153)}=2.67$; $p<.01$) and a higher number of prior admissions ($M=3.2$; $SD=3.7$ vs $M=1.3$; $SD=3.5$; $t_{(153)}=2.41$; $p<.01$) compared to the oral antipsychotic group. Additionally, a higher percentage of patients in the LAIA group were diagnosed with schizophrenia (60%) compared to the oral antipsychotic group (24%) ($X^2_{(1, N = 155)} = 20.4$, $p<.01$). After two years, readmission rates were 66.6% for the oral antipsychotic group and 61.5% for the LAIA group ($X^2_{(1, N = 155)} = 8.5$, $p > .05$). However, the time to readmission was shorter for patients on oral antipsychotics ($M=172.4$; $SD=162.0$) compared to those on LAIAs ($M=326.2$; $SD=211.4$; $t_{(153)}=3.05$; $p<.01$). Notably, 86.6% of patients on oral antipsychotics were readmitted within the first year, while only 52% of those on LAIAs experienced readmission during the same period ($X^2_{(1, N = 155)} = 8.5$, $p = .001$).

Conclusions: Long-acting injectable antipsychotics (LAIAs) appear to reduce hospital readmissions, with a more pronounced

effect in the first few months post-discharge. However, after two years, the readmission rates between LAIAs and oral antipsychotics become comparable. This data suggests that while LAIAs may reduce early readmissions, their long-term effectiveness is on par with oral antipsychotics.

Attention flexibility is associated with retinal cup-to-disk ratio in patients with schizophrenia spectrum disorders

S. Jerotic^{1,2*} and N. Maric^{1,3}

¹Faculty of Medicine, University of Belgrade; ²Clinic for Psychiatry, University Clinical Centre of Serbia and ³Institute of Mental Health, Belgrade, Serbia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.601

Introduction: In recent years, there has been increasing interest in the potential use of retinal imaging as a non-invasive and easily accessible tool for investigating the neurobiological underpinnings of schizophrenia. Studies have suggested that patients with schizophrenia spectrum disorders (SSD) have structural abnormalities in the retina, including changes in retinal thickness and the ratio of the retinal cup-to-disk ratio.

Objectives: To investigate the relationship between retinal cup-to-disk ratio and cognitive performance in patients with SSD using a high-definition retinal imaging device – optical coherence tomography (OCT) scanner.

Methods: The sample was comprised of twenty patients with SSD (F20-F29 according to ICD-10 criteria). All diagnoses were confirmed by a researcher using the Mini International Psychiatric Interview. All patients underwent complete ophthalmological examination, excluding any ocular pathology. Retinal thickness was measured in both eyes of all patients with a high-definition spectral-domain OCT device. Examined retinal parameters were: total retinal nerve fiber layer thickness (RNFL); RNFL thickness in all eye quadrants (nasal, temporal, superior, inferior); RNFL symmetry; average macular volume (MV); average macular thickness (MT); ganglion cell layer thickness (GC); average retinal cup-to-disk (C/D) ratio, vertical C/D ratio. Cognitive performance of all patients was tested using the Intra/Extradimensional Set Shift Task (IED). IED is a component of a state-of-the-art computerized battery for cognitive assessment – Cambridge Neuropsychological Automated Test Battery. IED is a measure of maintenance, shifting and flexibility of attention. Associations between retinal variables and IED measures were determined with Pearson correlation analyses.

Results: Mean age of patients was 33 ± 7.5 years. Fifty five percent of the sample was male, illness duration was 6.2 ± 3.9 years. Daily dosage of chlorpromazine was 225.7 ± 108.8 mg. Retinal C/D ratio in the right eye was positively associated with IED total errors ($r=0.50$; $p=0.02$) and negatively with IED stage progression ($r=-0.52$, $p=0.18$). Likewise, vertical C/D ratio was positively associated with IED total errors ($r=0.49$; $p=0.02$) and negatively with IED stage progression ($r=-0.52$, $p=0.18$).

Conclusions: Previous analyses of retinal parameters in patients with schizophrenia point towards enlargement of retinal cup-to-

disk ratio, irrespective of any underlying somatic comorbidities. Our data shows worsening of attention flexibility in association with the increase of cup-to-disk ratio in patients with schizophrenia spectrum disorders. The significance of cup-to-disk retinal disturbance in schizophrenia spectrum disorders and its connection with cognitive performance should be further evaluated and supplemented with measurements of functional adaptation in these patients.

Schizo - obsessive disorder - separate clinical entity or elusive comorbidity? - a systematic review

R. Niewiadomski^{1*}, J. Maciejczyk-Kawecka¹, M. A. Ciołek², K. Wilczyński^{1,3} and M. Janas-Kozik^{1,3}

¹Pediatric Centre of John Paul II, Sosnowiec; ²Students' scientific association at the Department of Psychiatry and Psychotherapy of Developmental Age and ³Department of Psychiatry and Psychotherapy of Developmental Age, Medical University of Silesia, Katowice, Poland

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.602

Introduction: In some clinical scenarios obsessive and delusive symptoms exhibit several similarities, making it challenging to differentiate between schizophrenia spectrum disorder (SSD) and obsessive-compulsive disorder (OCD). There are numerous reports of patients suffering from those disorders and manifesting both psychotic and obsession-like features, which makes accurate distinction even more complicated. We found several conflicting theories attempting to elucidate this overlap, one being the existence of the separate clinical entity - schizo-obsessive disorder.

Objectives: The aim of this study is to consolidate current knowledge, synthesize existing theories and explore diagnostic implications.

Methods: We conducted a systematic literature review following the PRISMA protocol, we scrutinized studies addressing obsession-like symptoms in SSD, psychotic symptoms in OCD, and comorbidity of those disorders. We included peer-reviewed non-interventional studies published in English and Polish from 2013 onwards. The search was performed in the following medical databases: PubMed, Science Direct, Scopus, and Web of Science. Synthesis utilized a narrative approach due to diverse study designs, outcomes and observational nature of the collected data.

Results: We identified several dozen articles, which revealed a range of diverse findings, often inconclusive, and occasionally conflicting. Although, the collected data indicate the schizo-obsessive spectrum exhibits clinical relevance.

Conclusions: The ambiguity in results emphasizes the necessity for further investigations into pathomechanism of schizophrenia and OCD. Future research, particularly involving children and adolescents, should strive for a comprehensive understanding of the nuanced manifestations of obsessive-like and psychotic symptoms in both disorders, aiding in refining diagnostic criteria and developing effective intervention strategies.

Psychosis following traumatic brain injury: A case study and a brief overview

H. Khiari*, A. Hakiri, S. Rouai and R. Ghachem

Psychiatry B, Razi hospital, Mannouba, Tunisia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.603

Introduction: Psychosis resulting from traumatic brain injury (TBI) is a relatively uncommon but potentially severe and disabling outcome. The complex relationship between TBI and the onset of psychosis is marked by significant scientific uncertainty and differing opinions.

Objectives: To investigate the occurrence of psychosis following traumatic brain injury (TBI) and explore the intricate relationship between TBI and the development of psychosis.

Methods: A comprehensive case report was conducted on a 38-year-old patient who, after a severe TBI at the age of 23, exhibited signs of psychosis. Developmental history, family background, clinical assessments, magnetic resonance imaging (MRI), and electroencephalogram (EEG) results were analyzed.

Results: The patient, at the time of writing aged 38, was born at full term with a regular presentation and uneventful delivery, with no indications of perinatal or obstetric complications. Developmentally, he reached all milestones within the expected range, and there were no significant premorbid characteristics. There was no family history of schizophrenia in a first- or second-degree relative; a paternal cousin had had psychosis-like symptoms, but reportedly remained well without any medication.

At the age of 23, the patient was knocked from his motorcycle by a car and sustained a severe traumatic brain injury (TBI), with initial loss of consciousness and was in a coma state for approximately a month, with later sequelae of cerebellar syndrome and predominant right-sided pyramidal syndrome.

Magnetic resonance imaging (MRI) a year following the TBI showed sequelae of bifrontal and temporal contusion lesions.

An EEG did not indicate any evidence of epilepsy, and a repeat EEG 14 years later revealed no diagnostic abnormality.

A year after the accident, his surroundings have noticed social withdrawal, a turning inward with a religious fervor, and persecutory remarks focused on his brother. At the age of 26, he presented to a psychiatric service having auditory hallucinations. He was deluded, believing himself to be a prophesied redeemer figure who is expected to appear and bring justice and righteousness to the world. He had an inappropriate affect. A diagnosis of schizophrenia was made, and neuroleptics prescribed. His auditory hallucinations faded, but the subsequent course was of repeated episodes of florid psychosis requiring maintenance neuroleptic treatment, eventually haloperidol decanoate (150mg monthly).

Conclusions: Psychosis following TBI is an uncommon yet potentially severe consequence, carrying the risk of significant debilitation. The relationship between TBI and psychosis is complex, but notable distinctions exist in clinical, epidemiological, and neurobiological aspects when compared to primary psychotic disorders.

Disclosure of Interest: None Declared

EPP0458

Examining the effect of family-based intervention programs used in psychosis on the disease: a systematic review

Z. Kutlutürk*, M. C. Aktaş and C. H. AYHAN

Mental Health and Psychiatric Nursing, Van Yuzuncu Yil University, Van, Türkiye

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.604

Introduction: Psychosis is a complex mental health condition that can have a significant impact on individuals and their families. Family-based intervention programs have been developed to provide support and education to both individuals with psychosis and their families. These programs aim to improve clinical and family outcomes, reduce relapse rates, and enhance the overall well-being of individuals and their families. This study examined the effect of family-based intervention programs used in psychosis on the disease by synthesizing evidence from a systematic review of relevant studies. Family interventions have shown promising results in improving clinical and family outcomes in long-standing psychosis (Sadath et al., 2015). These interventions focus on improving relationships through problem-solving and enhancing the understanding of the illness and its treatment (Kuipers et al., 2010).

Objectives: The aim of this study was to evaluate the effect of intervention programs implemented for the families of individuals diagnosed with psychosis on the course of the disease.

Methods: The study was conducted between August and September 2023 in 3 databases (PubMed, Cochrane Library, Science Direct) using the keywords “psychosis”, “family interventions”, “family in psychosis”. These databases were preferred because they contain a significant amount of evidence-based literature in the field of biomedical sciences and psychology. Studies conducted between 2013 and 2023, whose full texts were accessed and written in Turkish and English were included in the study.

Results: As of September 2023, 16 national and international research articles on the subject have been reached and the literature review continues. When the literature review is finalized, all study results will be presented together.

Conclusions: This review provides an overview of the effects of intervention programs implemented for the families of individuals diagnosed with psychosis on the course of the disease and solution suggestions. Family-based intervention programs have shown promise in improving clinical and family outcomes in psychosis. These programs focus on enhancing relationships, providing education, and reducing relapse rates. However, the implementation of family interventions in routine clinical services can be challenging due to various barriers. Peer support programs have emerged as a valuable addition to family interventions, providing a supportive environment for families to share their experiences and support one another. Future research should focus on addressing barriers to implementation and further exploring the benefits of peer-driven family support services in early intervention programs for psychosis.

Evaluating the relationship between blood lipids, cardiac risk index, and suicidal behaviors in first-episode psychosis

L. Güçlü^{1*}, M. Şen², Y. H. Balcıoğlu², P. Çelikkıran², S. S. Kırlioğlu Balcıoğlu³, H. Gökçay⁴, N. Karamustafalıoğlu² and Ü. H. Yeşilkaya²

¹Faculty of Medicine, Bahcesehir University; ²Psychiatry, Bakirkoy Prof. Mazhar Osman Training and Research Hospital for Psychiatry-Neurology- and Neurosurgery; ³Psychiatry, Basaksehir Cam and Sakura City Hospital and ⁴Psychiatry, Bagcilar Training and Research Hospital, Istanbul, Türkiye

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.605

Introduction: Schizophrenia patients have demonstrated a high prevalence of suicidal behavior. There isn't yet a definitive explanation of the neurobiological mechanisms of suicidal behavior (SB) in psychotic patients. While subthreshold indices of dyslipidemia were observed in schizophrenia patients, it has shown that there is a relationship between dyslipidemia and suicidal behavior.

Objectives: The study aimed to investigate possible associations between SB and lipid profile including cardiovascular biomarkers in first-episode psychosis (FEP) as compared with healthy controls (HC).

Methods: The study sample consisted of 173 subjects (111 male, 62 female). The sample included 31 drug-naïve FEP patients with current SB (FEP+S), 66 drug-naïve FEP patients without SB (FEP-S), and 76 mentally and medically HC subjects. Blood samples were collected from all participants to determine total cholesterol (TC), low- and high-density lipoproteins (LDL and HDL), and triglycerides (TG). Castelli Risk Index-I, Castelli Risk Index-II, and atherogenic index were calculated. Symptoms were assessed by using the Positive and Negative Syndrome Scale. Nonparametric Kruskal-Wallis and Mann-Whitney tests were used for pairwise comparisons of account of lipid parameters in three groups. A binomial logistic regression analysis was performed to examine the predictive power of lipid profile in the presence of SB in FEP.

Results: The results of Kruskal-Wallis test revealed that a statistical difference was found in TC and TG between groups. Despite statistical significance was observed in TG between all patient groups (FEP+S and FEP-S) and controls, as well as in TC between FEP-S and controls, there was no significant difference between FEP-S and FEP+S for any lipid parameters or cardiovascular biomarkers. No significant correlation was identified between lipid profile and symptom severity. No significant relationships were able to predict the presence of SB in FEP.

Conclusions: In this study, plasma levels of lipid parameters and biomarkers of cardiovascular risk in all patient groups (FEP+S and FEP-S) and HC were compared. Current results show no linkage between SB and lipid profile, but significantly lower levels of cholesterol in FEP. Therefore, cholesterol might have a protective role in terms of psychosis while CI1, CI2, and AI were not increased in psychosis. Thus, increased cholesterol levels or cardiovascular risk in schizophrenia patients, that several studies found, may ensue after antipsychotic use. Overall, present findings suggest that lipid profile abnormalities are specifically associated with FEP rather than SB. Controversy of results may reveal that research on SB requires an understanding of whether the patient had concomitant psychosis.

Disclosure of Interest: None Declared

Relapse prevention with cariprazine in patients with early-stage schizophrenia

C. U. Correll^{1,2}, Z. B. Dombi^{3*}, P. L. Herman³ and Á. Barabásky³¹The Donald and Barbara Zucker School of Medicine at Hofstra/Northwell, New York, United States; ²Charité – Universitätsmedizin, Berlin, Germany and ³Global Medical Division, Gedeon Richter Plc., Budapest, Hungary

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.606

Introduction: Relapse is defined as the return of psychotic symptoms after a period of improvement/stability. Relapse is often associated with the disruptive re-hospitalization of patients. Importantly, relapse history is a strong predictor of subsequent relapses and poorer outcomes. Therefore, relapse prevention in the beginning of the disorder is especially important. Cariprazine, a novel D₃-D₂ partial agonist, has been effective in preventing relapse compared to placebo in stabilized patients with schizophrenia.

Objectives: To present the efficacy of cariprazine in preventing relapse in patients with early-stage schizophrenia.

Methods: Post-hoc analysis of data from a ~96 weeks, multicentre, randomized, double-blind, placebo-controlled, parallel-group study in adults with schizophrenia. The study was composed of two parts: a 20-week open-label treatment phase and a double-blind treatment phase up to 72 weeks. During the open-label phase, patients were stabilized with cariprazine 3.0-9.0 mg/day. Then, they were randomized to continue cariprazine (fixed dosing: 3.0, 6.0, or 9.0 mg/day) or receive placebo. Relapse was defined as a deterioration of symptom scores as measured by the Positive Negative Syndrome Scale (PANSS), admission to a psychiatric hospital, exhibiting aggressive behaviour, or risk of suicide. In the present analysis, patients with a schizophrenia diagnosis history of 0-5 years were defined as early-stage patients. Baseline characteristics, and risk ratios (after the double-blind phase) with number-needed-to-treat (NNT) were calculated.

Results: Of 200 patients, 71 (35.5%) met the early-stage criteria: 32 patients in the cariprazine (CAR) and 39 in the placebo (PBO) arm. The mean age was 31.6 years in both groups with an average illness duration of 2.51+/-1.03 years in the CAR and 2.75+/-1.24 years in the PBO arm. 47% of patients in the CAR arm and 77% in the PBO arm were men. The average number of previous hospitalisations was comparable in the two groups (CAR: 2.3; PBO: 2.6), as was the severity of illness: mean PANSS Total score: 89.2 (CAR), 90.4 (PBO). Patients in both groups were highly compliant (pill-count: CAR: 98.2%; PBO: 99.5%). The main reported adverse effects were headache (CAR: 11.3%, PBO: 7.0%), insomnia (CAR: 5.6%, PBO: 4.2%), and increased triglycerides (CAR: 5.6%, PBO: 1.4%), discontinuation due to adverse event was 3.1% in the CAR and 2.6% in the PBO group. Altogether, 9.4% of patients relapsed in the cariprazine group compared to 48.7% on placebo (risk ratio=0.19 (95% confidence interval (CI): 6.3-59.2%, p=0.0041; NNT: 2.5 (95%CI: 1.7-5.1)).

Conclusions: In this post-hoc analysis of patients within the first five years of schizophrenia, the relative risk of relapse was 81% reduced with cariprazine with prevention of one additional relapse after each third patient exposed to cariprazine vs placebo. Cariprazine seems to be a good treatment option for early-stage patients for preventing relapse.

“Neighborhood Vulnerability and Disability in First Episode of Psychosis”.

I. Leal^{1*}, A. IZQUIERDO² and M. cabello²¹psiquiatria, HOSPITAL DE LA PRINCESA, MADRID and²psiquiatria, Universidad autonoma de madrid, spain, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.607

Introduction: Neighborhood socioeconomic status seems to be related to functioning in patients with first episode of psychosis (FEP).

Objectives: The present study aimed to assess if neighborhood vulnerability and risk of social exclusion could predict functional outcomes in people with FEP after controlling for other key variables identified in previous literature.

Methods: A total of 137 patients with FEP (DSM-IV-TR criteria) and 90 controls comprised the study sample from February 2013 to May 2019. Functioning was assessed with the WHO Disability Assessment Schedule. Neighborhood vulnerability was measured using a multidimensional socioeconomic deprivation index; data for the index were collected by the Madrid City Council and based on the participant's home address. Multilevel mixed-effects regression analyses were conducted to estimate the effects of neighborhood vulnerability on functioning.

Results: Our results show that FEP patients could be more vulnerable to the effects of neighborhood-level characteristics than healthy controls ($B = 1,570.173$; $z = 3.91$; $P < .001$). In addition, our findings suggest that higher neighborhood vulnerability is related to greater functional disability in people with FEP, after controlling for other relevant confounders ($B = 1,230.332$; $z = 2.59$; $P = .010$). based on the participant's home address. Multilevel mixed-effects regression analyses were conducted to estimate the effects of neighborhood vulnerability on functioning.

Results: Our results show that FEP patients could be more vulnerable to the effects of neighborhood-level characteristics than healthy controls ($B = 1,570.173$; $z = 3.91$; $P < .001$). In addition, our findings suggest that higher neighborhood vulnerability is related to greater functional disability in people with FEP, after controlling for other relevant confounders ($B = 1,280.332$; $z = 2.59$; $P = .010$).

Conclusions: These results highlight the importance of incorporating contextual factors into assessment of patients with FEP, since psychosocial difficulties observed in these patients could be

partially related to the quality of neighborhood social-related resources.

Direct adjusted comparison of expressed emotion towards patients with schizophrenia between halfway houses and family settings

P. Ferentinos^{1*}, S. Douki², E. Kourkouni³, D. Dragoumi², N. Smyrnis¹ and A. Douzenis¹
¹2nd Department of Psychiatry, “Attikon” University General Hospital, National and Kapodistrian University of Athens; ²Department of Psychiatry, Evangelismos” General Hospital and ³Center for Clinical Epidemiology and Outcomes research, Athens, Greece
*Corresponding author.
doi: 10.1192/j.eurpsy.2024.608

Introduction: Rates of high expressed emotion (EE) towards patients with schizophrenia have only indirectly been compared between families and community residential facilities, since studies including patients in both settings are unfortunately lacking. High EE rates in staff-patient studies are typically lower than in families, with negligible rates of high emotional overinvolvement (EOI). However, indirect comparisons can suffer from many biases.

Objectives: This study directly compared patients with schizophrenia living in halfway houses or with their families on the EE of their caregivers, adjusting for patient- and caregiver-related confounders.

Methods: We included 40 inpatients with schizophrenia living in halfway houses and 40 outpatients living with their families and recorded the EE of the caring staff (N=22 nurses) or parents (N=56), respectively, through Five Minutes Speech Sample interviews. Each nurse rated 1-12 inpatients and each inpatient was rated by 2-5 nurses, totaling 155 nurse ratings. Each outpatient was rated by one or both parents. Due to the multilevel structure of EE ratings, generalized linear mixed models were fitted. We first adjusted only for differences in patient-related confounders between groups and then added basic caregiver-related demographics.

Results: Compared to outpatients, inpatients were older (p=0.001), less well educated (p=0.002), had a longer disease duration (p=0.047), more hospitalizations (p=0.012), lower severity of psychotic (p=0.027) and, specifically, negative symptoms (p=0.015), and lower perceived criticism (p=0.001). Nurses were younger (p<0.001) and better educated (p=0.001) than parents. After adjusting for patient-related confounders only, EOI was significantly higher in parents (p=0.027) while criticism did not significantly differ between groups. However, after also adjusting for caregiver demographics (age, gender and education), criticism was significantly higher in nurses (p=0.027) while differences in EOI became non-significant.

Conclusions: Differences in EE, when directly compared between parents and professional caregivers, may be explained by differences in patient-related characteristics, caregiver demographics as well as other caregiver characteristics to be investigated in future studies.

*Corresponding author.
doi: 10.1192/j.eurpsy.2024.609

Introduction: The Positive and Negative Syndrome Scale (PANSS) has been used as a universal instrument for clinical assessment of psychopathology in schizophrenia. Different studies have analyzed the factorial structure of this scale and have suggested a five-factor model: positive, negative, excited, depressive, and cognitive/disorganized factors. Two of the most used models are the Marder’s solution and the Wallwork’s one.

Objectives: The aim of this work was to study the correlations of the two cognitive factors (Marder and Wallwork) with a cognitive assessment performed with a standard cognitive battery, in a sample of patients with first psychotic episode of schizophrenia.

Methods: Seventy four patients with first psychotic episode of schizophrenia (26.9, SD:7.8 years old; 70.3% male) were included. The cognitive assessment was performed with the MATRICS Consensus Cognitive Battery (MCCB). The MCCB present seven cognitive domains: Speed of processing, Working memory, Attention/Vigilance, Verbal Learning, Visual Learning, Reasoning and Problem Solving, and Social cognition). Pearson correlations were performed between MCCB scores and Marder’s PANSS cognitive factor (P2, N5, G5, G10, G11, G13, G15) and Wallwork’s one (P2, N5, G11).

Results: Correlation between MCCB scores and cognitive factors of Marder and Wallwork can be seen in the table.

	Marder’s cognitive factor	Wallwork’s cognitive factor
Speed of processing	r = -0.461; p<0.001	r = -0.455; p<0.001
Attention/Vigilance	r = -0.414; p<0.001	r = -0.415; p<0.001
Working memory	r = -0.449; p<0.001	r = -0.468; p<0.001
Verbal Learning	r = -0.511; p<0.001	r = -0.405; p<0.001
Visual Learning	r = -0.252; p=0.024	r = -0.254; p=0.029
Reasoning and Problem Solving	r = -0.244; p=0.036	r = -0.272; p=0.019
Social cognition	r = -0.268; p=0.024	r = -0.202; p=0.091

Conclusions: Both PANSS cognition factors show a moderate correlations with Speed of processing, Working memory, Attention/Vigilance and Verbal Learning assessed by MCCB. More discrete correlations were found with Visual Learning, Reasoning and Problem Solving, and with Social cognition (in fact, non-significant correlation with Wallwork's cognitive factor was found).

The polymorphism ZNF804A rs1344706 is differentially associated with negative symptoms domains in schizophrenia

T. Lezheiko, N. Kolesina and V. Golimbet*

Clinical Genetics Laboratory, Mental Health Research Center, Moscow, Russian Federation

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.610

Introduction: Negative symptoms (NS) are an important clinical characteristic of schizophrenia. In recent years, clinical research on NS has focused on their clinical heterogeneity. Based on two-factor analysis, it has been proposed to divide NS into abulia-apathy (AA) and expressive deficit (ED) domains. A number of studies have shown that these domains have different effects on the clinical features of schizophrenia, which suggests different pathophysiological mechanisms of their development. Neurobiological differences between AA and DE have been identified in neuroimaging and immunological studies but there is less research on the genetic background of NS.

Objectives: To search for an association between the rs1344706 polymorphism of the zinc finger protein gene (ZNF804A) and the AA and ED subdomains. The rs1344706 polymorphism is one of the best-supported risk variants for schizophrenia. The risk genotype AA has been shown to be associated with clinical presentations of the disease.

Methods: The study included 1116 (741 (66.3% women) patients with schizophrenia. The diagnosis was made according to ICD-10 criteria (item F20). The average age of the patients was 38.4 (13.6) years, age at disease onset was 26.1 (10.6) years. NS were assessed with the PANSS. The PANSS-derived AA domain consisted of Emotional withdrawal (PANSS item N2), Apathetic social withdrawal (N4), Active social avoidance (G16). The DE domain included Blunted affect (N1), Poor rapport (N3), Lack of spontaneity (N6), Mannerism and posturing (G5), Motor retardation (G7), Disturbance of volition (G13). Genotyping of the ZNF804A rs1344706 polymorphism was carried out using HRM-PCR. ANOVA with genotype and sex as independent variables, and age at the time of disease manifestation and its duration as covariates was used. Post hoc tests were performed using Bonferroni correction.

Results: A significant effect of the rs1344706 polymorphism on the severity of symptoms in the AA domain was revealed ($F=5.88$, $df=2$, $p=0.002$). In carriers of the CC genotype, the severity of symptoms

was significantly lower than in carriers of the AA genotype and the AC genotype (8.4(3.5), 9.4(7.4) and 8.8(3.5) points, respectively). This effect was independent of sex and was not mediated by age at onset or duration of disease. There was no effect of the rs1344706 polymorphism on the severity of symptoms in the ED domain.

Conclusions: The association of the ZNF804A rs1344706 (A/C) polymorphism with NS of schizophrenia has not been reported so far though some studies have found the effect of this polymorphism on PANSS positive symptoms and PANSS total score. The finding of the association with NS can be explained by the fact that the NS heterogeneity was taken into account in the present study.

Rates of perinatal environment risk factors in schizophrenia patients with higher and lower schizophrenia polygenic risk scores

M. Alfimova¹, M. Gabaeva¹, T. Lezheiko¹, V. Plakunova¹ and V. Golimbet^{1*}

¹Clinical Genetics Laboratory, Mental Health Research Center, Moscow, Russian Federation

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.611

Introduction: Understanding the relations between genetic (G) and environmental (E) factors in the development of schizophrenia is important for psychosis prevention. These relations may vary from G x E correlations to G x E interactions and independent additive effects of genetic load and environment. The G x E interactions mean that genetic variants associated with schizophrenia make an individual vulnerable to specific environmental exposures thus enhancing the risk of disease manifestation in those who possess such genetic variants. In the case of independent effects, environmental exposure might serve as the main cause or an additional to genetic load external trigger which is needed for the illness development. Thus, the rate of independent environmental risk factors is expected to be higher in patients with a lower genetic liability to schizophrenia.

Objectives: The study aimed to confirm this hypothesis by comparing schizophrenia patients with higher and lower polygenic risk scores for schizophrenia (SZ-PRS) on the rate of urbanicity, winter birth and obstetric complications (OC), as previous data suggested their independence from the genetic burden of the disease.

Methods: SZ-PRS were calculated for 861 patients with schizophrenia spectrum diagnoses (ICD-10, F2), predominantly of Slavic decent, based on the latest GWAS. For patients comprising the highest and lowest SZ-PRS deciles, information on the environmental risk factors was extracted from medical records. Each environmental factor was coded as present/absent. The presence were defined as being born in the most urban environment (a city's population > 5 million), in winter months and having at least one OC from a predefined list (Alfimova *et al.* Int J Mol Sci 2022; 23: 12629). In addition, hypoxia/asphyxia, and low birth weight were analyzed separately. Polyenvironmental risk scores (PERS) aggregating the three factors were calculated using natural logarithms of the odds ratios (OR) from an umbrella review (Radua *et al.* World

Psychiatry 2018; 17: 49-66). Logistic regression adjusted for ancestry-related principal components, demographic, and technical variables was applied to compare the SZ-PRS deciles on each factor and PERS.

Results: None of the factors alone or PERS predicted SZ-PRS decile membership.

Conclusions: The results did not support the hypothesis. Future research needs reliable data on the frequency of the studied factors in the general population where the patients come from. The study was supported by the Russian Science Foundation, grant no. 21-15-00124.

Clinical, psychological and brain imaging investigation of first episode psychosis patients treated at Semmelweis University, Department of Psychiatry and Psychotherapy, Budapest, Hungary

R. I. Zsigmond^{1*}, L. Hermán¹, V. Simon¹, G. Csukly¹, E. Vass¹, M. Baradits¹ and J. Réthelyi¹

¹Semmelweis University, Budapest, Hungary

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.612

Introduction: First episode psychosis (FEP) is the first manifestation of psychotic disorders lasting at least one week, but not longer than 2 years, causing personal suffering and decreased functional outcome of patients. The early intervention in FEP is crucial. Published results on early intervention programmes indicate that during the first 5-10 years relapse prevention and functional outcomes can be improved and mental health care costs can be reduced, compared to treatment as usual.

Objectives: Our objective was to examine FEP patients at the Department of Psychiatry and Psychotherapy. Our aim was to create a homogeneous sample and identify factors that can help in early differential diagnosis and therapy. Our goal was to compare the neuropsychological performance and MRI results of patients and healthy controls.

Methods: Male and female inpatients hospitalized at our department due to a first psychotic episode and consenting to participate were included, since 2019 October. Cases with drug induced psychosis and organic background in the etiology of the psychotic episode were excluded. Male and female healthy controls were matched by age and education. Including healthy controls is still in progress. The duration of the project is 36 months, 24 months for recruiting patients and healthy controls, 12 month for analyzing data. The investigation includes detailed clinical, neuropsychological examination (baseline, 6th, 12th, 18th, 24th month) and MRI (baseline and in the 24th month).

Results: Forty patients and sixteen healthy controls were included. 60% of the patients were rehospitalized due to relapses. Neuropsychological tests (RBANS, faux pas, Baron-Cohen eyes test) indicate cognitive dysfunction compared to healthy subjects. Using resting state fMRI second level analysis we found alterations in thalamo-cortical connectivity. We found significant differences in the connectivity of the thalamus and frontal lobe, postcentral gyrus, insula and cerebellum.

Conclusions: Our FEP research, although limited by the COVID-19 pandemic, shows promising results that can help in better understanding of the underlying factors of psychotic disorders.

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.613

Introduction: New drugs in the treatment of dual psychosis: use of cariprazine in schizophrenia, other psychotic disorders and use of cocaine. A case series in a specific outpatient psychiatric clinic for substance use disorders.

Objectives: The main objective of this case series is to observe and describe the tolerability and clinical response to different doses of cariprazine in a series of patients with dual psychosis, specifically cocaine users; with a special attention upon psychotic symptoms, disruptive behaviour, affective symptoms and cocaine use pattern.

Methods: This series consists of an observation of a total of 20 patients treated on an outpatient basis. All of them had a either a diagnosis of Schizophrenia or Other Non Specified Psychotic Disorder meeting the DSM-5 criteria, as well as a Cocaine Use Related Disorder meeting the DSM-5 criteria. All of them received treatment with cariprazine in different doses from 1,5mg to 6mg per day, as a solo treatment or as an adjuvant to another previous antipsychotic treatment when antipsychotic augmentation was justified. We observed patients that had started cariprazine in the past three months and that had active drug use or had had one in the past three months.

We monitored the tolerance to the treatment, the clinical response in terms of positive and negative symptoms of schizophrenia, affective symptoms, disruptive behavior, and the response in terms of substance use; for a period of six months of follow-up, with psychiatric consultation at least every month and nurse consultation every two weeks in our clinic.

Results: 95% of the patients did not present any side effect related to cariprazine. In one patient (5%) the treatment had to be stopped due to akathisia that did not disappear after two weeks and symptomatic treatment with benzodiazepines. 60% of patients either stopped using (50%) or reduced their use frequency (50%). 70% of the patients presented an improvement in positive symptoms and behavior. Also, one third of them presented a slight improvement in negative symptoms. 20% of patients referred a significant improvement in depressive symptoms.

Conclusions: The main conclusion of this case series is that cariprazine at any dosis between 3mg and 6mg per day has a positive outcome, both in the psychotic domain and the substance use disorder. We hope this case series will help our colleagues treat their patients suffering from these pathologies in an optimal way. This could also set a basis to encourage a proper clinical trial to assess if new antipsychotics such as cariprazine could be a new standard for the treatment of Dual Disorders.

Exercise addiction: is it linked to eating disorders? A cross-sectional study in a sample of Tunisian athlete students

N. Smaoui¹, O. Bouattour^{1*}, R. Feki¹, I. Gassara¹, M. Maalej¹, N. Charfi¹, J. Ben Thabet¹, M. Maalej¹, S. Omri¹ and L. Zouari¹

¹psychiatry C department, Hedi chaker university hospital, sfax, Tunisia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.614

Introduction: Eating disorders and sports addiction are becoming increasingly common among athletes. It's important to be aware of these disorders in order to improve their overall prevention.

Objectives: The aim of our study was to determine the links between exercise addiction (EA) and eating disorders in Tunisian students at the Institute of Physical Education and to examine the factors associated with these disorders.

Methods: An anonymous self-administered questionnaire was distributed to students in the Sfax and Gafsa sports sections during March 2023. The Exercise Addiction Inventory (EAI) was used to study exercise addiction. It is a scale whose purpose is to separate individuals into 3 groups: those at risk of exercise addiction (score ≥ 24), those non-addicts with symptoms (score 13 to 23) and those non-addicts without symptoms (score 0 to 12).

Eating disorders were assessed using the SCOFF-F questionnaire (Sick, Control, One stone, Fat, Food), with a score of 2 or more indicating possible eating disorders.

Results: We collected 240 participants. The mean SCOFF-F and EAI scores were 1.7 ± 1.3 and 16.6 ± 4.1 respectively. Among the participants, 52.9% of students were at risk of developing eating disorders and 2.5% of students were at risk of exercise addiction. In our study, 82.5% of students took part in regular physical activity in a gym. The main reasons for going to the gym were muscle strengthening (57.9%) and preparation for a sporting competition (37%).

Among students exercising outside the institute, the mean SCOFF score was significantly higher for those doing so to prepare for a sports competition ($p=0.001$), for professional obligations ($p=0.005$) or for weight loss ($p=0.001$). Participants at risk of exercise addiction had a higher mean SCOFF score, but the difference was not significant ($p=0.051$).

Conclusions: Our study shows that eating disorders were widespread among Tunisian athlete students, and were higher among students at risk of exercise addiction.

Suicidal behaviour and intravenous drug use in chemsex context

J. Curto Ramos^{1,2*}, A. Rodríguez Laguna², P. Barrio², L. Ibarguchi², A. García², I. Azqueta² and H. Dolengevich Segal³

¹Department of Psychiatry, Clinical Psychology and Mental Health, La Paz University Hospital; ²Apoyo Positivo and ³Dual Disorders Program. Department of Psychiatry, Henares University Hospital, Madrid, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.615

Introduction: Several studies have called attention to the mental health disorders associated with chemsex --the intentional use of drugs before or during sexual intercourse GBMSM (gay, bisexual and men who have sex with men) population-. Sexualized intravenous drug use is also known as slam or slamsex. There are few studies that analyze the mental health differences between intravenous drug users compared to non-intravenous drug users in chemsex context.

Objectives: To describe the suicidal behaviour in a sample of users with sexualized drug use (chemsex) attended by the non-governmental organization Apoyo Positivo in the program "Sex, Drugs and You" and to compare the suicidal behaviour between intravenous drug users compared to non-intravenous drug users.

Methods: A cross-sectional descriptive analysis of a sample of users attended by the non-governmental organization Apoyo Positivo in the program "Sex, Drugs and You" between 2016-2019 was performed.

Results: We included 217 participants. 37 had attempted suicide at least once. The percentage of chemsex users who have attempted suicide were significantly higher in the intravenous drug use group compared to the non-intravenous drug use group ($p<0.05$).

Conclusions: Possible risk factors for suicidal behaviour among chemsex users include slamsex. Other possible risk factors previously described in other studies include adversities experienced due to one's sexual orientation and an increased risk for HIV and other STI infections. Further studies analyzing the relationship between chemsex, slamsex and suicidal behaviour are needed.

Current Challenges and Future Directions of Research in Cell Phone Addiction

O. Vasiliu

Psychiatry, Dr. Carol Davila University Emergency Central Military Hospital, Bucharest, Romania

doi: 10.1192/j.eurpsy.2024.616

Introduction: Behavioral addictions (BAs) are intensely explored during the last decades due to their impact on the quality of life, functionality, socio-economical negative consequences, and high risk of mental health negative consequences. BAs are new challenges for clinicians and researchers due to a lack of well-defined diagnostic criteria, very few available epidemiological data, and

scarce information about efficient therapeutic interventions. Cell phone addiction (CPA) has been raising a significant interest for mental health specialists because of its increasing prevalence and potential long-term physical and mental complications. Therefore, an analysis of the available data about the main characteristics of this pathology seems granted.

Objectives: The main objective of this review was represented by the need to find relevant reports about the epidemiological, clinical, and therapeutic interventions in CPA.

Methods: A narrative review focused on the available treatments for food addiction was performed through a search in four electronic databases (PubMed, Cochrane, EMBASE, and Web of Science/Clarivate) using the paradigm “cell phone addiction” or “smartphone dependence” and “treatment” or “epidemiology” or “diagnostic criteria” or “risk factors.” No inferior time limit for published papers was established, and the superior limit was July 2023.

Results: A relatively large number of papers regarding this topic were found (n=772), but after applying the inclusion and exclusion criteria, only 29 articles remained. Female gender and adolescents, but also high anxiety levels, insomnia, excessive Internet use, less physical activity, and a higher level of dependence have been correlated with CPA. Six validated scales have been identified as possible instruments for monitoring the CPA evolution. Different diagnostic criteria have been suggested, but they still lack clinical validation. Cognitive-behavioral therapy could be helpful, and smartphone applications that limit online time could also be efficient. Treatment of previously mentioned vulnerability factors is also recommended to obtain long-term favorable effects.

Conclusions: CPA is an increasingly explored BA, but validated diagnostic criteria are still missing. The treatment is also based on extrapolations from other addictions. Therefore large sample-based therapy trials are needed.

Relationship Between Neutrophil-Lymphocyte Ratio and Treatment Retention in Individuals with Opioid Use Disorder

Y. Taylan¹ and M. B. Sönmez^{2*}

¹Istanbul Sultanbeyli State Hospital, İstanbul and ²Trakya University School of Medicine, Edirne, Türkiye

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.617

Introduction: Inflammatory processes may play a role in the pathophysiology of substance use disorders. Chronic opiate use may lead to inflammation, and elevated inflammation markers have been observed in individuals with opioid use disorder (OUD). The Neutrophil-Lymphocyte Ratio (NLR) serves as an indicator of systemic inflammation. NLR can be employed in both diagnosis and treatment monitoring as an inflammatory marker to gauge the severity of OUD.

Objectives: Our aim was to assess the utility of NLR as a marker of chronic inflammation in diagnosing and monitoring treatment in individuals with OUD.

Methods: A total of 200 patients with OUD and 78 healthy control subjects were enrolled in the study. Patients were initially admitted

to a 28-day abstinence-based inpatient program and subsequently transitioned to outpatient buprenorphine/naloxone (B/N) maintenance treatment after hospitalization at the Alcohol and Substance Addiction Treatment Center in Trakya University School of Medicine (Edirne, Türkiye). NLR was employed as a measure of systemic inflammation. Blood samples were collected the morning following admission for detoxification. Patients were categorized into two groups: the treatment retention group and the dropout/relapse group based on their 3-month and 12-month follow-up results. Clinical data were obtained from patient records.

Results: At the 3-month follow-up, the median NLR with interquartile range was 1.34 (1.05-1.99) in the treatment retention group (n=112) and 1.72 (1.11-2.46) in the dropout/relapse group (n=88). At the 12-month follow-up, the median NLR with interquartile range was 1.28 (0.88-1.85) in the treatment retention group (n=52) and 1.56 (1.07-2.33) in the dropout/relapse group (n=148). The median NLR in the control group (n=78) was 1.36 (1.12-1.74). According to the 3-month and 12-month follow-up data, the difference between the groups concerning NLR was statistically significant ($\chi^2=9.072$, $p=0.011$; $\chi^2=11.165$, $p=0.004$; respectively). Pairwise comparisons indicated that patients in the dropout/relapse group had significantly higher baseline NLR values than those in the treatment retention group and healthy controls according to the 3-month ($p=0.038$ and $p=0.019$, respectively) and 12-month follow-up data ($p=0.012$ and $p=0.040$, respectively). NLR did not differ significantly between the treatment retention and control groups in both follow-ups ($p>0.05$).

Conclusions: Our findings suggest that elevated baseline NLR is associated with dropout/relapse in OUD, indicating its potential as a marker for treatment follow-up in these patients.

Relationship of Interoceptive Accuracy with Craving, Personality Dimensions, and Alexithymia in Alcohol Use Disorder

E. Kahyacı Kılıç¹ and M. B. Sönmez^{2*}

¹Edirne Sultan 1. Murat State Hospital and ²Trakya University School of Medicine, Edirne, Türkiye

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.618

Introduction: Interoception encompasses processes that involve receiving, processing, and integrating bodily signals with external stimuli, ultimately influencing ongoing motivated behaviors. Disruptions in these interoceptive processes are believed to contribute to the development and progression of alcohol use disorder (AUD). Interoceptive accuracy (IAC), the objective dimension of interoception, has been shown to be decreased in patients with AUD. Traits linked to substance use vulnerability, such as personality dimensions and alexithymia, may be associated with decreased IAC.

Objectives: Our objective was to compare the heartbeat perception (HBP) scores, as a measure of IAC, between abstinent inpatients with AUD and healthy controls. Additionally, we aimed to investigate potential associations between IAC and variables such as alcohol craving, personality dimensions, and alexithymia.

Methods: The study comprised 48 abstinent inpatients with AUD and 68 healthy control subjects. All participants completed a heart rate tracking task, serving as an objective physiological measure of IAC. In addition to the IAC task, several assessments were administered to the patient group, including the Alcohol Use Disorders Identification Test (AUDIT), the Penn Alcohol Craving Scale (PACS), the Temperament and Character Inventory (TCI), and the Toronto Alexithymia Scale (TAS-20). Patients were recruited for a 28-day abstinence-based inpatient treatment program, and all assessments were conducted during the final week of hospitalization at the Alcohol and Substance Addiction Treatment Center in Trakya University School of Medicine (Edirne, Türkiye).

Results: Patients' HBP scores (mean \pm standard deviation: 0.59 ± 0.21) were significantly lower than those of healthy control subjects (0.74 ± 0.15) ($t = -4.469$, $p < 0.001$). The patients' HBP scores showed significant negative correlations with AUDIT ($r = -0.312$, $p = 0.035$), PACS ($r = -0.361$, $p = 0.019$), and TAS-20 scores ($r = -0.406$, $p = 0.004$). Additionally, there was a significant positive correlation between patients' HBP scores and TCI self-directedness scores ($r = 0.371$, $p = 0.009$), and a near-significant correlation with TCI persistence scores ($r = 0.282$, $p = 0.052$). TCI novelty seeking, harm avoidance, reward dependence, cooperativeness, and self-transcendence scores did not significantly correlate with patients' HBP scores ($p > 0.05$).

Conclusions: Our findings may support the hypothesis that interoceptive processes play a role in AUD, and that certain traits linked to vulnerability to alcohol use are associated with decreased IAC.

Factors influencing delays in the diagnosis and treatment of bipolar disorder in adolescents and young adults: A systematic scoping review.

A. Levit^{1*}, J.-J. Nunez^{1,2}, E. Morton^{1,3} and K. Keramatian^{1,2,4}

¹Department of Psychiatry, University of British Columbia; ²Mood Disorders Clinic, Djawad Movafighan Centre for Brain Health, Vancouver, Canada; ³School of Psychological Sciences, Monash University, Melbourne, Australia and ⁴Coastal Early Psychosis Intervention Program, North Vancouver, Canada

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.619

Introduction: Bipolar Disorder (BD) is a complex psychiatric condition that typically manifests during late adolescence and early adulthood. Over the past two decades, international studies have reported that BD often goes unrecognized and untreated for several years, which can lead to negative clinical and functional outcomes. However, the components of delay in the diagnosis and treatment of BD in adolescents and young adults and various factors influencing those components have not been systematically explored.

Objectives: To determine the known factors that contribute to delays in the treatment of BD in adolescents and young adults and identify current knowledge gaps.

Methods: A conceptual framework based on the *Model of Pathways to Treatment* by Scott and colleagues was used as a foundation for

our search and extraction strategy to ensure all components of delay and potential factors influencing each component are explored. We used the Preferred Reporting Items for Systematic Reviews and Meta-Analyses guideline (PRISMA-ScR) to systematically search the electronic databases of MEDLINE (OVID), EMBASE, PsycINFO and CINAHL for peer-reviewed original research articles published from January 01, 2000 through March 29, 2023. Inclusion was restricted to studies with quantitative or qualitative data on individuals diagnosed with bipolar spectrum disorders with symptomatic onset or study participation between the ages of 13-24. Grey literature and studies not published in English were excluded due to resource limitations. Two independent reviewers screened the references retrieved by the literature search based on our inclusion criteria. The findings of included studies were summarized in a narrative and tabular form according to component of delay.

Results: Our search yielded 5180 unique citations, of which 44 articles met our inclusion criteria. We present findings on the patient, illness, and healthcare provider/mental health system factors contributing to the delays in illness appraisal, help-seeking, diagnosis, and treatment.

Conclusions: To the best of our knowledge, this is the first systematic scoping review to explore the potential factors that influence delays in the treatment of BD in adolescents and young adults. Findings from this review will inform clinical practice and policy. We also demonstrate the utility of a systematic approach to identifying the components of delay, from symptom recognition through treatment, as a methodology to help identify knowledge gaps to inform future research.

Concentration of HSPA1A and transthyretin proteins in the blood serum of patients with bipolar disorder

L. Smirnova^{1*}, E. Epimakhova¹, A. Seregin¹, A. Ryzhkova² and G. Simutkin³

¹Laboratory of Molecular Genetics and Biochemistry, Mental Health Research Institute, Tomsk National Research Medical Center of the Russian Academy of Sciences; ²Biochemistry, Siberian State Medical University and ³Affective States Department, Mental Health Research Institute, Tomsk National Research Medical Center of the Russian Academy of Sciences, Tomsk, Russian Federation

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.620

Introduction: Insufficient knowledge about the pathophysiological processes in bipolar disorder (BD) leads to difficulties in differentiating this disorder from other affective disorders. Quantitative analysis of serum protein profiles in BD expands our understanding of the pathophysiology of the disease and may aid in subsequent diagnosis. As a result of a previously conducted comparative mass spectrometric study of serum proteins in patients with depression, bipolar disorder and healthy donors, increased expression of Heat Shock 70kDa Protein1A (HSPA1A) and transthyretin was identified.

Objectives: Determination of HSPA1A and transthyretin concentrations in the blood serum of patients with mental disorders.

Methods: Blood serum of 28 patients with bipolar disorder aged 49 years [33;52], 30 patients with recurrent depressive disorder aged 40 years [31; 51] and 130 patients with schizophrenia aged 38 years [31;49], as well as 20 mentally and somatically healthy individuals aged 35 years [31;40] was studied. The amount of Heat shock protein 1A (HSPA1A) and Transthyretin (thyroxine and retinol transport protein) was determined using a Enzyme-linked Immunosorbent Assay Kit from Homo sapiens (Cloud-Clone Corp). Statistical data processing was carried out in the Statistica 12.0 program.

Results: A statistically significant ($p = 0.016$) increase in the level of HSPA1A was found in patients with BD (0.84 [0.59; 1.09] ng/ml), compared with healthy individuals (0.61 [0.51; 0.77] ng/ml). HSPA1A plays a pivotal role in the protein quality control system, ensuring the correct folding of proteins. It is known that this protein is involved in the embryonic development of the central nervous system, as well as in neuroprotection by preventing the death of neurons due to its anti-apoptotic properties. A statistically significant ($p = 0.047$) increase in the level of transthyretin was found in patients with BD 21.8 pg/ml, compared with healthy individuals 19.4 pg/ml. Transthyretin plays an important role in ensuring the normal state of the central nervous system and is involved in cognitive processes.

Conclusions: Thus, the HSPA1A and transthyretin are probably involved in the pathogenesis of BD and can be proposed as be proposed as an additional paraclinical criterion for differential diagnosis.

EPP0484

How Many Criteria Should be Required to Define the DSM-5 Mixed Features Specifier in Depressed Patients?

M. Zimmerman

Psychiatry, Brown University, Providence, United States

doi: 10.1192/j.eurpsy.2024.621

Introduction: During the past 2 decades there has been intense interest in the clinical significance of the concurrence of manic symptoms in depressed patients. DSM-5 introduced a mixed features specifier for both bipolar depression and major depressive disorder. Studies of the DSM-5 mixed features specifier have generally found a low prevalence of mixed depression. One approach towards increasing the sensitivity of the DSM-5 mixed features criteria is to lower the classification threshold.

Objectives: In the present study we examine the impact of lowering the DSM-5 diagnostic threshold from 3 to 2 criteria on the prevalence and validity of the DSM-5 mixed features specifier for depression.

Methods: Four hundred fifty-nine psychiatric patients in a depressive episode were interviewed by a trained diagnostic rater who administered semi-structured interviews including the DSM-5 Mixed Features Specifier Interview. The patients were rated on clinician rating scales of depression, anxiety and irritability, and measures of psychosocial functioning, suicidality, and family history of bipolar disorder.

Results: If the DSM-5 diagnostic threshold is lowered from 3 to 2 symptoms, then the prevalence of mixed features based on the

DSM-5 majority of episode time frame tripled from 3.9% to 13.1% ($n=60$). Based on a past week time frame prevalence more than doubled from 9.4% to 22.9% ($n=105$) going from the 2 and 3 symptom threshold, respectively. There was no difference between the patients with 2 mixed features and patients with 0 or 1 mixed features on family history of bipolar disorder, psychosocial impairment, presence of comorbid disorders, age of onset, history of suicide attempts or psychiatric hospitalization.

Conclusions: The results of the present study do not support lowering the DSM-5-TR diagnostic threshold for the mixed features specifier in depressed patients from 3 to 2.

EPP0485

Understanding Lithium intoxication in Bipolar Disorder: a comparative analysis and clinical implications

O. Martin-Santiago^{1*}, C. D. Andres-Lobo¹, T. Jimenez-Aparicio¹, C. Vallecillo-Adame¹ and A. Perez-Escudero²

¹Hospital Clinico Universitario, Valladolid and ²Complejo Asistencial, Zamora, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.622

Introduction: Lithium treatment is a proven method for bipolar disorder management, but its narrow therapeutic range and the risk of severe side effects, including lithium intoxication, pose significant clinical hurdles. Lithium intoxication, a potentially life-threatening complication, can occur during treatment, raising ongoing questions about its clinical factors, risk elements, and best practices for management.

Objectives: Our objective is a comparative analysis between patients who have experienced lithium intoxication and those who have not, aiming to identify influencing factors and enhance clinical care.

Methods: We collected demographic data, age at lithium treatment initiation, treatment duration, therapeutic adherence, Mental Health consultations, and lithium level monitoring from 14 individuals requiring clinical attention due to lithium intoxication and 14 patients with similar gender, age, and diagnosis with lithium treatment but without intoxication during four years of follow-up.

Results: Regarding the results, the age of onset of lithium treatment in patients with lithium intoxication was 30.2 years ($SD=8$), and the duration of lithium treatment averaged 11.1 years ($SD=8.8$), which did not significantly differ from the control group with ages of onset at 38.1 years ($SD=15.1$) and treatment duration of 9.27 years ($SD=8.8$), respectively. Lithium intoxication patients developed severe complications, including hospitalizations in medical-surgical units, the necessity for dialysis, and death, one fatal case. Although therapeutic adherence to lithium, measured through pharmaceutical dispensation, exceeded 90% and was comparable in both groups, patients affected by lithium intoxication exhibited a significantly higher treatment discontinuation rate ($OR\ 32.5$; 95% CI, 3.1 to 337.8) during the follow-up period. Patients who experienced lithium intoxication had an average of psychiatric consultations every 11.2 months ($SD=13.4$), with 35.7% not attending at least once a year, while the control group had an appointment every 5.31 months ($SD=2.7$) ($p > 0.05$). Lastly,

despite both groups having a similar frequency of plasma lithium level monitoring, occurring approximately every 5.5 months (SD=2.6) and 7.8 months (SD=4.8), respectively, in 28.5% of those who suffered from lithium intoxication did not undergo any monitoring for periods exceeding 18 months ($p < 0.05$).

Conclusions: Our research highlights the significance of delivering thorough clinical care and continuous monitoring to patients receiving lithium treatment for bipolar disorder. Ensuring effectiveness therapeutic adherence and maintaining strict monitoring of lithium levels are critical factors that significantly enhance treatment safety. Appropriate management has the potential to improve the quality and safety of care for people with bipolar disorder who are dependent on lithium therapy.

Pharmacogenetic intervention in the Child and Adolescent Autism Day Therapeutic Unit

A. Alvarez^{1*}, N. Santamaria², V. Bote¹, R. Medina¹, B. Sanchez², I. Mendez², J. A. Monreal², M. J. Arranz³ and A. Hervás²

¹University Hospital Mutua Terrassa, Terrassa, Spain; ²Mental Health, University Hospital Mutua Terrassa and ³Mutua Terrassa Foundation, Terrassa, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.623

Introduction: The ASD Therapeutic Day Unit is a tertiary care unit that consists of 20 beds, designed to facilitate the evaluation and treatment of children and adolescents with ASD who present high psychiatric comorbidity with behavioral problems, communication/language problems, sensory, and/or in the management of their repetitive and restricted interests. In addition to diagnosis and genetic counseling and clinical care, we offer the possibility of performing an individualized pharmacogenetic study in order to offer appropriate pharmacological treatment to patients with ASD and comorbidities.

Objectives: The objective is to promote pharmacological tolerability, avoid unwanted side effects, as well as avoid the use of polypharmacy, in children with a tendency to poor drug metabolism.

Methods: A review of the medical history of the patients included in the Blood Extraction Program of the ASD Day Therapeutic Unit is carried out during the year 2022. The existing medications at admission, the results of the pharmacogenetic analyzes carried out, and the pertinent changes in the pharmacological treatment of these children.

Results: 37 children were included in the program during 2022. The genes CYP1A2, CYP2C19, CYP2D6, CYP3A4 and 5-HTT were analyzed. The variant studied is described, as well as the observed genotype and the expected phenotype.

Of the 37 patients, 11 maintained the same pharmacological treatment as at the beginning of admission, 5 were not taking pharmacological treatment and 25 underwent a treatment modification. The most frequently modified treatment was risperidone with aripiprazole ($n=10$), secondly risperidone with guanfacine ($n=5$), and thirdly fluoxetine with aripiprazole ($n=2$).

Furthermore, the degree of pharmacological polytreatment was reduced. 18 patients switched to a single drug, instead of 14. 11 patients 2 drugs (instead of 14), 3 patients 3 drugs instead of 4 and 5 patients remained without drug treatment.

Conclusions: Patients with ASD have worse tolerability to pharmacological treatments than other patients with severe mental disorders.

The use of pharmacogenetics allows improving the cost/effectiveness of medical prescription, avoiding undesirable side effects or lack of effectiveness in the treatment of patients with ASD.

Promoting the implementation of pharmacogenetics in patients with ASD (among others) would improve the clinical situation of these patients more effectively and would improve the economic expenditure derived from erroneous prescription and/or excessive polypharmacy.

The uncharted territory of female adult ADHD: a comprehensive review

B. A. Oroian*, G. Costandache, E. Popescu, P. Nechita and A. Szalontay

Institute of Psychiatry "Socola" Iasi, Iasi, Romania

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.624

Introduction: Attention-Deficit/Hyperactivity Disorder (ADHD), once considered a predominantly childhood condition, has increasingly gained recognition as a prevalent and clinically significant concern among adult women. They often display a distinctive symptom profile characterized by high levels of inattention, emotional dysregulation, and difficulties in executive functioning. Diagnosis of female adult ADHD is frequently complicated by gender bias in traditional diagnostic criteria, which may fail to account for the unique ways in which women manifest the disorder.

Objectives: This comprehensive literature review aims to characterize the unique symptomatology of female adult ADHD, including variations in inattention, hyperactivity, and impulsivity, as well as the presence of emotional dysregulation. It also seeks to explore the diagnostic challenges stemming from gender bias in diagnostic criteria and the role of comorbidity in diagnostic complexity. Additionally, the review assesses the broad spectrum of functional impairments experienced by adult women with ADHD, spanning academic, occupational, interpersonal, and emotional domains.

Methods: This literature review comprises a systematic examination of published research articles, clinical studies, and relevant academic literature addressing female adult ADHD. A comprehensive search strategy involving electronic databases, including PubMed, PsycINFO, and Google Scholar, was employed to identify peer-reviewed articles published between 2000 and 2023. The selected studies underwent critical appraisal for quality and relevance to the review's objectives.

Results: The synthesis of existing literature reveals that female adult ADHD presents a distinctive clinical picture characterized by a higher prevalence of inattention, emotional dysregulation, and comorbid conditions such as mood and anxiety disorders. Diagnostic challenges arise from gender bias in diagnostic criteria and

the absence of overt hyperactivity, often leading to delayed diagnosis or misdiagnosis. Functional impairments extend to academic, occupational, interpersonal, and emotional domains, affecting the overall quality of life for affected individuals. Gender-specific factors, including societal expectations and biases in healthcare evaluation, contribute to diagnostic disparities and hinder timely access to appropriate interventions.

Conclusions: The literature review underscores the critical need for enhanced recognition, understanding, and tailored support for female adults with ADHD. The distinct symptomatology, diagnostic complexities, functional impairments, and gender-specific factors contribute to a multifaceted clinical landscape. Advancing gender-sensitive diagnostic criteria, increasing awareness among healthcare professionals, and developing interventions that address the unique needs of this population are essential steps toward improving the quality of life and outcomes for female adults with ADHD.

Clinical features of suicidal behaviour in youth with borderline personality disorder

V. Kaleda^{1*}, A. Kuleshov¹ and E. Krylova¹

¹Mental Health Research Centre, Moscow, Russian Federation

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.625

Introduction: Borderline personality disorder (BPD) in youth has the greatest spectrum of psychopathology and is strictly associated with nonsuicidal self-injury (NSSI) and suicidal behaviour [Guile et al. *Adolesc Health Med Ther* 2018; 9 199-210; *Paris Med.* 2019; 55(6):223]. The formation of autoaggressive behaviour and suicidal activity is due to the psychopathological features of BPD, which include affective instability, impulsivity and impaired self-identity.

Objectives: The aim of the study was to investigate the psychopathological features of suicidal behaviour in BPD in youth.

Methods: Clinical and psychopathological examination with assessment of suicidal behaviour at the time of, 6 and 12 months later. For additional psychometric examination of patients we used: SCID-II questionnaires, Barratt Impulsiveness Scale (BIS-11), Toronto Alexithymic Scale (TAS), Columbia Suicide Severity Rating Scale (C-SSRS). Sample: N=62 male and female youth males and females in two equal groups of 31, respectively, with an established diagnosis of BPD and the presence of suicidal behaviour. The mean age of first referral in both groups was 19.1 ±2.2 years.

Results: This study defined 2 variants of suicidal behaviour in patients with BPD in youth: 1) Expansive - with predominance of impulsiveness (BIS-11 70±3), affective instability, associated with psychosocial factors as a trigger of suicidal activity. Suicidal attempts were made at the height of psychoemotional stress. These patients were characterised by moderately high scores of the C-SSRS scale 2±1, in which patients noted the absence of a plan and specific intentions before the attempt, and a lower incidence of repeated attempts after 6 (N=6 (19.4%) and 12 months N=10 (32.2%). 2) Rationalistic variant of suicidal behaviour was found in patients with predominance of self-identification disorders,

dissociative disorders and high level of alexithymia TAS 81±4.2 in the clinical picture. Suicidal ideation was revealed in all patients, often throughout the entire youth period, and attempts were characterised by thoughtfulness and led to severe consequences, including fatal outcome. Patients with rationalistic variant of suicidal activity had higher C-SSRS scale scores of 4±1, with the presence of suicidal intentions and high frequency of attempt recurrence after 6 (N=11 (35.5%) and 12 months (N=17 (54.8%)).

Conclusions: The variant of suicidal behaviour depended on the degree of severity and correlation of the psychopathological structure of BPD in youth. Less favourable prognosis was characteristic of the rationalistic variant due to the high frequency of repeated attempts. The results obtained require further analysis and contribute to the development of differentiated therapeutic strategies.

Weight changes in esketamine nasal spray and quetiapine extended-release treated patients with treatment resistant depression: Results from ESCAPE-TRD study

A. Reif^{1,2*}, A. Fagiolini³, E. Buntinx⁴, H. Ruggeri⁵, Y. Godinov⁶, J. Buyze⁷, S. Mulhern-Haughey⁸ and I. Bitter⁹

¹Goethe University Frankfurt, University Hospital, Department of Psychiatry, Psychosomatic Medicine and Psychotherapy, Frankfurt;

²Fraunhofer Institute for Translational Medicine and Pharmacology ITMP, Theodor-Stern-Kai 7, 60596, Frankfurt am Main, Germany;

³Department of Molecular Medicine, University of Siena School of Medicine, Siena, Italy; ⁴Medical Center Anima, Alken, Belgium; ⁵CEN (Centro especializado en Neurociencias), Córdoba, Argentina; ⁶Janssen EMEA, Sofia, Bulgaria; ⁷Janssen Pharmaceutica NV, Beerse, Belgium;

⁸Janssen EMEA, Dublin, Ireland and ⁹Department of Psychiatry and Psychotherapy, Semmelweis University, Budapest, Hungary

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.626

Introduction: In ESCAPE-TRD, esketamine nasal spray (ESK-NS) significantly increased the probability of remission at Week (Wk)8 and being relapse-free through Wk32 after remission at Wk8 versus (vs) quetiapine extended-release (QTP-XR), in patients (pts) with treatment resistant depression (TRD). Safety data were consistent with established profiles of each treatment, with no new safety signals identified (Reif et al. *DGPPN* 2022; P-01-04).

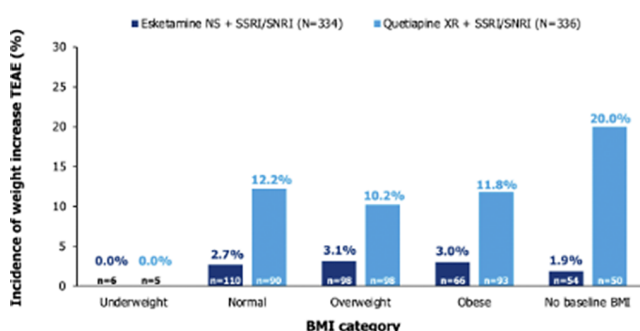

Objectives: To explore weight changes and their impact on treatment discontinuation in ESCAPE-TRD.

Methods: ESCAPE-TRD (NCT04338321) was a randomised, open-label, rater-blinded, phase IIIB trial comparing efficacy and safety of ESK-NS vs QTP-XR in pts with TRD. Safety analyses were conducted on pts who received ≥1 dose of study treatment. Treatment-emergent adverse events (TEAEs) were defined as occurring at or after the first dose of study treatment and within 14 days/30 days (non-serious/serious) of the last dose. A ≥7% increase/decrease in weight from screening was considered for evaluation as a TEAE. Weights were measured and are reported as observed, with no missing data imputation.

Results: 336 and 340 pts were randomised to ESK-NS and QTP-XR; 334 and 336 were included in the safety population. Over the 32-week study, a TEAE of weight increase was reported in fewer pts treated with ESK-NS than QTP-XR (9 [2.7%] vs 42 [12.5%]), leading to treatment discontinuation in 0 vs 6 (1.8%) pts, respectively. Incidences of weight increase TEAEs were balanced across pts categorised as normal, overweight or obese by baseline body mass index (BMI; **Figure**). A weight decrease TEAE was reported in 7 pts (2.1%) in the ESK-NS arm vs 0 pts in the QTP-XR arm. Mean (standard deviation [SD]) weight at baseline was 76.4 (16.2) kg (ESK-NS; n=334) vs 79.1 (16.9) kg (QTP-XR; n=336). At Wk32, mean weight was maintained (76.5 [16.3] kg) in ESK-NS treated pts (n=249; mean [SD] change from baseline: 0.1 [4.0] kg) and increased (80.7 [15.6] kg) in QTP-XR treated pts (n=203; mean [SD] change from baseline: 2.5 [5.1] kg).

Image:

Figure. Incidence of weight increase TEAEs during ESCAPE-TRD by treatment arm and baseline BMI category

Safety set. Patients categorised according to BMI at baseline (underweight: <18.5 kg/m²; normal: 18.5–<25 kg/m²; overweight: 25–<30 kg/m² and obese: ≥30 kg/m²). Weight increase TEAEs were based on weight relative to screening. Data reported as observed; n numbers refer to total numbers of patients in a BMI category at baseline.

Conclusions: Increase in weight was uncommon with ESK-NS; weight increases were more common with QTP-XR and resulted in more treatment discontinuations. Weight increase was independent from baseline BMI.

A scoping review of the literature on the prevalence and correlates of anxiety and depression among undergraduate health science students

G. Agyapong-Opoku^{1*}, B. Agyapong², G. Obuobi-Donkor³ and E. Eboime³

¹School of Health and Health Performance, Dalhousie University, Halifax; ²Department of Psychiatry, University of Alberta, Edmonton and ³Department of Psychiatry, Dalhousie University, Halifax, Canada
*Corresponding author.

doi: 10.1192/j.eurpsy.2024.627

Introduction: Health science students in post-secondary institutions experience high levels of depression and anxiety due to

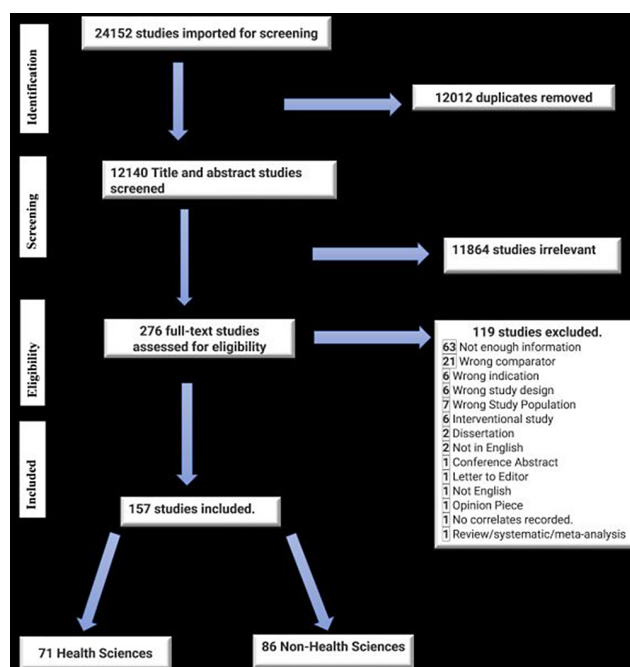

increased stress levels, workload, low socioeconomic status, and history of family mental illness, among other factors. Given the significant negative impact that depression and anxiety can have on undergraduate health science students, it is essential to understand the prevalence and correlation of these conditions in this population.

Objectives: This scoping review aims to identify, document and analyze the literature on the prevalence and determinants of anxiety and depression among undergraduate health sciences students and identify gaps in knowledge for future research.

Methods: The scoping review was planned and executed by the Preferred Reporting Items for Systematic Reviews and Meta-Analyses extension for the Scoping Reviews statement. A comprehensive and systematic search was carried out for five databases, namely MEDLINE, Scopus, EMBASE, CINAHL and PubMed.

Results: From the literature identified by our search strategy, the lowest prevalence for anxiety was 5.8%, and the highest was 82.6%, with a median of 44.25%. The prevalence of depression ranged from a high of 88.8% to a low of 2.1%, with a median value of 34.8%. Our analysis revealed that correlates of anxiety and depression among health science students include sociodemographic factors such as age, sex, gender, relationships, ethnicity and family history, personal health conditions, and academic and socioeconomic issues.

Image:

Conclusions: With the high incidence of anxiety and depression among health science students, there is an increasing need to find practical remedies to support these students. It is also essential for policymakers and university authorities to implement interventions such as supportive text messages and other strategies geared toward providing support and improving the psychological well-being of health science students.

EPP0495

Factors associated with anxious distress in major depressive episodes: a cross-sectional study

F. Bartoli¹, B. Bachi¹, T. Callovin¹, D. Palpella¹, S. Piacenti¹, M. Morreale¹, M. E. Di Lella^{1*}, C. Crocamo¹ and G. Carrà^{1,2}

¹Department of Medicine and Surgery, University of Milano-Bicocca, Monza, Italy and ²Division of Psychiatry, University College London, London, United Kingdom

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.628

Introduction: The comorbidity between depression and anxiety is a common occurrence. The DSM-5 introduced the “anxious distress” (AD) specifier that can be applied to any depressive episode – both in major depressive disorder (MDD) and bipolar disorder (BD) – when symptoms such as feelings of tension, restlessness, difficulty concentrating, and fear that something awful may happen or to lose control are present. Longitudinal data showed that the AD specifier may be an effective predictor of chronicity, time to remission, and functional disability in depressive disorders. In addition, evidence on AD proved its association with increased depressive symptom severity.

Objectives: Available literature seems to suggest that AD occurs in a specific subgroup of patients, thus enabling a peculiar clinical profile to be outlined. To expand knowledge in this field, we performed a cross-sectional study aimed at identifying clinical correlates of AD in people with major depressive episodes.

Methods: Adult people admitted to two psychiatric inpatient units in the northern area of the Metropolitan City of Milan from May 2020 to December 2022 were screened for a major depressive episode and relevant specifiers using the Structured Clinical Interview for DSM-5 (SCID-5). Data on socio-demographic and clinical variables were collected. The severity of depressive and manic symptoms was assessed using the Montgomery-Åsberg Depression Rating Scale (MADRS) and Young Mania Rating Scale (YMRS), respectively. Univariate comparisons between participants with and without AD were conducted, and two multiple logistic regression models were arranged to investigate the association between AD and candidate explanatory variables.

Results: We included 206 inpatients with a major depressive episode (mean age = 48.4 ± 18.6 years; males = 38.8%), of whom 155 diagnosed with MDD and 51 with BD. AD was present in 137 participants (66.5%). Mixed features ($p=0.049$), higher YMRS scores ($p=0.004$), psychotic features ($p<0.05$), and a diagnosis of MDD ($p<0.05$) were found to be associated with AD in the multiple logistic regression analysis.

Conclusions: Notwithstanding some limitations, such as the cross-sectional design and the inclusion of inpatient only, our study highlights the association of AD with mixed and psychotic features, as well as with MDD. Clinical implications of these results include the possible contribution in delineating a specific symptom profile in people with AD during a major depressive episode.

The Influence of Depression in the Evolution of Parkinson's Disease: A Psychiatric Perspective

A. H. I. Abu Shehab^{1,1*}, T. Simona², I. A. Ciureanu³, D. C. Voinescu⁴, ? L. Burlea⁵ and A. Ciubară⁶

¹Psychiatry Department, “Elisabeta Doamna” Psychiatric Hospital, Galati; ²Psychiatry Department, Carol Davila University of Medicine and Pharmacy, Bucharest; ³Director of Communication Center, University of Medicine and Pharmacy “Grigore T. Popa”, Iași; ⁴Rheumatology department, “Dunărea de Jos” University - Faculty of Medicine and Pharmacy, Galati; ⁵Technology, Prothesis and Implantology, University of Medicine and Pharmacy “Grigore T. Popa”, Iași and ⁶Psychiatry Department, “Dunărea de Jos” University - Faculty of Medicine and Pharmacy, Galati, Romania

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.629

Introduction: Parkinson's disease (PD) is a neurodegenerative condition that is predominantly characterised by its motor symptoms. Nevertheless, it is important to note that non-motor symptoms, particularly depression often occur concurrently, exerting a substantial influence on the progression of the disease and the overall well-being of individuals affected by it.

Objectives: The objective of this study is to examine the influence of depression on the advancement of Parkinson's disease (PD) from a psychiatric perspective. This analysis will involve an assessment of the common neurobiological pathways involved and the potential implications for clinical treatment and care.

Methods: A comprehensive assessment of the literature was conducted, focusing on clinical observations, neurochemical interactions, and neuroimaging investigations that provide insight into the concurrent presence of depression and Parkinson's disease (PD). This study aimed to investigate the potential impact of depression on the severity of Parkinson's disease symptoms, the course of the disease, and the responsiveness to treatment.

Results: Depression in Parkinson's disease (PD) is not only a reactive occurrence, but rather it may be attributed to common pathophysiological mechanisms, such as changes in dopamine and serotonin pathways. The coexistence of depression among individuals with Parkinson's disease (PD) has been linked to heightened severity of motor and cognitive symptoms, accelerated development of the disease, and diminished effectiveness of therapy interventions. Furthermore, the presence of depression in individuals with Parkinson's disease intensifies the psychosocial difficulties experienced by both patients and their carers.

Conclusions: The recognition and management of depression in individuals with Parkinson's disease (PD) is of utmost importance in order to enhance treatment approaches and enhance the overall well-being of patients. The establishment of interdisciplinary collaboration between neurologists and psychiatrists is necessary in order to guarantee a holistic approach to patient care.

Cannabis use in first episode psychosis in Tunisia

E. Bergaoui*, R. Lansari, O. Chehaider, W. Ben Flah, A. Larnaout and W. Melki

Psychiatry D, Razi hospital, Manouba, Tunisia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.630

Introduction: The use of cannabis is associated with developing psychotic disorders, especially for those with a pre-existing vulnerability and elevated familial risk for psychosis.

Objectives: To assess cannabis use during first episode psychosis and its relationship with patients' clinical symptoms and functioning.

Methods: We assessed 50 patients hospitalized for first episode psychosis using three scales: CAST test (Cannabis Abuse Screening Test), Positive and Negative Syndrome Scale (PANSS) and Global Assessment of Functioning (GAF).

Results: The sex ratio of our population was 4 men to 1 woman. The average age was 25.6 ± 6.16 years. About 60% of the patients used cannabis. The average duration of untreated psychosis was 10 months, with extremes ranging from one week to 24 months. Forty-four patients were antipsychotic-naïve (88%). For patients who used cannabis, the mean score of CAST test was 11.3 ± 4.16 , with extremes between 4 and 18. The risk of dependence was high in 81% of cannabis users. The PANSS total scale showed a mean score of 58.29 ± 12.90 with extremes between 35 and 91. The average score at GAF scale was 30 with extremes between 20 and 70. Duration of untreated psychosis was significantly correlated to negative scale of PANSS ($p=0,012$; $r=0,420$), PANSS total score ($p=0,011$; $r=0,424$) and GAF levels ($p=0,012$; $r=-0,420$).

There was no association between age of onset of psychosis and cannabis use ($p=0,181$) nor CAST scores ($p=0,747$). There was no correlation between CAST and GAF scores ($p=0,641$).

However, there was a significant and positive correlation between CAST scores and positive scale of PANSS ($p=0,04$; $r=0,432$).

Conclusions: Cannabis use is neither necessary nor sufficient to cause psychosis on its own. However, it has an influence on the prognosis. Early intervention programs should address cannabis and substance use problems early in the course of illness.

Relevance of sociodemographic characteristics on patients with bipolar disorder and substance use disorder

I. A. Silva^{1*}, C. Silva², I. Faria² and V. S. Melo³

¹Unidade Local de Saúde do Norte Alentejano, Portalegre; ²Centro Hospitalar e Universitário de Coimbra, Coimbra and ³Centro Hospitalar do Médio Tejo, Tomar, Portugal

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.631

Introduction: Substance use disorder is a common comorbidity with bipolar disorder, having implications on its diagnosis, treatment

adherence, and number of hospitalizations. Understanding the particular characteristics of this population is of the utmost importance to improve clinical outcomes.

Objectives: Our aim is to analyze the sociodemographic characteristics of the patients in the inpatient unit of a tertiary hospital and to reflect on its impact on treatment. Our study looks over a 3-year period, and all patients analyzed have a dual diagnosis of both bipolar disorder and substance use disorder.

Methods: We collected, retrospectively, data from the hospital platform and analyzed it on SPSS Statistics 26, along with a literature review.

Results: In the analyzed period of 3 years, there were 2384 hospitalizations in the Coimbra's University Hospital psychiatric ward, and 88 hospitalizations were coded with a dual diagnosis of bipolar disorder and substance use disorder.

Regarding gender distribution, 41% of the patients were female and 49% of the patients were male, with a mean age of 47 years.

There were 12 patients who were re-hospitalized once (7 of them were men) and 6 who were re-hospitalized twice (4 of them were men) during the analyzed period.

At the time of hospitalization, 60.5% of male patients were single, 21.1% were divorced, and only 15.8% were married, while female patients were mainly married (35.7%) and only 28.6% were single. Female patients had more frequent support from social and community institutions (17.9% vs 5.3% in men) while 2.6% of men had no support from family or institutions.

Regarding education, more men accomplished high school education (21.1% vs 17.9% in women) and university education (18.4% vs 14.3%). In our sample, there were 3.6% of women who were illiterate.

During their lifetime, female patients were hospitalized around 5 times and men around 3.7 times, despite the fact that the mean age of female patients on their first hospitalization was 36 years, and in male patients, it was 34 years.

Treatment adherence is more significant in female patients (70.3% vs 69.2% in men), even though women maintain active substance abuse more frequently (42.9 vs 39.5%).

Conclusions: Male and female patients have different backgrounds and different support either in spouses, family, or social institutions. These nuances may play an important role in the number of re-hospitalizations, treatment adherence, and maintenance of abstinence.

Taking these aspects into consideration may help improve clinical outcomes.

Cerebrovascular insult as a consequence of poor health behaviour in patients with schizophrenia and bipolar disorder

M. Arnautovic Tahirovic^{1*}, M. Zuko¹, I. Lokmic Pekic¹, N. Sirucic¹ and A. Tahirovic²

¹Psychiatric hospital of Canton Sarajevo and ²Psychiatric clinic, Clinical centre university of Sarajevo, Sarajevo, Bosnia and Herzegovina

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.632

Introduction: Cerebrovascular insult (CVI) in patients with psychiatric diseases is to a large extent more prevalent and is accompanied by a worse prognosis after a incident. Despite the higher mortality, these patients are less frequently subjected to CT angiography and interventional intervention on the blood vessels of the brain.

Objectives: To show the frequency of cerebrovascular insults in patients with schizophrenia (SCH), bipolar affective disorder (BP), and depression, depending on age, gender, socioeconomic characteristics, professional qualifications, and dietary habits.

Methods: A total of 1200 patients with SCH, BD and depression were treated over a period of five years.

Results: 11.1% SCH patients had CVI and 3,7% a cases of bipolar affective diseases. CVI was most often experienced by patients who were married, employed, or retired, and who lived in urban areas. Smoking, elevated blood pressure values, elevated BMI do not have a significant impact on the occurrence of CVI in all groups. Patients with elevated values of glucose, total cholesterol and LDL cholesterol and CRP had a higher incidence of cerebrovascular insult.

Conclusions: It is necessary to work on raising the awareness of people suffering from psychiatric diseases regarding lifestyle and eating habits, and to conduct periodic health examinations. It is important to recognize high-risk patients and educate them about preventive measures.

Sleep disorders and addiction A study of 100 patients

Y. BENSALAH^{1*}, M. SABIR¹ and F. ELOMARI¹

¹Psychiatric Hospital Ar Razi, Salé, Morocco

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.633

Introduction: Several studies have demonstrated a high prevalence of sleep-related complaints in subjects with an addiction to psychoactive substances (alcohol, cannabis, nicotine, cocaine) Sleep disorders negatively influence the quality of life of subjects suffering from addiction and increase the risk of relapse

Objectives: To assess the prevalence of sleep disorders in patients with problematic use of psychoactive substances as well as associated factors

Methods: This is a descriptive and analytical cross-sectional study carried out among 100 patients followed at Ar-Razi hospital Salé in Morocco for problematic use of psychoactive substances from June 1 to August 30, 2023

A questionnaire was used assessing the socio-demographic and clinical characteristics of our population

Sleep quality was assessed by the Pittsburgh Scale (PSQI)

Results: There were 100 patients, with ages ranging from 18 to 56 years old and the majority of whom were males.

History of somatic pathology was reported in 36% of patients

The majority of patients had an associated anxiety disorder (60%) The most consumed psychoactive substances were tobacco (95%), followed by cannabis, benzodiazepines and alcohol.

75% of patients reported poor sleep quality

There was a statistically significant difference between the risk of relapse and the reduction in sleep quality

Conclusions: The prevalence of poor sleep quality in patients with disorders linked to psychoactive substance use is high, hence the importance of early detection in order to improve treatment.

A comparative study of psychological factors in Men who have Sex with Men (MSM) with and without HIV

K. E. Sgoura¹, A. Papadopoulou^{2*} and V. Efstathiou¹

¹Psychology Department, National and Kapodistrian University of Athens and ²Second Department of Psychiatry, National and Kapodistrian University of Athens, "Attikon" University General Hospital, Athens, Greece

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.634

Introduction: As a result of the notable progress in HIV / AIDS prevention and treatment globally, the HIV epidemic is considered controlled to the extent that individuals living with HIV manage to have a similar life expectancy to HIV-negative individuals and a good level of health. However, the "epidemic" related to the stigma of HIV-positive individuals, particularly of Men who have Sex with Men (MSM), still remains an issue, while it has been associated with a profound negative impact on individuals' mental health.

Objectives: The present study aimed to compare anxiety, depression, social support, loneliness, and psychological resilience between MSM with and without HIV. Furthermore, the study investigated the correlates of HIV related stigma in MSM with HIV.

Methods: The sample of the study comprised a total of 139 adult MSM. According to their self-report 84 individuals were HIV-negative (age in years: M = 24.58, SD = 5.55), while the remaining 55 individuals were HIV-positive (age in years: M = 38.99, SD = 10.95). Furthermore, the majority of individuals in both groups reported Greek nationality. Participants completed a questionnaire on socio-demographic characteristics, the Hospital Anxiety and Depression Scale to assess anxiety and depression, the UCLA Loneliness Scale to measure loneliness, the Brief Resilience Scale (BRS) to evaluate psychological resilience, and the Multidimensional Scale of Perceived Social Support (MSPSS) to assess social support. HIV-positive individuals additionally completed the HIV Stigma Scale-Brief Version, a brief scale measuring social stigma related to HIV.

Results: According to the findings, MSM with and without HIV did not differ in anxiety ($p = 0.908$), depression ($p = 0.904$), social support ($p = 0.657$), loneliness ($p = 0.086$), and psychological resilience ($p = 0.600$). Furthermore, it emerged that among HIV-positive MSM, stigma was positively associated with anxiety ($r = 0.479, p < 0.001$), depression ($r = 0.479, p < 0.001$), and loneliness ($r = 0.532, p = 0.001$), while the correlation was negative with social support ($r = -0.456, p < 0.001$) and resilience ($r = -0.400, p < 0.003$). No significant association was found between stigma and age in HIV-positive individuals ($r = 0.099, p = 0.474$).

Conclusions: In conclusion, the findings of this study identified possible risk factors as well as protective factors for the mental health of HIV-positive MSM. As long as stigma associated with HIV continues to be a risk factor for the development of psychosocial problems in those living with HIV, it is advisable for both policymakers and the research community to take more proactive steps in order to offer the necessary support and attention to those who are living with HIV and experiencing multiple forms of stigma.

Exploring the Link Between Personality Traits and Self-Care Dimensions in Individuals Affected by Type 2 Diabetes Mellitus: A Comprehensive Systematic Review and Meta-Analysis

K. Dimou^{1*}, E. Dragioti¹, G. Tsitsas², S. Mantzoukas³ and M. Gouva¹

¹Research Laboratory Psychology of Patients, Families and Health Professionals, Department of Nursing, School of Health Sciences, University of Ioannina, Ioannina; ²Department of Economy and Sustainable Development, Harokopio University, Athens and ³Research Laboratory Integrated Care, Health & Well-being, Department of Nursing, School of Health Sciences, University of Ioannina, Ioannina, Greece

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.635

Introduction: Type 2 diabetes mellitus (T2DM) is a prevalent, chronic metabolic disorder that exerts diverse effects on individuals' physical and psychological well-being.

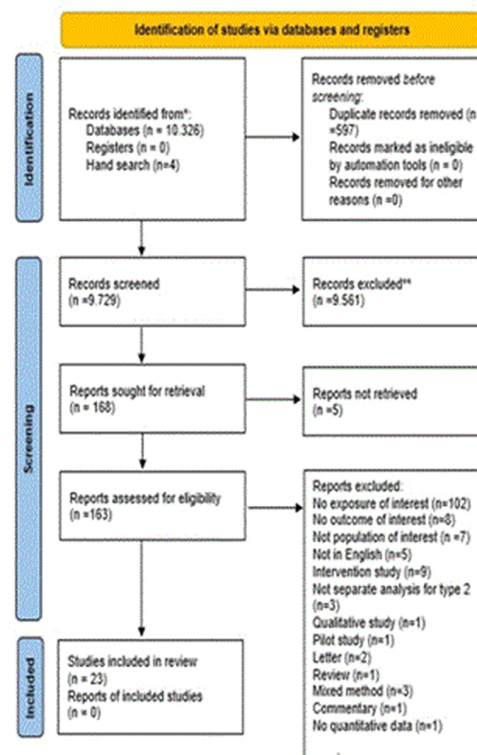

Objectives: Our aim was to investigate the potential correlation between personality traits and self-care aspects among individuals living with T2DM.

Methods: We conducted a thorough search in PsycINFO, CINAHL, and PubMed/Medline for peer-reviewed articles from inception to January 9, 2023. Following PRISMA guidelines, two reviewers independently screened, extracted data, and assessed bias. We used random-effects meta-analysis for pooling estimates

Results: We identified 23 studies meeting our inclusion criteria. Openness, conscientiousness, and agreeableness were linked to better foot care compliance (OR = 2.53, 95% CI = 1.49-4.28; OR = 1.84, 95% CI = 1.10-3.08; and OR = 2.07, 95% CI = 1.23-3.48, respectively). Openness was also associated with improved overall self-care behaviors (OR = 2.00, 95% CI = 1.17-3.41), while conscientiousness reduced smoking likelihood (OR = 0.96, 95% CI = 0.93-0.99), and agreeableness enhanced medication adherence (OR = 1.68, 95% CI = 1.34-2.31). However, extraversion and neuroticism were linked to lower medication adherence (OR = 0.77, 95% CI = 0.61-0.96 and OR = 0.51, 95% CI = 0.40-0.65, respectively). Neuroticism also negatively affected overall self-care behaviors (OR = 0.67, 95% CI: 0.55-0.81).

Image:

PRISMA 2020 flow diagram for new systematic reviews which included searches of databases and registers only

Conclusions: Personality traits should be considered when addressing self-care in T2DM patients.

Disclosure of Interest: None Declared

EPP0505

Personality traits and cognition as predictors of long-term quality of life after transplantation for alcoholic liver disease

S. Medved^{1*}, B. Aukst Margetić^{2,3}, A. Ražić Pavičić^{1,3}, T. Filipec Kanižaj^{3,4} and V. Medved^{1,3}

¹University Hospital Center Zagreb; ²Univeristy Hospital Center Sestre milosrdnice; ³Medical School University of Zagreb and ⁴University Hospital Merkur, Zagreb, Croatia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.636

Introduction: Liver transplantation (LT) is a crucial treatment for end-stage alcoholic liver disease, the most common liver disease in developed countries. Personality traits and cognition, a relatively stable characteristics, are known to be significantly associated with

quality of life (QoL). However, how they impact QoL in long-term LT survivors is unclear.

Objectives: The study aimed to assess the associations between personality traits and cognition and their impact on the QoL in long-term LT survivors.

Methods: First time LT recipients due to end-stage alcohol liver disease without long-term complications were consecutively included during standard outpatient care. Sociodemographic and clinical data was collected. Personality traits were assessed using 50-item International Personality Item Pool of the Five-factor model (IPIP), cognition using Mini Mental State Examination (MMSE), and QoL using EuroQoL-5D (EQ-5D) questionnaire.

Results: Eighty-three participants were included (mean age 62.9 \pm 7.03y, 90.6% male). Median MMSE score was 27 \pm 2.00, and median years since LT 5 \pm 2.91. Significant positive associations were found between IPIP dimensions Extraversion (B=0.297, p <0.01), Agreeableness (B=0.384, p <0.01), Conscientiousness (B=0.511, p <0.01), and Emotional stability (B=0.432, p <0.01) with EQ-5D visual analogue scale (EQ VAS). IPIP dimension Conscientiousness (B=0.338, p <0.01) and Emotional Stability (B=0.379, p <0.01) were significantly associated with descriptive dimension of EQ-5D (EQ-5D-3L). MMSE score was significantly associated with QoL (EQ-VAS B=0.291, p <0.01; EQ-5D-3L B=0.283, p <0.05, respectively). However, MMSE score was not shown to be a statistically significant predictor of QoL, whereas Conscientiousness was a significant predictor of EQ-VAS (β 1.404, t 3.125), and Emotional stability of EQ-5D-3L (β 0.011, t 2.132).

Conclusions: Some personality traits predicted QoL in long-term LT survivors. Therefore, assessment of personality traits should be considered as a part of pre-LT evaluation within a regular psychiatric clearance evaluation.

Prevalence and predictors of PTSD and resilience among Adolescents and Young Adults: Findings from the MoreGoodDays Support Program in Alberta, Canada

A. Belinda^{1*}, R. Shalaby¹, K. Hay², R. Pattison², E. Eboime³, M. Korthuis⁴, Y. Wei¹ and V. I. O. Agyapong^{1,3}

¹University of Alberta; ²Kickstand, Edmonton; ³Dalhousie University, Halifax and ⁴Glenrose Rehabilitation Hospital Foundation, Edmonton, Canada

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.637

Introduction: Adolescents and young adults have particularly been impacted by the COVID-19 pandemic, leading to a rise in the incidence of mental health issues. Increased exposure to traumatic

events may lead to decreased resilience and subsequently increased likely PTSD.

Objectives: This study sets out to examine the predictors and prevalence of likely PTSD and determine the level of resilience among adolescents and young adults.

Methods: A cross-sectional study using an online survey questionnaire was adopted to collect sociodemographic and clinical information from the subscribers of MoreGoodDays. The PTSD Checklist Civilian (PCL-C) and the Brief Resilience Scale (BRS) was respectively used to assess likely PTSD and resilience Data was analyzed with SPSS version 25 using chi-squared tests and multivariate logistic regression analysis.

Results: 343 of MoreGoodDays subscribers who participated in the survey were about 343. Most were female (79.0%), and 13.7% were male. Overall, 95 (45.7%) of respondents had likely PTSD and 109 (51.7%) had likely low resilience. Approximately 176 (51.3%) respondents had received mental health counselling, and 64 (35.4%) expressed the desire to receive mental health counselling. When all other variables are controlled in the regression model, respondents who have received mental health counselling in the past year were 13.7 times more likely to experience likely PTSD (OR = 13.70; 95% CI: 1.23- 142.86) and 15.15 times more likely to experience low resilience than those who did not (OR = 15.15; 95% CI: 1.46- 166.67). Again, those who would like to receive mental health counselling were 20.8 times more likely to experience PTSD than those who did not (OR = 20.76; 95% CI: 2.61- 165.401) and 29.4 times more likely to experience low resilience than those who did not (OR = 29.42; 95% CI: 3.31- 261.445). Finally, those with four or more ACE scores were 6.2 times more likely to experience likely PTSD than those who had zero scores (OR = 6.24; 95% CI: 1.46- 26.67).

Conclusions: MoreGoodDays subscribers were disproportionately affected by likely PTSD and low resilience, reflecting the devastating effect of the COVID-19 pandemic. Increased ACE has been linked to low resilience, which may also lead to a rise in mental health issues. Strategies to promote resilience may reduce the incidence of likely PTSD. Educational institutions may adopt innovative mental health interventions, including psychological interventions such as mobile text technology, to support the mental health of this cohort. Policymakers and government agencies are encouraged to give the mental health of young adults and youth more prominence on their agenda.

PTSD, dissociative experiences, and depressive symptoms in a clinical sample of women who featured in pornographic productions

F. K. El Khoury¹, V. Hérouin^{2*} and M. Fareng²

¹Department of social epidemiology, Sorbonne Université, INSERM, IPLESP and ²Clinical Psychologist, Paris, France

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.638

Introduction: The mental health of the people who featured in Pornographic Productions (PP) is underexamined. However, PP frequently involve unsimulated violent acts mostly experienced by

women. Furthermore, some women participating in PP also report being coerced into unwanted sexual acts. Therefore, featuring in a PP could be experienced as a traumatic event, and could be associated with negative mental health disorders.

Objectives: Our study examines mental health indicators among Women who have participated in at least one PP (WPP), and who consulted clinical psychologists, after referral by WPP support groups.

Methods: Thirty-six women were recruited by two clinical psychologists during an individual consultation. Participants completed the French versions of the post-traumatic stress disorder (PTSD) Checklist for DSM-5 (PCL-5), the Dissociative Experiences Scale (DES), as well as the 13-item Beck Depression Inventory (BDI-13). Data on socio-demographic characteristics, lifetime experience of sexual violence prior to participating in a PP, as well as the perceived effect of participating in a PP were also measured.

Results: The mean age of participants was 31.2 (std=7), and the average age at first participation in a PP was 23.4 (std=6). The majority (78%) of participants reported lifetime experience of sexual violence prior to participation in a PP. Thirty women (83%) had a PCL5 score over 33 indicative of probable PTSD, and 28 women (78%) had a DES score of 30 or more indicating high levels of dissociation. Further, 16 participants (44%) reported a BDI-13 score over 16 indicating severe depression.

Conclusions: This study highlights the high prevalence of PTSD, dissociative experiences, and depressive symptoms in a clinical population of women who featured in at least one PP. Further studies are needed to better understand the scale of the problem and optimize care interventions.

Randomized Controlled Trials to Treat Obesity in Military Populations: A Systematic Review and Meta-Analysis

D. Gravina^{1,2*}, J. L. Keeler^{1,3}, M. N. Akkese¹, S. Bektas^{1,4}, P. Fina⁵, C. Tweed^{3,6}, G. D. Willmund⁷, L. Dell’Osso², J. Treasure^{1,3} and H. Himmerich^{1,3}

¹Institute of Psychiatry, Psychology and Neuroscience, King’s College London, Centre for Research in Eating and Weight Disorders, London, United Kingdom; ²University of Pisa, Department of Clinical and Experimental Medicine, Pisa, Italy; ³Bethlem Royal Hospital, South London and Maudsley NHS Foundation Trust, London, United Kingdom; ⁴Hacettepe University, Department of Psychology, Ankara, Türkiye; ⁵Sigmund Freud University Vienna, Faculty of Psychology, Vienna, Austria; ⁶Royal Navy Reserve, London, United Kingdom and ⁷Military Hospital Berlin, Bundeswehr Center for Military Mental Health, Berlin, Germany

*Corresponding author.
doi: 10.1192/j.eurpsy.2024.639

Introduction: In recent years, overweight and obesity have reached an alarmingly high incidence and prevalence worldwide; they have also been steadily increasing in military populations. Military personnel as an occupational group are often exposed to stressful and harmful environments that represent a risk factor for disordered eating with major repercussions on both physical and mental health.

Objectives: This study aims to explore the effectiveness of weight loss interventions and to assess the significance of current obesity treatments for military populations.

Methods: Three online databases (PubMed, PsycInfo, and Web of Science) were screened to identify randomized controlled trials (RCTs) aiming to treat obesity in active-duty military personnel and veterans. Random-effects meta-analyses were conducted for body weight (BW) and body mass index (BMI) values, both longitudinally comparing treatment group from pre-to-post intervention, and cross-sectionally comparing the treatment group to controls at the end of the intervention.

Results: A total of 21 studies were included: 16 cross-sectional (BW: n=15; BMI: n=12) and 16 longitudinal (BW: n=15; BMI: n=12) were meta-analyzed, and 5 studies were narratively synthesized. A significant small overall BW and BMI reduction from baseline to post-intervention was observed (BW: $g = -0.10$; $p = 0.015$; BMI: $g = -0.32$; $p < 0.001$), together with a decreased BMI ($g = -0.16$; $p = 0.001$) and nominally lower BW ($g = -0.08$; $p = 0.178$) in the intervention group compared to controls at post-intervention time-point. When conducting additional meta-analyses dividing by sample type, a significant decrease in both BMI ($g = -0.35$; $p < 0.001$) and BW ($g = -0.12$; $p = 0.041$) from pre-to-post intervention was observed in active-duty military personnel but not for veterans. Recommendations for clinical practice have been outlined from the findings of this study and summarized in Figure 1.

Image:

Topic	Clinical recommendations	Practical implications	Level of evidence	RCTs (n)
Short-term weight loss intervention for obesity (up to 6-12 months).	Individual group-based or comprehensive lifestyle intervention	Physical activity (aerobics, resistance or high intensity); no sufficient evidence from RCTs regarding a superior effectiveness of one type, frequency, or intensity of physical activity.	High	18
		Dietary and nutritional interventions such as meal replacements promoting low caloric balance intake and healthy meal plans provided by a registered dietitian (when available) and individualized to each patient.	High	12
		Cognitive behavioral therapy, psychoeducational strategies, and motivational techniques for cognitive, emotional, and social factors that influence weight management.	High	12
		Structured outcome monitoring over time (clinical or self-monitoring): body weight, BMI, fat percentage, waist-to-hip ratio, abdominal circumference.	High	12
		Internet-based intervention when in-person programs are not available.	Good	5
		Behavioral therapy plus use of technology (e.g., pedometer).	Weak	2
		Pharmacological intervention (e.g., Orlistat).	Weak	1

Conclusions: Despite limitations, such as the heterogeneity across the included interventions and the follow-up duration, our findings highlight how current weight loss interventions are effective in term of BW and BMI reductions in military populations, and how a

comprehensive approach with multiple therapeutic goals should be taken during the intervention.

From guided self-help to comprehensive ED treatment

B. Babusa¹, K. Bai-Nagy^{1*}, J. Kovács¹, Á. Dósa¹, G. Salavecz¹, F. Túry¹ and G. Purebl¹

¹Semmelweis University, Faculty of Medicine, Institute of Behavioural Sciences, Budapest, Hungary

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.640

Introduction: The incidence of eating disorders is increasing in Hungary and Central-Eastern Europe. The number of complex/severe cases is also increasing. Accordingly, several new unmet needs of the users and their relatives appear in the clinical care.

Objectives: As a possible response to these unmet needs, we have introduced a multifaceted care model for eating disorders. To facilitate easily accessible yet effective care close to home, a support programme with an online guided self-help tool and regular consultations with first responder psychiatrists or clinical psychologists has been introduced. For non (or partial) responders, a multifaceted modular treatment programme has been developed with an individualised combination of different therapeutic approaches, including family therapy, dialectical behaviour therapy (DBT) specific to binge eating disorder and bulimia, CBT and the use of virtual reality as an adjunct treatment. The most severe cases are referred for (also multifaceted) inpatient treatment. In terms of research, we want to focus on the key issues for rapid, cost-effective treatment. Firstly, we want to develop an individual profiling system at the start of therapy to assess which individual combination of modules can produce a rapid therapeutic response. Secondly, we want to identify the active gamechanger elements of therapy that are associated with the greatest change in symptoms.

Methods: Patients complete the following questionnaires:

- in the guided self-help group: Eating disorder inventory, (EDI-I), McMaster Family Assessment Device (FAD), Eating Disorder Diagnostic Scale (EDDS), Eating Behavioral Severity Scale, Eating Disorders Symptom Impact Scale (EDSIS-S)

- in DBT groups: Eating Disorder Examination Questionnaire (EDE-Q), Three Factor Eating Questionnaire-R21, Rosenberg Self-Esteem Scale, Patient Health Questionnaire-(PHQ-9), Cognitive Emotion Regulation Questionnaire (CERQ)

- in individual therapies: Mini International Neuropsychiatric Interview (MINI) and Structured Clinical Interview for DSM 5- Alternative Model for Personality Disorders (SCIP-5-AMPD), EDI-I, Mentalization Questionnaire (MZQ), Dissociation Questionnaire (DIS-Q), Symptom Checklist-90 (SCL-90), (PHQ-9), Childhood Trauma Questionnaire (CTQ) and Young Parenting Inventory (YPI).

Results: Patient recruitment and therapies are currently underway, the first preliminary results are expected in the spring period.

Conclusions: In order to provide individualized care more effectively, it is important to identify the factors that determine which therapeutic modalities work best for the patient.

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.641

Introduction: Childhood maltreatment (CM) is associated with distinct clinical and biological characteristics in people with eating disorders (EDs). The measurement of local gyrification index (LGI) may help to better characterize the impact of CM on cortical structure.

Objectives: The objective of this study was to investigate the association of CM with LGI in women with EDs.

Methods: Twenty-six women with anorexia nervosa (AN) and 24 with bulimia nervosa (BN) underwent a 3T MRI scan. All participants filled in the Childhood Trauma Questionnaire. All neuroimaging data were processed by FreeSurfer. LGI maps underwent a general linear model to evaluate differences between groups with or without CM. People with AN and BN were merged together.

Results: Based on the Childhood Trauma Questionnaire cut-off scores, 24 participants were identified as maltreated and 26 as non-maltreated. Maltreated people with EDs showed a significantly lower LGI in the left middle temporal gyrus compared with non-maltreated people, whereas no differences emerged in the right hemisphere between groups.

Conclusions: The present study showed that in people with EDs, CM is associated with reduced cortical folding in the left middle temporal gyrus, an area that could be involved in ED psychopathology. This finding corroborates the hypothesis of a 'maltreated ecophenotype', which argues that CM may allow to biologically, other than clinically, distinguish individuals with the same psychiatric disorder.

The Portuguese version of the Screen for Disordered Eating: Validity and reliability in the perinatal period

A. T. Pereira¹, R. Lima², J. M. Pinto¹, D. Pereira¹, A. Macedo¹, C. Marques¹, A. I. Araújo¹, B. Barbosa² and C. Pinto Gouveia^{1*}

¹Institute of Psychological Medicine and ²Faculty of Medicine, University of Coimbra, Coimbra, Portugal

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.642

Introduction: Despite the increased knowledge about the prevalence and consequences of eating disorders (ED), they continue to be underdiagnosed and undertreated. Being more common in women of childbearing age, the perinatal period may play a decisive role in the incidence and course of these pathologies. The Screen for Disordered Eating (SDE) was developed for the screen of ED in primary care.

Objectives: Our aim was to analyze the psychometric properties of the Portuguese Version of SDE in women during the perinatal period.

Methods: Participants were 346 women with a mean age of 31.68 of years old (± 4.061 ; range: 18-42). 160 were pregnant (second or third trimester) and 186 were in the post-partum (mean baby's age=4.37 months (± 2.87 ; range: 1-12). They answered an online survey including the Portuguese version of the SDE and of the Eating Disorder Examination – Questionnaire (EDE-Q-7).

Results: Confirmatory Factor Analysis showed that the unidimensional model presented good fit indexes in pregnancy ($\chi^2/df=2.0335$; RMSEA=.0547, $p<.001$; CFI=0.9976 TLI=0.9939, GFI=0.9906). The Cronbach's alfa were $\geq .65$. All the items contributed to the internal consistency and presented high internal validity. Pearson correlations between SDE and EDE-Q-7 total scores were significant ($p<.001$) positive and high in pregnancy (.639), postpartum (.583) and the perinatal period (.617).

Conclusions: The Portuguese version of SDE has shown good validity (construct and concurrent) and internal consistency. As such, SDE might be a useful tool to screen ED in women during the perinatal period.

Clinical and psychopathological features of parents of patients with anorexia nervosa.

O. Khaustova^{1*} and L. Sak¹

¹Bogomolets National Medical University, Kyiv, Ukraine

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.643

Introduction: Anorexia nervosa (AN) is a widespread chronic mental disorder with severe negative medical and social consequences. Treating patients with AN is a complex and time-consuming process, as persistent forms are often encountered. The studies' results indicate a possible influence of psychoemotional state and/or existing psychopathological manifestations in parents on AN development.

Objectives: To investigate the clinical and psychopathological characteristics of parents of patients with AN based on the study of emotional regulation, alexithymia, depression, and anxiety.

Methods: The study population (N=110) consisted of fathers (N=47 (42.7%)) and mothers (N=63 (57.3%)) of patients with AN. The mean age was M=44.90 (SD=5.9; SE=0.567). All participants completed the emotional regulation scale (DERS), Toronto Alexithymia Scale (TAS-26), Hospital Anxiety and Depression Scale (HADS).

Results: According to DERS: "rejection" - 21.86 (SD=5.675; SE=0.541); "goals" - 19.13 (SD=2.028; SE=0.193); "impulse" - 24.17 (SD=4.908; SE=0.468); "awareness" - 21.93 (SD=1.999; SE=0.191); "strategies" - 30.75 (SD=2.173; SE=0.207); "clarity" - 18.58 (SD=1.486; SE=0.142). The sum was 136.42 (SD=8.119; SE=0.774). The TAS results of the study group were 80.45 (SD=13.699), which characterizes the average personality type as alexithymic. According to HADS, the average values were distributed: the anxiety scale M=7.96 (SD=1.347) the depression scale

M=7.95 (SD=1.442). These indicators can be considered as the extreme limit of the norm or subclinically expressed anxiety and depression. The next step was to find statistically significant relationships between the DERS methodology and the HADS and TAS for the study group. According to Spearman's correlation coefficient, there is a direct stable relationship between the variables "anxiety" and "impulse" ($r=0.257$), awareness ($r=0.255$), and the total score of emotional regulation according to "DERS" ($r=0.246$); A direct correlation was found between the indicators "depression" and "rejection" ($r=0.151$), "goals" ($r=0.233$), "awareness" ($r=0.138$); Alexithymia, in turn, has a direct correlation with the "goals" scale and an inverse correlation with the "strategies" scale ($r=-0.141$)

Conclusions: Parents of patients with AN have various manifestations of psychoemotional disturbances, namely subclinical levels of depression and anxiety, high levels of alexithymia, and emotional regulation problems. The correlation analysis showed that the anxiety score for parents of patients with AN is higher if difficulties with impulse control, emotional awareness, and general emotional regulation are problematic. Depressive tendencies are also associated with the subjects' rejection of emotional reactions and problems with goal-directed behavior. The inverse correlation indicates that the higher the index of alexithymia, the less limited access to emotion regulation strategies, and vice versa.

Exploring the associations between involuntary treatment and gender in a portuguese acute psychiatric unit

A. F. Silva^{1*}, R. M. Lopes¹, V. S. Melo¹, C. A. Rodrigues¹, P. M. Coelho¹, F. M. A. Santos¹, I. S. Fernandes¹ and L. P. Delgado¹

¹Psychiatry and Mental Health Department, Centro Hospitalar Médio Tejo, Tomar, Portugal

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.644

Introduction: Involuntary admission rates differ between gender across various countries. In several European Union countries, men are more frequently involuntarily admitted, while an opposite trend, associating women with involuntary care, has been observed in countries like Switzerland, Brazil, and China.

Objectives: Considering the contradictory evidence about gender and involuntary care in the literature, we aim to analyze the gender patterns of involuntary care in Centro Hospitalar Médio Tejo's Psychiatric Acute Unit, exploring the gender differences in diagnosis among involuntary patients.

Methods: We stored and analyzed the data using Microsoft Excel and IBM SPSS Statistics. We studied psychiatry admissions at Centro Hospitalar Médio Tejo, Portugal over 2 years. The Acute Psychiatric Unit, located within a general hospital, has 24 beds, and offers acute mental healthcare services to adults aged 18 and above, serving a coverage area of approximately 251,000 residents. As part of our data collection process for all admissions to the Acute Psychiatry Unit, we recorded information such as gender, age, diagnosis at discharge, treatment type (voluntary or involuntary), and length of stay.

Results: From January 1, 2021, to December 31, 2022, there were 686 psychiatry admissions at Centro Hospitalar Médio Tejo, of which 125 (18,2%) were involuntary. The admission rates were approximately 136.6 per 100,000 people annually, with 24.9 being involuntary admissions per 100,000 people annually. In our analysis of involuntary admissions, women had a lower rate of such admissions, making up 6.4%, while men had a higher rate at 11.8%. No other gender identity was mentioned. Schizophrenia-related disorders were the primary cause for involuntary admissions for both genders, with 67.9% for men and 50% for women. Mood disorders were the second most common reason for involuntary admission, accounting for around 40.9% of cases for women and a significantly lower 16% for men. Involuntarily hospitalized patients exhibited longer lengths of stay independently of the gender. Men hospitalized involuntarily tended to be younger, whereas for women, involuntary hospitalizations were associated with older ages.

Conclusions: In conclusion, our study reveals gender differences in psychiatric involuntary admissions, with more men being involuntarily admitted than women. Schizophrenia group disorders were the most common diagnoses among male and female involuntary patients. Furthermore, all hospitalized women exhibited a higher prevalence of mood disorders, a trend that was more pronounced among those admitted involuntarily. These gender trends match the overall patterns seen in the epidemiology of schizophrenia and mood disorders. Additionally, women with schizophrenia generally exhibit better social functioning than men, which may explain the lower needs of involuntary hospitalization.

Association between social distancing and incident microvascular events among individuals with diabetes mellitus: a population-based cohort study

Y. Y. Liang^{1*} and Y. He¹

¹Center for Sleep and Circadian Medicine, The Affiliated Brain Hospital of Guangzhou Medical University, Guangzhou, China

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.645

Introduction: Social isolation and loneliness have been rising social determinants of cardiometabolic health.

Objectives: To investigate the associations of social isolation and loneliness with diabetic microvascular complications (DMC) among individuals with type 2 diabetes mellitus (T2DM) and assess the extent to which intermediate risk factors explained the associations.

Methods: Data for individuals with T2DM (n=24,297, 62.2% male; mean age=60.0 years) were taken from the UK Biobank. Social isolation and loneliness were assessed using self-reported questionnaires. DMC, mainly including diabetic kidney disease, diabetic retinopathy, and diabetic neuropathy, were identified by linking hospital records and death registries.

Results: In the multivariate-adjusted model, social isolation was associated with an increased risk for incidence of any DMC

(most vs. least: HR: 1.13; 95% CI: 1.05-1.22), especially diabetic kidney disease and neuropathy; loneliness was also associated with any DMC (yes vs. no: HR: 1.12; 95% CI: 1.02-1.23) and diabetic kidney disease. Social isolation and loneliness ranked similarly in relative strength for predicting DMC as other conventional risk factors, such as smoking, high blood pressure, and physical activity. The association between social isolation and DMC was mainly attributed to health behaviors, while the association between loneliness and DMC was primarily explained by health behaviors, psychological factors, and diabetes-related factors.

Conclusions: Social isolation and loneliness were independently associated with a higher risk for incident DMC among individuals with T2DM, which were largely explained by subsequent unhealthy lifestyles, psychosocial stress, and diabetes-related factors. These findings underscore social isolation and loneliness as novel modifiable risk factors for predicting DMC.

Prenatal psychological distress, access to mental health care and pathways between risk/protective factors and maternal postnatal depressive symptoms in the E.L.F.E. french birth cohort

A.-L. Sutter-Dallay^{1*}, M. Bales², M.-A. Charles³ and V. D. W. Judith⁴

¹Perinatal psychiatry, Charles Perrens Hospital and Bordeaux University; ²Perinatal psychiatry, Charles Perrens Hospital, Bordeaux; ³Joint Unit ELFE, INSERM INED EFS and ⁴Social epidemiology team, Sorbonne University and INSERM U 1136 Pierre Louis-epidemiology and public health, Paris, France

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.646

Introduction: Mental health of pregnant and post-partum women is sensitive to environmental factors. However, access to mental healthcare remains difficult, while little is known about protective factors nor about interactions between different exposures.

Objectives: To explore on a large sample of women from the general population (i) the environmental and pregnancy characteristics independently associated with prenatal psychological distress and access to mental health care during pregnancy (ii) pathways between maternal, infant and parenthood

vulnerabilities or risk/protective factors and postnatal depressive symptoms (PNDS) at 2 months post-partum (PP)

Methods: The data from the French ELFE birth cohort were used. Available information about prenatal psychological status, access to mental health care and vulnerabilities-risk/protective factors for PNDS were collected during the maternity ward stay and at 2 months PP. PNDS were evaluated with the Edinburgh Postnatal Depression Scale (EPDS) at 2 months. Maternal/pregnancy characteristics independently associated with prenatal psychological distress and access to mental health care were explored using multivariate analyses. Pathways between risk/protective factors and PNDS at 2 months were investigated through Structural Equation Modeling.

Results: Of the 15,143 mothers explored in the prenatal part of the study, 12.6% reported psychological distress (PPD), 25% had a prenatal consultation with a mental health specialist, 11% used psychotropic drugs of which 4% had no specialist follow-up. Decreased likelihood to consult a mental health specialist was found in young women, with intermediate educational level and born abroad. PPD was more frequent in women with very low economic status, alcohol/tobacco use, unplanned pregnancy, late pregnancy declaration, multiple and complicated pregnancy. In the postnatal part of the study (n=11,583) partner's perceived antenatal emotional support, consultation with a mental health specialist before pregnancy, financial difficulties, prenatal psychological distress and experience of pregnancy were directly associated with the severity of maternal PNDS at 2 months PP, as well as perceived postnatal support, infant's self-regulation skills, maternal ability to understand infant crying and infant hospitalisation.

Conclusions: Perinatal professional support should begin antenatally and target the couple's prenatal functioning, with particular attention to women presenting history of psychiatric disorders, especially when of low socioeconomic status. After delivery, addressing infant and parenthood characteristics is recommended.

doi: 10.1192/j.eurpsy.2024.647

Introduction: Breast milk is a dynamic type of nourishment that changes based on the needs of the child. An increasing amount of data suggests that mental health may be an important factor in such modulation. In addition, breast milk contains extracellular vesicles (EVs), which are currently considered an important dynamic system of communication between cells, even of different individuals.

Objectives: Purpose of this article is to investigate whether changes in breast milk in terms of EVs concentrations are related to maternal mental health.

Methods: This is a case-control study for which we enrolled mothers of infants with bronchiolitis (N=33) and mothers of healthy infants (N=13). Breast milk samples were taken and EVs concentrations were quantified. Maternal mental health was assessed by administration of five different psychometric scales: Edinburgh Postnatal Depression Scale (EPDS), State Trait Anxiety Inventory (STAI-S, STAI-T), Barkin Index of Maternal Functioning (BIMF), The Connor-Davidson Resilience Scale 10 items (CD-RISC). Subsequently, scale scores were related to evs concentrations by negative binomial regressions adjusted for case-control.

Results: As maternal resilience increases, the EVs of neutrophilic origin (p=0.0447) and those of endothelial origin (p=0.0078) decrease¹. In contrast, an increased EPDS score is associated with higher levels of B-lymphocyte EVs (p=0.0376). Scores on the STAI-S scale impact many more populations of EVs²: we observed an increased Incidence Rate Ratio (IRR) of neutrophil-derived EVs (p<0.0001), T-lymphocyte- derived EVs (p=0.0214), NK-cell-derived EVs (p=0.0202), T-reg CD4+ CD25+ (p=0.0141) and endothelial marked EVs (p=0.0180). An increase in STAI-T scale scores also was associated with a significant increase in CD177+ neutrophil-derived EVs (p=0.0028) and endothelial-derived EVs (p=0.0111)³.

Women's emotional dependence on men and its relationship to intimate partner violence

F. Tabib^{1*}, F. Guermazi¹, D. Mnif¹, F. Cherif¹, I. Feki¹, I. Baati¹ and J. Masmoudi¹

¹Department of psychiatry A, UHC Hedi Chaker, Sfax, Tunisia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.648

Introduction: A woman's emotional dependence on a man refers to a marked need for care, protection, and support, even in situations where the woman is able to function autonomously. This dependence fosters a fusional bond that makes it difficult for the woman to leave the relationship, however unhealthy it may be. This puts the victim at greater risk of suffering and tolerating violence, in particular intimate partner violence (IPV).

Objectives: To study the emotional dependence of women who are victims of IPV, and to determine the factors associated with this dependence.

Methods: We conducted a descriptive and analytical cross-sectional observational study, carried out over a 10-month period from March 2021 to December 2021, among female victims of IPV consulting psychiatric emergencies at UHC Hedi Chaker, Sfax, Tunisia for medical expertise at the request of the court.

Emotional dependence was assessed using the Emotional Dependence Questionnaire (EDQ) which contains 20 items. Responses are given on a seven-point Likert-type scale which is recoded so that a high score reflects a high level of emotional dependence in relationships.

Results: The total number of participants was 120 with an average age of 37.27 years. The majority had secondary education or less (62.5%), were professionally active (53.3%), and were financially dependent on their partners (26.7%). As for the women's clinical characteristics, 19.2% were under psychiatric care, 15% had attempted suicide and 10% had a history of childhood abuse. Tobacco was the only psychoactive substance consumed by 12.5% of the women. The average length of marriage was 12.34 years, exceeding 10 years in 44.2% of cases. Marital conflicts had existed since the very beginning of the relationship in 91.7% of cases.

The mean total score of the EDQ was 79.38, indicating a slight emotional dependence of these women on their spouses. It was correlated with childhood violence ($p=0.028$), smoking ($p=0.049$), early conflict ($p<10^{-3}$), and personal psychiatric history ($p=0.02$).

Conclusions: A link, probably bidirectional, may occur between emotional dependence and IPV, particularly a link with maintaining the relationship in an IPV context. However, the slight emotional dependence of our victims may explain why they seek help from the police and report the violence.

Comparing the characteristics of hospitalized patients admitted in involuntary or voluntary treatment after first episode psychosis

F. Leitão^{1*}, S. A. Pinho², S. Sousa¹, J. Loureiro¹, C. Cunha¹, J. R. Silva¹, G. Franca¹, N. Oliveira¹, P. M. Ferreira¹ and A. M. Moreira¹

¹Serviço de Saúde Mental e Comunitária do Porto Ocidental and
²Serviço B, Hospital de Magalhães Lemos, Centro Hospitalar e Universitário de Santo António, Porto, Portugal

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.649

Introduction: Individuals experiencing psychotic symptoms often lack insight into their conditions, especially in first psychotic episodes. According to the Portuguese Mental Health Law, involuntary hospitalization may be necessary in cases of severe mental disorder, involving a threat to the patient or his/her legal assets, when there is a refusal of the necessary treatment.

Objectives: The aim of our study was to characterize patients admitted involuntarily for first psychotic episode and to compare them with the patients undergoing inpatient voluntary treatment.

Methods: Out of a total of 87 patients diagnosed with first psychotic episode, hospitalized between 2020 and 2022 in our service, at *Hospital Magalhães Lemos*, 65 were included in the study. Exclusion criteria included patients from other residential areas. 40 patients were admitted under involuntary treatment, whereas 25 were hospitalized voluntarily. For both groups, we calculated the duration of untreated psychosis, the prevalence of psychoactive substance abuse, the type of treatment provided and the number of re-hospitalizations.

Results: Patients in involuntary treatment had longer duration of untreated psychosis (71 vs 38 weeks). Among these patients, 53% had comorbid psychoactive substance abuse, in contrast with only 36% of voluntarily treated patients. Upon discharge, 58% of patients in involuntary treatment were prescribed depot anti-psychotic medication, whereas only 12% of the ones in voluntary treatment. Out of 40 patients admitted involuntarily, 11 were re-hospitalized, but only 4 of the 25 patients in voluntary treatment (28 vs 16%).

Conclusions: Patients in involuntary treatment probably suffered from more severe disease, as seen for the higher duration of untreated psychosis and frequent comorbid substance abuse. Injectable medication was the preferred choice at the time of discharge for this group. Additionally, they experienced higher rates of re-hospitalizations. Recent changes in Portuguese Mental Health Law, that aims to safeguard the rights and responsibilities of individuals with mental health care needs, motivated this study.

EPP0526

Comorbidity costs for the healthcare of mental patients

P. Dr. Fadgyas-Freyler

Health Policy, Corvinus University Budapest, Budapest, Hungary

doi: 10.1192/j.eurpsy.2024.650

Introduction: Most patients with mental disorders exhibit multiple comorbidities. Without doubt the presence of multiple co-occurring somatic and mental disorders is associated with a higher insurance spending for the psychiatric patients. The details of this association need to be elucidated.

Objectives: The aim of current study was 1) to delineate the typical nonmental comorbidities that occur among mental patients, and 2) to investigate social health insurance spending on comorbidities compared to the direct mental care costs of the same population. The analysis offers unique insight into the health care spending, since it focuses not only the costs of psychiatric care but reflects the whole range of treatments delivered to this group.

Methods: A database with the claim records of the Hungarian NHIF was created including direct healthcare costs for mental diagnosis. Patients were recorded either in primary or in specialist care with at least one mental health diagnosis in the last pre-pandemic year (2019). Adopting a case-control design, spending and comorbidities were compared to the control group, which comprised patients who did not have any mental diagnosis. Cases and controls were matched on demographic characteristics like age, gender, place of residence with deprivation index and marital status..

Results: Mental problems affected in 2019 more than 1,5 million persons in Hungary. Half of them did not access specialist care but were only seen with the mental diagnosis by a GP. Direct insurance spending for mental care is around 156 million EUR/year with 4% of the total direct health spending. Besides these costs another 665 million EUR (+17% of all health spending) were reimbursed for the same patient group for the treatment of other diseases. With regards to affected patient numbers, the three most important comorbidities were cardio-vascular conditions (34% of mental patients with 14% of all spending of the group); diseases of the digestive system (29% vs 14%); and musco-skeletal conditions (28% / 9%) In terms of spending three other disease groups also have to be considered as of high significance: carcinomas (4% patients vs 13% of spending); neurological disorders (13% /vs 7%); and diseases of the endocrine, nutritional and metabolic system (24% vs 6%).

Conclusions: The analysis aims to raise awareness for the complex issues of comorbidities of mental patients. We see that this patient group suffers heavily from other conditions the costs of which is much higher than the direct mental care costs. A better understanding of the coexistence of somatic and mental disorders and a holistic approach of treatment (care integration, reimbursement across different types of care, etc.) would be desirable.

Deinstitutionalization in Georgia-why it is so slowN. Zavrashvili^{1*} and G. Matiasvili¹¹School of health sciences, The University of Georgia, Tbilisi, Georgia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.651

Introduction: Mental health reform represents one of the most transformative changes in the field of healthcare, as it not only changes the forms of services but also the nature of services offered. While many countries have successfully implemented such reforms, others, including Georgia, have struggled with a protracted and inconsistent process. Despite decades of advocacy by professionals for deinstitutionalization and the development of community-based services, psychiatric hospital treatment continues to dominate in Georgia.

Objectives: The purpose of the review is to explore the concept of deinstitutionalization within the mental health landscape and assess its status in the context of Georgia. It aims to study the lessons learned from successful deinstitutionalization and illuminate achievements and challenges surrounding deinstitutionalization in Georgia's reality.

Methods: A qualitative analysis including desk review, in-depth interviews and focus group discussions was conducted. Proceeding from the research objectives we analyzed the existing legislation, strategic documents and clinical practices concerning individuals with mental disorders; Interviews were also conducted with key informants on the shortcomings and problems in deinstitutionalization practices

Results: The review findings reveal, that despite recent progress such as the development of community mobile teams and increased funding allocated for community services within mental health budget, several issues persist: there is no agreement among stakeholders on how to restructure existing hospital beds and financial provisions remain unresolved. The field of mental health in Georgia suffers from a lack of human resources. Attracting new personnel, ensuring regional distribution, and enhancing qualifications are necessary components of deinstitutionalization that require the involvement of all stakeholders, coordinated and time-planned action. The current mental healthcare system in Georgia is characterized by a lack of coordination and collaboration among its various components. Establishing patient care pathways with clear referral criteria is crucial for improving the efficiency of mental health services. This research highlights that successful deinstitutionalization requires additional funds, time, and trained people. Institutions should have a long-term (3-5) year development plan, detailing the source of funding, activities to be implemented, and expected outcomes. In the absence of such a plan, progress remains sporadic, intermittent, uncoordinated, and less effective.

Conclusions: In conclusion, the protracted nature of deinstitutionalization in Georgia requires a multifaceted approach involving various stakeholders. By addressing identified challenges and promoting coordination among mental health components, Georgia can guide a more effective course toward a community-based, patient-centered mental healthcare system.

A Cost-Effectiveness Analysis of a Ketamine-assisted Psychotherapy Program Compared to Online Group Psychotherapy in British Columbia, Canada

V. Tsang

UBC, Vancouver, Canada

doi: 10.1192/j.eurpsy.2024.652

Introduction: Depression continues to present significant economic burdens to the Canadian healthcare system. Novel therapies, including those that incorporate psychoactive substances such as ketamine, present an opportunity to evaluate both clinical and economic effectiveness against current standards of care, which may be repeatedly proving ineffective in treating depression for some individuals.

Objectives: This paper evaluates the cost-effectiveness of the Roots to Thrive ketamine program compared to group psychotherapy covered through the medical services plan in British Columbia, Canada.

Methods: A discrete-time Markov-model is used to estimate depressive states over five cycles for a treatment cohort and a synthetic control cohort. The transition probabilities for the treatment cohort are calculated from Roots to Thrive program data (n = 62) over the past 3 years, with the control cohort using published values from the literature. Both cohorts use the same starting state distribution, excess healthcare utilization rates for each severity level of depression, and utility outcomes based on depression state severity.

Results: Compared to the control cohort, the Roots to Thrive program was less expensive and produced better outcomes as measured by PHQ-9 scores and Quality-Adjusted life years over 5 treatment cycles. On average, the Roots to Thrive program would save \$14,481 and produce 0.94 additional QALY's per individual compared to group psychotherapy of three patients per provider in the current standard of care.

Conclusions: From an economic perspective, incorporating the Roots to Thrive program - or a program like it - into care in British Columbia would provide both an improvement in health outcomes and reduce expenditure by the ministry of health. These funds could be reinvested into other areas of the healthcare system to improve the lives of all British Columbians, even those that do not engage in psychedelic-assisted psychotherapy.

Gamma activity in Autism Spectrum Disorder: Enhanced response to visual inputB. Kakuszi^{1*}, B. Szuromi², M. Tóth¹, I. Bitter¹ and P. Czobor¹¹Psychiatry and Psychotherapy, Semmelweis University and ²OMI-Újgyula Hospital, Budapest, Hungary

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.653

Introduction: Autism spectrum disorder (ASD) is a childhood onset neurodevelopmental condition, that leads to permanent disability in a high proportion of cases. ASD is associated with a heterogeneous symptom presentation, which - besides social interaction and communication difficulties - encompasses altered sensory reactivity, including excessive hyper-sensitivity to stimuli, especially in the visual domain. Meta-analyses of fMRI studies revealed increased reactivity in visual task conditions in the temporal and occipital brain regions. Neural oscillations in the EEG gamma band are viewed as a candidate neurobiological marker for higher order sensory and perceptual processes, and social interactions.

Objectives: We investigated changes in gamma activity in the EEG in the eyes open (EO) vs. eyes closed (EC) condition in order to identify the neurobiological underpinning of the enhanced sensitivity to visual input in ASD as compared to typically developing (TD) subjects.

Methods: EEGs were obtained in EC and EO condition in ASD (N=23) and TD subjects (N=24) in an ongoing study. For EEG recording we used a high-density 128-channel BioSemi system, with 0.5 Hz frequency resolution. The spectral power in the gamma band (30-100Hz) was quantified by the power spectral density. To investigate whether changes in the gamma band were linked to changes in arousal instead of enhanced visual processing, we also examined alterations in the alpha band (8-13Hz) in the EO condition. Spectral power changes were determined for each EEG channel by computing the difference between the EC and EO conditions (EO-EC).

Results: Spectral power in the gamma band showed changes in the opposite direction in the two study groups: ASD subjects manifested significant ($p < 0.05$) increase, while TD subjects had a decrease in the EO vs. EC condition in the temporal and occipital brain regions. By contrast, the changes in the alpha band were similar, with both groups exhibiting a spectral power decrease in the EO compared to the EC condition.

Conclusions: In ASD, an enhancement of gamma activity is present in the EO as compared to the EC condition in the posterior brain areas. These brain areas are involved in the processing of visual information, and gamma activity is considered as a measure of perceptual processes. Thus, the gamma alterations in the EO vs. EC condition may underlie the hyper-sensitivity symptoms to visual stimuli in ASD, and EEG can offer a simple to use tool to delineate the neurobiological foundation of the symptom presentation.

Enhancing Quality of Life in the Elderly: The Impact of Psychosomatic Exercises on Healthy Aging

K. Argyropoulos¹, R. Sfakianaki², A. Argyropoulou³, D. Avramidis⁴, P. Gourzis^{5*} and E. Jelastopulu¹

¹Public Health, School of Medicine; ²Social Sciences, Hellenic Open University; ³Health Center of Andravida; ⁴School of Medicine, Patras, Greece and ⁵Psychiatry, School of Medicine, Patras, Greece

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.654

Introduction: Older individuals constitute a significant portion of the population, and concerted efforts are underway to enhance the quality of this life stage by minimizing health issues and maximizing opportunities.

Objectives: This study aims to investigate the impact of psychosomatic exercises, including practices like yoga, meditation, and tai chi, as an alternative approach to promoting healthy aging and ultimately enhancing the quality of life among elderly individuals.

Methods: The study comprised 84 participants, with 51 individuals engaging in various forms of psychosomatic exercises and 33 serving as the control group, having no prior exposure to such practices. Data collection was carried out electronically, with the initial section gathering socio-demographic information and health-related details about the participants. The second part consisted of the WHOQOL-BREF quality of life scale, consisting of 26 questions, which assessed six domains: Overall Quality of Life and General Health, Physical Health, Psychological Health, Social Relationships, and Environment. Statistical analysis was performed with SPSS 26.

Results: The average age of the participants was 66.7 years. A statistically significant positive correlation was identified within the first subscale of the tool, "Overall Quality of Life and General Health," with scores of 74.3/100 for those engaging in psychosomatic exercises and 66.7/100 for those who did not ($t(82) = -2.513$, $p = 0.014$). However, no statistically significant differences were observed in the remaining subscales.

Conclusions: Psychosomatic exercises, including yoga, meditation, and tai chi, hold promise as a means to improve the overall quality of life and general health of elderly individuals. These practices could serve as valuable components of strategies aimed at promoting healthy aging. Further research is needed to explore their effects in greater detail and across various dimensions of well-being.

Pursuing Sleep Architecture Remodeling: Effects of Psychopharmaceuticals on Sleep Structure

J. Camilo

Psychiatry, CHTMAD, Vila Real, Portugal

doi: 10.1192/j.eurpsy.2024.655

Introduction: Sleep plays a pivotal role in overall physical and mental health, exerting a profound influence on general well-being and quality of life. The influence of psychopharmaceuticals on sleep structure is a critical research area, given their widespread use in the treatment of psychiatric disorders, yet their precise effects on sleep remain inadequately understood.

Objectives: This study aims to investigate how psychopharmaceuticals affect sleep architecture by identifying commonalities and disparities among different classes of psychotropic medications.

Methods: Systematic review of the literature encompassing studies assessing the effects of psychopharmaceuticals on sleep structure. Electronic databases such as PubMed were employed to identify pertinent studies published within the last decade.

Results: Diverse classes of psychopharmaceuticals have varying effects on sleep architecture. Additionally, prolonged use of specific psychopharmaceuticals was correlated with sleep disturbances,

such as insomnia. These findings hold significant implications for clinical practice, emphasizing the necessity of an individualized approach in treating patients with psychiatric disorders.

Conclusions: Psychopharmaceuticals exert a substantial impact on sleep architecture, with effects contingent on drug class and duration of use. Understanding these alterations is crucial for optimizing the treatment of patients with psychiatric disorders, striking a balance between therapeutic benefits and potential sleep-related adverse effects. Furthermore, these discoveries underscore the importance of closely monitoring the sleep of patients undergoing psychopharmacological treatment and tailoring therapeutic approaches in accordance with individual needs.

The possible role of platelet APP processing in the pathophysiology of Alzheimer's Disease

R. Gurrieri^{1*}, M. G. Carbone², A. Arone³, S. Palermo³, D. Marazziti^{3,4} and A. Gemignani¹

¹Department of Surgical-Medical and Molecular Pathology and Critical Care Medicine, University of Pisa, Pisa; ²Division of Psychiatry, Department of Medicine and Surgery, University of Insubria, Varese; ³Department of Clinical and Experimental Medicine, University of Pisa, Pisa and ⁴Saint Camillus International University of Health and Medical Sciences, Unicamillus, Roma, Italy
*Corresponding author.

doi: 10.1192/j.eurpsy.2024.656

Introduction: Alzheimer's disease (AD) stands as the most prevalent form of dementia. Alzheimer's Disease is acknowledged to have a complex origin, a gradual neurodegenerative progression, and a wide-ranging clinical profile marked primarily by progressive memory loss, cognitive decline, and various functional impairments that significantly diminish the quality of life: Key characteristics of AD encompass the presence of amyloid plaques, which are characterized by the pathological accumulation of insoluble β -amyloid ($A\beta$) aggregates within the brain tissue and blood vessel walls. Several reports have indicated the existence of cerebral abnormalities within platelets in individuals afflicted by AD.

Objectives: The objective of this investigation was to review studies investigating the metabolism of APP in platelets among individuals with AD to identify potential dependable peripheral indicators leading to novel approaches to its management and treatment.

Methods: A systematic review according to the PRISMA guidelines was carried out, by accessing the PubMed database up to June 2023. The authors screened the titles and the abstracts of all the potentially relevant papers on the basis of a strict list of exclusion and inclusion criteria.

Results: A total of thirty-two studies were included. The evidence points towards the observation that AD individuals exhibit various modifications in platelet APP processing when compared to matched healthy controls, that are frequently associated with the severity of cognitive impairment and functional independence. The majority of the evidence supports changes in platelet ADAM-10 activity, β -secretase activity, APP ratio, a state of heightened platelet

activation or hyper-responsiveness, and a potential release of platelet APP via vesicular mechanisms, which may ultimately contribute to $A\beta$ production.

Conclusions: Platelets offer a promising peripheral model for detecting and evaluating molecular changes associated with AD, as they hold the potential to provide vital insights into the development of an effective diagnostic tool and open doors to innovative therapeutic approaches.

The European Portuguese version of the Reproductive Concerns After Cancer Scale for male cancer survivors: A preliminary psychometric validation study

J. Silva¹, A. Bártoło^{2,3}, I. S. Silva^{3,4}, A. F. Oliveira⁵, A. Louro³, A. Torres^{5,6*}, I. M. Santos⁷ and S. Monteiro^{5,8,9}

¹University of Aveiro, Department of Education and Psychology, Aveiro; ²Portugalense University, I2P—Portugalense Institute for Psychology, Porto; ³Piaget Institute, RECI - Research Unit in Education and Community Intervention, Viseu; ⁴TERRA Associate Laboratory, University of Coimbra, Centre for Functional Ecology-Science for People & the Planet (CFE), Coimbra; ⁵Department of Education and Psychology, University of Aveiro, CINTESIS@RISE, Aveiro; ⁶Department of Psychology and Education, Faculty of Social and Human Sciences, University of Beira Interior (UBI), Covilhã; ⁷Department of Education and Psychology, University of Aveiro, William James Center for Research, Aveiro; ⁸Department of Social and Management Sciences and ⁹Center for Global Studies, Open University, Lisbon, Portugal
*Corresponding author.

doi: 10.1192/j.eurpsy.2024.657

Introduction: Cancer treatments can affect male fertility. However, the reproductive concerns of this population remain little explored. There is a need to invest in understanding how concerns related to fertility and parenting affect psychosocial adjustment, in order to improve counseling in this context. To this end, it is a priority to provide reliable and valid measures for assessing this construct.

Objectives: This study aimed to translate, adapt and preliminarily explore the psychometric properties of the Portuguese version of the Reproductive Concerns After Cancer Scale - Male Version (RCAC-M).

Methods: Translation and back-translation were carried out by two independent translators. A reconciled version was obtained and evaluated by a panel of experts who ensured its cultural adaptation. Before studying the psychometric properties, a pre-test was carried out involving a focus group of 5 male cancer survivors who assessed the adequacy of the measure. The preliminary validation included 32 male cancer survivors aged between 18 and 55. Recruitment was carried out by providing an online questionnaire. A principal component analysis was carried out to explore the factor structure of the measure and to analyze the reliability and convergent validity of the measure.

Results: The results showed good internal consistency of a version consisting of 17 items, grouped into four factors: fertility potential,

child health and future life, personal health and future life, and acceptance. Significant moderate associations were found between reported concerns and other constructs that are consistently related to this variable in the literature, namely the importance of parenting and symptoms of anxiety and depression.

Conclusions: The original structure of the scale was not corroborated. However, this study suggests the promising character of the Portuguese version of the RCAC-M as a reliable and valid tool for assessing the reproductive concerns of male cancer survivors.

A case of steroid induced psychosis in a patient with mediastinal lymphoma

B. Orgaz Álvarez*, M. Velasco Santos, P. Ibáñez Mendoza, Á. de Vicente Blanco and G. García Cepero

Hospital Universitario La Paz, Madrid, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.658

Introduction: Corticosteroids are a key part of many cancer treatment regimens and neuropsychiatric side effects have long been recognised. Steroid-induced psychosis is a disorder classified under substance or medication-induced psychosis in the *Diagnostic and Statistical Manual of Mental Disorder, 5th edition*. Management strategies include treatment with antipsychotic medication and reducing corticosteroid dosage.

Objectives: To describe the case of steroid induced psychosis in a patient with mediastinal lymphoma and provide a concise literature review.

Methods: Clinical case report and brief literature review.

Results: 27-year-old male with a diagnosis of Stage IV Primary Mediastinal Lymphoma according to the Ann Arbor classification was admitted to the Haematology ward for chemotherapy treatment (R-DA EPOCH). Two days after admission the patient developed acute psychotic symptoms consisting of thought block, kinaesthetic hallucinations, and delusions. Prior to admission, the patient had been on corticosteroid treatment for two months (up to 8mg/day of dexamethasone), with a significant dose increase (up to 200mg/day of prednisone) at the beginning of chemotherapy treatment two days prior to symptom development. The patient had no personal or family history of mental health issues, no substance misuse and had not received any psychopharmacological treatment prior to admission.

Medical evaluations including a cranial CT scan, an MRI, EEG, blood tests and lumbar puncture were all within normal parameters, discounting organic or metastatic causes for the symptoms. Considering a potential episode of steroid-induced psychosis, the patient was started on olanzapine at a dosage of 10mg per day. The patient exhibited a positive response, with symptoms alleviating within 24 hours of the initial dose. In terms of corticosteroid therapy, haematologists adjusted the prednisone regimen to 100mg per day, and due to the encouraging progress, the olanzapine dosage was subsequently reduced to 5mg per day.

Conclusions: This case underscores the importance of considering the possibility of steroid induced psychosis as a differential

diagnosis specially in patients on high dose steroids presenting with psychotic symptoms. A multidisciplinary approach is crucial to ensure optimum treatment and care.

I smell something weird - Ictal olfactory hallucinations in patients with primary brain tumors

M. Mousinho^{1*}, D. Antão², A. Soares³, T. Pimentel^{2,3}, D. Salgado² and M. Fernandes^{2,3}

¹Mental Health Department, Local Health Unit of Baixo Alentejo, Beja;

²Neurology Department and ³Neurophysiology Laboratory, Portuguese Institute of Oncology, Lisboa, Portugal

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.659

Introduction: Ictal olfactory hallucinations (the experience of a smell due to a focal seizure in the absence of an environmental stimulus for the sensation) are rare. They often appear in a context of a brain tumor located in the orbitofrontal or mesotemporal region. However, their accurate prevalence, etiology and anatomical origin remains unclear, as few studies focused on this type of seizures specifically.

Objectives: To evaluate the clinical, neurophysiological and imaging characteristics of patients with brain tumors and olfactory seizures.

Methods: We present a 3-year retrospective patient record study carried out at the Portuguese Institute of Oncology in Lisbon. Clinical records of 572 patients admitted due to a primary Central Nervous System (CNS) tumor, for their first neuro-oncology appointment, between July 2020 and July 2023, were reviewed.

Results: 8 patients with olfactory seizures were identified. Five were men. The mean age was 57.75 (ages between 15 and 70 years old). In seven patients, olfactory seizures constituted the initial clinical presentation of the tumor. In two patients, focal olfactory seizures had progression to bilateral tonic clonic. Most seizures were perceived as unpleasant (smells of metal, ammonia, "hot blood", "dead bodies" were described). Tumors involved the temporal lobe in all patients, the insula in two of them and, for the majority, the lesion was right-sided. Six patients were diagnosed with Glioblastoma IDH wildtype (Grade 4, WHO), one patient with Oligodendroglioma, IDH-mutated and 1p/19q-codeleted (Grade 2, WHO) and the pediatric patient with a diffuse pediatric type high-grade glioma, H3 and IDH wildtype. The average follow-up time was 6.8 months, two patients died.

Conclusions: This is the first retrospective study carried out in Portugal that documents the prevalence of olfactory seizures in patients with primary CNS tumors. Given the scarce literary evidence, we consider that olfactory seizures may be more frequent than documented, particularly in the presentation of brain tumors. As so, active semiological investigation may contribute to an earlier diagnosis.

Differences in clinical variables of cervical cancer in women with schizophrenia

F. Casanovas^{1,2*}, F. Dinamarca³, S. Oller¹, A. Trabsa^{1,4}, L. Martínez-Sadurni^{1,4}, R. Rodríguez-Seoane¹, N. Zabaleta¹, L. M. Martin¹, V. Perez-Sola^{1,2} and A. I. Ruiz¹

¹Institut de Salut Mental, Hospital del Mar, Barcelona; ²Centro de Investigación Biomédica en Red de Salud Mental (CIBERSAM), Madrid; ³Departmeny of Psychiatry, Hospital de la Santa Creu i Sant Pau and ⁴Programa de doctorat en psiquiatria i medicina legal, Universitat Autònoma de Barcelona, Barcelona, Spain

*Corresponding author.
doi: 10.1192/j.eurpsy.2024.660

Introduction: Schizophrenia is associated with a reduced life expectancy, not only because of suicide, but also medical causes such as cancer. Standardized mortality for cancer is higher in patients with schizophrenia, specially for lung, breast and colorectal locations (Ni et al, 2019). Other less frequent tumor locations have not been deeply studied.

Thir mortality gap could be related to a delayed diagnosis due to several reasons, such as lower inclusion in screening programs (Solmi et al, 2019). Since cervical cancer has a very efficient screening technique, women with schizophrenia and cervical cancer could have a worse prognosis because of a delayed diagnosis. However, there is a lack of research in this tumor location.

Objectives: To analyze clinical differences in women with cervical cancer with and without a diagnosis of schizophrenia.

Methods: We carried out a retrospective cohort analysis with adult patients from the cancer registry of Hospital del Mar diagnosed between 1997 and 2021. The information was crossed with the Minimum Basic Data Set (MBDS) to identify those cancer patients with a diagnosis of schizophrenia using International Classification of Diseases (ICD) 9 codes 295*. The socio-demographic variables were age and sex. The clinical oncological variables included tumor location, place of first consultation, stage, first treatment intention, vital status and place of decease. We used t-student for continuous data and Chi-squared test for categorical variables. We performed a post-hoc analysis using Bonferroni correction for multiple comparisons to identify specifically which categories were significantly different between groups.

Results: We identified 13 women with schizophrenia and cervical cancer, and 1354 women with cervical cancer without schizophrenia. The proportion of this location was higher in the schizophrenia group (8% of all cancers vs. 4.4%; p=0.03). The proportion of diagnoses through screening program was significantly lower (7.7% vs 14.6%; p=0.04). There was a trend of fewer diagnoses in situ in patients with schizophrenia (30.8% vs 55.6%) and less radical intention as first treatment option (15.4% vs 3.5%) but without statistical significance in both cases. There was a higher proportion of deceased patients in the group with schizophrenia (46.2% vs 15% p=0.002), and also a higher proportion of deaths outside hospital facilities (30.8% vs 6.6%; p=0.003).

Image:

		Schizophrenia		Non-schizophrenia		Ux2	p value

	Outpatient clinics	7	53.8%	967	71.4%		
	Screening programs	1	7.7%	198	14.6%		
Stage	In situ	4	30.8%	753	55.6%	6.64	0.157
	I	2	15.4%	70	5.2%		
	II	1	7.7%	67	4.9%		
	III	1	7.7%	29	2.1%		
	IV	1	7.7%	55	4.1%		
	Unknown	4	30.8%	380	28.1%		
Treatment	Radical	11	84.6%	1220	90.1%	5.98	0.113
	Oncologic not radical	0	0	36	2.7%		
	Palliative/Symptomatic	2	15.4%	47	3.5%		
	Unknown	0	0	51	3.8%		
Vital status at last contact	Alive	7	53.8%	1151	85.0%	9.65	0.002
	Deceased	6	46.2%	203	15.0%		
Place of death	Palliative care	1	7.7%	35	2.6%	13.91	0.003
	Out-of-hospital	4	30.8%	89	6.6%		
	In-hospital	1	7.7%	79	5.8%		

Table 1. Characteristics of cervical cancer cases with and without schizophrenia (1997-2021)

Conclusions: Women with schizophrenia receive less diagnoses of cervical cancer through screening programs and more in emergency facilities, which could lead to more advanced stages and fewer indication of radical treatments. This ultimately leads to a higher proportion of deaths, and more frequently outside of hospital facilities.

Our data supports the idea that the increased mortality for cancer is related to a delayed diagnosis. Women with schizophrenia need special care to ensure their inclusion in early detection programs for cancer.

Family caregivers of patients with Head and Neck Cancer seen at an oncologic outpatient service of a Brazilian public university: A qualitative study on reports regarding interpersonal emotional handling

S. A. Silva¹, E. R. Turato^{1*}, C. S. P. Lima¹, R. S. E. Sant'Ana¹, L. S. Valladão¹, A. C. O. Bispo¹, C. G. Santos¹, J. R. P. D. L. Rodrigues¹ and M. R. Suedt¹

¹Lab of Clinical-Qualitative Research, University of Campinas, Campinas, Brazil

*Corresponding author.
doi: 10.1192/j.eurpsy.2024.661

Introduction: Humanistic studies applied to the health-illness clinic go beyond explaining cause-effect relationships among disease phenomena, treatments, and preventions. Qualitative research aims to understand symbolic relationships built in life experiences among the manifestations and the people. How to act in front of a person whose physical appearance and odour can be unpleasant, such as in the HNC - Head Neck Cancer? Or whose life history may have been marked by deviant behaviours and negligence in self-care?

Objectives: To interpret emotional meanings attributed through open interviews conducted with relatives about the domestic care of patients with HNC under clinical treatment.

Methods: Sample composed of family caregivers of patients with HNC, sent sequentially by colleagues from the clinical service who were informed of the research. The study used the Clinical-Qualitative Method (Turato. Portuguese Psychos. J, 2000 2(1): 93-108). Semi-Directed Interview with Open-ended Questions In-Depth and Field Notes was used for data collection. The employ of the Seven Steps of the Clinical-Qualitative Content Analysis (Faria-Schützer et al. Cien Saude Colet. 2021; 26(1): 265-274) has permitted the understanding of the topics. Sample closed with 12 persons according to the information saturation strategy (Fontanella et al. Cad Saude Publica. 2008; 24(1): 17-27), conducted by the first author, a female psychologist. To interpret the empirical material, we use Medical/Health Psychology, the psychodynamics of relationships of the Balintian framework, disease and illness while modes of un-health, psychic defence mechanisms against anguish. Validation by peers from the Lab of Clinical-Qualitative Research Laboratory, at the State University of Campinas.

Results: For this presentation, we listed three categories from the free-floating re-readings: (1) Certain need to recognize the care provided as a handling strategy with effort, putting in this 'validation' their relief regarding natural suffering of the care process; (2) Caregiver's psychological fantasies of omnipotence in the care process, frequently perceiving the reality a phenomenologically and necessarily distorted by the caregiver. (3) Moments of impotence feeling in front of the finitude reality that it knows will arrive.

Conclusions: The family caregivers can present certain emotional defences, such as subtle magical thinking, in which they distort the reality experienced as a management strategy and validation of their care. They act so to alleviate their psychological and existential suffering. Group meetings with family members to talk openly about the difficulties on the psychological management of patients with HNC, coordinated by a psychotherapist, are effective as a space for creativity in daily management at home and a space for catharsis.

EPP0539

Severe Hyperhidrosis Secondary to Bupropion Use and Treatment. A case report.

A. Oliva Lozano^{1*}, J. Garde Gonzalez¹, M. A. Morillas Romerosa¹ and P. Herrero Ortega¹

¹Psychiatry, Hospital La Paz, Madrid, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.662

Introduction: Hyperhidrosis, the excessive and uncontrollable sweating, is a well-documented side effect of various medications. Among these, bupropion, a commonly prescribed antidepressant and smoking cessation aid, has been associated with the development of severe hyperhidrosis in a subset of patients. This clinical report aims to shed light on a compelling case of severe hyperhidrosis induced by bupropion use and the subsequent treatment strategies employed.

The patient under discussion is a 42-year-old female with a history of recurrent major depressive disorder and a previous favorable response to selective serotonin reuptake inhibitors (SSRIs). Due to side effect concerns and a desire to quit smoking, she was transitioned to bupropion, a norepinephrine-dopamine reuptake inhibitor (NDRI), at a standard therapeutic dose of 150 mg daily.

Approximately four weeks after initiating bupropion therapy, the patient began experiencing debilitating symptoms of excessive sweating, particularly affecting her palms, soles, and axillae. The profuse sweating episodes occurred throughout the day and night, significantly impairing her quality of life, social interactions, and occupational functioning. No previous history of hyperhidrosis was reported, and physical examinations revealed no underlying medical conditions or dermatological issues.

Objectives: To acknowledge the importance of recognizing and addressing medication-induced side effects within the realm of psychiatry and an early implementation of patient-centered treatment.

Methods: Clinical case report and a brief literature review.

Results: The treatment of hyperhidrosis secondary to bupropion use presents a challenging clinical scenario that requires a delicate balance between managing the distressing side effect and ensuring the continued efficacy of psychiatric therapy. Given the rarity of severe hyperhidrosis as a side effect of bupropion, there is a limited body of evidence guiding treatment strategies. Gradual withdrawal in the dose of bupropion was initiated, with careful monitoring of depressive symptoms to prevent relapse, switching to Duloxetine 90mg daily, with adequate effectiveness. In this particular case, the combination of medication adjustment and psychological support led to a significant reduction in hyperhidrosis symptoms. The patient reported improved social interactions, enhanced self-esteem, and restored occupational functioning. Importantly, her depressive symptoms remained well-managed, underscoring the success of the treatment strategy.

Conclusions: This clinical report highlights the importance of a patient-centered approach when addressing rare medication-induced side effects within the field of psychiatry. Bupropion withdrawal and regular follow-up showed effective in the treatment of the symptoms. Future research may provide additional insights and treatment options for cases like this, further enhancing patient care and outcomes.

Fecal Microbiota Transplantation in the treatment of mood disorders : A literature review

F. ASKRI^{1*}, K. MAHFOUDH¹, K. BEN YOUNES², E. HERELLI², U. OUALI¹ and A. AISSA¹

¹PSYCHIATRY A and ²PSYCHIATRY C, RAZI HOSPITAL, MANOUBA, Tunisia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.663

Introduction: Many researchers have turned their attention to studying the relation between the gut microbiota to mood disorders. In fact, studies in the last 5 years have shown that the change in microbiota in animals can cause anxiety a depression –like behaviors.

In humans, considering the fact that there was a difference between in human gut microbiota between depressed persons and healthy controls, many clinicians suggest different treatment ways to compensate the microbiome imbalance such as Fecal microbiota transplantation (FMT).

FMT is an ancient tool that used to treat food poisoning and severe diarrhea. Recent studies have shown its efficacy in autism spectrum disorders but not enough studies have shown its contribution in treating mood disorders.

Objectives: The aim is to explore and understand the use of fecal microbiota transplantaion in the mood disorder treatment

Methods: We conducted a literature search for English articles on PubMed using the keywords : mood disorder, Fecal microbiota transplantation, treatment.

Results: 13 results were initially found on the pubmed database. we identified 4 eligible studies.

02 case studies reported that patients diagnosed with bipolar disorder type 2 improved after repetitive FMT treatment, 01 randomised controlled trial concluded good tolerability and feasibility of FMT in major depression disorder but was not designed to measure clinical outcomes. Finally, 01 study protocol is still conducting on the efficacy and safety of FMT n in a population with bipolar disorder during depressive episodes.

Conclusions: No results have shown the efficacy of FMT in treating mood disorders yet. However, it is considered well tolerated and safe. Further studies are needed to conclude its efficacy.

A spark of genius and a flash of madness: Nikola Tesla and his struggles with mental illness

S. Jesus Magueta^{1*}, A. L. Costa¹, G. Simões¹, A. I. Gomes¹, C. Madaíl Grego¹ and P. Garrido¹

¹Departamento de Psiquiatria e Saúde Mental, Centro Hospitalar do Baixo Vouga, Aveiro, Portugal

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.664

Introduction: An example of the unification of the contrast between artistic creativity and discipline of science, Nikola Tesla engineer and physicist, was also a prolific inventor that contributed to the transformation of modern society. Having resurfaced in the mainstream culture as a mythical figure, he appears to be enjoying a renaissance of posthumous recognition and praise. Through accounts available directly from his autobiography and descriptions offered by those who worked with him, the existence of the inventor's *eccentricities* appear to reveal the existence of mental health disorder.

Objectives: The authors explore Tesla and the psychopathology that accompanied him throughout his periods of brilliance and as well as hardship.

Methods: The authors conducted a brief non-structured narrative literature review. The keywords used during the research, alone or in combination, included: Nikola Tesla, psychopathology and mental illness. The works consulted included: news articles, autobiographies and biographies. Of these, those that were written in the English language and deemed most pertinent to the explored theme were chosen for review in this work.

Results: The popular image of the *mad scientist*, which describes a brilliant but solitary and eccentric individual focused on their work is one that could be applied to Tesla. Documents reveal that he suffered a nervous breakdown, as well as having symptoms that point to a probably presence of obsessive-compulsive disorder, of which included counting and cleanliness rituals, exacerbated by chronic insomnia.

Conclusions: There appears to be anecdotal evidence pointing to an eventual relationship between creative genius and mental pathology. Although not formally evidenced through the scientific literature, exploring the life and accomplishments of Tesla serve as a significant example of a spark of genius perhaps ignited by mental illness. Tesla demonstrated suffering associated with his symptoms especially when considering the end of his life. At the time, adequate mental health interventions and treatments were not widely available, with his diagnosis probably being considered the quirks of genius and not the symptoms of disease.

Health Outcomes and Health Services Utilization Evaluation Protocol: Assessing the Impact of the Nova Scotia Rapid Access and Stabilization Program

M. K. Adu^{1*}, R. D. L. Dias¹, G. Obuobi-Donkor¹, N. Ezeanozie¹, S. Sridharan¹, J. Morrison¹, P. Simon¹, B. Taylor², M. MacKinnon², S. Gossen¹, B. Agyapong³, L. Wozney¹ and V. I. Agyapong¹

¹Department of Psychiatry, Dalhousie University; ²Mental Health and Addictions Program, Nova Scotia Health, Halifax, NS and ³Department of Psychiatry, University of Alberta, Edmonton, AB, Canada

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.665

Introduction: Emergency psychiatric care, unplanned hospital admissions, and inpatient health care are the costliest forms of mental health care. According to Statistics Canada (2018), almost 18% (5.3 million) of Canadians reported needing mental health support. However, just above half of this figure (56.2%) have reported their needs were fully met. To further expand capacity and access to mental health care in the province, Nova Scotia Health has launched a novel mental health initiative, the Rapid Access, and Stabilization Program (RASP).

Objectives: This study evaluates the effectiveness and impact of the RASP on high-cost health services utilization (e.g. ED visits, mobile crisis visits, and inpatient treatments) and related costs. It also assesses healthcare partners' (e.g. healthcare providers, policy-makers, community leaders) perceptions and patient experiences and satisfaction with the program and identifies sociodemographic characteristics, psychological conditions, recovery, well-being, and risk measures in the assisted population.

Methods: This is a hypothesis-driven program evaluation study that employs a mixed methods approach. A within-subject comparison will examine health services utilization data from patients attending RASP, one year before and one year after their psychiatry assessment at the program. A controlled between-subject comparison will use historical data from a control population will examine whether possible changes in high-cost health services utilization are associated with the intervention (RASP). The primary analysis involves extracting secondary data from provincial information systems, electronic medical records, and regular self-reported clinical assessments. Additionally, a qualitative sub-study will examine patient experience and satisfaction, and examine health care partners' impressions.

Results: The results for the primary, secondary, and qualitative outcome measures to be available within 6 months of study completion. We expect that RASP evaluation findings will demonstrate a minimum 10% reduction in high-cost health services utilization and corresponding 10% cost savings, and also a reduction in the wait times for patient consultations with psychiatrists to less than 30 calendar days. In addition, we anticipate that patients, healthcare providers, and healthcare partners would express high levels of satisfaction with the new service.

Conclusions: This study will demonstrate the results of the Mental Health and Addictions Program (MHAP) efforts to provide stepped-care, particularly community-based support, to individuals with mental illnesses. Results will provide new insights into a novel community-based approach to mental health service delivery and contribute to knowledge on how to implement mental health programs across varying contexts.

Is gaming disorder related to psychological trauma? A scoping review

H. W. Fung¹, C. T. Y. Cheung², P. Lam³, G. F. Yuan^{4,5}, M. Y. C. Wong⁶, H. W.-H. Ling⁷, S. K. K. Lam², A. K. C. Chau^{8*} and V. W. P. Lee¹

¹Department of Social Work, Hong Kong Baptist University; ²Nethersole School of Nursing, Faculty of Medicine, The Chinese University of Hong Kong, Hong Kong, Hong Kong; ³Institute of Sociology, National Tsinghua University, Hsinchu, Taiwan, Province of China; ⁴South Carolina SmartState Center for Healthcare Quality, Arnold School of Public Health; ⁵Department of Health Promotion, Education, and Behavior, Arnold School of Public Health, University of South Carolina, Columbia, SC, United States; ⁶Department of Health and Physical Education, The Education University of Hong Kong; ⁷Department of Social Work and Social Administration, The University of Hong Kong and ⁸Institute of Health Equity, The Chinese University of Hong Kong, Hong Kong, Hong Kong

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.666

Introduction: Gaming disorder has become a global concern and it could have a variety of health and social consequences. The trauma model has been applied to the understanding of different types of addictions as behavioral addictions can sometimes be conceptualized

as self-soothing strategies to avoid trauma-related stressors or triggers. However, much less is known about the relationship between trauma exposure and gaming disorder.

Objectives: To inform prevention and intervention strategies and to facilitate further research, we conducted the first scoping review to explore and summarize the literature on the relationship between trauma and gaming disorder.

Methods: A systematic search was conducted on the Web of Science, Scopus and ProQuest. We looked for original studies published in English that included a measure of trauma exposure and a measure of gaming disorder symptoms, as well as quantitative data regarding the relationship between trauma exposure and gaming disorder.

Results: The initial search generated 412 articles, of which 15 met the inclusion criteria. All of them were cross-sectional studies, recruiting participants from both clinical and non-clinical populations. Twelve of them (80%) reported significant correlations between trauma exposure and the severity of gaming disorder symptoms ($r = 0.18$ to 0.46 , $p < 0.010$). Several potential mediators, including depressive symptoms and dissociative experiences, have been identified. One study found that parental monitoring moderated the relationship between trauma and gaming disorder symptoms. No studies reported the prevalence of trauma or trauma-related symptoms among people with gaming disorder.

Conclusions: There is some evidence supporting the association between trauma and gaming disorder, at small to medium effect sizes. Future studies should investigate the mediators and moderators underlying the relationship between trauma and gaming disorder. The longitudinal relationship between trauma exposure and the development of gaming disorder should be clarified. A trauma-informed approach may be a helpful strategy to alleviate gaming disorder symptoms.

Similar cognitive characteristics between gaming disorder and other psychiatric disorders

S. Tei^{1*} and J. Fujino²

¹Department of Psychiatry, Kyoto University, Kyoto and ²Department of Psychiatry and Behavioral Sciences, Tokyo Medical and Dental University, Tokyo, Japan

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.667

Introduction: Cognitive characteristics that differentiate normal from problematic gaming need to be identified, owing to the growing popularity of internet games and the rapid rise in mental health problems. Gaming disorder (GD) involves playing games despite their negative effects and is often related to unsuccessful attempts to reduce gaming. GD frequently results in adverse outcomes related to education, employment, and social responsibilities, thereby significantly influencing daily life.

Objectives: We aimed to elucidate the neurocognitive features underlying GD development and preservation, and possible overlapping features between GD and other psychiatric disorders.

Methods: We performed a literature search to identify GD-related studies. We focused on two key aspects: (a) altered executive functions

(EFs) and (b) gaming urge. We mainly searched the PubMed and Web of Science databases using relevant keywords. All retrieved literature were assessed for eligibility to reduce selection biases.

Results: Our preliminary review identified that GD features prominent deficits in EFs, including cognitive inflexibility, poor response inhibition, altered decision-making, and intensified susceptibility to game-related stimuli. These deficits were found to be associated with abnormal neural activity in brain regions subserving EFs and reward-based learning. Hence, excessive gaming may maladaptively suppress controlled and conscious processing, which can amplify automatic and implicit processes to develop gaming urges. In addition, many of these neuropsychological deficits have been observed in other addictions and seemingly unrelated disorders such as autism spectrum disorder (ASD). Similar EF deficits have been identified in ASD, which involve reduced cognitive flexibility and related dysfunction, including excessive attention focus, restricted interest, maladaptive reward processing, and reduced self-control. However, there is considerable variation among individuals and study methods, which requires more comprehensive research strategies.

Conclusions: We elucidated comparable cognitive features among individuals with GD, addiction disorders, and ASD. These similarities provide clues regarding GD etiology, ideas for improving preventative therapies, and markers for risk evaluation. Additional investigations on how GD and other disorders possess similar and distinctive cognitive functions are worth pursuing. It is also crucial to further examine the extent of shared cognitive features in the general population, wherein the peripheral pathological characteristics lie on a continuum with typical and atypical populations.

Depressive disorders and intravenous drug use in chemsex context

J. Curto Ramos^{1,2*}, A. Rodríguez Laguna², P. Barrio², L. Ibarguchi², A. García², I. Azqueta² and H. Dolengevich Segal³

¹Department of Psychiatry, Clinical Psychology and Mental Health, La Paz University Hospital; ²Apoyo Positivo and ³Dual Disorders Program. Department of Psychiatry, Henares University Hospital, Madrid, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.668

Introduction: Several studies have called attention to the mental health disorders associated with chemsex -the intentional use of drugs before or during sexual intercourse GBMSM (gay, bisexual and men who have sex with men) population-. Sexualized intravenous drug use is also known as slam or slamsex. There are few studies that analyze the mental health differences between intravenous drug users compared to non-intravenous drug users in chemsex context.

Objectives: We aim to describe the mental health outcomes including current and past depressive disorders diagnosis in a sample of users with sexualized drug use (chemsex) attended by the non-governmental organization Apoyo Positivo in the program "Sex, Drugs and You" and to compare the differences of current and previous diagnosis of depressive disorders between intravenous drug users compared to non-intravenous drug users.

Methods: A cross-sectional descriptive analysis of a sample of users attended by the non-governmental organization Apoyo Positivo in the program "Sex, Drugs and You" between 2016-2019 was performed.

Results: We included 217 participants. Current or past diagnosis of depression was found in 137 participants. Depressive disorders were significantly higher in the intravenous drug use group compared to the non-intravenous drug use group ($p < 0.05$).

Conclusions: Our study reports high levels of depression in chemsex users. The participants in our sample who engaged in intravenous drug use presented a higher frequency of depressive disorders than non intravenous drug use participants. Further studies analyzing the relationship between chemsex, slamsex and depression are needed. A multidisciplinary team is necessary to address chemsex and provide care and mental health treatment to chemsex users.

Anxiety Disorders and Somatoform Disorders

EPP0549

Prevalence of Generalized Anxiety Disorder Among Five European Countries Before and During COVID

D. Karlin¹, S. J. Suponcic², N. Chen³, C. Steinhart¹ and P. Duong^{1*}

¹MindMed, New York; ²Value & Access Advisors, LLC, Tallahassee and ³Cerner Enviza, an Oracle company, Kansas City, United States

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.669

Introduction: Globally, there is a mental health crisis, and anxiety is the most prevalent mental health condition. However, the impact of the COVID-19 pandemic (COVID) on generalized anxiety disorder (GAD) prevalence has not been quantified across European countries, and such impact could establish a new baseline of GAD estimates in European countries.

Objectives: To assess GAD by severity level before and during COVID in 5 European countries, using the 7-Item GAD Questionnaire (GAD-7).

Methods: Adults (age 18+) in France, Germany, UK, Italy, and Spain completed a short survey in May 2020 to assess the impact of COVID on their mental health. All respondents had previously participated in the National Health and Wellness Survey, a nationally representative survey of the adult general population in each country, before COVID (December 2019–March 2020). In both surveys, respondents completed the GAD-7. GAD symptoms were defined by GAD-7 score as mild (5-9), moderate (10-14), and severe GAD (≥ 15). Positive screen was defined as GAD-7 score ≥ 10 . Positive screen and GAD symptom severity prevalence were reported for the pooled European sample and by country, both before and during COVID. Chi-square and McNemar's tests were used to evaluate the difference in GAD severity across countries and changes over baseline in GAD positive screen during COVID. P-values were reported for both tests.

Results: In total, 2401 adults were included in analysis (France, $n=482$; Germany, $n=487$; UK, $n=487$; Italy, $n=474$; Spain, $n=471$). Prior to COVID, 311 (13%) screened positive for GAD, with 208 (9%) moderate and 103 (4%) severe in the pooled European sample. During COVID, the distribution of GAD symptoms almost

doubled, as 576 (24%) screened positive for GAD, and shifted towards greater severity with 337 (14%) moderate and 239 (10%) severe in the pooled European sample (**Figure 1**). Before COVID, the prevalence of positive screen ranged from 11% (France, Germany, Spain) to 16% (UK). Statistically significant increases in positive screen over baseline levels were observed across all countries ($p < 0.01$), except Germany. Spain was the most impacted by COVID (increase: 16%), followed by Italy, France, and UK (increase: 14%, 12%, and 9%, respectively). Germany was the least affected, overall (increase: 4%) (**Figure 2**).

Image:

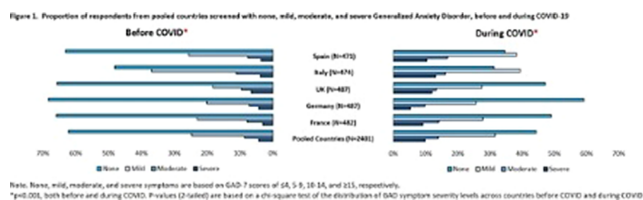

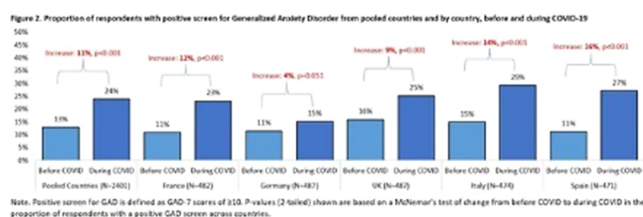

Image 2:

Conclusions: During COVID, estimates of positive screen for GAD increased substantially to 24% across 5 European countries. Surges in positive screen and GAD symptom severity were observed in all 5 countries, with more profound impact in Spain, Italy, France, and UK. With new baseline GAD estimates, the country-specific data of COVID impact on GAD could help to inform appropriate allocation of mental health resources.

Sociodemographic factors as a predictor for pregnancy-related anxiety

M. Abdelkefi^{1*}, R. Walha², R. Feki¹, W. Zid², I. Gassara¹, N. Smaoui¹, S. Omri¹, N. Charfi¹, L. Zouari¹, J. Ben thabet¹, M. Maalej bouali¹, K. Chaabene² and M. Maalej¹

¹psychiatry C department and ²Gynecology-Obstetrics department, Hedi Chaker university hospital, sfax, Tunisia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.670

Introduction: Pregnant women are particularly vulnerable to a wide variety of psychiatric symptoms, including anxiety related to pregnancy and childbirth.

Objectives: The purpose of our study was to determine the socio-demographic characteristics of pregnant women and investigate their relationship with pregnancy-related anxiety.

Methods: The study was conducted from February to July 2023 among pregnant women in their 3rd-trimester consulting at the Gynecology-obstetrics department of the Hedi Chaker University Hospital of Sfax, Tunisia. Women with obstetric conditions favorable to vaginal delivery (cephalic presentation and eutrophic fetus) were interviewed using a questionnaire including their sociodemographic characteristics and the brief version of the pregnancy-related anxiety questionnaire PRAQ-R2.

Results: A total of 350 women were included in our study. The mean age of the participants was 28 years [16-41 years] with the majority being married (95.7%). One hundred and eighty-eight women (53.7%) did not graduate from high school and 213 (60.9%) were housewives. Half of the participants (52.9%) lived in the city, and 38.9% reported low income. Almost half of them (46.28%) were multiparous.

The mean score of the PRAQ-R2 was 31.24 ± 7.53 .

We found a positive correlation between the PRAQ-R2 scale score and age younger than 30 years ($p < 0.001$), low educational level ($p = 0.006$), and low income ($p = 0.031$).

Conclusions: Our findings suggest that demographic factors seem to predict anxiety related to pregnancy and are worth examining in future studies for a better understanding of this symptom in pregnant women.

Drug repurposing as add-on treatment strategy for mania and bipolar depression: systematic synthesis and qualitative appraisal of the existing meta-analytic evidence

D. Cavaleri^{1*}, F. Bartoli¹, C. Crocamo¹ and G. Carrà^{1,2}

¹Department of Medicine and Surgery, University of Milano-Bicocca, Monza, Italy and ²Division of Psychiatry, University College London, London, United Kingdom

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.671

Introduction: In the complex pathophysiology of bipolar disorder (BD), increasing evidence supports the involvement of neurobiological abnormalities beyond the classical ones, suggesting them as potential alternative therapeutic targets. Several drugs approved for different indications have thus been repurposed for the treatment of BD, all of them supported by a plausible biological rationale. Some recent reviews have provided an update on these possible additional treatment options for mania and bipolar depression, but no systematic synthesis and qualitative evaluation of meta-analytic findings has been made.

Objectives: To provide a guidance on the available evidence on these treatments and their potential role in clinical practice, we

conducted an umbrella review of meta-analyses of randomized placebo-controlled trials investigating drugs repurposed as add-on treatments for mania and bipolar depression.

Methods: We performed a systematic search and screening of the existing literature looking for the most up-to-date or comprehensive meta-analyses of randomized controlled trials (RCTs) on adults suffering from BD during an acute mood episode (mania or depression) which compared a repurposed drug and placebo as adjunctive treatments. We performed a critical appraisal according to "A MeaSurement Tool to Assess systematic Reviews" Version 2 (AMSTAR 2). We synthesized meta-analytic findings regarding efficacy, tolerability, and safety, also assessing the quality of evidence using the "Grading of Recommendations, Assessment, Development and Evaluations" (GRADE) approach.

Results: In nine eligible meta-analyses investigating 12 drugs (four for mania and eight for bipolar depression) we observed a heterogeneous quality of reporting was according to AMSTAR 2.

In mania, allopurinol (for symptoms reduction and remission at 4-8 weeks) and tamoxifen (for response and symptoms reduction at 4-6 weeks) showed higher efficacy than placebo, with evidence of low and very low quality, respectively.

In bipolar depression, modafinil/armodafinil (for response, remission, and symptoms reduction at 6-8 weeks) and pramipexole (for response and symptoms reduction at 6 weeks) were superior to placebo, with low-quality evidence. Results on celecoxib and N-acetylcysteine were of low quality and limited to certain outcomes.

Conclusions: Overall, the lack of evidence of high and moderate quality does not allow firm conclusions on the clinical utility of repurposed drugs as adjunctive treatments for mania and bipolar depression, limiting recommendations for their use in clinical practice. However, since some lines of evidence seem to hold some potential, and standard treatments for mania and bipolar depression remain not entirely satisfactory, the search for novel therapeutic targets and strategies for the management of BD warrants further research in the field.

Cognitive reserve in Older Adults with Bipolar Disorder and its relationship with cognitive performance and psychosocial functioning

L. Montejo^{1*}, C. Torrent¹, S. Martín², A. Ruiz², M. Bort², G. Fico², V. Oliva², M. De Prisco¹, J. Sanchez-Moreno¹, E. Jimenez¹, A. Martinez-Aran¹, E. Vieta³ and B. Solé¹

¹Bipolar and Depressive Disorders Unit, Hospital Clinic of Barcelona, CIBERSAM, IDIBAPS, University of Barcelona; ²Bipolar and Depressive Disorders Unit, Hospital Clinic of Barcelona, IDIBAPS, University of Barcelona and ³Bipolar and Depressive Disorders Unit, Hospital Clinic of Barcelona, CIBERSAM, IDIBAPS, Departament de Medicina, Facultat de Medicina i Ciències de la Salut, University of Barcelona, Barcelona, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.672

Introduction: Cognitive reserve (CR) refers to the ability of the brain to cope with damage or pathology. In bipolar disorder (BD), it has been seen that the effects of the disease may potentially reduce

CR, thus compromising cognitive outcomes. This concept takes on special relevance in late life in BD, due to the increased risk of cognitive decline because of the accumulative effects of the disease and the potential effects of aging. Therefore, we believe that CR may be a protective factor against cognitive decline in older adults with bipolar disorder (OABD).

Objectives: The aim of this study was to study the CR in OABD compared with healthy controls (HC) and to analyze its association with psychosocial functioning and cognitive performance.

Methods: A sample of euthymic OABD, defined as patients over 50 years old, and HC were included. CR was assessed using the CRASH scale. Differences in demographic, clinical, and cognitive variables between patients and HC were analyzed by t-test or X2 as appropriated. Lineal simple and multiple regressions analyses were used to study the association of CR and several clinical variables with functional and cognitive performance.

Results: A total of 83 participants (42 OABD and 41 HC) were included. Compared to HC, OABD exhibited poorer cognitive performance ($p < 0.001$), psychosocial functioning ($p < 0.001$) and lower CR ($p < 0.001$). Within the patient's group, the linear simple regression analysis revealed that CR was associated with psychosocial functioning ($\beta = -2.16$; $p = 0.037$), attention ($\beta = 3.03$; $p = 0.005$) and working memory ($\beta = 2.98$; $p = 0.005$) while no clinical factors were associated. Age and CR were associated with processing speed and verbal memory, but after applying multiple regression model, only the effect of age remained significant ($\beta = -2.26$; $p = 0.030$, and $\beta = -2.23$; $p = 0.032$ respectively). CR, age, and number of episodes were related to visual memory, but the multiple regression showed that only age ($\beta = -2.37$; $p = 0.023$) and CR ($\beta = 3.99$; $p < 0.001$) were associated. Regarding executive functions only the number of manic episodes were significant. CR and age at onset were associated with visuospatial ability, but multiple regression only showed association of CR ($\beta = 2.23$; $p = 0.032$). Other clinical factors such as number of depressive or hypomanic episodes, illness duration, admissions, type of BD, and psychotic symptoms were not associated.

Conclusions: To the best of our knowledge, this is the first report that studies the CR in a sample of OABD. We demonstrated that OABD had lower CR than HC. Importantly, we observed that CR was associated with cognitive and psychosocial functioning in OABD, even more than disease-related factors. These results suggest the potential protector effect of CR against cognitive impairment, supporting that improving modifiable factors associated with the enhancement of CR can prevent cognitive decline.

Lithium management around delivery: a retrospective observational cohort study

M. L. Imaz Gurruchaga^{1*}, M. Torra Santamaria², K. Langohr³ and R. Martin-Santos⁴

¹Unit of Perinatal Mental Health Clinic-BCN; ²Pharmacology and Toxicology Laboratory, Hospital Clinic; ³Department of Statistics and Operational Research, Universitat Politècnica de Catalunya and ⁴Psychiatry and Psychology, Hospital Clinic, Barcelona, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.673

Introduction: During the perinatal period lithium is proven effective as maintenance therapy and to prevent postpartum psychosis. Pregnancy affects all aspects of kidney physiology altering the pharmacokinetics of lithium. To minimize the risk of both maternal and neonatal complications around delivery, several authors have provided clinical advice on lithium dosing around delivery: decreasing dose by 30-50%, suspend lithium therapy 24-48 hours before scheduled cesarean section or induced delivery or even discontinuing lithium after first signs of labour.

Objectives: To evaluate the validity of these recommendations by investigating 1) maternal lithium serum concentrations changes around delivery, 2) the lithium transplacental passage at delivery and 3) the association between neonatal lithium serum concentration at delivery and neonatal outcomes.

Methods: Psychopathologically stable women with a singleton pregnancy (n=66) who used lithium around delivery, were included in this retrospective observational cohort study (HCB/2020/1305). All women were advised to suspend lithium administration at the onset of labour in the event spontaneous deliveries. Study date: demographic, psychiatric, obstetric and neonatal outcomes for each mother-infant pair obtained from the hospital medical records. Lithium serum concentrations were determined by means of an AVL 9180 electrolyte analyzer based on the ion-selective electrode (ISE) measurement principle. Limit of quantification (LoQ) was 0.20 mEq/L.

Results: The most common psychiatric diagnosis was a bipolar disorder type I (n=54, 90%). Forty mothers (61%) were on lithium monotherapy. Mean (SD) umbilical cord and intrapartum maternal lithium serum concentration was 0.59 (0.13) mEq/L and 0.55 (0.13) mEq/L respectively. There was a strong positive correlation

between umbilical cord and maternal lithium serum concentrations (Pearson correlation coefficient 0.95 (95%IC: 0.91,0.97). In a subsample (N=22) a paired t test indicates that the maternal serum lithium concentrations at delivery were significantly lower (mean difference=0.19 mEq/L, 95%CI=0.13-0.25) than those during obtained the day before delivery hospitalization, after a mean (SD) of 31.29 (\pm 11.92) hours (SD=11.92) have elapsed since the taking the last dose of lithium prior to delivery. Four women (6%) relapsed early postpartum. There were no significant differences between lithium monotherapy (N=18/40) and polytherapy (N=11/26) groups with regard to acute neonatal complications (p>0.05). The only acute neonatal complication associated to umbilical cord lithium serum concentration was hypotonia [0.712 (0.298) vs. 0.534 (0.214) (F=5.065; df=1,60; p=0.028)].

Conclusions: When lithium is used around delivery, maternal and neonatal well-being can be maximized by maintaining maternal serum lithium concentrations at the minimal effective level and discontinuing briefly when presenting to hospital for delivery.

Cortisol awakening response in bipolar patients with comorbid type 2 diabetes mellitus

M. Battipaglia^{1*}, N. Attianese¹, S. Donato¹, R. Ceres¹, R. Cerra¹, A. M. Monteleone¹, P. Monteleone² and G. Cascino²

¹University of Campania "L. Vanvitelli", Naples and ²University of Salerno, Salerno, Italy

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.674

Introduction: Bipolar Disorder (BD) is a severely debilitating psychiatric disorder with high rates of morbidity and mortality, and patients with BD have a 10-year reduction in their life expectancy. Bipolar disorder (BD) is frequently associated with type 2 diabetes mellitus (T2DM). BD patients with comorbid T2DM have been shown to have three times higher odds of a chronic course and rapid cycling and are more likely to present worse outcomes to treatment with lithium and/or other mood stabilisers when compared to BD patients without IGM (impaired glucose metabolism).

Objectives: The functioning of the hypothalamic-pituitary-adrenal (HPA) axis has been never investigated in BD with respect to the glucose metabolic status. Therefore, we assessed the cortisol awakening response (CAR) in bipolar patients with or without comorbid T2DM.

Methods: Twenty euglycemic bipolar patients [12 males and eight females; mean age (\pm SD): 47.4 \pm 14.4 years; mean (\pm SD) duration of illness: 18.3 \pm 12.1 years], 16 BD patients with T2DM [11 males and five females; mean age (\pm SD): 63.6 \pm 12.8 years; mean (\pm SD) duration of bipolar illness: 17.1 \pm 10.8 years; mean (\pm SD) duration of T2DM: 5.2 \pm 5.3 years], 18 healthy subjects [seven males and 11 females; mean age (\pm SD): 45.0 \pm 12.1 years] and 12 non-psychiatric subjects with T2DM [eight males and four females; mean age (\pm SD): 56.7 \pm 11.2 years; mean (\pm SD) duration of

T2DM: 5.2 ± 3.5 years] were recruited. Saliva cortisol was measured at awakening and after 15, 30, and 60 min.

Results: With respect to both healthy controls and controls with T2DM, euglycemic and diabetic BD patients exhibited a CAR occurring at significantly lower levels. No significant difference emerged in the CAR between the two groups of bipolar patients. Controls with T2DM had an overall post-awakening cortisol production significantly higher than healthy controls.

Conclusions: Our results show that the CAR of patients with BD is reduced in terms of overall cortisol production but normal in terms of cortisol reactivity independently from the occurrence of comorbid T2DM. The dampened CAR points to a tuning down of the functioning of the HPA axis in both euglycemic and diabetic BD patients, which may be a factor of vulnerability, since a preserved HPA axis functioning is essential to deal with stressors, which may precipitate affective episodes

Endogenous phenotype of diagnostic transition from major depressive disorder to bipolar disorder: a prospective cohort study

S. Shim

psychiatry, soonchunhyang university cheonan hospital, cheonan, Korea, Republic Of

doi: 10.1192/j.eurpsy.2024.675

Introduction: This study investigated sensor-level electroencephalography (EEG) power and related source-level cortical activity using resting-state EEG in patients with MDD and BD.

Objectives: This study aims to comparing bipolar disorder (BD) and major depressive disorder (MDD) to understand neuropathology of these disorders.

Methods: A total of 68 patients with MDD were enrolled and recorded EEG. Among patients with MDD, 17 patients with MDD converted to BD during the study periods. Clinical symptoms and EEG measures were compared between two groups. This study applied machine learning to differentiate the two groups using sensor and source-level features

Results: At the sensor level, patients with BD showed higher power of AF3 channel in the theta beta band ($p=0.011$) and FC5 channel in the low alpha band ($p=0.014$), compared to MDD. At the source-level, compared to MDD, patients with BD showed higher activity in the right anterior cingulate ($p=0.011$) and left parahippocampal gyrus ($p=0.035$). The best classification performance for MDD and BD showed an accuracy of 80.88%, a sensitivity of 76.47%, and a specificity of 82.35% based on theta and low alpha band power and activity features.

Conclusions: Our findings might suggest different theta and low alpha band activity between patients with BD and MDD might serve clinically as a candidate neuromarker for differentiating two distinct mood disorders.

Assessing the dimensions of psychological (in) flexibility in adolescence: Validation of the Portuguese Version of the Multidimensional Psychological Flexibility Inventory - short form

M. Cunha^{1,2}, S. Flórido³, C. Pinto-Gouveia^{4*} and A. Galhardo³

¹ISMT; ²CINEICC, UC; ³Clinical Psychology, ISMT and ⁴Psychiatry Department, UC, Coimbra, Portugal

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.676

Introduction: Psychological Flexibility (PF) is a complex and extensively studied concept within the Acceptance and Commitment Therapy (ACT) framework. PF denotes one's capacity to effectively navigate psychological distress and challenges while aligning one's actions with deeply held values. Given its association with mental health and overall well-being, it is crucial to develop assessment tools able to capture the various facets of flexible behaviour and design strategies for its enhancement.

Objectives: To adapt the Portuguese version of the Multidimensional Psychological Flexibility Inventory (MPFI-24; Grégoire et al., 2020) for the adolescent population.

Methods: The study involved 269 adolescents aged 12 to 18 years old. Participants completed a set of self-report instruments, including the MPFI24-A, the Depression, Anxiety, and Stress Scales-21 (DASS-21), Mental Health Continuum - Short Form (MHC-SF), and the PsyFlex-A, which also assesses PF. A subsample also completed the MPFI24-A four weeks later to assess test-retest reliability.

Results: Two models, specifically the six-factor correlated model and the bifactor model, emerged as presenting the best fit when analysing data separately for the Flexibility and Inflexibility indices. The MPFI24-A demonstrated good reliability for both overall scores ($\alpha = .90$ and $\alpha = .85$, respectively) and good test-retest reliability. The PF index showed significant positive associations with PsyFlex-A scores, perceived mental health, and a moderate negative association with depression and anxiety. Conversely, the Psychological Inflexibility (PI) index presented the opposite association pattern with these variables and showed no significant correlation with PF as measured by the PsyFlex-A. The two indices of the MPFI24-A demonstrated a weak positive correlation. Significant differences between boys and girls were found for the PF index, with boys showing higher scores. No significant differences were found between boys and girls concerning the PI index.

Conclusions: Results suggest that the MPFI24-A is a reliable and valid instrument for assessing adolescents' psychological flexibility and inflexibility competencies. Although further clarification of the MPFI24-A factor structure and the utility of different factors is warranted, the findings support its overall applicability.

Who Is Right? Behavioral Problems from the Perspectives of Parents and Children with ADHD symptoms

K. Sitnik-Warchulska^{1*}, B. Izydorczyk², I. Markevych², M. Szwed², A. Sawicki³ and M. Lipowska^{1,3}

¹Institute of Applied Psychology; ²Institute of Psychology, Jagiellonian University, Krakow and ³Institute of Psychology, University of Gdansk, Gdansk, Poland

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.677

Introduction: Diagnosing behavioral problems in children and adolescents, which include conduct symptoms, anxiety, or somatic complaints, is frequently based on subjective perceptions and interviews with family or caregivers. However, current theoreticians and practitioners of systemic theory are increasingly emphasizing that there are multiple subjective narratives about oneself, the world, and one's symptoms. The question is whether these narratives are equivalent, and if not, under what circumstances do they diverge?

Objectives: The study aimed to investigate whether the perception of behavioral problems among young adolescents with ADHD aligns with their parents' perspective, and whether family bonding is a factor in this association.

Methods: The analytic sample comprised about 200 children, aged 10-14 years, and their parents, mostly coming from well-situated families. The data were collected as a part of the NeuroSmog project. The variables were measured by the Child Behaviour Checklist (CBCL), the Youth Self Report (YSR), the Family Adaptation and Cohesion Evaluation Scales (FACES-IV). The structural equation modelling (SEM) to analyse data was used. The models were also stratified by age, sex, and social status.

Results: There is a significant difference between the perspectives of parents and children regarding the level of behavioral problems. Family bonding is associated with behavioral problems among children, but this relationship is only evident from their perspective.

Conclusions: The perception referring to family narratives has the most significant impact on individual functioning.

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.678

Introduction: Zuranolone (ZRN) is a positive allosteric modulator of both synaptic and extrasynaptic gamma-aminobutyric acid type A receptors and a neuroactive steroid approved as an oral, once-daily, 14-day treatment course for adults with postpartum depression in the US and under investigation for adults with major depressive disorder (MDD). The randomised, double-blind, placebo-controlled, Phase 3 CORAL Study assessed the efficacy and safety of ZRN 50 mg vs placebo, each co-initiated with an open-label standard-of-care antidepressant (ADT). Patients who completed CORAL could roll over into open-label SHORELINE, which assessed the safety and tolerability of ZRN 50 mg and need for repeat treatment courses in adults with MDD.

Objectives: To assess the safety and tolerability (primary endpoint) and need for repeat ZRN 50 mg treatment courses (secondary endpoint) in adults with MDD who previously enrolled in CORAL.

Methods: CORAL enrolled adults (18–64 years) with MDD and 17-item Hamilton Rating Scale for Depression (HAM-D-17) total score ≥ 24 . After completing the 6-week CORAL Study, patients who enrolled in SHORELINE could enter a 46-week observation period to assess the safety and need for 14-day repeat ZRN treatment course(s), with a total of ≤ 4 repeat treatment courses permitted. Patients were screened every 2 weeks with the 9-item Patient Health Questionnaire, and scores ≥ 10 prompted a HAM-D-17 assessment within 1 week. Patients with HAM-D-17 total score ≥ 20 were eligible for repeat ZRN course(s) ≥ 8 weeks after completing the prior ZRN treatment course.

Results: Among the 190 patients from CORAL who rolled over into SHORELINE and received ≥ 1 ZRN treatment course in either study, 133 (70.0%) had received ZRN+ADT and 57 (30.0%) received placebo+ADT in CORAL. Overall, 118 rollover patients received ≥ 1 open-label ZRN treatment course in SHORELINE. For patients who received ≥ 1 ZRN treatment course in either study, 76.8% received 1 (54.2%; 103/190) or 2 (22.6%; 43/190) total ZRN treatment courses across both studies in up to 1 year in study. The most common ($>5\%$) treatment-emergent adverse events (TEAEs) during treatment and 14 days following the last ZRN dose were somnolence (16.1% of patients), dizziness (8.5%), headache (8.5%), fatigue (7.6%), sedation (5.9%), and nausea (5.1%); study-period TEAEs (73.7%; 87/118) for the majority of patients were mild/moderate (69.5%; 82/118) in severity and occurred primarily during the treatment period (58.5%; 69/118). No signals for increased suicidal ideation/behaviour were observed.

Conclusions: Safety and tolerability among rollover patients were consistent with previous studies; most of the TEAEs reported by adults with MDD who received ZRN were mild/moderate in severity. Most patients who rolled over from CORAL to SHORELINE received ≤ 2 total treatment courses in up to 1 year in study.

Exploring the impact of religiosity and spirituality on depressive symptoms in homeless people

P. H. F. Camargo^{1*}, J. V. G. N. de Moraes² and L. M. VITORINO²

¹Medicine, Faculty of Medicine of Itajubá and ²Medicine, Faculty of Medicine of Itajubá, Itajubá, Brazil

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.679

Introduction: Depression is a major concern among homeless individuals. Studies link religiosity and spirituality (RS) with lesser depressive symptoms, but evidence is scarce among the homeless.

Objectives: This study aims to assess the association between RS and depressive symptoms in homeless individuals in Brazil.

Methods: This cross-sectional study involved 456 homeless individuals in São Paulo, Brazil. It received approval from the Ethics and Research Committee of the Faculty of Medicine of Itajubá, Brazil. We used adjusted linear regression models to analyze the association between RS and participants' depressive symptoms. Depressive symptoms were assessed with the Patient Health Questionnaire-9 (PHQ-9). We used the P-DUREL to measure religiosity, FACIT-Sp12 for spirituality, and the Brief-RCOPE scale for religious-spiritual coping strategies.

Results: Out of 482 invited participants, 456 (94.6%) completed all questionnaires, mostly males (75%) with an average age of 44.53 (SD 12.62) years. About 49.6% had depressive symptoms (PHQ-9 ≥ 10 points). After controlling for sociodemographic and health variables, factors such as temple/church attendance (≥ 3 times

per month), increased religiousness (both organizational and intrinsic), positive religious/spiritual coping, and peace, faith and meaning were inversely related to depressive symptoms. Conversely, dysfunctional use of RS, such as in negative spiritual-religious coping strategies, correlated with heightened depressive symptoms.

Conclusions: High depressive symptom prevalence was found among Brazilian homeless individuals. Functional use of RS was negatively linked to depressive symptoms, while dysfunctional RS, like negative spiritual-religious coping strategies, correlated with higher depressive symptoms. These findings can aid healthcare professionals, particularly psychologists and psychiatrists, in addressing RS in the homeless population.

Efficacy and acceptability of S-adenosyl-L-methionine (SAME) for depressed patients: a systematic review and meta-analysis of randomized controlled trials

N. Limveeraprajak^{1*}, S. Nakhawatchana¹, A. Visukamol¹, C. Siripakkaphant², S. Suttajit³ and M. Srisurapanont³

¹Faculty of Medicine Ramathibodi Hospital, Mahidol University, Bangkok; ²Faculty of Medicine and ³Department of Psychiatry, Chiang Mai University, Chiang Mai, Thailand

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.680

Introduction: Current treatment options for depression remain unsatisfactory. SAME, a naturally occurring body chemical available as a dietary supplement, was discovered in the 1950s. SAME deficiency is associated with depression.

Objectives: This systematic review and meta-analysis aimed to investigate the efficacy and acceptability of SAME in treating patients with depression. The primary efficacy outcome was measured through the reduction in depression severity scores. All-cause dropout rates were assessed as indicators of treatment acceptability.

Methods: To include the randomized trials comparing SAME with other agents, we conducted a search on PubMed, Embase, and the Cochrane Library from their inception until April 27, 2023. The quality of trials was assessed using version 2 of the Cochrane risk-of-bias tool for randomized trials (RoB 2). Depression severity and overall dropout rates were synthesized using a random-effect model for frequentist pairwise meta-analysis.

Results: We categorized 23 trials (N = 2,234) into 11 trials comparing SAME vs. placebo, 5 trials comparing SAME + antidepressant vs. placebo + antidepressants, and 7 trials comparing SAME vs. antidepressants. SAME demonstrated a significantly greater reduction in depressive symptoms compared to placebo (SMD = -0.58, 95%CI [-0.93; -0.23], I² = 68%), as can be seen in Figure 1. A trend was observed wherein SAME showed a lesser reduction in depressive symptoms compared to antidepressants (SMD = 0.06, 95%CI [-0.06; 0.18], I² = 49%). When administered alongside ongoing antidepressant treatment, SAME did not significantly differ from placebo in reducing depressive symptoms (SMD = -0.16, 95%CI [-0.44; 0.13], I² = 57%). In the subgroup analysis of 11 trials comparing SAME and placebo, it was found that while the intramuscular (SMD = -0.92, 95%CI [-1.39; -0.44]) and oral routes

(SMD = -0.66, 95%CI [-1.24; -0.08]) revealed the efficacy of SAME, the intravenous route did not exhibit the same efficacy (SMD = -0.16, 95%CI [-0.47; 0.14]). The efficacy of SAME was not influenced by factors such as physical illness, history of antidepressant nonresponse, proportion of females, age, duration and dosage of SAME supplementation, publication year, and baseline depression severity. There was no significant difference in dropout rates between SAME and controls.

Image:

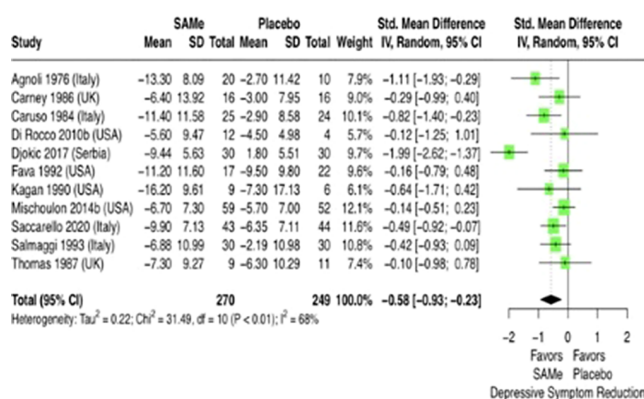

Figure 1. SAME vs. Placebo

Conclusions: Limited evidence suggests that SAME is well accepted and effective in reducing depressive symptoms. However, its antidepressant effect may not be as strong as that of traditional antidepressants. Randomized-controlled trials comparing SAME to antidepressants in depressed patients, both with and without ongoing antidepressant use, are still necessary.

Surveillance and monitoring program of child neurodevelopment in population born during social confinement due to covid contingency: monteria-colombia experience

C. Otalvaro¹, A. Romero^{1*} and M. C. Florian²

¹Cordoba, Universidad de Córdoba and ²Cordoba, Georges Noble School, Monteria, Colombia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.681

Introduction: The American Academy of Pediatrics reports an incidence of 1 in every 54 children (Council on Children with Disabilities, 2021). The unique circumstances surrounding children born in 2020, who have experienced the COVID-19 pandemic since birth, present a distinct set of challenges for their neurodevelopmental well-being. The pandemic has led to reduced opportunities for learning and social interaction, masking mandates, decreased social support for research, and the potential misattribution of Autism Spectrum Disorders ASD symptoms to the effects of social isolation.

Objectives: This study aims to develop such a program for children born during the COVID-19 pandemic (2020-2022).

Methods: All children born in March 2020 were included in the study. The initial assessment involved administering the ASQ-3 to evaluate their development across the specified domains. Diagnostic Evaluation: Among the population, 6% (4 children) displayed concerning signs on the ASQ-3, warranting further diagnostic evaluation by specialized health professionals for possible ASD.

Results: Early Intervention and School Monitoring: Of the remaining 72% (46 children), who did not require diagnostic evaluation, intervention guidelines were provided, both within the school environment and at home. These children were reevaluated after a three-month period. Follow-up in the School Environment: Those children who underwent reevaluation were categorized into three groups: Nine children fell into the “gray” category on the ASQ-3 and were subsequently referred for diagnostic evaluation. Thirty-seven children progressed to the “white” category on the ASQ-3 after receiving intervention guidelines in both school and home settings. The findings of this research underscore the potential impact of the COVID-19 pandemic on the neurodevelopment of children born in 2020. 6% of the evaluated population were referred for diagnostic evaluation due to signs of ASD, suggesting a potential association between the pandemic and an increased risk of ASD within this cohort. 72% of children who received intervention guidelines demonstrated significant improvements in their neurodevelopment, highlighting the critical role of early intervention and school-based monitoring.

Conclusions: Implementing support strategies within educational settings was linked to positive developments in neurodevelopmental outcomes. Consequently, school-based neurodevelopmental monitoring, complemented by cohesive curricular guidelines, emerges as a beneficial approach for enhancing child development outcomes. The ASQ-3, as a structured instrument, proves invaluable in facilitating neurodevelopmental surveillance within educational settings, particularly in contexts with high demand and limited access to specialized care.

Psychological distress and coping strategies of hospital nurses during covid-19 pandemic in Greece

C. Papanthanasou^{1*} and K. C. Patithras²

¹Department of Psychology, Panteion University of Social and Political Sciences and ²Department of Medicine, National and Kapodistrian University of Athens, Athens, Greece

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.682

Introduction: Hospital nurses have played a crucial role during the covid-19 pandemic. Research demonstrates the extent to which nurses were experiencing acute stress and psychological distress during the waves of the pandemic.

Objectives: The purpose of this study was to assess the psychological distress (stress, depression, and anxiety) of nurses working in public hospitals in Greece during the covid-19 pandemic, to identify their coping strategies, and to explore the eventual

sociodemographic and work environmental influence on distress and the coping strategies.

Methods: Sample consisted of 317 nurses working in public hospitals. A self-report online questionnaire was used for data collection. The first part of the questionnaire comprised the Depression, Anxiety, and Stress Scale (DASS-21), the second part included the Greek version of the Ways of Coping questionnaire (WAYS), the third part the Oslo Social Support Scale (OSSS-3), and the fourth part included participants' sociodemographic data. Analyses were conducted using SPSS statistical software (version 26.0).

Results: 18.4% of participants presented severe depression, 39.9% very severe anxiety, and 22.5% very severe stress. Significantly lower levels of depression, anxiety, and stress were experienced by those who slept more than 5 hours a day, compared to those who slept up to 5 hours. Participants who were infected with the coronavirus had significantly higher levels of depression, anxiety, and stress. Additionally, participants who received moderate/high social support experienced overall less anxiety, stress, and depression than those who received low social support. Finally, the more they sought social support to deal with their problems and the more they avoided stressful situations, the higher the levels of depression, anxiety, and stress.

Conclusions: A staff care protocol must be applied by every hospital, including rest breaks and night-shift naps, psychosocial support for those who get infected by SARS-CoV-2 and their families, peer support (groups and mentoring), and coping skills trainings.

EPP0571

Covid-19 pandemic and mental health among adolescents and young adults: results from two studies conducted in North of Italy

L. Pedrini^{1*} and S. Meloni¹

¹UO Psichiatria, IRCCS Centro San Giovanni di Dio, Fatebenefratelli di Brescia, Brescia, Italy

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.683

Introduction: The northern region of Italy had been the epicenter of the first wave of Covid-19. The youth population residing in this area experienced an extended period of restrictive measures implemented to curb the spread of the virus. Given the adverse effects of social distancing and lockdown measures, there is a concern regarding the mental health of young individuals in this region. However, there remains a notable scarcity of studies exploring the long-term impact of the pandemic on the mental health of this vulnerable population.

Objectives: To assess psychopathological symptoms among adolescents and young adults in order to evaluate the extent of their impact in the context of the Covid-19 pandemic. To explore potential risk factors and resilience factors in youth who have experienced the effects of the pandemic.

Methods: Two studies are performed. *Study n1* has observational design and includes 7,146 adolescents and young adults (age range 14–25) evaluated during the fourth wave of the COVID-19 through standardized measures for depression, anxiety, anger, somatic symptoms, resilience, loneliness and post-traumatic growth. *Study*

n2 has prospective design and includes 153 students (mean age 16.1 ±0.49), evaluated before the Covid-19 pandemic (November 2019–January 2020) and 1 year later (April–May 2021) to measure anxiety, depression, stress, emotional dysregulation, maladaptive behaviours.

Results: Study 1. Clustering methods identified two groups of students with different psychological features, that we further defined as “poor mental health” and “good mental health”. Those with poor mental health were characterized by higher scores of loneliness and self-harm, followed by being of female gender, presenting binge eating behaviors and, finally, having unsatisfying family relationships.

Study 2. Over the course of one year, significant changes in various psychological parameters were observed: an increase in anxiety, stress for future uncertainty, and higher frequency of maladaptive behaviours. Stress related to social domains (i.e., school attendance, romantic relationships, peer pressure) decreased over the year. Cluster analysis identified three distinct groups of youths based on their changes in psychopathological symptoms over time: those who worsened (N=23; 15%), improved (N=55; 34%), or remained stable (N=75; 46%). Furthermore, adolescents who reported an increase in self-harm (OR=2.61; p<0.001), binge-drinking (OR=3.0; p=0.007), aggressiveness (OR 1.92; p=0.004), and binge-eating (OR 2.55; p=0.003) were more likely to be associated with a worsened mental health condition.

Conclusions: The findings from these studies substantiated the significant psychological distress caused by the COVID-19 pandemic. Furthermore, they yielded valuable further insights regarding into the factors linked to distinct patterns of mental health outcomes.

EPP0572

Impact of the COVID-19 pandemic on the manifestation and course of mental illness in elderly

V. Pochueva^{1*}, T. Safarova¹, O. Yakovleva¹ and V. Sheshenin¹

¹FSBSI “Mental Health Research Center”, Moscow, Russian Federation

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.684

Introduction: COVID-19 is a multisystem disease affecting not only the respiratory, gastroenterstitial and vascular systems, but also the central nervous system, which leads to a wide range of neurological and mental complications. 3 years of experience in combating the pandemic has shown that elderly people burdened with chronic somatic diseases are the most vulnerable risk group for the development of severe course and complications of COVID-19.

Objectives: To study the impact of COVID-19 on the onset and course of mental illness in elderly inpatients

Methods: We examined 67 inpatients aged 50 to 95 years with various mental pathologies, who underwent COVID-19 from February 2020 to December 2021. 46 people had previous history of mental disease (PHMD), in 21 cases the disease developed for the first time. Statistical analysis was performed.

Results: In the manifest group of patients, depressive episodes predominated (42.9%), including psychotic episodes (9.5%). In 28.6% of cases, organic disorders were diagnosed in the form of

emotional lability, organic depression, mild cognitive impairment and delirium. In 23.8% of patients, neurotic disorders were observed in the form of depressive reactions, panic and generalized anxiety disorder. In one case (4.8%), acute polymorphic psychosis with symptoms of schizophrenia was diagnosed. The PHMD group includes affective disorders - 45.7%; organic disorders, including dementia 26.1%; schizophrenic spectrum disorders - 19.6% and neurotic somatoform disorders - 8.7%. In the acute and subacute periods of COVID-19, acute psychotic states (APS) developed in both groups of patients (in 23.3% and 30.4%, respectively) in the form of delirium, psychotic depression, or polymorphic psychosis. APS were more common in PHMD patients with organic (50%) and schizophrenic spectrum disorders (33.3%) with a predominance of delirium. In the long-term period of COVID-19, PHMD patients more often than non-PHMD (60.9% and 38.1%) developed cognitive impairment (CI), especially in schizophrenia-like (77.8%) and organic (83.3%) disorders. CI developed twice as often after APS (89.5% and 39.6%, $p < 0.001$), reaching the degree of dementia in 15.8% of cases. APS were significantly associated ($p < 0.05$) with the development of CI (0.567733), the age of patients (0.410696) and the presence of previous cerebrovascular insufficiency (0.404916).

Conclusions: The age-related features of the mental consequences of COVID-19 are the occurrence of APS in the acute period of infection and the deterioration of cognitive activity at a remote stage. The PHMD patients, especially with disorders of organic and schizophrenic spectrum, were found to be more vulnerable to the effects of COVID-19. In them, the occurrence of APS was a risk factor for the development of dementia, while in primary diseased, and patients with affective and neurotic disorders, CI was reversible or had the character of a mild cognitive disorder.

Youth mental health resilience during the COVID-19 pandemic: A critical review

S. Irnat^{1*}, S. Boukhorb¹, S. Hmimou¹, M. Anssoufouddine², A. Soulaymani¹, M. Abdalli Mari², A. Mokhtari¹ and H. Hami¹

¹Laboratory of Biology and Health, Faculty of Sciences, Ibn Tofail University, Kenitra, Morocco and ²Medical Service, Regional Hospital Center of Anjouan, Mutsamudu, Comoros

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.685

Introduction: The COVID-19 pandemic has had a profound impact on mental health worldwide because of complex societal disruptions and neuropsychiatric consequences stemming from SARS-CoV-2 infection. All age groups have been affected by this pandemic, with particular focus on the vulnerabilities faced by children and adolescents who have experienced multiple stressors. These stressors involve various emotional, physiological, and behavioral challenges stemming from different factors, such as mandatory social distancing due to school closures, increased parental stress caused by the incessant spread of the pandemic, severe trauma from losing family members, a surge in cyberbullying linked to higher online activity, and a worrying rise in unreported incidents of child abuse. Empirical reports document an increase in

suicidal tendencies and suicide attempts among adolescents during this crisis.

Objectives: This study conducted a comprehensive review of existing literature focused on the mental health of individuals aged 0-24 years in both pre-pandemic and pandemic eras. This study conducted comparative analyses to identify significant changes.

Methods: Adhering strictly to the PRISMA guidelines, we conducted comprehensive searches on Google Scholar and PubMed to identify peer-reviewed articles published in English.

Results: Most studies revealed deteriorating mental health conditions among adolescents and young adults following pandemic onset. These conditions were characterized by high rates of depression, anxiety, and psychological distress. Furthermore, several studies have identified a notable increase in negative emotions and heightened feelings of loneliness. Primary school children experienced a decline in attention span, emotional regulation, hyperactivity, and enthusiasm for academic engagement.

Conclusions: Based on the analysis of data from both the pre-pandemic and pandemic periods, it is evident that the COVID-19 pandemic had a detrimental impact on the mental well-being of children and young individuals. Therefore, it is crucial to identify the risk factors and protective measures linked with pandemics to enhance mental health resilience and better equip societies to cope with future health emergencies and other crises.

Comparing IM Lorazepam and IM Clothiapine for Agitated Psychosis in Hospitalized Patients

• Kverashvili^{1,2}, E. Malik^{1,2*}, •. Shele^{2,3} and •. Stryjer^{1,2}

¹Psychiatry, Abarbanel Mental Health Center, Bat-Yam; ²Psychiatry, Faculty of Medicine, Tel-Aviv University, Tel-Aviv and ³Psychiatry, Lev Hasharon Mental Health Center, Netanya, Israel

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.686

Introduction: When patients in a closed hospital ward experience acute psychosis and become highly agitated or pose a risk to themselves and others, it's often crucial to provide immediate sedative treatment. However, there is currently no consensus on whether the preferred medication for these situations should be antipsychotic drugs or benzodiazepines.

Objectives: This study aimed to compare how well a single intramuscular dose of 2-4 mg Lorazepam performs against 40 mg Clothiapine in terms of effectiveness and side effects. These treatments were administered as immediate emergency measures to patients experiencing psychosis with severe agitation or behaviors that posed a risk to themselves or their surroundings.

Methods: We conducted a retrospective clinical study involving 100 patients experiencing aggressive psychosis. These patients were divided into two groups. The first group comprised 50 patients who received a single intramuscular (IM) dose of up to 40 mg Clothiapine. The second group consisted of 50 patients who received IM treatment with 2-4 mg Lorazepam. We assessed the patients'

outcomes around 8 hours after treatment or upon receiving any additional treatment.

Results: There were no significant statistical differences in the demographic and clinical characteristics (e.g., age, gender, number of hospitalizations, duration of illnesses, psychiatric diagnosis, comorbidity) of the patients between the two groups ($p > 0.05$).

Before treatment, there were no statistical differences in the severity of clinical symptoms (CGI-S) between the two groups [CGI-S (Mean \pm SD): 5.32 ± 1.09 vs. 5.38 ± 1.4 , $p = 0.8$].

However, in the Clothiapine group, a statistically significant clinical improvement (CGI-I) was observed after treatment [CGI-I (Mean \pm SD): 2.42 ± 0.9 vs. 1.96 ± 1.16 , $p = 0.029^*$].

There were no significant differences in the need for physical restraint or additional medication following the initial treatment between the two groups ($p > 0.05$).

Furthermore, there were no statistically significant differences in the major side effects of the drugs, the necessity for referral to the general emergency room, or incidents of falls ($p > 0.05$).

Conclusions: When dealing with a psychotic state marked by severe agitation or threats to oneself and others, the use of IM Clothiapine as a treatment option may offer certain advantages over IM Lorazepam. Importantly, these advantages come without significant exposure to side effects or potential risks associated with Clothiapine.

Euthanasia - A Novel Intricacy for Psychiatry's Purview?

Í. Alberdi-Páramo^{1,2*}, M. Pérez-Lombardo¹, J. Pemán-Rodríguez³, J. E. Ibáñez Vizoso¹, R. Á. Baena Mures⁴, L. Niell Galmés⁴, J. Rodríguez Quijano¹ and G. Montero-Hernández⁵

¹Psiquiatría, Hospital Clínico San Carlos; ²Universidad Complutense de Madrid, Madrid; ³Psiquiatría, Hospital Nuestra Señora Candelaria, Tenerife; ⁴Psiquiatría, Fundación Alcorcón, Madrid and ⁵Psiquiatría, Red Salud Mental Vizcaya, Bilbao, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.687

Introduction: Numerous countries, notably within Europe, have sanctioned the practice of euthanasia. Extant legal frameworks meticulously define the extent, essence, and application of euthanasia, encompassing divergent characterizations, explications of entitlements, procedural modalities, and provisions for access. Nonetheless, the precise function of psychiatrists within these legislative contours remains conspicuously nebulous.

Objectives: The present inquiry undertakes a comprehensive evaluative review of the euthanasia phenomenon vis-à-vis the intricate tapestry of European legislative paradigms, with an emphasis on elucidating the multifaceted involvement of psychiatry within this evolving landscape.

Methods: A nuanced narrative review is undertaken, encapsulating the contemporary state-of-affairs, fundamental conceptual architectures, the tenets of the Spanish Organic Law 03/2021, and the pharmaceutical armamentarium deployed in the orchestration of euthanasic practices. Additionally, the methodological blueprint

employed within a prominent tertiary healthcare institution situated in Madrid is meticulously expounded.

Results: To date, euthanasia has garnered legal imprimatur across diverse jurisdictions including, but not limited to, the Netherlands, Belgium, Colombia, Canada, Spain, and New Zealand. The ambit of assisted death and its application to the domain of mental infirmities is meticulously deconstructed. Within the overarching realm of foundational concepts, a rigorous delineation is rendered between euthanasia, medical succor in the throes of mortality, assisted self-termination, facilitated demise, provision of mortal release, judicious calibration of therapeutic enterprise, and the contours of palliative sedation. Distinction between the principal executor and the advisory consultant is rendered salient. The rubric of conscientious objection emerges as an inviolable entitlement of healthcare practitioners enmeshed in the provisionary matrix.

The enduring incumbency of the psychiatrist as a pivotal appraiser of cognitive and volitional faculties holds firm. The conspicuous influence of psychopathological constellations upon the contours of euthanasia eligibility precipitates cogent deliberation.

Conclusions: As the frontiers of euthanasia expand to encompass an augmented array of legal jurisdictions, this study underscores the increasingly intricate role inhabited by psychiatrists in the matrix of evaluative assessments. The proclivity of mental maladies to exert a substantial gravitational pull upon determinations of eligibility for euthanasia accentuates the exigency for refined explication of roles and responsibilities within this evolving sphere, a clarion call resonant not only within the precincts of psychiatry but reverberating across the broader firmament of medical praxis.

Mental health assessment during the full-scale invasion within the general Ukrainian population: state, beliefs and behaviors, query to change (cross-sectional study)

Y. Korniiiko^{1*}, M. Bajbouj¹, K. J. Jonas², J. Mueller³ and S. Kemna¹

¹Department of Psychiatry and Affective Neuroscience, Charité University Hospital, Berlin, Germany; ²Department of Work and Social Psychology, Maastricht University, Maastricht, Netherlands and ³Department of Quantitative Methods in Public Health (METIS), EHESP, Paris, France

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.688

Introduction: The Russian invasion in Ukraine has significantly affected the mental health (MH) of the local population while access to mental health support remains limited due to multiple reasons coming from both the provider and acceptor sides. The war obviously negatively impacts MH but has also paradoxically given an "open window" for shifting current practices both in the healthcare system and within society. Investigation of current people's attitudes on this matter should be the primary step to address the issue and initiate any change.

Objectives: 5 main objectives identified to analyze within the convenience sample were: MH state and self-care behaviors during

the full-scale invasion, MH stigma and self-stigma, intention to use professional MH support, beliefs on access to professional MH support, query to change current MH attitudes and practices.

Methods: This research was conducted using primary data collection. The online questionnaire consisted of 5 blocks and was designed based on PHQ-9, DASS-21, PCL-5, Brief-COPE and CAMI. 332 civilians underwent the survey in March-April 2023 and were divided by age, gender, location and situation; inclusion criteria were to be >16 y.o. being affected by war and capable of completing the survey in Ukrainian. Relevant ethical measures were applied. Descriptive and correlational analysis was used to analyze the data.

Results: The majority of respondents rated their mental health as good. Anxiety was the most prevalent emotion, particularly among younger age groups. Different genders and age groups exhibited varying combinations of emotions, such as fatigue, peace, anger, sadness etc. Many participants felt self-reproach for not doing enough; coping strategies varied among age groups. Females were 8.14 times more likely to seek mental health support, and those inside Ukraine were 0.32 times less inclined. 66.2% never seek any MH services, with older men leading; only 8.7% consult specialists during crises, showing gender differences. Distrust in specialist qualifications is one of the barriers on access in people's beliefs and is more prevalent among older generations. The absence of self-mental health stigma makes individuals 1.91 times more open to accessing support. Location affects openness to change, with Ukraine-based individuals being less open. Lastly, 29.5% consider alternative stress-coping methods, with 40% open to future psychological help.

Conclusions: Our findings show differences in populational attitudes towards MH in Ukraine during the war and therefore the importance of any potential intervention to precisely tailor certain subgroups, beliefs behaviors and needs within them to have a higher chance of being accepted and increase MH support utilization in the population overall.

Stigmatizing attitudes of doctors, practicing psychiatry in Slovenia; Eustigma study results

P. Rus Prelog^{1*}, A. Mirkovič² and D. Ōri^{3,4}

¹Centre for Clinical Psychiatry, University Psychiatric Clinic Ljubljana;

²Child Psychiatry Unit, University Children's Hospital, Child Psychiatry Unit, University Medical Centre Ljubljana, Ljubljana, Slovenia; ³Institute of Behavioural Sciences, Semmelweis University and ⁴Department of Mental Health, Heim Pal National Pediatric Institute, Budapest, Hungary

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.689

Introduction: The perception that individuals afflicted with mental disorders may exhibit potential harm or unpredictability is common in the general population and, as studies have shown, mental health-related stigma is not confined to the broader public but is progressively emerging as a concern within professional circles as

well, adding additional burden to patients in psychiatric settings who already encounter an array of impediments stemming from societal prejudice.

Objectives: In this cross-sectional study, we aimed to investigate the attitudes of adult and child psychiatrists towards people with mental health problems in Slovenia.

Methods: The stigmatizing attitudes were measured by an internet-based, anonymous survey using the Opening Minds Stigma Scale for Health Care Providers (total score and three subscales are the following: attitude, disclosure and help-seeking, social distance).

Results: Altogether, n=90 practitioners (n=18 males, n=72 females) completed the survey. The bifactor ESEM model showed the best model fit (RMSEA=0.060, CFI=0.970, TLI=0.939); however, exploratory factor analysis results indicated the weakness of items 1 and 11. Those participants who have a possibility to attend case discussion groups are more willing to disclose their own mental health issues or seek help (8 (7-9) vs 9 (8-11.5)); however, they prefer more social distance from their patients (9(7.5-10) vs 7(6-9)). Gender differences were found as well, women seem to keep more social distance (p=0.031). Interestingly, those practitioners who reported spending 75% of their working hours with patients kept less social distance compared to those who engage in other activities (p=0.028).

Conclusions: This study is the first to describe the stigmatizing attitude of psychiatric practitioners in Slovenia from their perspective, and it provides directions for anti-stigma interventions.

Adverse childhood experiences and 8-year trajectories of depressive symptoms in community-dwelling older adults: Results from the English Longitudinal Study of Ageing

A. K. C. Chau^{1*}, J. K. N. Chan², H. W. Fung³, E. T. C. Lai^{1,4} and I. Y. Y. Ho¹

¹Institute of Health Equity, The Chinese University of Hong Kong;

²Department of Psychiatry, School of Clinical Medicine, LKS Faculty of Medicine, The University of Hong Kong; ³Department of Social Work, Hong Kong Baptist University and ⁴Department of Medicine and Therapeutics, Faculty of Medicine, The Chinese University of Hong Kong, Hong Kong, Hong Kong

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.690

Introduction: The negative impact of adverse childhood experiences (ACEs) on mental health has been well documented. While most of the evidence comes from samples of adolescents and young adults, few studies have investigated whether ACEs contribute to poorer mental health among older adults. In particular, depressive symptoms are common in old age, and they display heterogeneous patterns of development across individuals. Therefore, it is important to examine if ACEs are predictive of distinct trajectories of depressive symptoms among older adults.

Objectives: Using longitudinal data from the English Longitudinal Study of Ageing (ELSA), we aimed to examine if ACEs could

differentiate between distinct trajectories of depressive symptoms over eight years in community-dwelling older adults.

Methods: Participants from ELSA aged 60 or above who reported no psychiatric diagnoses and completed the items of ACEs at baseline (wave 3) were included in the current study. Nine items of ACEs were subject to a principal component analysis to identify the underlying subtypes. Data of depressive symptoms from waves 3 to 7 (2-year apart), assessed with the 8-item Centre for Epidemiological Studies Depression Scale, were extracted for modelling the distinct trajectories using latent class growth analysis. The trajectories were predicted by subtypes of ACEs using multinomial logistic regression, adjusting for childhood socioeconomic status, sex, age and ethnicity.

Results: The final sample consisted of 4057 participants (54.4% female, mean age= 71.34 (SD= 8.14)). We identified five trajectories of depressive symptoms (Figure 1): 'low stable' (73.4%), 'increasing then decreasing' (9.9%), 'high decreasing' (7.1%), 'high stable' (5.7%) and 'moderate increasing' (4.0%). Four subtypes of ACEs (i.e., sexual abuse, separation from natural parents, family dysfunction and physical assault) were evident. Compared to the 'low stable' group, higher levels of family dysfunction were reported in the 'increasing then decreasing' (aOR = 1.35, 95% CI [1.10 - 1.66], $p = .012$), 'high stable' (aOR = 1.59, 95% CI [1.30 - 1.96], $p < .001$) and 'moderate increasing' (aOR = 1.55, 95% CI [1.18 - 2.04], $p = .011$) groups. The 'high stable' group also reported a higher level of separation from natural parents than the 'low stable' group (aOR = 1.34, 95% CI [1.04 - 1.72], $p = .047$). Sexual abuse and physical assault did not predict any group differences.

Image:

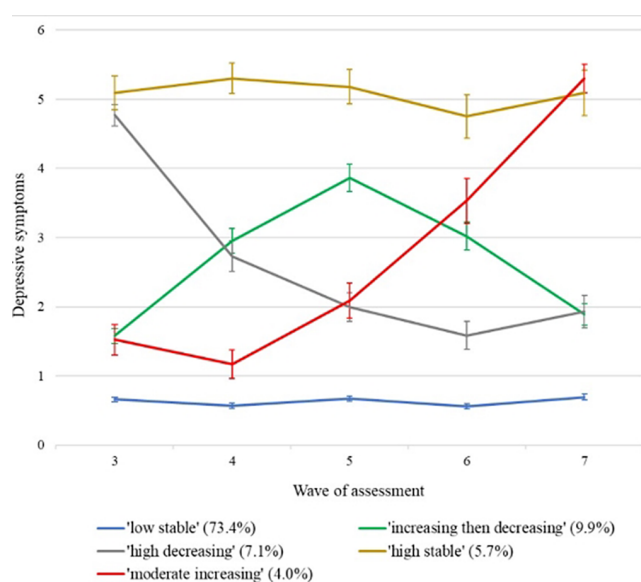

Figure 1. Latent classes of trajectories of depressive symptoms among older adults. Means of depressive symptoms and 95% confidence intervals across waves of assessment per trajectories are plotted in the figure.

Conclusions: Distinct trajectories of depressive symptoms among older adults were predicted by family dysfunction in childhood. Our findings suggested that the negative impact of ACEs on mental health may extend beyond adolescence and young adulthood into the old age.

Chronic and transient loneliness in western countries: risk factors and association with depression. A follow-up study.

J. Domènech-Abella^{1*} and C. Domènech²

¹Research, Parc Sanitari Sant Joan de Déu, Sant Boi de Llobregat and

²Mental Health, Hospital Sant Joan de Déu, Barcelona, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.691

Introduction: While transient loneliness refers to feelings that last for a short time (less than two years), chronic loneliness alludes to feelings that last more than two years. Transient loneliness can appear after stressful life events such as retirement and loss of close social connections whereas chronic loneliness is more strongly related to maladaptive social cognition, poor social support, and lack of intimate relationships. In comparison to transient loneliness, chronic loneliness is more strongly linked to mental health problems, particularly the incidence and recurrence of depression. Therefore, understanding the specific risk factors for both types of loneliness would be of great utility in mitigating their impact on mental health.

Objectives: Our aim was to test distinct measures and risk factors for chronic and transient loneliness as well as cross-sectional and longitudinal associations of transient and chronic loneliness with depression.

Methods: Responses from participants in Wave 5 (T1, 2013) and Wave 6 (T2, 2015) of The Survey of Health, Ageing and Retirement in Europe (SHARE) (N=45,490) were analyzed. The existence of clinically significant symptoms of depression was defined as reporting a value ≥ 4 on the Euro-D scale. Loneliness was measured through 3-item loneliness scale and a single question. Both measures were tested in separate logistic regression models to identify risk factors for transient (loneliness at T1 but not at T2) and chronic loneliness (loneliness at both time points) as well as their impact on depression.

Results: Between 47% and 40% of the cases of loneliness became chronic, according to the UCLA scale and the single question, respectively. Risk factors for both loneliness courses were being female, not being married, having a low educational level, having a poor physical health, having a poor social network and living in a culturally individualistic country. Risk factor for chronic loneliness were stronger, particularly those related to health status and social networks. Chronic loneliness showed also a strong association with depression both cross-sectionally and longitudinally, while transient loneliness showed a weaker cross-sectional association and markedly lower probabilities in the longitudinal association.

Conclusions: Risk factors for chronic loneliness and measures of the temporal dimension of loneliness should be considered in psychosocial interventions designed to prevent mental disorders.

EPP0582

Social determinants of involuntary psychiatric hospital admissions in Ontario, CanadaK. P. Fung^{1*} and S. Kim²¹University of Toronto, Toronto and ²McMaster University, Hamilton, Canada

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.692

Introduction: In Ontario, Canada, patients may be admitted to the hospital involuntarily if they are deemed to be suffering from symptoms of a mental disorder that may result in imminent serious bodily harm to themselves or others, or that may cause serious physical impairment to themselves (e.g., inability to keep themselves safe and warm in the winter). This measure can be life-saving. However, in addition to ethical and human rights considerations, resorting to coercive admissions may be an indication that those who are suffering from mental illness are not able to access or receive timely and appropriate intervention. While recent studies have suggested that the rate of involuntary hospital admission may be increasing, data on social determinants of involuntary hospital admissions are limited.

Objectives: We examined social factors associated with involuntary admissions using a Canadian provincial database.

Methods: Binary logistic regression models were conducted to examine the associations between social factors (low income, indigeneity, rurality, housing type) and involuntary admissions, controlling for age, sex, and psychiatric diagnoses. Data from March 2019 to March 2021 was extracted from the Ontario Mental Health Reporting System admission dataset, comprising of a sample of 9,848 patients admitted to eight psychiatric hospitals in Ontario. Odds ratios and 95% confidence intervals are reported.

Results: In 2021, the proportion of involuntary patients increased significantly by 6.8 percentage points to 55.7% compared to the previous year (48.9%). Indigenous status (First Nations, Metis, Inuit) [1.75 (1.38-2.21) **], living in rural areas [2.78 (2.48-3.12)], living in assisted residence [1.41 (1.21-1.64) **], homelessness [1.63 (1.38-1.91) **], male sex [1.21 (1.10-1.33) **] and younger age [0.99 (0.98-0.99) **] were associated with involuntary admissions, while income was not a significant factor. Compared to a diagnosis of a psychotic disorder, substance use disorders [0.11 (0.10-0.13) **] and mood and anxiety disorders [0.32 (0.29-0.36) **] showed decreased odds of involuntary admission, while neurocognitive disorders increased the odds of involuntary admission [3.86 (2.91-5.11) **].

Conclusions: Consistent with other findings, involuntary psychiatric hospital admissions in ON, Canada, have increased recently, which may in part be related to the pandemic. Rurality, indigenous status, and unstable housing have been found to be associated with involuntary admissions. The study findings support the need for better preventive and intervention strategies to serve vulnerable psychiatric patients, including addressing the social determinants of health such as housing, and increasing access to culturally competent and safe community-based mental health supports and services.

Comparison of Val66met Polymorphism of BDNF gene in patients of bipolar disorder and healthy controls.M. Srikantamurthy^{1*}, S. Moirangthem², B. Viswanath², M. Purushottam³ and S. Jain²¹Department of psychiatry, Orygen youth health, Melbourne, Australia;²Department of psychiatry and ³Department of molecular genetics, National Institute of Mental Health and Neurosciences, Bangalore, India

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.693

Introduction: The study aims to explore the utility of BDNF Val66Met polymorphism as a potential biomarker in Indian bipolar disorder patients and its correlation with clinical characteristics.

Objectives: Genotyping Val66Met in BDNF gene Exploring its association with bipolar disorder (BD).

Methods: 150 consenting BD patients and matched controls were recruited using a case-control study design. BD severity was assessed using Young's mania rating scale and the Clinical Global Impression - Severity (CGI-S) scale. BDNF Val66Met polymorphism was identified through real-time PCR after DNA extraction. Data was tested for normal distribution. Genotype frequencies between two groups were compared and the Hardy-Weinberg equilibrium assumptions were tested using Chi-Square tests. Clinical-genotypic associations were explored using the Kruskal-Wallis test and confirmed using hierarchical regression.

Results: Our sample had more males (60%) than females (40%) with mean age of 35.05 years. Most patients had established bipolar disorder and were severely ill (CGI: 38.75, YMRS). Val66Met SNP genotype frequency differed significantly between cases and controls. Val66Val genotype and Val allele were higher in cases. Results consistent with Hardy-Weinberg equilibrium.

Table 1. Genotype frequencies of BDNF (rs6265) in cases and controls

	GENOTYPE		
	CC	CT	TT
CASES	94(62.6%)	47(31.3%)	9(6%)
CONTROL	71(47.3%)	69(46%)	10(6.6%)
CHI-SQUARE- 7.431	DF(Degree of freedom) - 2	p-value- 0.024	

Table 2. Dominant genotype frequencies in cases and controls

	DOMINANT GENOTYPE	
	CC	CT+TT
CASES	94(62.6%)	56(37.3%)
CONTROLS	71(47.3%)	79(52.6)
CHI-SQUARE-7.125	DF(Degree of freedom)-1	p-value-0.007

Table 3. Allelic frequencies of BDNF (rs6265) in BD cases and healthy controls

	ALLELIC VARIATION	
	C	T
CASES	235(78.3%)	65(21.6%)
CONTROLS	211(70.3%)	89(29.6%)
CHI-SQUARE-5.032	DF(Degree of freedom)-1	p-value- 0.024

Conclusions: Our study found that Val66Val genotype and Val allele were higher in cases and could be a potential biomarker for bipolar disorder (BD), which is consistent with previous research conducted on the European population. However, further investigations are required to gain a more comprehensive understanding of its impact on BD, including its association with serum BDNF levels, treatment outcomes, and a more diverse study population.

EPP0585

Pharmacogenomics in Psychiatry: An Asian Perspective

S. E. Goh
Institute of Mental Health, Singapore, Singapore
doi: 10.1192/j.eurpsy.2024.694

Introduction: Pharmacogenomic testing in psychiatry is an emerging area with the potential clinical application of guiding medication choice and dosing. However, this has not been adopted widely due to a combination of barriers that include a varying evidence base, clinician and patient familiarity and acceptance, uncertainty about cost-effectiveness, and regulatory requirements.

Objectives: This review aims to examine recent updates in this field and provide a contextualised summary and recommendations for Asian populations. The recommendations serve to guide healthcare professionals in the utility of pharmacogenomic testing in psychiatric practice.

Methods: A review of recent literature about current evidence and guidelines surrounding pharmacogenomics in psychiatric practice was carried out with particular attention paid to literature evaluating Asian populations. Literature was reviewed for the different classes of psychotropics with supplementary information about Asian populations included where available. Existing evidence about combinatorial pharmacogenomic panels was also reviewed.

Results: In line with the available body of evidence, we recommend that pharmacogenomic testing should be employed as an augmenting tool to guide medication selection and dosing in certain clinical situations, and not as part of standard or routine clinical practice. Pharmacogenomic testing should also be mainly limited to the known drug-gene pairs such as the anti-depressants and CYP2C19 or CYP2D6. Clinicians should also be aware that many of the gene-drug associations have not been evaluated for clinical outcomes. Combinatorial pharmacogenomic panels are not presently recommended as there is limited and inconclusive available evidence on clinical outcomes.

Conclusions: Pharmacogenomic testing in psychiatry is not recommended as standard or routine clinical practice. Exceptions may include concerns about drug concentrations (due to

metaboliser status) or potential severe adverse drug reactions/ Pharmacogenomic testing should be mainly limited to the known drug-gene pairs such as the anti-depressants and CYP2C19 or CYP2D6.

GWAS in interaction with childhood traumas implicates novel variants and genes previously associated with suicide-related factors in the background of suicidal ideation

X. Gonda^{1,2*}, S. Krause^{3,4}, B. Erdelyi-Hamza^{2,3}, S. Sutori⁴, Z. Gal⁴, N. Eszlari^{1,4}, G. Bagdy^{1,4}, G. Juhasz^{1,4} and D. Torok⁴
¹NAP3.0-SE Neuropsychopharmacology Research Group- Hungarian Brain Research Program; ²Department of Psychiatry and Psychotherapy; ³Doctoral School of Mental Health Sciences and ⁴Institute of Pharmacodynamics, Semmelweis University, Budapest, Hungary
*Corresponding author.
doi: 10.1192/j.eurpsy.2024.695

Introduction: Although suicide claims more lives than war and homicide, we still have no sufficient and effective methods either for its prediction or for its prevention. Our screening methods are laborous and subjective both on the side of the patient and on the side of the clinician. Understanding the genetic background of suicidal behaviour would help identify biomarkers for screening as well as pathways as potential targets for novel intervention and prevention approaches. However, in spite of a number of GWAS studies, results are few and rarely replicate, and generally accurate phenotyping and sufficient consideration of environmental stressors is also missing.

Objectives: In our present study we performed a genome-wide analysis study for suicidal ideation in interaction with early childhood traumas in a deep-phenotyped general population sample.

Methods: Our analysis used data from 1800 volunteers in the NewMood project. As outcome phenotype the suicidal ideation item of the Brief Symptom Inventory was used. A modified version of the Childhood Trauma Questionnaire was used to assess early adverse experiences. A genome-wide association analysis was performed with Plink 1.9, including a total of 3,474,641 variants after quality control steps, followed by genome-wide by environment interaction analyses. Our models included control variables for sex, age, and the top 10 genomic principal components. Functional annotation of SNPs was carried out using FUMA v1.5.6, gene-based tests were performed using MAGMA v1.08.

Results: 7 SNPs met suggestive significance in main effect analyses, of which 2 reached genome-wide significance including *rs79912020* (p=3.21E-10, β=0.746) and *rs10236520* (p=1.71E-08, β=0.484), with no significant findings in gene-based tests. Interaction analyses with childhood adversities yielded 31 SNPs that met genome-wide significance, including *rs7983955* (p=2.28E-11, β=0.182), *rs141039461* (p=3.90E-11, β=0.0541), *rs12692827* (p=3.69E-10, β=0.0612) as the top SNPs. In interaction with childhood adversities, 31 genes showed a significant association in gene-based tests, including *RBFOX1* (p=1.09E-10), *GRM7* (p=1.20E-10), *MTCH1* (p=5.59E-09), and *CDH13* (p=6.60E-09) as the most significant findings.

Conclusions: Our results indicate several important novel SNPs associated with suicidal ideation when considered in interaction with the effect of childhood adversities. Furthermore, gene-based analyses replicate several genes playing a key role in central nervous system function such as *GRM7* (encoding metabotropic glutamate receptor 7) or previously implicated in association with suicide (*CDH13*) or suicide-related factors such as aggression (*RBFOX1*). *Corresponding author.

doi: 10.1192/j.eurpsy.2024.696

Introduction: Addressing mental and physical health problems and promoting wellbeing in educational settings is a global priority. Teachers present a high risk of stress and burnout, which negatively impacts their professional performance as well as their mental and physical health. Compassion-based interventions have been found effective in promoting psychosocial and physiological wellbeing.

Objectives: The current paper presents preliminary findings of the impact of a 6-module Compassionate Mind Training intervention for Teachers (CMT-T) on immunological markers and the Conserved Transcriptional Response to Adversity (CTRA; a gene expression signature that involves a group of 53 genes: pro-inflammatory genes, type I interferon response and genes related to antibody synthesis).

Methods: A pilot non-controlled study was conducted in a sample of public-school teachers in Portugal ($n=36$). Participants were assessed at 4 time-points: 1) Extended Baseline Control_M0, in order to establish a within-subjects psychological and biophysiological baseline (8 weeks before the start of the CMT-T); 2) Pre-intervention_M1 (8-weeks after M0); 3) Post-intervention_M2 (8-weeks after M1); and 4) Follow-up_M3

(3 months after the CMT-T end). In all assessment moments, participants completed a set of psychological self-report measures and were assessed in immunological and epigenetic biological markers through the collection of blood. After M1, teachers completed the 8-week group CMT-T intervention and given access to its resources and materials. They were instructed to practice daily and incorporate the teachings in their personal and professional lives. All assessments and the CMT-T intervention took place at the schools.

Results: Preliminary data on the impact of CMT-T on Immune Response Profiling revealed that teachers' Natural Killer (i.e., NK) cells were decreased after the CMT-T intervention. In regard to the CTRA gene expression, results showed that type one interferon response genes (e.g., IFI16, IFI27L2, IFITM2, IFITM3, IFITM4P) were decreased after the intervention. In addition, we observed that the gene c-Jun, a pro-inflammatory gene, had a decreased expression after the CMT-T intervention.

Conclusions: These preliminary findings seem to corroborate previous studies involving the type one interferon response, the pro-inflammatory genes and antibody synthesis genes in a signature involving 53 genes previously described as the CTRA gene signature. Furthermore, our results suggest that cultivating compassion using a compassion focused intervention may have a positive impact on markers of the immune system response, associated with how our bodies respond to stress, infection and cancer, as well as, on reducing the expression of genes related to our bodies' response to stress and inflammation.

ASCL1 dysfunction contributes to the pathogenesis of schizophrenia by regulating genes associated with neuronal signature formation and neuroplasticity

D. Abashkin¹, E. Marilovtseva¹, D. Karpov¹ and V. Golimbet^{1*}

¹Clinical Genetics Laboratory, Mental Health Research Center, Moscow, Russian Federation

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.697

Introduction: ASCL1 (Achaete-scute homolog 1) is a neuron-specific transcription factor involved in CNS maturation in the mammalian brain. It has been shown to be associated with schizophrenia (SZ), Parkinson's disease, and the development of brain tumors. ASCL1 is expressed in the neuroblastoma cell line SH-SY5Y, which is a widely used model for the study of neurodevelopmental diseases, including SZ.

Objectives: The aim of this work was to study the effect of functional ASCL1 knockout on the transcriptional landscape of SH-SY5Y cells in undifferentiated and neuron-like phenotypes.

Methods: For ASCL1 deletion, SH-SY5Y was sequentially transduced with two lentiviral vectors. One pLV-rTA-Cas9-(nls)-pCMV-eGFP-PuroR-T2A-rTetR (derived from pCW-Cas9 and pEGFP-Puro) construct encoded Cas9. Stably transduced lines were selected for 3-5 days on puromycin (2 g/L). The inducibility of Cas9 expression was checked after adding the inducer oxytetracycline to the culture medium. The second construct (based on pLK05-tagRFP) encoded, a pair of guide RNAs targeting the start

and end of the ASCL1 gene. The sgRNA construct was transduced into the SH-SY5Y-Cas9 cell line in parallel with a nontemplate control (NTC gRNA) as a negative control. Cas9 expression was induced with oxytetracycline for 2 days. Individual clones were obtained by serial dilutions. ASCL1 partial deletion in the clones was confirmed by PCR followed by Sanger sequencing. Disruption of ASCL1 protein synthesis was confirmed by western blot analysis. SH-SY5Y differentiation was induced by retinoic acid (RA). The transcriptomes of mutant clones and NTC controls before and after RA-induced differentiation were sequenced using Illumina technology.

Results: RNAseq data show that a wide range of genes are differentially expressed between control NTC gRNA and wild-type SH-SY5Y. This can be explained by insertional mutagenesis of lentiviral vectors and/or cellular response to the presence of lentiviral constructs. Therefore, we compared the transcriptomes of the ASCL1-del line with NTC control. Differentially expressed genes (DEGs) are predominantly associated with the pathogenesis of SZ, bipolar and depressive disorders. DEGs in ASCL1-del are involved in cell mitosis, neuronal projection, neuropeptide signaling, and formation of intercellular contacts including the synapse. During RA-induced differentiation, ASCL1 activity is restricted to the regulation of a small subset of genes involved in neuroplasticity.

Conclusions: We have established a valid cellular model to study ASCL1-mediated mechanisms associated with SZ. ASCL1 dysfunction promotes SZ development predominantly before neuronal differentiation begins, slowing cell proliferation and preventing the formation of neuronal signatures.

A Randomized Clinical Trial Comparing the Effects of Mindfulness-Based and Cognitive Behavioral Therapy-Based Stress Reduction in Medical Students

A. Yay Pençe^{1*}, M. Çöldür², Z. Atalay², S. Aslan¹, B. Beba³, C. Coşkun Sayın⁴ and I. Ekmekçi Ertek¹

¹Gazi University, Ankara; ²MEF University, İstanbul, Türkiye; ³Mindfulness Macedonia, slojpe, North Macedonia and ⁴Mindfulness and Compassion Academy, İstanbul, Türkiye

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.698

Introduction: Medical students face an enormous amount of stress (Dyrbye LN *et al. Ann Intern Med* 2008; **149**: 334-41). They suffer from higher rates of depression, anxiety, and suicide compared to the general population. Despite experiencing more mental health problems, there is a lack of research exploring ways to improve their mental health. Although there are a few small sample studies investigating the effectiveness of Mindfulness-Based Stress Reduction (MBSR) on medical students, there is no study comparing its effectiveness against an active intervention group in the literature (van Dijk I *et al. Acad Med* 2017; **92**: 1012-1021)

Objectives: We aimed to compare the effects of the Mindfulness-Based Stress Reduction (MBSR) and the Cognitive Behavioural

Based Stress Reduction (CBSR) group interventions on depressive and anxious symptoms and perceived stress of medical students.

Methods: 323 medical students applied to participate in one of the group interventions and were assessed with the Mini International Neuropsychiatric Interview. Of these, 253 (77% female, mean age=21.9 ± 2.9 years) were allocated into online MBSR (n=127) and online CBSR (n=126) groups after randomization. Their anxiety and depressive symptoms and perceived stress levels were assessed at baseline and after 8 weeks of interventions. 33,2% of participants (MBSR: n=39; CBSR: n=45) completed the protocol by attending five or more sessions. Both intention-to-treat (ITT) analysis and per-protocol (PP) analysis were used to assess outcomes. In the ITT analysis, we used multiple imputation to address missing values. All assessments and group interventions were done online.

Results: In the ITT analysis, both MBSR and CBSR were found to be slight to moderately effective in reducing symptoms of depression (MBSR: d=.50; CBSR: d=.40), anxiety (MBSR:d=.73; CBSR: d=.52), and perceived stress (MBSR: d=.48; CBSR: d=.42), but they were no superior to each other. In the PP analysis, both interventions moderately to strongly improved the symptoms of depression (MBSR: d=1.03; CBSR: d=.74), anxiety (MBSR: r=-.74; CBSR: r=-.72), and perceived stress (MBSR: r=-.80; CBSR: r=-.68). While there was no statistically significant difference between them in reducing depressive symptoms and perceived stress, MBSR was found to be significantly more effective than CBSR in reducing anxiety symptoms (u=469, z=-2.756, p=0.006).

Conclusions: Both MBSR and CBSR improve symptoms of depression and anxiety in medical students after 8 weeks of interventions. Completing the protocol or attending more sessions may increase the effectiveness of the interventions. While the interventions did not show superiority to each other in terms of effectiveness in reducing depressive symptoms and perceived stress, MBSR appears to be more effective in reducing anxiety symptoms compared to CBSR in the group that completed the protocol.

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.699

Introduction: Humanitarian workers (HWs) face significant challenges while providing aid to those in need, often leading to psychological exhaustion and the risk of primary or secondary trauma.

Objectives: Our study aimed to validate and adapt the Greek version of the Brief Resilient Coping Scale (BRCS) for HWs in Greece.

Methods: We conducted a cross-sectional study between September and December 2022. Participants were recruited through a self-administered questionnaire distributed via social media to humanitarian groups. Additionally, the questionnaire was sent via email to these groups' members, who then forwarded it to their respective networks. The questionnaire included the BRCS, a 4-item measure designed to capture tendencies to cope with stress in a highly adaptive manner. A score of 4-13 points indicates low resilient copers, 14-16 points medium resilient copers and 17-20 points high resilient copers. Cronbach's alpha was used to assess internal consistency. Confirmatory Factor Analysis (CFA) was employed to evaluate model fit. Adequate or good fit criteria included a χ^2 test p -value ≥ 0.05 , Root Mean Square Error Approximation (RMSEA) ≤ 0.08 , Standardized Root Mean Squared Residual (SRMR) ≤ 0.05 , and a Comparative Fit Index (CFI) or Tucker-Lewis Index (TLI) ≤ 0.90 . Statistical analyses were performed using STATA and SPSS software.

Results: A total of 151 humanitarian workers (76% females), with a mean age of 39.3 ± 10.6 years participated in the study. The mean BRCS score was 65.6/100. Participants were categorized as follows: 34.6% as low resilient copers, 38.6% as medium resilient copers, and 26.8% as high resilient copers. Cronbach's alpha for the BRCS was 0.84, indicating good internal consistency. CFA results supported the one-factor solution proposed by the original researchers, with acceptable global fit indices: Chi-square p -value = 0.303, SRMR = 0.028, RMSEA = 0.036, CFI = 0.991, TLI = 0.974.

Conclusions: The findings of our study show that the Greek version of BRCS is a valid and reliable tool that can be used to evaluate resilient coping among humanitarian workers in Greece.

Artificial intelligence, Internet addiction, and palliative care

S. Tei^{1*} and J. Fujino²

¹Department of Psychiatry, Kyoto university, Kyoto and ²Department of Psychiatry and Behavioral Sciences, Tokyo Medical and Dental University, Tokyo, Japan

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.700

Introduction: Recent advances in artificial intelligence (AI) have recaptured and revised the essential roles of death in life and mind. However, their prospects and risks require further study. Because of the development of digital technologies (for example, AI-based chatbots), the process of bereavement may have become complex, immersive, and even addictive. Furthermore, AI-enabled generation of medical notes can ease the administrative burden for healthcare professionals; however, the clinical application of generative AI remains largely speculative.

Objectives: This study aimed to illuminate the emerging concept and experience of death, bereavement, and addiction associated with cybernetics, thereby expanding their cognitive and ethical aspects.

Methods: In this preliminary review, we performed a literature search to identify the current state-of-the-art literature on AI and Internet addiction. We also inspected the possible adaptations to

pursue mental well-being with the modified death concept. We mainly searched the PubMed and Web of Science databases using relevant keywords. All retrieved studies were assessed for eligibility to reduce the selection bias.

Results: Current cybernetics have meaningfully recontextualized death that allows interaction with deceased individuals (for example, scholars and artists) to establish their virtual, besides biological, existence using AI-based chatbots. Furthermore, AI consistently provides evidence-based answers to public health inquiries; nevertheless, it may offer unsuitable advice rather than referrals that can sometimes facilitate suicide or harm (instead of help) people in grief, thus requiring more fine-tuned governance. Accordingly, the maladaptive use of existing AI-related communication (such as metaverse characters) can increase Internet addiction prevalence and further complicate autonomy and self-motivation. In addition, excessive internet access is frequently associated with reduced self-control, cognitive flexibility, and exaggerated automatic processing.

Conclusions: We are challenged to acknowledge the tradeoffs of AI and consider ways to compromise by employing flexible perspectives. The emerging concept of death affects or improves the conventional one. The potential advantages and pitfalls of AI-related technology must be carefully weighed against the profound effects they may have on people's identities, relationships, and mental health. These issues require continued monitoring and assessment in light of the AI/cybernetic-related studies. We hope these results will inspire further research into the appropriate use of AI and palliative care, including suicide prevention, euthanasia, and grief management.

Assessing Changes in Quality of Life Measures, Resilience, and Personal Recovery, Pre- and Post-Discharge from Inpatient Mental Health Units in Alberta: Analysis of Control Group Data from a Randomized Trial.

E. Owusu^{1*}, R. Shalaby¹, W. Mao¹, H. Elgendy¹, N. Shalaby¹, B. Agyapong¹, A. Nichols², E. Eboreime³, M. A. Lawal¹, N. Nkire¹ and V. I. Agyapong^{1,3}

¹Psychiatry, University of Alberta, Edmonton; ²Alberta Health Services, Queen Elizabeth II Hospital, Grande Prairie and ³Psychiatry, Dalhousie University, Halifax, Canada

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.701

Introduction: The transition from hospital to community settings for most mental health service users is often hindered by challenges that affect community adjustment and continuity of care. The first few weeks and days after discharge from mental health inpatient units represent a critical phase for many service users.

Objectives: This paper aims to evaluate the changes in quality of Life status, resilience, and personal recovery of individuals with mental health challenges recently discharged from acute mental health care into the community.

Methods: Data for this study were collected as part of a pragmatic stepped-wedge cluster-randomized, longitudinal approach in

Alberta. A paired sample t-test and Chi-squared/Fisher test were deployed to assess changes from baseline to six weeks in the recovery assessment scale (RAS), brief resilience scale (BRS), and EuroQol-5d (EQ-5D), using an online questionnaire.

Results: A total of 306 service users were recruited, and 88 completed both baseline and six weeks, giving a response rate of 28.8%. There was no statistically significant change in the level of resilience, recovery and quality of life as measured with the brief resilience scale, recovery assessment scale and EQ-5D from baseline to six weeks ($p > 0.05$).

Conclusions: The study showed that there was neither an improvement nor deterioration in resilience, recovery, or quality of life status of service users six weeks post-discharge from inpatient mental health care. The lack of further progress calls into question whether the support available in the community when patients leave inpatient care is adequate to promote full recovery.

Exploring Burnout: A Study on Psychiatric Nurses in Tunisia

H. Khiari^{1*}, A. Hakiri¹, M. Bouchendira² and R. Ghachem¹

¹Psychiatry B and ²Psychiatry G, Razi hospital, Mannouba, Tunisia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.702

Introduction: Burnout, marked by persistent workplace stress without effective management, is particularly pertinent for psychiatry nurses, considering the nature of their work environment and its potential impact on the quality of care they deliver.

Objectives: To assess the prevalence of burnout among psychiatric nurses and to identify the socio-demographic and clinical factors associated with it.

Methods: Cross-sectional, descriptive, and analytical study conducted over the course of one month from October 11th to November 8th 2023. Participants included were psychiatric nurses working in Razi Hospital, Tunisia. We collected data using pre-established questionnaire which included socio-demographic and clinical data of the participants. The assessment of Burnout was conducted using the Maslach Burnout Inventory (MBI), validated in Arabic. Statistical analysis was performed using the Statistical Package for Social Sciences (SPSS) in its 25th version.

Results: We collected data from 55 nurses working in Razi psychiatry hospital during the time of the study. Among them, 80% (n=44) were female. Their median age was 35 (Min=25, Max=62). Most of participants were married (81.8%, n=45) and 70.9 (n=39) had kids. In our sample, 5.5% (n=3) and 23.6% (n=13) had respectively personal psychiatric and somatic history. Some addictive behaviors were identified among our participants, especially smoking (14.5%, n=379) and alcohol use (3.6%, n=2).

Regarding working conditions, 81.8% (n=45) were assigned shift work. They worked in the men's ward (43.6%, n=24), the women's ward (34.5%, n=19), or in both (21.8%, n=12). Furthermore, 45.5% (n=25) reported witnessing a suicide attempt during their work, and 74.5% (n=41) were victims of aggression, primarily by patients

(82.5%, n=33). Sixty percent (n=33) said expressed a desire to transfer.

According to the MBI, 49.1% (n=27) had high emotional exhaustion, 27.3% (n=15) had high depersonalization and 67.3% (n=37) had low personal accomplishment.

A significant association was found between low personal accomplishment and the desire to transfer to another department ($p=0.026$). No further links were found with other clinical data.

Conclusions: Our findings provide a thorough examination of burnout among psychiatric nursing professionals, underscoring the critical need for specific interventions tailored to their unique challenges.

A Systematic Review of the Impact of Intergenerational Learning on the Psychosocial Well-being of Primary School Children and Older Adults.

E. Tsiloni^{1*}, E. Dragioti², M. Gouva², S. P. Vassilopoulos¹ and M. Mentis¹

¹Department of Educational Sciences and Social Work, University of Patras, Patra and ²Research Laboratory Psychology of Patients, Families & Health Professionals, Department of Nursing, School of Health Sciences, University of Ioannina, Ioannina, Greece

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.703

Introduction: In recent times, there has been a growing emphasis on the significance of fostering intergenerational learning and interaction. This involves individuals from diverse age groups engaging in purposeful and mutually beneficial activities aimed at enhancing their knowledge, skills, and values.

Objectives: This systematic review was undertaken to explore the psychosocial consequences of intergenerational learning experiences among primary school-age children and older adults.

Methods: In accordance with the PRISMA guidelines, a comprehensive review of both quantitative and qualitative data was conducted. Electronic databases such as PubMed, Scopus, and ERIC were meticulously searched up to July 26, 2022, using the following Population (P) - Exposure (E) - Outcome (O) criteria: primary school-age children and older adults (P), participation in intergenerational learning (E), and psychosocial effects (O). Additionally, we extensively scrutinized the reference lists of included datasets and pertinent review articles (Figure 1). To evaluate the quality of the eligible studies, we employed the Mixed Methods Appraisal Tool (MMAT). Data analysis was structured around a narrative synthesis approach.

Results: A total of seventeen studies were deemed eligible for inclusion in this review. The findings regarding the psychosocial consequences of engaging in intergenerational activities for both children and older adults predominantly underscored positive improvements in their attitudes, well-being, happiness, and various other aspects of their social and psychological well-being, although certain methodological limitations were identified (Figure 2).

Image:

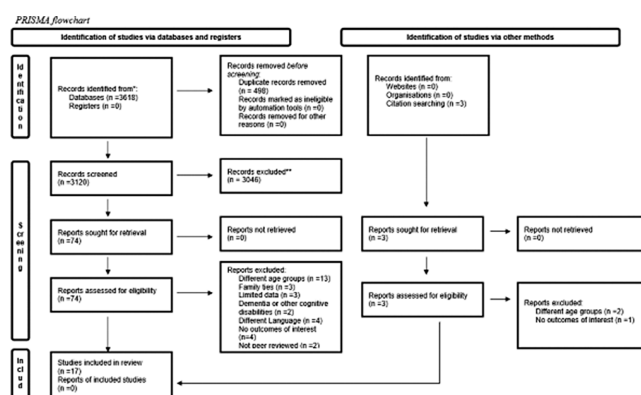

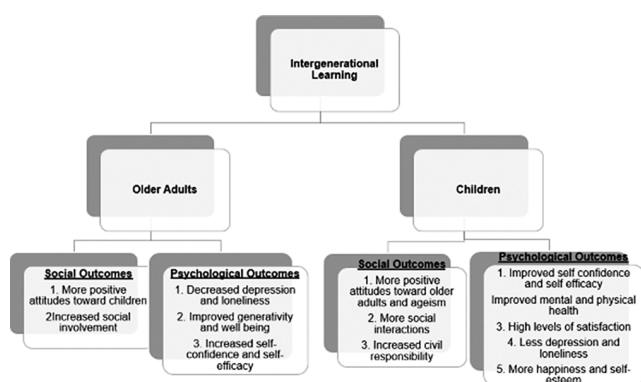

Image 2:

Conclusions: Promoting intergenerational interactions and learning experiences holds promise as a means to enhance the overall quality of life and well-being for both younger and older members of our communities.

Manifestations of antisocial behavior in older adults: A review of current literature

M. Arts^{1,2*}, A. Videler^{1,3} and A. van Dam^{1,2}

¹Tranzo Scientific Center for Care and Welfare, Tilburg School of Social and Behavioral Sciences, Tilburg University, Tilburg;

²Research and Innovation, GGZ WNB Mental Health Institute, Halsteren and ³Mental Health Institute, Innovation and Quality, GGZ Breburg, Tilburg, Netherlands

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.704

Introduction: Antisocial behavior in older adults is a problem for their relatives and health care providers. Antisocial behavior may present differently in the older population which makes it more difficult to diagnose adequately and apply therapeutic

interventions. This literature review provides an overview of diverse conceptualizations of antisocial behavior in older adults and the way it affects recognizability of diagnostic categories and the applicability of interventions.

Objectives: To gain insight into the various manifestations of antisocial behavior in older adults.

Methods: A systematic review design was performed. In this review, an extensive manual and electronic literature search was conducted for papers published from 1980 to 2023. For this purpose we used the electronic databases PubMed and Embase. The review will include empirical and quantitative studies of older adults with antisocial behavior.

Results: The results from the literature indicate that antisocial behavior does probably not decrease with age nor the burden on their social environment. Rather, the manifestations of antisocial behavior change as this population ages. Personality disorders are determined by several dimensional trait domains. The domains which are highly predictive for antisocial behavior include antagonism and disinhibition.

Conclusions: These findings challenge the notion of antisocial behavior decreasing with age. This review underscores the need to shift from traditional personality disorder categories to a dimensional trait perspective. Therefore, specific interventions are needed for older adults.

Clinical and psychopathological features of very late onset of schizophrenia-like psychosis

V. Pochueva^{1*} and I. Kolykhalov¹

¹FSBSI Mental Health Research Center, Moscow, Russian Federation

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.705

Introduction: Very late onset schizophrenia-like psychosis takes the 3rd place among late-life psychosis, after dementia and affective disorders associated psychosis. It's still unknown the real place of this psychosis.

Objectives: to investigate the clinical and psychopathological features and short-terms outcomes of late-onset schizophrenia and schizophrenia-like psychosis

Methods: 45 patients, mean age 70,6 ± 8,70 years, median age of manifestation psychosis - 68 [61; 75] years with late-onset schizophrenia (n=19, 42,2%), late-onset schizoaffective disorder (n=9, 20%), late-onset delusional disorder (n=7, 15,5%) and late-onset organic schizophrenia-like disorder (n=10, 22,3%) underwent clinical examination. Psychopathological, psychometric (PANSS, HAM-D, CDSS, MoCA) and statistical methods were applied.

Results: 3 clinical groups were allocated. The 1st group included 15 patients (33%) and was characterized with severe polymorphic psychotic symptoms, included catatonic and paraphrenic signs with mental disorganization. They had the highest score of PANSS (105,46±17,99, p=0,002) and the lowest score of MoCA (14,2±2,16, p=0,05) in compare with 2nd and 3rd groups. They also had symptoms of depression (CDSS 6,28±5,29), compared with the 3rd group (HAM-D 21,00±5,92, p=0,05). In short-terms outcomes was formed negative symptoms and cognitive impairment with

decreasing social and daily activity. The 2nd group (22 cases, 49%) included patients with prevalence of delusions of persecution, more rare auditory hallucinations and more often acoasms. They had medium score PANSS (90,22±16,79), with minimal cognitive decline (MoCA average score 20,33±4,27). The short-term outcomes were characterized with formation of residual positive and negative symptoms, that impact on daily and social activity. The 3rd group included 8 patients (8%) with prevalence of delusion symptoms, such as misidentification, persecutory and reference delusions, which were mood-congruent. They had medium PANSS score (89,75±18,90) with more severe depressive symptoms by HAMD scale in compare with 2nd group (22,00±10,00, $p=0,07$) and minimal cognitive decline (MoCA average score 25,00±1,00, $p=0,05$) in compare with 1st group. This group was characterized with high level of reduction of productive symptoms and restoration of premorbid social and daily activity in short-term outcomes. **Conclusions:** features of clinical characteristics, including the nature and severity of cognitive impairment at the onset of disease, are significant for prognosis and outcomes of disease. The data obtained could be served for the development of personalized therapeutic approaches that take into account the syndromic features and course of late-onset psychosis.

Examining Sexual Well-being across the Lifespan: Assessing the Relationship between Sexual Satisfaction and Adjustment to Aging

I. Miguel¹, S. von Humboldt^{2*} and I. Leal²

¹Portuguese Institute of Psychology (I2P) & Department of Psychology and Education - Portuguese University, Porto and ²William James Center for Research, ISPA – Instituto Universitário, Lisbon, Portugal

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.706

Introduction: Sexual satisfaction is relevant to aging well, throughout the lifespan.

Objectives: This study aims to compare the perspectives of sexual satisfaction and adjustment to aging in three age cohorts, across the life span; and to analyze whether sexual satisfaction influences the perceptions of AtA.

Methods: This cross-sectional study comprised participants from three different age cohorts (18-44; 45-64; and 65+ years). Four measures were used to meet the defined objectives: (a) Adjustment to Aging Scale (ATAS); (b) New Sexual Satisfaction Scale (NISS-S); and (c) sociodemographic, health and lifestyle questionnaire. Data were subject to One-way ANOVAs and hierarchical regression analyses.

Results: Social support emerged as the most relevant dimension in the multifactorial nature of AtA. Generational differences were found in sense of purpose and ambitions [$F(2, 616) = 14.203, p = .000$], social support [$F(2, 616) = 10.65, p = .000$] and body and health [$F(2, 616) = 8.73, p = .000$]. Participants aged 65 and older showed significantly lower levels of sense of purpose and ambition, body and health, and social support. Younger participants showed the highest score for body and health. Age-related decreases in

sexual satisfaction were also found, as younger participants showed statistically higher levels of sexual satisfaction, followed by middle-aged and older participants. Sexual satisfaction predicts all the dimensions of AtA, exception made for aging in place and stability, where age is the main predictor. Ego-centered sexual satisfaction positively predicted sense of purpose and ambitions ($\beta = .212, p < .05$) and social support ($\beta = .311, p < .001$); while partner/sexual activity centered sexual satisfaction was a positive predictor of zest and spirituality ($\beta = .255, p < .01$), body and health ($\beta = .239, p < .001$), and social support ($\beta = .168, p < .05$).

Conclusions: Sexual satisfaction decreases with age and is positively related to all dimensions of AtA, hence gerontological interventions and program policies with older people would strongly benefit of including sexual satisfaction as a relevant variable for aging well.

Keywords: sexual well-being; sexual satisfaction; adjustment to aging; generational groups; lifespan.

Subgroups of patients with late onset schizophrenia-like psychoses revealed by the analysis of glutathione-dependent enzymes and inflammation markers

T. Prokhorova^{1*}, I. Boksha¹, L. Androsova¹, E. Tereshkina¹, V. Pochueva¹ and O. Savushkina¹

¹FSBSI "MENTAL HEALTH RESEARCH CENTRE", Moscow, Russian Federation

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.707

Introduction: While chronic inflammation and enhanced imbalance of pro- and antioxidant, including glutathione-dependent, systems contribute substantially to pathogenesis of mental disorders in old age, extent of oxidative stress and degree of inflammatory processes severity are varying among patients with late onset schizophrenia.

Objectives: Revealing various phenotypes in patients with late onset schizophrenia basing on measurement of activity levels for blood glutathione-dependent enzymes and inflammation markers and analysis of their links with clinical features of the patients.

Methods: Of 59 studied women patients 34 were with late onset (after 40 years) and 25 with very late onset (after 60 years) schizophrenia or schizophrenia-like psychoses (F20; F22.8; F25; F23; F06.2 by ICD-10). 34 mentally healthy women elder than 50 years comprised controls. Glutathione reductase (GR), glutathione-S-transferase (GST), neutrophil elastase (NE), and $\alpha 1$ -routinase inhibitor ($\alpha 1$ -PI) activities were measured in blood. PANSS, CDSS and CGI-S were used to assess the severity of psychotic symptoms, depression and treatment effectiveness.

Results: In the whole group of patients, GR was lower ($p < 0.05$), and $\alpha 1$ -PI was higher ($p < 0.0001$) than in control group. Clustering the patients by their biochemical and immunological signs revealed two clusters (C1, $n=34$, and C2, $n=25$) significantly differing by GST ($p < 0.0001$), NE ($p < 0.0001$), and $\alpha 1$ -PI ($p < 0.001$) activities. As compared with controls, GST and $\alpha 1$ -PI were higher ($p < 0.05$ and $p < 0.0001$), and NE was lower ($p < 0.05$) in C1. As compared with controls, GR activity was lower ($p < 0.05$), NE activity was higher

($p < 0.001$), and $\alpha 1$ -PI activity was much higher ($p < 0.001$) in C2. Patients of C1 and C2 did not differ in age, diagnosis, severity of the disease, but differed in clinical features of the course of the disease: significantly more patients with very late onset schizophrenia (76%) were met in C1 ($\chi^2 = 13.41$, $p < 0.001$). Also, different clinical-biological correlations were found in these clusters. Particularly, negative correlations of baseline NE activity with PANSS general psychopathology subscale scores ($R = -0.39$, $p < 0.05$) and with total PANSS scores ($R = -0.39$, $p < 0.05$) were found in C1. Positive correlation of GST activity with PANSS positive subscale score was found in C2 ($R = 0.43$, $p < 0.05$).

Conclusions: The revealed clusters differ in the extent of the glutathione antioxidant system impairment and in levels of the immune response markers. The revealing of the patient subgroups on the basis of biological markers reflecting impairments in metabolic and immune systems can represent interest in the search for individual treatment approaches.

Prevalence of ADHD in Adults: An Umbrella Review of International Studies

G. Ayano¹, L. Tsegay², Y. Gizachew³, M. Necho⁴, K. Yohannes⁵, S. Demelash⁶, T. Anbesaw⁴ and R. Alati^{1*}

¹Population Health, Curtin University, Perth, Australia; ²Aksum University, Aksum; ³Bethel Medical College, Addis Ababa; ⁴Wollo University, Amhara, Ethiopia; ⁵SWEDSD, Department of Women's and Children's Health, Uppsala University, Uppsala, Sweden and ⁶Ethiopian Public Health Institute, Addis Ababa, Ethiopia

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.708

Introduction: Attention deficit hyperactivity disorder (ADHD) is a neurodevelopmental disorder commonly diagnosed in school-age children. However, it can affect individuals of all age groups. This study aimed to provide a comprehensive analysis of the prevalence of ADHD in adults by conducting an umbrella review of systematic reviews and meta-analyses.

Objectives: To provide a comprehensive synthesis of published evidence on the prevalence of Attention Deficit Hyperactivity Disorder (ADHD) in adults through an umbrella review of systematic reviews and meta-analyses, with the aim of highlighting the significance of addressing and managing ADHD in the adult population.

Methods: To conduct this study, we adhered to the guidelines outlined in the Preferred Reporting Items for Systematic Review and Meta-Analysis (PRISMA). We systematically searched databases such as PsychINFO, Web of Science, PubMed, and Scopus to identify relevant studies. Our review protocol was registered with PROSPERO (registration number: CRD42023389704). The quality of the studies included in our analysis was assessed using the A Measurement Tool to Assess Systematic Reviews (AMSTAR). For the purpose of conducting a meta-analysis, we employed a random-effects model.

Results: Our umbrella review examined findings from five systematic reviews that encompassed data from 57 unique international

primary studies undertaken between 2009 and 2021. These studies involved a total of 21,142,129 adult participants. The meta-analysis, employing an inverse variance-weighted random effect model, yielded a pooled prevalence estimate for ADHD in adults of 3.10% (95% confidence interval: 2.60%–3.60%). Regarding ADHD subtypes, our analysis revealed that ADHD-I (inattentive type) remained the most prevalent among adults, followed by ADHD-HI (hyperactive type) and ADHD-C (combined type).

Conclusions: Our results underscore the relatively high prevalence of ADHD among adults, with ADHD-I emerging as the most common subtype. These findings emphasize the need for proactive measures to prevent, mitigate, identify, and effectively manage ADHD in the adult population.

Investigation of the Effect of Curcumin on Metabolic Dysfunction Caused by Clozapine in Rats

M. Aydin^{1*}, U. Egilmez¹, D. Eryavuz² and A. Unlu²

¹Psychiatry and ²Biochemistry, Selcuk University, Konya, Türkiye

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.709

Introduction: Antipsychotics disrupt intracellular cholesterol traffic and prevent the exit of low-density lipoprotein (LDL)-derived cholesterol from the endosome/lysosome compartment. It was showed that curcumin accelerated the release of cholesterol-containing exosomes from cells with impaired intracellular cholesterol traffic due to antipsychotic treatment and suggested that curcumin may help minimize the negative metabolic effects associated with chronic antipsychotic treatment.

Objectives: This study aimed to investigate the effectiveness of orally administered curcumin to rats in preventing and treating metabolic syndrome-related side effects such as weight gain and dyslipidemia caused by clozapine.

Methods: In our research, a total of 32 male rats (Wistar Albino), 12 weeks old, produced at Selçuk University Experimental Research and Application Center, were used. All animals divided into 4 groups. Venous blood collection and weight measurements were taken from all groups at the beginning. 32 rats were randomly divided into 4 separate groups: control, only oral clozapine, oral clozapine + 50 mg/kg curcumin, and the oral clozapine + 100 mg/kg curcumin group. Groups II-III-IV were given 15 mg/kg clozapine orally daily for 3 weeks. AST, ALT, glucose, total cholesterol, Triglyceride, HDL, LDL and insulin were studied from the blood samples taken at the beginning and at the end of the experiment.

Results: There was no statistically significant difference in comparisons of weight and insulin measurements between the groups at the end of the experiment ($p > 0.05$). In glucose measurements at the end of the experiment, the control group was found to have significantly higher glucose values compared to the other groups ($p < 0.001$). As a result of posthoc analyses, LDL measurements in the control group were found to be lower than those in the CLZ and CLZ + 50 c groups ($p < 0.05$). AST value of the control group was significantly higher than the CLZ+100c group ($p = 0.011$). Measurements of the control group for ALT were found to be higher than those of the CLZ+50c and CLZ+100c groups ($p < 0.05$). There was

no statistically significant difference between the groups in HDL, TG, Cholesterol comparisons ($p > 0.05$).

In the control group, the average weight at the end of the experiment was significantly higher than at the beginning ($p = 0.045$). In the CLZ group, the mean glucose at the end of the experiment was significantly lower than at the beginning ($p < 0.001$).

Conclusions: Metabolic problems due to antipsychotics negatively affect treatment compliance. Treatment support methods that can solve or help this problem may be useful. Our study ended in conflicting results. Needs for new experiments...

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.710

Introduction: *Toxoplasma gondii*, a ubiquitous protozoan parasite, has been previously associated with psychiatric disorders.

Objectives: To assess the prevalence of IgG antibodies against *T. gondii* in psychiatric patients from Western Romania.

Methods: We included 464 psychiatric patients admitted to the Psychiatric Clinic, County Emergency Hospital of Arad, Western Romania. Clinical evaluation and laboratory tests were conducted in these patients, including serological tests to determine the presence of *T. gondii* IgG antibodies.

Results: Of the 464 psychiatric patients, 258 (55.5%) were residing in rural areas and 245 (52.7%) were female. *T. gondii* IgG antibodies were demonstrated in 325 (70.04%) of 464 study participants and the seroprevalence tended to increase with age.

A significant higher *T. gondii* IgG seroprevalence was found in psychiatric patients aged between 40 to 59 years ($p < 0.001$) and in patients aged ≥ 60 years ($p = 0.001$) compared to patients aged 19 to 39 years. A higher *T. gondii* IgG seroprevalence was determined in psychiatric patients residing in rural areas compared to those residing in urban areas ($p = 0.04$). *T. gondii* IgG seroprevalence was higher in females compared to males ($p = 0.04$).

Assessment of seroprevalence by diagnostic revealed that *T. gondii* IgG antibodies were identified in 23 (85.19%) of 27 patients with delusional disorders, 24 (82.76%) of 29 with dementia, 51 (70.83%) of 72 with organic disorders, 75 (70.75%) of 106 with schizophrenia, 81 (70.43%) of 115 patients with depression, 17 (62.96%) of 27 with bipolar disorders, 27 (58.7%) of 46 with mood disorders and 7 (53.85%) of 13 with impulsive-control disorders.

Conclusions: The presence of *T. gondii* antibodies was demonstrated in a significant number of patients who attended the Psychiatric Clinic in Arad County, Western Romania. Results of this study suggest that *T. gondii* may be associated with several psychiatric disorders.

Examining the Incidence and Predictors of Low Resilience and Potential PTSD Among Residents in Two Canadian Provinces Amidst the 2023 Wildfires

M. K. Adu^{1*}, R. Shalaby², B. Agyapong², R. D. L. Dias¹ and V. I. Agyapong^{1,2}

¹Department of Psychiatry, Dalhousie University, Halifax, NS and

²Department of Psychiatry, University of Alberta, Edmonton, AB, Canada

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.711

Introduction: The recent wildfires in Canada provide a clear illustration of the significant and lasting damage they inflict on the well-being of individuals and communities. Evaluating the occurrence and factors associated with post-traumatic stress disorder (PTSD) and low resilience is valuable for policymakers in public health.

Objectives: The study aimed to assess the prevalence and predictors of low resilience and likely PTSD among subscribers of Text4Hope, an e-mental health program that delivered daily supportive messages to residents of Nova Scotia (NS) and Alberta (AB) during the recent wildfires.

Methods: Data collection was through a self-administered online survey completed by residents of the affected regions of NS and AB from May 14 to June 23, 2023. Data were analyzed using Statistical Package for the Social Sciences.

Results: Out of 298 respondents, the prevalence of low resilience and likely PTSD in our sample were 52.0% and 39.3% respectively. Unemployed respondents were about 3 times more likely to experience both low resilience and PTSD symptoms compared to those employed. Respondents with a history of mental health diagnosis were about 4 times more likely to experience likely PTSD compared to those with no history of mental health diagnosis.

Conclusions: This research demonstrated that the likelihood of PTSD was predicted by both unemployment and a history of mental health diagnosis, with unemployment also being linked to low resilience during the wildfire. These results provide valuable insights for designing clinical interventions and developing psychosocial support programs tailored for vulnerable populations.

Promotion of Mental Health

EPP0604

Postgraduate students' mental health, it is the time to be aware and act.

A. A. Alageel

Psychiatry Department, College of Medicine, Imam Mohammad Ibn Saud Islamic University (IMSIU), Riyadh, Saudi Arabia

doi: 10.1192/j.eurpsy.2024.712

Introduction: Education is markedly associated with well-being, leading to the acquisition of healthy behaviors while at the same increasing hiring and salary. However, stress among academics is worrying, especially in younger researchers who experience significant levels of job insecurity, the imbalances between life and job,

stressful relationships with supervisors and funding difficulties. Several studies have indicated that most graduate students spent over 40 hours per week on their postgraduate program, more than 70 % were not able to complete their programs within the set timeframe, and had uncertainty related to their job

Objectives: In this review, we discuss the mental health of postgraduate students focusing on depression, anxiety, stress, and smartphone addiction.

Methods: a review presentation of the mental health of postgraduate

Results: According to meta-analysis, depression prevalence among postgraduate participants ranges from 6.2% to 85.4% in 36 studies. The pooled prevalence was 34% (26,579 individuals; 95% CI: 28–40). A study using the GAD-7 scale to evaluate the prevalence of anxiety concluded that 41% of postgraduate students suffered moderate to severe GAD, which is about six times the prevalence of GAD among the general population. A Study demonstrated 51.0% of the participants had smartphone addiction. A significant association was also observed between extensive smartphone use and depression ($P = 0.001$). Of the smokers in this study, 41.5% were addicted to smartphones ($P = 0.039$). Smartphone addicts had approximately two times the chance of having insomnia ($OR = 2.113$) ($P = 0.013$). In addition, they showcased more ADHD symptoms ($OR = 2.712$) ($P < 0.001$).

Conclusions: Studies identified a higher prevalence of mental illnesses among postgraduate students than in the general population. Although students affected are highly educated, their awareness of mental health is not sufficient to know their mental symptoms and seek help. Therefore, we suggest launching wellness programs to enhance their mental health.

EPP0606

Impact of Ageism on Civic Engagement and Mental Health Among Older Adults: A Qualitative Study

S. von Humboldt^{1*}, A. Costa², N. Ilyas³ and I. Leal¹

¹William James Center for Research, ISPA – Instituto Universitário;

²ISPA – Instituto Universitário, Lisbon, Portugal and ³Center for Clinical Psychology, University of the Punjab, Lahore, Pakistan

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.713

Introduction: Ageist beliefs and attitudes may restrict the opportunities for older adults to participate actively in their communities, resulting in strong effects on mental health.

Objectives: This study has three objectives: 1) To investigate the effect of ageism on older adults' civic activities; 2) To analyze the influence of ageism on mental health; and 3) To explore the impact of civic participation on older adults' mental health.

Methods: This qualitative study included 391 older people from three different nationalities (Portuguese, Brazilian and English) ranging in age from 65 to 88 years old. All the interviews went through the process of content analysis.

Results: For the first objective, findings encompass four major themes: (1) Social disapproval (86%); (2) Perceived Ineptitude (84%); (3) Anticipated Failure (83%); and (4) Inability to Contribute (77%). For the second objective, findings indicated six categories: (1) Helplessness and Despair (89%); (2) Rage (81%); (3) Self-Perceived Inability (77%); (4) Sense of Unimportance (71%); (5) Anxiety (68%); and (6) Outbursts of Emotion (63%). For the

third objective, the following five major subjects emerged: (1) Meaningfulness (81%); (2) Embracing Social Belonging (80%); (3) Cognitive Abilities (71%); (4) Personal Empowerment (67%); (5) Emotional Expression (54%). Additionally, findings indicated that the most verbalized themes for the three objectives were the same across the three nationalities.

Conclusions: The results of this study offered insight into how ageism, mental health, and civic engagement are related. Ageism seems to have a negative impact on mental health. Ageism also made it difficult for people to participate in civic life, which has been linked to better mental health. These findings emphasize the need to identify ageism and encourage inclusive civic involvement to improve older individuals' mental health.

Keywords: Mental health; ageism; civic participation; older adults.

EPP0607

Adolescents' mental health and well-being in light of their substance use and the presence of special education needs

R. Dudok^{1*} and B. Pikó²

¹Doctoral School of Education and ²Department of Behavioral Sciences, University of Szeged, Szeged, Hungary

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.714

Introduction: Promoting mental health during adolescence is an essential health education objective and a crucial time for the formation of healthy mindset and behaviors. During this period, individuals are more likely to engage in health risk behaviors that can contribute to mental health problems that manifest in later adulthood. It has been demonstrated that optimal psychological health and the quality and application of students' emotional and social skills may prevent and reduce the onset of risky health behaviors, such as substance abuse. Students with specific learning difficulty (SpLD) are at higher risk to develop problem behaviors and they require special attention for promoting their mental health.

Objectives: The aim of the present study is to investigate mental health and well-being, and health behaviors as well as substance use in a sample of adolescents including those with SpLD, using the SDQ 'Strengths and Difficulties Questionnaire', a widely utilized instrument for the multidimensional assessment of mental health in children and adolescents.

Methods: Our study included 276 school-aged children (mean age: 13.57 years; SD: 1.81; boys: 54.7%), 143 of whom had SpLD. We utilized a self-administered, anonymous questionnaire that included the Adolescent Psychological Well-Being Questionnaire, the Life Satisfaction Scale, and the WHO Well-Being Questionnaire. Peer support, individual internal psychological resources, and health risk behaviors were also assessed.

Results: The statistical analyses revealed a number of noteworthy differences. First, the SDQ scores of smoking and drinking adolescents were substantially different from those of their peers on the dimensions of emotional symptoms, conduct problems, and hyperactivity in the case of smoking ($p < .05$), and on the dimensions of hyperactivity and prosocial behavior in the case of drinking ($p < .05$). On the other hand, significant differences were found between boys and girls, particularly in the domains of prosocial and affective symptoms ($p < .05$). Individuals with SpLD exhibited distinct

patterns, particularly in the domains of emotional symptoms and peer relationship problems ($p < .05$). Furthermore, all of the investigated components of mental well-being had significant negative correlations with the SDQ dimensions of emotional symptoms, conduct problems, hyperactivity, and peer relationship problems, whereas the dimension of prosocial behavior showed a significant positive correlation ($p < .05$).

Conclusions: Our findings support differences in mental health domains according to the adolescents' substance using status or the presence of SpLD. The results of this study may contribute to the development of health promotion programs and intervention strategies as well as draw attention to the unique challenges faced by children with special education needs.

Analysis of drug-drug interactions in spontaneous adverse drug reaction reports from EudraVigilance focusing on psychiatric drugs and somatic medication

D. Dubrall^{1,2*}, R. Weber², M. Boehme², M. Schmid¹, B. Sachs^{2,3} and C. Scholl²

¹University Hospital of Bonn, 53127; ²Federal Institute for Drugs and Medical Devices, 53175 and ³University Hospital RWTH Aachen, 52074, Germany

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.715

Introduction: Patients with severe mental illnesses (SMI) are often exposed to polymedication. Additionally, the risk of somatic diseases is twice as high in patients with SMI as in individuals without a psychiatric disorder. Furthermore, drug-drug interactions (DDI) between psychiatric drugs and somatic medications are a well-known cause of adverse drug reactions (ADR).

Objectives: The aim of this study was to analyse whether already known DDI related to psychiatric drugs and somatic medication still occur in everyday clinical practice.

Methods: Therefore we identified all spontaneous ADR reports contained in the European ADR database EudraVigilance from Germany received between 01/2017 and 12/2021 reported for patients older than 17 years in which antidepressants, antipsychotics and mood stabilizers were reported as suspected/interacting ($n = 9,665$). ADR reports referring to intentional overdoses and suicide attempts were excluded ($n = 9,276$ left). We used the ABDA drug information system in order to identify all potential DDI (pDDI). The identified reports with pDDI were then assessed individually to determine whether the respective DDI occurred.

Results: 1,271 reports with 728 potentially interacting drugs pairs related to psychiatric drugs and somatic medications with 2,655 pDDI were found. Restricted to potentially interacting drug pairs with more than 10 reports, (i) hyponatremias related to antidepressants and diuretics ($n = 362$, 32.6%), (ii) bleeding events related to selective serotonin reuptake inhibitors (SSRI) and platelet aggregation inhibitors, anticoagulants or non-steroidal antiinflammatory drugs (NSAID) ($n = 295$, 17.5%), and (iii) increased beta-blocker effects related to SSRIs and beta-blockers ($n = 126$, 11.3%) were the most frequently identified pDDI. After individual case assessment, in

33.3% (14/42), 23.7% (45/190) and 17.4% (8/46) of the reports bleeding events related to SSRIs and anticoagulants, SSRIs and platelet aggregation inhibitors and SSRIs and NSAIDs were reported. Hyponatremia was reported in 7.6% (22/289) of the reports related to antidepressants and diuretics and increased beta-blocker effects in 6.9% (8/116) of the reports related to SSRIs and beta-blockers.

Conclusions: According to our analysis, well-known DDI still occur in the treatment of psychiatric patients with psychiatric drugs and somatic medication. Whenever possible, alternative drug combinations with a lower potential of DDIs may be considered or appropriate monitoring measures should be conducted.

Antipsychotic use and associating factors among persons with substance-induced psychosis and first-episode psychotic disorders. A nationwide register-linkage study

J. Jeyapalan^{1,2*}, S. Niemela^{1,3} and H. Taipale^{4,5,6}

¹Department of Psychiatry, University of Turku, Turku; ²Department of Psychiatry, Vaasa Central Hospital, Vaasa; ³Department of Psychiatry, University Hospital Turku, Turku, Finland; ⁴Clinical Neuroscience, Karolinska Institute, Stockholm, Sweden; ⁵Niuvanni Hospital, Kuopio and ⁶Neuroscience Centre, University of Helsinki, Helsinki, Finland

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.716

Introduction: Far less is known about the preceding factors of antipsychotic use among persons with substance-induced psychosis (SIP) and first-episode psychosis (FEP). There is no prevention research on how persons with SIP differ from persons with other psychosis episodes like FEP. Antipsychotic medication is the general essential and necessary element in the treatment of SIP and FEP. Antipsychotics are used as first-line therapy, commencing with a low dose and titrating upwards. There are no exciting treatment guidelines for treating Substance-induced psychosis in the long term. (A review of some studies published by the Oxford Journals Schizophrenic Bulletin indicated that drug-induced psychosis lasted longer than a month in individuals between 1 and 15% of the time.)

The aim of the study was to investigate antipsychotic use and associated factors in persons with SIP and compare it with persons with other FEP

Objectives: 1 To study the antipsychotic use among persons with SIP compared with FEP from 3 years before until three years after their first diagnosis first incident of psychosis)

2. To study associating background factors with antipsychotic use among patients with SIP

Methods: Incident Swedish SIP cases ($n = 7320$) during 2006-2016 were identified from health care registers and matched 1: with persons with FEP ($n = 7320$) by age, gender, and calendar year of diagnosis. Prevalence of antipsychotic use was assessed as point prevalence every six months, from 3 years before until 3 years after the first diagnosis. Factors associating with antipsychotic use among SIP were analyzed with multivariable logistic regression, including information on sociodemographic and work-related background, including disability pension and sickness absence, SIP types, and psychiatric diagnoses.

Results: Among SIP and FEP, the prevalence of antipsychotic use was low before the first diagnosis (3-7% in SIP, 8-16% in FEP), peaked 6 months after the first diagnosis (23% in SIP, 54% in FEP) and stabilized after that. After 3 years of first diagnosis, 19% of persons with SIP and 45% of persons with FEP used antipsychotics. Antipsychotic use one year after diagnosis among SIP was associated with previous substance use disorder, depression, anxiety, and personality disorder diagnoses, being on disability pension or on long-term sickness absence (>90 days), and cannabis- or multi-substance-induced psychosis.

Image:

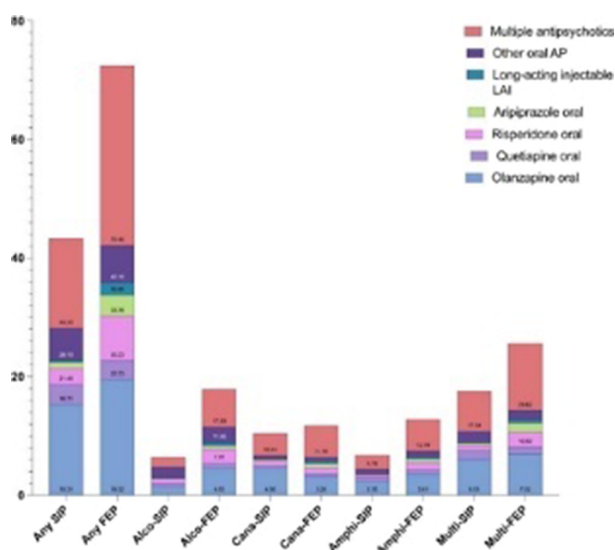

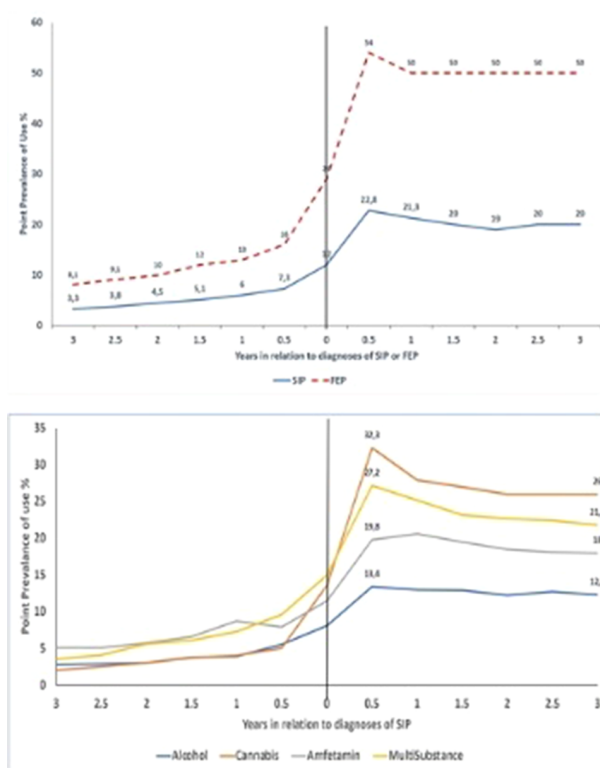

Image 2:

Conclusions: As expected, patients with FEP were using more frequently antipsychotics compared to SIP except for long-acting antipsychotics.

Although SIP is considered short-lived, antipsychotic use after an incident SIP episode is relatively common, especially among those with cannabis SIP with the highest prevalence of antipsychotic use. Previous substance use disorder and cannabis SIP were highly associated with patients who use antipsychotics frequently.

EPP0612

Half a Decade of Intravenous Ketamine Administration: Our Observation Results and Insights regarding its safety

P. Argitis¹, A. Karampas¹, M. Peyioti^{1*}, T. Koukouras¹, S. Karavia¹ and Z. Chaviaras¹

¹Psychiatric, General Hospital of Corfu, Corfu, Greece

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.717

Introduction: Ketamine, originally an anesthetic, has emerged as a potent tool in the fight against treatment-resistant depression and suicide. Clinical trials have demonstrated its ability to induce remission of severe depressive symptoms, with effects that can extend over several weeks. Furthermore, research highlights Ketamine's potential to rapidly reduce suicidal ideation. This suggests Ketamine's role as an intervention in suicide prevention, especially when conventional treatments prove ineffective. While isolated cases report severe respiratory depression, primarily when combined with other medications, most incidents involve temporary apneic episodes following high-dose intravenous administration. Understanding Ketamine's safety profile is vital for its clinical optimization and ensuring patient well-being during use

Objectives: This presentation serves to describe, and evaluate our clinic's safety protocol implemented for intravenous (IV) Ketamine infusions at the General Hospital of Corfu. Our primary goal is to rigorously assess the safety and tolerability of IV Ketamine in a clinical setting

Methods:

Patients must meet stringent criteria:

- Exclude those over 70.
- MMSE score above 25.
- Controlled blood pressure.
- No cardiac insufficiency, myocardial ischemia, or high intraocular/intracranial pressure.
- Absence of thyrotoxicosis, psychosis, or seizures.

Pre-infusion comprehensive evaluation:

- Includes ECG, blood biochemistry studies, and frequent blood pressure checks.
- Requires a 2-hour fast.

Ketamine infusion:

- IV Ketamine administered at 0.5mg/kg in 100ml N/S.
- Continuous monitoring of oxygen saturation (PO2) and cardiac rhythm.
- Blood pressure checks every 15 minutes.

Treatment typically involves 7 sessions over a span of a month, with an initial test dose of 0.25 mg/kg.

Results: Ketamine infusions were administered to a total of 208 patients. The majority of participants experienced a slight increase in blood pressure, while there were no significant changes in cardiac rhythm. Additionally, almost all patients reported experiencing dizziness or headaches during the infusion. Notably, nearly half of the patients reported an alteration in taste perception as a side effect. It's important to highlight that all observed side effects, spontaneously resolved within an hour after the conclusion of the infusion. However, in a small subset of cases (six instances), the side effects were severe enough to necessitate the premature termination of the ketamine infusion

Conclusions: Although ketamine demonstrates a favorable safety profile with minimal major side effects when administered following our established safety protocol. However, we want to underscore the critical importance of vigilant patient monitoring during ketamine administration and the prompt addressing of any adverse effects. This proactive approach is paramount to ensure the safety and overall well-being of patients receiving ketamine treatment

Exponential increase in the number of prescriptions for ADHD medication between 2012 and 2022 for in Poland.

M. Rzeszutek^{1*} and L. Konowalek¹

¹Department of Child Psychiatry, Medical University of Warsaw, Warsaw, Poland

*Corresponding author.

doi: 10.1192/j.eurpsy.2024.718

Introduction: ADHD medication prescribing trends are increasing in North America and both Northern and Western Europe (Raman, Sudha R *et al. Lancet Psychiatry*. 2018;5(10):824-835). Methylphenidate and atomoxetine are two substances available for use in ADHD in children and adolescents in Poland. To our knowledge, there is the lack of data on prescription trends for Poland and Middle-Eastern Europe.

Objectives: The aim of the study is to estimate the increase in the total number of prescriptions for methylphenidate and atomoxetine and factors influencing it, like the impact of the proportion of prescriptions for women and for people aged 18-24 on.

Methods: Methylphenidate and atomoxetine prescription data for the period between 2012-2022 and for patients aged 5-59 were obtained from e-Health Centre, which contains data on prescribed medications in Poland. We conducted a series of linear regression models to explore the relationship between the number of prescriptions as the dependent variable and calendar year as the independent variable. Additionally, we considered two more variables: Percentage of prescriptions for women and percentage of prescriptions people aged 18 – 24. Further, we decided to run a mediation analysis to see whether the effect of calendar year was mediated by percentage of women.

Results: We analyzed data on 925,536 prescriptions for methylphenidate and atomoxetine.

The model demonstrates a robust and statistically significant ability to explain the variance in the log-transformed dependent variable ($R^2 = 0.98$, $F(2, 8) = 201.14$, $p < 0.001$). The model's intercept, corresponding to calendar year = 0 and percentage of prescriptions for women = 0, is estimated at -93.95, with a 95% confidence interval of [-152.74, -35.15]. The t-statistic for the intercept is -3.68, and the associated p-value is 0.006, demonstrating its statistical significance.

Within this model, the effects of the independent variables are as follows:

1. Calendar year ($\beta=0.05$, $t=4.07$, IC95%: (0.02, 0.08), $p<0,004$)
2. Percentage of prescriptions for women ($\beta=0.06$, $t=4.18$, IC95%: (0.02, 0.09), $p<0,003$)

The inclusion of the percentage of prescription for people aged 18-24 doesn't improve the model's ability to explain the variation in the number of prescriptions.

Mediation analysis showed that the indirect effect of percentage of prescriptions for women were significant.

Conclusions: These results provide robust evidence for the predictive power of the model, with both calendar year and percentage of women emerging as statistically significant and positively associated with the log- transformed dependent variable.

Between 2012 and 2022, the number of prescriptions for methylphenidate and atomoxetine increased exponentially in Poland. The percentage of prescriptions for women significantly contributed to the increase in the total number of prescriptions for methylphenidate and atomoxetine in Poland.

doi: 10.1192/j.eurpsy.2024.719

Introduction: Bipolar disorder (BD) is a recurrent disorder, causing functional impairment and **raised mortality, particularly due to suicide**. However, the difficulty in predicting suicidal behaviors relies in the **lack of clear biomarkers**.

Machine learning (ML) has emerged as a promising tool to enhance suicidal prediction. However, most **ML studies focused on lifetime attempts**, without having a predictive time window, and **did not employ time-dependent variables**. Moreover, most studies lie on cross-sectional databases, without including more than one time-point.

Objectives: First, we aimed to predict 12-months **suicide attempts** in a naturalistic sample of BD patients, using clinical and demographic data.

Second, we aimed to improve the prediction by including information from intermediate visits (1, 3, and 6 months), mimicking more closely the clinician's way of thinking and the multiple observations a patient receives.

Methods: A sample of 163 BD patients (53% females, mean age 44.7, SD 15.3) were recruited.

Based on EHR, **56 clinical and demographic features were extracted, including hospitalizations, suicidal behaviors lifetime and in the last 12 months**, along with comorbidity, family history, work, and therapies. **Patients were followed up for 12 months.**

Support Vector Machine (SVM) was used to differentiate subjects who attempted suicide versus those who did not **in a 12-month time window**, within a repeated nested Cross-Validation. The SVM was optimized weighting the hyperplane for uneven group sizes. Then, **we repeated the analysis including information from intermediate visits** (1, 3, 6 months after the first contact). **For each visit, we created a composite score** based on current therapy, new admissions, and ER presentations. To avoid circularity, all the information (ER, admission etc.) related to a suicide attempt were not included.

Results: During the 12-months follow-up, **9.8% of patients attempted suicide.** The results from the 12-months suicide prediction model obtained an Area Under the Curve of 0.71 (with a Balanced Accuracy (BAC) of 68%).

After incorporating the composite scores based on intermediate visits in the model, the prediction raised to an Area Under the Curve of 0.78 (BAC 73%), suggesting that including intermediate visits is a valid method to improve prediction.

The features that contributed the most to the prediction were **the composite score at 6-month visit, lifetime number of suicide attempts, suicide attempts in the last 12 months, substance of abuse** (other than cannabis), and antipsychotics.

Conclusions: ML proved a good prediction accuracy for suicide in a 12-months time window, and the prediction was improved by including data from intermediate visits. **The model showed the importance of time-dependent features, such as attempts in the last 12 months.** Our analysis might help in identifying early clinical risk factors and underlies **the importance of multiple evaluations in populations at risk.**

Suicidal behavior in homeless population and its relationship with experienced aggressions: A seven-year longitudinal study.

F. Calvo^{1*}, R. Alfranca², X. Solench-Arco³, C. Giral⁴, I. Forcada² and S. Font-Mayolas⁵

doi: 10.1192/j.eurpsy.2024.720

Introduction: Suicide is a serious and complex public health issue that affects millions of people worldwide. Among the most

vulnerable populations are homeless individuals (HIs), whose suicide rate is significantly higher than that of the general population.

Objectives: The aim of this study was to analyze mortality and suicidal behavior in a cohort of HIs during a seven-year follow-up. Additionally, the study sought to identify variables linked to mortality in this population.

Methods: The study was conducted in the province of Girona, Spain, and included 154 HIs who were literally experiencing homelessness. Self-report questionnaires were used to gather sociodemographic data, assess suicide risk, and measure the severity of substance dependence. The follow-up was carried out between 2015 and 2022, collecting data on mortality, suicide attempts, episodes of overdose, and violence experienced from public health services (psychiatric and primary health care services).

Results: During the seven-year follow-up, 23 individuals (14.3% of the sample) passed away, with an average age at the time of death of 52.6 years. The main causes of death were cancer, suicide (excluding overdose), and accidental overdose. Methods used for suicide included drug overdose, jumping, and vein slashing. All deceased individuals had scores above the threshold on the Plutchik Suicide Risk Scale and had reported previous suicide attempts.

Individuals who experienced violence during the follow-up period exhibited more severe suicidal ideation, more suicide attempts, and more non-lethal overdose episodes. Substance dependence, particularly cocaine dependence and dual pathology, was significantly associated with higher mortality.

Conclusions: This study reveals a high mortality rate among HIs, especially due to suicide and accidental overdose. The most significant variables related to mortality were suicidal ideation, the number of previous non-lethal overdoses, and substance use disorders, with cocaine dependence being prominent. The results underscore the need for specific prevention and treatment programs to address suicide risk factors and improve the mental health of homeless individuals. The importance of conducting interventions in specialized centers that detect and address suicide risk in this vulnerable population is also emphasized.

Certain immune parameters may have a significant impact on suicidal behaviour - a naturalistic study among psychiatric in-patients

V. Voros^{1*}, E. Saghy², C. Molnar¹, M. Kovacs¹, B. Peto¹, S. Kovacs², A. Zemlenyi², S. Fekete¹, T. Tenyi¹ and P. Osvath¹

¹Department of Psychiatry and Psychotherapy and ²Center for Health Technology Assessment and Pharmacoeconomic Research, Faculty of Pharmacy, University of Pecs, Pecs, Hungary

doi: 10.1192/j.eurpsy.2024.721

Introduction: Several research already proved the role of certain immunological factors (neutrophil-lymphocyte (NLR), monocyte-lymphocyte (MLR) and platelet-lymphocyte (PLR) ratio, and C-reactive protein (CRP)) in the background of suicidal behaviour.

Objectives: The aim of this research was to study the association between routinely measurable low-grade inflammation parameters

and suicidal behaviour among patients in the acute psychiatric care setting.

Methods: The study population included psychiatric in-patients (N=100) consecutively treated with depressive disorders and/or suicidal behaviour in a University Clinic between December 1, 2020 and December 31, 2021. Three different patient-groups were generated based on their suicidal behaviour: suicide attempters (N=55) including *recent attempters* (N=36) and *past attempters* (N=19) and *non-suicidal patients* (N=45), who never had a suicide attempt. Basic socio-demographic data, the severity of depression and immunological parameters (white blood cell count: lymphocytes, monocytes, neutrophil, eosinophil, basophil granulocytes; thrombocytes; C-reactive protein) were recorded. Descriptive analyses and multivariate regression model were performed with RStudio version 4.2.3.

Results: CRP was significantly higher (2.00 vs. 1.00; $p=0.007$) in suicidal patients (N=55), however other immunological parameters did not differ significantly between the suicidal and the non-suicidal groups (NLR: 2.02 vs. 2.19; MLR: 0.22 vs. 0.11; PLR: 118 vs. 130). NLR and MLR showed significantly higher values (NLR: 2.83 vs. 1.93, $p=0.021$; MLR: 0.28 vs. 0.11, $p=0.01$) for those who currently attempted suicide (N=36) compared to the patients with no or past suicide attempt (N=64). In the regression analysis, the NLR and MLR showed significantly higher values in current suicide attempters even when gender, age, suicidal risk and severity of depression were included in the model. However, no significant differences were found when comparing current and past suicide attempters with the non-suicidal patients.

Conclusions: Despite the small number of cases in the samples, our results confirmed the association of certain immunological parameters (NLR, MLR) and acute suicidal behaviour. This relationship was found to be independent of depression and its severity. Our data suggest that, unlike the NLR and MLR parameters, the higher CRP value may not be related to acute suicide attempt, but rather to suicidal vulnerability, as a trait-marker. Markers of chronic systemic inflammation may help in the prediction of suicidal behaviour and in the development of new therapeutic options, however, further prospective studies are needed to identify the specific role of immunological factors in suicidal behaviour more precisely.

doi: 10.1192/j.eurpsy.2024.722

Introduction: Non-suicidal self-injury among adolescents has grown in recent years, becoming a significant public health issue. The high social and psychological impacts related to it are often characterized by substance abuse and the development of anxiety and depression. Furthermore, emotional dysregulation and heightened reactivity are associated psychological characteristics.

Objectives: The aim of this paper was to do a scoping review, mapping the existing literature on self-harming behaviors among

Brazilian adolescents, considering their sociodemographic and clinical characteristics.

Methods: We followed the adapted PRISMA checklist for scoping reviews. We searched eight databases: APA PsycNet, LILACS, MEDLINE, PubMed, Embase, Web of Science, The Cochrane Library, and Scopus. The selection of studies was conducted in accordance with the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) statement, where three independent researchers examined all titles and abstracts, applying the eligibility criteria. Accordingly, six studies were selected for descriptive analysis due to the variety of study types.

Results: A total of 2,032 youngsters were studied in the age range of 10 to 19 years-old, among over 15,000 reported cases of self-harming behaviors. Females accounted for 51.3% of the cases and had higher scores of impulsivity and loneliness to self-harming behavior ($P \leq 0.05$). Alcohol use was evident across both genders but showed higher measures for males in both age groups (10 to 14 and 15 to 19 years, $p < 0.001$).
